

# F5 TMSH Reference - 13.x

F5 TMSH references are collections of the available BIG-IP TMSH man pages.

## General

### grep

NAME  
grep - Display lines matching a pattern

SYNTAX  
list [component] "|" grep [ [option | pattern] ... ]  
show [component] "|" grep [ [option | pattern] ... ]  
options:  
-A [integer]  
-B [integer]  
-C [integer]  
-E  
-G  
-P  
-c  
-e [pattern]  
-i  
-m [integer]  
-n  
-o  
-v  
-w  
-x Note: Each option must be followed by a space.

Note: tmsh treats any argument that is not preceded by a supported option, and does not begin with a hyphen, as a search pattern preceded by -e.

DESCRIPTION  
You can use grep to filter the output generated by the commands list (configuration settings) and show (statistics and runtime status). You must type the character | before the grep specification. You can use multiple filters chained together.

EXAMPLES  
The following examples show how to use the grep utility in tmsh.

```
list ltm node | grep "^10\.2"  
list ltm virtual | grep -i seattle  
list ltm virtual | grep -i abc | grep -i ab | grep -i a
```

OPTIONS  
-A Display the specified number of lines of context after matching lines.  
-B Display the specified number of lines of context before matching lines.  
-C Display the specified number of lines of context before and after matching lines.  
-E Interpret patterns as extended regular expressions.  
-G Interpret patterns as basic regular expressions.  
-P Interpret patterns as Perl regular expressions.  
-c Display a count of the lines that match. If -v is specified the number of non-matching lines is displayed.  
-e Specify a pattern. This is useful to protect against patterns beginning with a hyphen.  
-i Case insensitive search.  
-m Stop reading input after the specified number of matching lines. If -c is specified the count will not exceed the value specified for -m. If -v is specified grep will stop after finding the specified number of non-matching lines.  
-n Prefix each line of output with the line number relative to the input.  
-o Show only the part of a matching line that matches the pattern.  
-v Invert the sense of matching, to select non-matching lines.  
-w Select only those lines containing matches that form whole words. The test is that the matching substring must either be at

the beginning of the line, or preceded by a non-word constituent character. Similarly, it must be either at the end of the line or followed by a non-word constituent character. Word-constituent characters are letters, digits, and the underscore.

-x Select only those matches that exactly match the whole line.

## time

#### NAME

Time - Date and Time formats.

#### MODULE

All tmsh modules.

#### SYNTAX

Date/Time Syntax  
now[ [ + | - ] [ d | h | w | m ] ]  
yyyy-mm-dd[ : | T ]hh:mm[:ss]  
mm-dd[-yyyy][ : | T ]hh:mm[:ss]  
mm/dd[/yyyy][ : | T ]hh:mm[:ss]

Date Range Syntax  
now[ [ + | - ] [ d | h | w | m ] ]--now[ [ + | - ] [ d | h | w | m ] ]  
yyyy-mm-dd[ : | T ]hh:mm[:ss]--yyyy-mm-dd[ : | T ]hh:mm[:ss]  
mm-dd[-yyyy][ : | T ]hh:mm[:ss]--indefinite  
epoch--mm/dd[/yyyy][ : | T ]hh:mm[:ss]  
now[ [ + | - ] [ d | h | w | m ] ]

#### DESCRIPTION

The date or time format is found in tmsh as an attribute or parameter for many configuration items. Below are the various formats supported for both Date/Time and Date Range. Please see the examples for further assistance in using the required formats.

#### DATE:TIME FORMATS

nowX This date format starts with now (the current time) and is optionally followed by + or - some time span. The format will look like the following: now[ [ + | - ] integer [ d | h | w | m ] ], where the user picks either before (-) or after (+) the current time and then specifies integer number of minutes(m), hours(h), days(d) or weeks(w). This format is case-insensitive.

#### Examples:

Input Date	Description
------------	-------------

now-3d	3 days ago.
now+3h	3 hours from now.
now-3m	3 minutes ago.
now+3w	3 weeks from now.

#### yyyy-mm-dd:hh:mm:ss

This format requires a year, month, day separated by - characters. A time is also required, which is specified as hour:minute:second, where the seconds are optional. The date and time must be separated by a : colon. Note: This is the default time format for output from tmsh.

#### Examples:

Input Date	Description
------------	-------------

2013-05-29:13:30	May 29th, 2013 at 1:30pm.
2000-01-04:12:22:30	January 4th, 2000 at 12:22pm and 30 seconds.

#### mm-dd-yyyy:hh:mm:ss

This format requires at least a month(m) and day(d) specified and optionally a year (y). If no year is specified, tmsh will auto-fill the year with the current year. A time is also required in the format of hour:minute:second, where the seconds are optional.

Examples:

Input Date        Description

3-12-2015:12:01:00    March 12th, 2015 at 12:01 pm.  
4-15:22:10:30        April 15th of this year at 10:10 pm and 30 seconds.

mm/dd/yyyy:hh:mm:ss

This format requires at least a month(m) and day(d) specified and optionally a year (y). If no year is specified, tmsh will auto-fill the year with the current year. A time is also required in the format of hour:minute:second, where the seconds are optional.

Examples:

Input Date        Description

3/12/2015:12:01:00    March 12th, 2015 at 12:01 pm.  
4/15:22:10:30        April 15th of this year at 10:10 pm and 30 seconds.

T Delimiter

Any of the above time formats may optionally use a capital letter T (as in the word Time) to separate the date from the time, instead of using a colon (:).

Examples:

Input Date        Description

9/16/2005T12:01:01    September 16th, 2005 at 12:01pm and 1 second.  
2011-11-12T00:03:30    November 12th, 2011 at 12:03am and 30 seconds.

Special Dates

There are two special dates that may be used in tmsh. They are indefinite and epoch. Below is an explanation of those dates.

indefinite

The date will be marked as being infinitely in the future (end of time).

epoch

The date will be marked as being infinitely in the past (beginning of time).

DATE RANGES

DateX--DateZ

A Date Range is 2 dates in a valid Date Format separated by a -- (double hyphen). The dates may be any of the Date Formats specified above. See examples below on how to use this notation.

Examples:

Input Date        Description

now-2d--now-4d        2 to 4 days ago.  
now--now-3m            From 3 minutes ago to now.  
epoch--3/12/2011:12:00:00    Everything older than March 12th, 2011 at noon.  
2008-03-12--indefinite    Everything after midnight on March 12th, 2008.

DateX

When specifying a date range, the second date may be left out. This will cause the system to assume the second date in the range to be now. Using this format for a date range may make it confusing when using the NowX date format listed above. The following examples will help clarify how to use this format with any supported Date Format.

Examples:

Input Date        Description

now-3d            From 3 days ago to now.  
now+3w            From now to 3 weeks from now.  
epoch            Everything before the current date and time.  
indefinite        Everything after the current date and time.

BIG-IP            2016-03-14            time(1)

**tmsh**

NAME

tmsh - Traffic Management Shell - A command line interface for managing the BIG-IP(r) system.

## DESCRIPTION

You can use tmsh to configure and manage the BIG-IP system in conjunction with the Configuration utility, which is the browser-based BIG-IP system and network management tool.

## MODULES

The structure of tmsh is hierarchical and modular. The highest level is the root module, which contains subordinate modules: auth, cli, gtm, ltm, net, sys and wom. Use the command help with no arguments to display the module hierarchy relative to the current module.

The gtm, ltm, net, sys, and wom modules also contain subordinate modules. All modules and subordinate modules contain components. To display the list of modules and components that are available in the current module type Tab or ? at the tmsh prompt.

Commands operate on components. To display the list of available commands type Tab or ? at the beginning of the command line. To display a list of components on which a command can operate type the command followed by a space followed by Tab or ?.

The following examples illustrate how to navigate the tmsh hierarchy.

To enter a module, type the name of the module at the tmsh prompt.

```
(tmsh)# ltm
```

The prompt displays the current module location.

```
(tmsh.ltm)#
```

You can display the components in a module using the commands list (configuration) and show (statistics and runtime status). The following command sequence displays the virtual server configuration of the BIG-IP system.

```
(tmsh.ltm)# list virtual
```

In the following examples, the commands list and show display information about only ltm components.

```
(tmsh.ltm)# list
```

```
(tmsh.ltm)# show
```

You can access any component in any module from any other module by specifying a complete path to the component. For example, from the ltm module, the following command displays all of the properties of the VLANs on the system. The forward slash / specifies that what follows is relative to the root module.

```
(tmsh.ltm)# list /net vlan all-properties
```

The forward slash is optional if the root module is the current module. For example, the following command sequences display profiles.

```
(tmsh)# list ltm profile
```

```
(tmsh)# list /ltm profile
```

```
(tmsh)# list / ltm profile
```

Most components also support component mode. You can navigate to a single component and run commands to manage that component. For example, from the ltm module, to navigate to the node component, use the following command.

```
(tmsh.ltm)# node
```

To display the properties of all nodes, use the following command.

```
(tmsh.ltm.node)# list
```

You can also navigate to a specific object (object mode). For example, from the node component, to enter object mode for a specific node, enter the command modify followed by the IP address of the node.

```
(tmsh.ltm.node)# modify 10.1.1.10
```

In object mode, you can configure property settings directly. For example, to set the connection limit for 10.1.1.10 to 10000, use the following command.

```
(tmsh.ltm.node.10.1.1.10)# connection-limit 10000
```

To exit a module enter the command exit at the tmsh prompt, as shown below.

```
(tmsh.ltm)# exit
```

```
(tmsh)#
```

## PRODUCT PROVISIONING

You must provision a BIG-IP system module before you can use tmsh to configure that product, for example, the Global Traffic Manager. The command sequence list sys provision displays the BIG-IP system modules that can be provisioned. For more information about provisioning, see the TMOS(r) Management Guide for BIG-IP Systems and help sys provision.

## LOADING/SAVING THE SYSTEM CONFIGURATION

The system applies all configuration changes that you make from within tmsh to the running configuration of the system.

You can save a portion of the running configuration known as the base configuration. You can also load the base configuration from the stored configuration files.

To save the base configuration to the stored configuration files, use the command sequence: save sys base-config.  
To replace the running base configuration with the configuration in the stored configuration files, use the command sequence: load /sys base-config.

Additionally, you can save the entire running configuration or load all of the stored configuration files.

To save the entire running configuration to the stored configuration files, use the command sequence: save /sys config.  
To replace the entire running configuration with the configuration in the stored configuration files using the command sequence: load /sys config.

#### HELP

tmsh tmsh includes man pages for each of the commands and components that are available within tmsh. You access the man pages using the following command syntax: help [ [command] | [full path to component] ].

For example, to access the man page for the vlan component from the root module, use this command sequence: help / net vlan.

You can also search the man pages for information on a specific topic. To do this you use the command syntax: help search [topic]. You can perform a help search from within any module in the tmsh hierarchy. For example, to find the man pages that contain a reference to VLANs, use this command sequence: help search vlan

To display a list of topics that are available in a module use this command sequence: help [full path to module].

For example, to display the topics that are available in the current module use this command: help. To display the topics that are available in the net module use this command sequence: help / net.

#### CONTEXT-SENSITIVE HELP

tmsh includes a context-sensitive help feature that provides help as you type commands. At any time, you can type a question mark (?) on the command line, and tmsh returns information to assist you in completing the command. Based on when you type the question mark, you get the following results.

When you type a question mark immediately following any portion of a command, tmsh returns possible completions for the command, but does not complete the command as the command completion feature does.

When you type a space before the question mark, tmsh returns descriptive text that explains the commands, components, or properties that you can configure.

When you type a question mark in the middle of a command, tmsh returns help on the command to the left of the cursor.

Note: To use a question mark in a Glob or regular expression, you must escape the question mark using quotation marks, apostrophes, or a backslash.

Additionally, you can request context-sensitive help for the last command in a series of commands. For more information, see ENTERING MULTIPLE COMMANDS, following.

#### COMMAND COMPLETION

At any point while typing or editing a command in tmsh, you can press the Tab key. tmsh either completes the current or next word, or displays possible completions for the current or next word. If tmsh displays nothing after you press the Tab key, no options exist to complete the word. If you move the cursor anywhere on the command line and press the Tab key, tmsh completes what is to the left of the cursor.

Command completion also reduces the amount of typing that is required to run commands. When you press the Tab key, the system automatically completes the current command-line element to as many unique characters as possible. If there is more than one possible completion the list of possible completions displays. Command completion also completes configuration object identifiers.

#### ENTERING MULTIPLE COMMANDS

You can enter multiple commands on the command line by separating the commands with semi-colons (;). For example, to display the properties of the self IP addresses and VLANs of the system, use this command sequence:

```
list / net self ; list / net vlan
```

When you enter multiple commands in this way, all of the commands are added to the command history in a single line item, regardless of whether any of the commands were successful. However, if one of the commands that you enter fails to parse, tmsh does not run the remaining commands you entered. tmsh audits commands as the commands run; therefore, if a command fails to parse, tmsh does not audit the remaining commands. For more information about the command history, see COMMAND HISTORY, following.

You can also specify multiple commands in a command alias by separating the commands with semi-colons. For example, to create an alias that displays the properties of the VLANs and VLAN groups on the system, use this command sequence:

```
create / cli alias vlans command "list / net vlan ; list / net vlan-group"
```

You can request context-sensitive help and utilize the command completion feature on the last command in a series of commands. For example, the following command sequence displays help for the vlan-

group component.

```
list / net vlan ; list / net vlan-group ?
```

#### COMMAND HISTORY

tmsh saves in the command history file each command that you enter. The command history persists when you log off of the system. The next time you log on to the system, you can search for, display, and then edit, the tmsh commands that you entered in previous sessions. The command history persists even through a restart of the BIG-IP system. For more information about the command history feature, see help history.

The following examples show how to use the command history feature.

To display the commands in the history list, enter either the command sequence show history or an exclamation point (!). tmsh displays a list of commands each preceded by a numeric ID.

To run a command from the history list, enter an exclamation point followed by the numeric ID of the command.

To run the previous command, enter !!.

#### FILTERING OUTPUT

You can filter the output generated by the commands list (configuration settings) and show (statistics and runtime status) using the UNIX grep utility. You must type the character | before the grep specification. You can use multiple filters chained together. For a list of supported grep options, see the Traffic Management Shell (tmsh) Reference Guide.

The following examples show how to use the grep utility in tmsh.

```
list ltm node | grep "^10\.2"
list ltm virtual | grep -i seattle
list ltm virtual | grep -i abc | grep -i ab | grep -i a
```

#### KEYBOARD BINDINGS

tmsh supports vi, emacs and default keyboard bindings. You can set the binding using the keymap preference. For more information, see help cli preference. For a detailed description of the default mapping, see the Traffic Management Shell (tmsh) Reference Guide.

Note that all mappings provide command-line editing and the capability to search the command history.

#### WILDCARD OBJECT IDENTIFIERS

You can specify configuration object identifiers using glob and regular expression syntax.

For glob and regular expression syntax rules, see help glob and help regex. Note that you can escape the glob and regular expression special characters using a back slash.

The following examples show how to use glob and regular expressions in tmsh.

Uses a glob expression to display the configuration of all nodes that begin with 10.1..

```
list ltm node 10.1.*
```

Uses a regular expression to display the configuration of all nodes that begin with 10. and contain .44.. Note that a regular expression must begin with an @ symbol. This identifies to tmsh that the identifier should be treated as a regular expression and not a glob or standard object identifier. The leading @ is not part of the regular expression.

```
list ltm node @^10\..*\.44\.
```

#### PREFERENCES

You can customize the behavior of tmsh. For more information, see help cli preference.

#### FILES

tmsh manages several files in a user's home directory.

\$HOME/.tmsh-history- contains command history.

#### STATISTICS

You can use tmsh to display statistics, including historical performance statistics. You can select the format in which the statistics display, as well as reset the statistics for some of the tmsh components. To determine if statistics are available for a component, see the man page for the specific component.

The following examples show how to display and reset statistics for the net interface component from the root module.

```
show net interface
reset-stats net interface
```

The following examples show how to display and reset statistics for the net interface component from the net module.

```
show interface
reset-stats interface
```

#### AUTOMATING TMSH

You can use tmsh to build TCL scripts to automate management of the BIG-IP. See the cli script help page.

#### COMMAND LINE OPTIONS

The following options can be specified when tmsh is started from the

system shell.

-a tmsh does not write commands to the command history file.

Note that if auditing is enabled, tmsh continues to write commands to the audit log. This option is useful when writing scripts from the system shell, because it stops the scripts from filling up the command history file. This option applies to the non-interactive mode only.

-c Run the specified command. A command that contains multiple arguments must be in quotes. No other options may be specified after -c

-d [ip address | host name]  
Connects to the specified blade in a clustered system.

-e Disables video highlighting in tmsh.

-h Displays options you can use when accessing tmsh from the system shell.

-m Generates a tmsh debug log named tmsh.out in the current directory.

Note that when you run a tmsh script, the shell generates a debug log file for the script named tmsh.out.[script name].

Using this option causes tmsh to run significantly slower.

-g Prevents tmsh from responding to user actions with questions. This option is useful when writing non-interactive shell scripts from the system shell.

-r  
This option allows the user to run TMSH the specified version. This is used to provide backwards compatibility for older TMSH syntax only. The version must be specified in the format maj.min.pt, for example 11.5.0

#### SEE ALSO

Detailed information on the following topics is available through the help command: cli preference, cli script, glob, help, regex, and sys provision.

For complete information about tmsh, see the Traffic Management Shell (tmsh) Reference Guide. This guide is available on the AskF5(sm) Knowledge Base ().

# Commands

## cd

### NAME

cd command - Change the current working folder.

### MODULE

All tmsh modules.

### SYNTAX

Use the command cd to change the current working folder.

```
cd [folder name]
cd /[folder name]
```

### DESCRIPTION

The command cd [folder name] changes the current working folder to allow the user navigation around the folder system (see sys folder). The command pwd displays the current working directory.

The current working folder may be listed in the tmos command prompt while in tmsh interactive mode (see cli preference).

Folder names are separated by a forward slash /.

There are two built-in folders:

/ is the root folder

/Common is the default folder for creating new configurations objects.

Additionally, the following directory entries:

. is the current folder

.. is the parent folder

#### EXAMPLES

```
cd /Common
```

Change the current working folder to /Common.

```
cd resources
```

Change the current working folder to resources. In this example the resources folder is relative to the current working folder. As an example, if the current working folder was /Common, the new working folder will be /Common/resources.

```
cd resources/profiles/udp
```

Multiple folders may be specified. Tab complete assists filling the command line with folder names.

```
cd /
```

Make the current working folder the root folder.

```
cd ../Alpha
```

Change the working directory by first going to the parent, and then switch to the sub-folder Alpha.

## cp

#### NAME

cp command - Creates a copy of a TMOS(tm) configuration object.

#### MODULE

All tmsh modules.

#### SYNTAX

Use the command cp within a tmsh module to create a copy of the component that resides in that module. To create a copy component that resides in another module, use the full path to the component.

```
cp [component] [source] [destination]
cp / [module...module] [component] [source] [destination]
```

#### DESCRIPTION

You must provide a unique name for each component destination of the copy operation.

#### EXAMPLES

```
cp template mytemplate newtemplate
```

From within the sys application module, creates a new Application Template named newtemplate with the same properties as mytemplate .

```
cp / cli script my_script1 my_script2
```

From within the sys application module, copies the my\_script1 script to my\_script2 within the cli module.

#### OPTIONS

component

Specifies the type of the component that you want to copy.

module

Specifies the module within which the component that you want to copy resides.

source  
Specifies the component to be copied.

destination  
Specifies a unique name for the component that will be created as part of the copy.

SEE ALSO

## create

NAME  
create command - Creates a TMOS(tm) configuration component.

MODULE  
All tmsh modules.

SYNTAX  
Use the command create within a tmsh module to create a component that resides in that module. To create a component that resides in another module, use the full path to the component.

```
create [component] [name] [property [value]...]
create / [module...module] [component] [name] [property [value]...]
```

DESCRIPTION  
You must provide a unique name for each component that you create.

EXAMPLES  
create pool pool1  
  
From within the gtm module, creates a Global Traffic Manager pool named pool1.  
  
create / ltm pool my\_pool  
  
From within the gtm module, creates a Local Traffic Manager pool named my\_pool.

OPTIONS  
component  
Specifies the type of the component that you want to create.  
  
module  
Specifies the module within which the component that you want to create resides.  
  
name Specifies a unique name for the component.  
  
property [value]...  
Specifies properties for the component and their values.

SEE ALSO  
tmsh

COPYRIGHT

BIG-IP 2016-03-14 create(1)

---

## delete

**NAME**  
delete command - Deletes a tmsh component.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the command delete within a tmsh module to delete a component that resides in that module. To delete a component that resides in another module, use the full path to the component.

```
delete [component] [name]
delete / [module...module] [component] [name]
```

**DESCRIPTION**  
You must provide the name of the component that you want to delete.

**EXAMPLES**

```
delete pool pool1
```

From within the gtm module, deletes the Global Traffic Manager pool named pool1.

```
delete / ltm pool my_pool
```

From within the gtm module, deletes the Local Traffic Manager pool named my\_pool.

**OPTIONS**

**component**  
Specifies the type of the component that you want to delete.

**module**  
Specifies the module within which the component that you want to delete resides.

**name** Specifies the name of the component that you want to delete. All may be used as an identifier for most component types.

**recursive**  
Deletes all items in the current folder and all sub-folders that match the module, component and the name specified. all may be used as the name identifier with this command.

**Note:** When using recursive and all together, you will be prompted to verify this action. If you wish to disable this prompt, you may run tmsh using the -q command-line option. This is very useful when writing scripts that use this command.

**SEE ALSO**

F5 Networks and BIG-IP (c) Copyright 2008-2010, 2013, 2016. All rights reserved.

**BIG-IP**      2016-03-14      delete(1)

---

## edit

**NAME**  
edit command - Opens the specified components in an editor.

**MODULES**  
All tmsh modules.

**SYNTAX**  
Use the command edit to create components or modify the configuration of components using a text editor. To edit a component that resides in another module, use the full path to the component.

```
edit [component] [name ... name | all]
edit / [module...module] [component] [name ... name | all]
```

**DESCRIPTION**  
You can use the command edit to create or modify components in the auth, cli, gtm, ltm, net, sys and wom modules, and iRules(r).

If you are assigned the role of Administrator, when you use the command edit, the system starts the vi editor. If you are assigned any other role, the system starts the pico/nano editor.

The system saves, in a temporary directory, the text file, named data,

that you are editing. When you save the file and close the editor, the system checks for errors, and then prompts you with an opportunity to continue editing and resolve any errors.

When you edit an existing component that can have associations, such as a Global Traffic Manager wide IP that can have pool member associations. but the component does not currently have associations, to create the new associations, you must use the full command syntax in the text file. For the full command syntax for each component, see the associated man page.

When you edit a component that has associations with components that are children of the component you are editing, the text file contains a line for the configuration of the child components that begins with the command modify, for example: pools modify { [existing pool members configurations] }. In this case, if you want to add or delete pool members, you must add additional lines to the text file, for example: pools delete { [pool members to delete] }.

If you want the text file that opens to contain all of the editable properties of the component that you want to edit, you must use the all-properties option at the end of the edit command sequence; otherwise, only the non-default properties display in the text file.

#### EXAMPLES

```
edit / gtm pool a*
```

From the root module, opens a file in an editor in which you can modify the configuration of all Global Traffic Manager pools with names that start with the letter a using the template that displays in the editor.

```
edit datacenter new_dc
```

From the gtm module, opens a file in an editor in which you can create the Data Center named new\_dc using the template that displays in the editor.

```
edit datacenter a*
```

From the gtm module, opens a file in an editor in which you can edit all existing datacenters with names that begin with the letter a.

```
edit datacenter new_datacenter existing_datacenter
```

From the gtm module, opens a file in an editor in which you can create a new datacenter and edit an existing datacenter. Note that when the file opens, a template displays that you can use to create a new datacenter followed by the configuration of the existing datacenter.

```
edit rule rule_1
```

From the gtm module, opens a file in an editor in which you can create an iRule named rule\_1 using the template that displays in the editor.

When the editor opens, and you are creating or editing an iRule, you must enclose the iRule syntax in brackets, for example, [ ...iRule... ]. Note that the template includes the brackets.

#### OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

component

Specifies the type of component that you want to create or modify.

module

Specifies the module within which the component resides.

name Specifies a unique name of each component that you want to create or modify.

## exit

#### NAME

exit command - Exits a tmsh module or component.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the command exit within a tmsh module or component to leave that module or component and return to the higher level of the shell structure.

exit

Note that to exit tmsh and return to the BIG-IP(r) system prompt, use the command quit.

**DESCRIPTION**  
For more information about the structure of tmsh, see the Traffic Management Shell (tmsh) Reference Guide.

**SEE ALSO**  
tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP      2012-04-05      exit(1)

---

## generate

**NAME**  
generate - Generate signed scripts using different algorithms for components (for example, iRules).

**MODULE**  
All tmsh modules.

**DESCRIPTION**  
Use the generate command to generate signed scripts for components. Currently two algorithms are supported: checksum and signature.

generate checksum  
generate signature signing-key

**SEE ALSO**  
ltm rule, sys application template

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

---

## help

**NAME**  
help command - Displays context-sensitive help text.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the command help within a tmsh module to display information about the components that reside within that module, or at the component level to display help about the component. To display help for a component that resides in one module from within another module, use the full path to the component.

Type the question mark (?) character anywhere in tmsh to display a list of modules, components, and commands that are available within the

module in which you are currently working.

```
?  
help  
help [module...module]  
help [component]  
help / [module...module] [component]  
help search [text]
```

#### DESCRIPTION

You can display tmsh man pages using the command help.

#### EXAMPLES

?

From within the gtm module, displays a list of modules, components, and commands that are available.

help pool

From within the gtm module, displays help about Global Traffic Manager pools.

help / ltm pool

From within the gtm module, displays help about Local Traffic Manager pools.

#### OPTIONS

component

Specifies the type of the component for which you want to display help.

search

Use the search option to find help topics that contain the specified text. The search is case insensitive. Text that contains a space or special tmsh characters must be quoted. Note that the search will not always find text that spans multiple lines.

module

Specifies the module within which the component for which you want to display help resides.

#### SEE ALSO

## install

#### NAME

install - Install and update components.

#### MODULE

All tmsh modules.

#### DESCRIPTION

Use the command install to install or update the following components. For the description and syntax see the help page for each component.

```
sys license  
sys software block-device-hotfix  
sys software block-device-image  
sys software hotfix  
sys software image
```

#### SEE ALSO

sys license, sys software block-device-hotfix, sys software block-device-image, sys software hotfix, sys software image, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2012. All rights reserved.

## list

**NAME**  
list command - Displays components that you have permission to view.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the list command within a tmsh module to display the properties of the components in that module. To display the properties of the components in one module from within another module, use the full path to the component.

```
list [component]
list [component] [name]
list [component] [name] [property]
list / [module...module] [component] [name] [property]
options:
  all-properties
  current-module
  non-default-properties
  one-line
  partition
  recursive
```

**DESCRIPTION**  
When the default Read partition is All, use the list command to display all of the components that you have permission to view within a tmsh module. When you specify a Read partition, the list command displays:

- o Only the components that you have permission to view in the current partition
- o All of the components that are not in partitions
- o All of the components in partition Common

**EXAMPLES**

```
list / ltm
```

From within the gtm module, displays the properties of all of the components in the ltm module, including the components in the ltm monitor, ltm persistence, and ltm profile modules.

```
list / ltm current-module
```

From within the gtm module, displays the properties of all of the components in the ltm module, not including the components in the ltm monitor, ltm persistence, and ltm profile modules.

```
list pool
```

From within the gtm module, displays the properties of all of the Global Traffic Manager pools.

```
list pool all-properties
```

From within the gtm module, displays all of the properties of all of the Global Traffic Manager pools.

```
list pool monitor
```

From within the gtm module, displays the monitor associated with each Global Traffic Manager pool.

```
list / ltm pool
```

From within the gtm module, displays the properties of all of the Local Traffic Manager pools.

**OPTIONS**

**all-properties**  
Displays the values of all of the properties of the specified component.

**component**  
Specifies the component that you want to display.

**current-module**  
Specifies to display only the components that reside in the specified module, not the components that reside in the sub-modules of that module.

For example, from within the ltm module to display only the components in the gtm module, and not the components in the gtm monitor and gtm settings sub-modules, use the following command sequence: list / gtm current-module.

**module**

Specifies the module within which the component that you want to display resides.

Note: When you use the command list at the module level, by default, the system does not display all of the components that reside in the specified module. To display the properties of some components you must explicitly specify the component. For example, from the ltm module, to display the virtual addresses for the Local Traffic Manager, use this command sequence:

```
list virtual-address
```

For more information about displaying the properties of a component, see the man page for the component.

**name** Specifies the unique name of the component.

**non-default-properties**  
Displays the values of all of the properties for which a user changed the value from the default value for the specified component.

**one-line**  
Displays the configuration for each object on one line. Configuration that consists of scripts will not be formatted on to a single line. This include ltm and gtm iRules and tmsh scripts.

**partition**  
Displays the administrative partition within which the specified component exists.

**property**  
Specifies the property of the component that you want to display.

**recursive**  
Specifies to display the components not only from the current folder but also from all sub-folders recursively.

## load

**NAME**  
load command - Replaces the running configuration of the BIG-IP(r) system with the configuration in the specified files. You can also use this command to import an ASM policy from a file / standard input, and to install the Anti-fraud engine / signatures update.

**MODULE**  
All tmsh modules.

**SEE ALSO**  
save, tmsh, asm policy, ltm dns dns-express db, sys config, sys geoip, sys ucs

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## modify

**NAME**  
modify command - Modifies a tmsh component.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the command modify within a tmsh module to modify a component that resides in that module. To modify a component in one module from within another module, use the full path to the component.

```
modify [component] [name] [property [value] ]...  
modify / [module...module] [component] [name] [property [value] ]...
```

**DESCRIPTION**  
You must provide the name of the component that you want to modify.

You can apply one or more property settings to multiple components using a single command sequence. For example, to associate the Local Traffic Manager pool named pool-1 with the virtual servers named virtual-1 and virtual-2, use this command sequence: modify ltm virtual virtual-1 virtual-2 pool pool-1

**EXAMPLES**

```
modify pool pool1 disabled
```

From within the gtm module, disables the Global Traffic Manager pool named pool1.

```
modify / ltm pool my_pool disabled
```

From within the gtm module, disables the Local Traffic Manager pool named my\_pool.

**OPTIONS**

**component**  
Specifies the type of the component that you want to modify.

**module**  
Specifies the module within which the component that you want to modify resides.

**name**  
Specifies the unique name of the component that you want to modify.

**property [value]...**  
Specifies the properties of the component that you want to modify and their new values.

**SEE ALSO**  
tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

**BIG-IP**      2016-03-14      modify(1)

---

## **mv**

**NAME**  
mv command - Renames or moves a TMOS(tm) configuration object.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the mv command within a tmsh module to move or rename the component that resides in that module. To move a component that resides in another module, use the full path to the component.

```
mv [component] [source] [destination]  
mv / [module...module] [component] [source] [destination]
```

**DESCRIPTION**  
You must provide a unique name for the source and destination of the move operation.

**WARNING** Currently MV is an experimental feature. By using this feature, you may be subject to loss of statistics and disruption in GTM service. If you plan to move or rename a Virtual Server, please contact your GTM administrator before doing so. You may enable this feature by setting the appropriate db variable. This can be done by issuing the command:

```
modify /sys db mcpd.mvenabled value true
```

This will turn on the feature and allow moving and rename of select objects through TMSH only. Once you have finished using the feature, we recommend disabling it once again. You may do this by issuing the following command:

```
modify /sys db mcpd.mvenabled value false
```

Please use responsibly.

#### EXAMPLES

```
mv cm device bigip seattle32
```

Renames the device named bigip to seattle32.

```
mv ltm pool mypool myotherpool
```

Renames the LTM Pool named mypool to myotherpool.

```
mv ltm pool /Common/by/mypool /Common/myotherpool  
/Common/sub/mythirdpool to-folder /Partition2/sub1
```

Moves the 3 pools in 3 different locations named mypool, myotherpool and mythirdpool into a single folder in another partition.

#### OPTIONS

**to-folder**

Specifies the folder to move the item or items into.

**component**

Specifies the type of the component that you want to move.

**destination**

Specifies a unique name for the component.

**module**

Specifies the module within which the component that you want to move resides.

**source**

Specifies the component to be moved.

## publish

#### NAME

publish - Finalizes changes in the policy by creating a read-only copy of it.

#### MODULE

All tmsh modules.

#### DESCRIPTION

Use the command publish to make wam policies available for usage in wam applications. You can also use this command to apply asm policies. For the description and syntax see the help page for wam policy or asm policy.

#### SEE ALSO

asm policy, wam policy, tmsh

#### COPYRIGHT

## pwd

**NAME**  
pwd command - Display the current working folder.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the command pwd to display the current working folder.

pwd

**DESCRIPTION**  
Display the current working folder

**EXAMPLES**  
pwd

**SEE ALSO**  
cd, help, sys folder, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2012-04-05 pwd(1)

---

## quit

**NAME**  
quit command - Exits tmsh.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the following command at the tmsh prompt to close tmsh and return to the BIG-IP(r) system prompt.

quit

Note that to exit a tmsh module or component, you use the command exit.

**SEE ALSO**  
tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2010. All rights reserved.

BIG-IP 2010-12-06 quit(1)

---

## reboot

**NAME**  
reboot command - Reboots the system or boots the system into a different volume.

**MODULE**

All tmsh modules.

#### SYNTAX

```
reboot
options:
slot [ [slot number] | all ]
volume [name]
```

#### DESCRIPTION

You can use the command `reboot` to reboot the system or cluster. If you do not specify an option, the local system reboots.

You can use the `volume` option to reboot a system into a specific volume. For a cluster, you can use the `volume` option to reboot all slots into the specified volume.

Additionally, for a cluster, you can use the `slot` option to reboot either a specific slot or all slots. Note that the `slot` option does not modify the active volume.

#### EXAMPLES

```
reboot
```

Immediately reboots the running image.

```
reboot volume HD1.2
```

If the volume `HD1.2` has a complete image on it, the system (or cluster) reboots into that image immediately. However, if a software installation is in progress on the volume the system reboots as soon as the installation is complete.

#### OPTIONS

```
slot [ [slot number] | all ]
```

Reboots either a specific slot or all slots in a cluster, without changing the active volume of the slot(s).

This option is only available in a clustered environment.

Note: The `slot` and `volume` options are mutually exclusive.

```
volume
```

Specifies the volume that you want to boot. The volume you specify becomes the default boot volume. You cannot specify the active volume. In a clustered environment all slots reboot into the same volume.

Note: The `slot` and `volume` options are mutually exclusive.

#### SEE ALSO

`install`, `sys software hotfix`, `sys software image`, `sys software status`, `sys software volume`, `tmsh`

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2012-09-04 reboot(1)

---

## reset-stats

#### NAME

`reset-stats` - Resets statistics for the specified components.

#### MODULE

All tmsh modules.

#### SYNTAX

Use the command `reset-stats` within a tmsh module to reset the statistics for the specified component to zero. To reset the statistics for the specified component in one module from within another module, use the full path to the component.

```
reset-stats [component]
reset-stats [component] [name]
reset-stats / [module...module] [component]
reset-stats / [module...module] [component] [name]
```

#### DESCRIPTION

You can reset statistics for a group of components, or you can reset statistics for a specific component.

After you reset statistics, when you run the command `show`, you may see a value of `nan`. This stands for not a number, which indicates that no data is currently available. Wait a few moments and run the command `show` again, and in most cases the `nan` value will be replaced by an

integer value.

It is important to note the following when you reset statistics:

- o For a data center, the system also resets the statistics for the servers in that data center.
- o For a Global Traffic Manager server, the system also resets the statistics for the virtual servers on that server.
- o For a Global Traffic Manager pool, the system also resets the statistics for the pool members.
- o For a Local Traffic Manager pool, the system also resets the statistics for the pool members.
- o For a VLAN, you must reset the statistics for the trunks and interfaces associated with the VLAN.
- o You cannot reset statistics for system-supplied profiles.

#### EXAMPLES

```
reset-stats pool
```

From within the gtm module, resets the statistics for all of the Global Traffic Manager pools.

```
reset-stats pool pool1
```

From within the ltm module, resets the statistics for the Local Traffic Manager pool named pool1.

```
reset-stats / ltm pool my_pool
```

From within the gtm module, resets the statistics for the Local Traffic Manager pool named my\_pool.

```
reset-stats all-stats
```

From within the sys performance module, resets all performance statistics for the system.

#### OPTIONS

**component**

Specifies the type of the component for which you want to reset statistics.

**module**

Specifies the module within which the component for which you want to reset statistics resides.

**name** Specifies the unique name of the component for which you want to reset statistics.

#### SEE ALSO

## restart

#### NAME

restart command - Restarts a service on the BIG-IP(r) system.

#### MODULE

All tmsh modules.

#### SYNTAX

Use the command restart within tmsh to restart a specified service.

```
restart
options:
/sys service [service name]
```

#### DESCRIPTION

You can use the command restart to restart a specified service.

#### EXAMPLES

```
restart /sys service mcpd
```

Restarts the mcpd daemon.

```
restart /sys service snmpd
```

Restarts the snmpd daemon.

#### OPTIONS

Tip: Use the tab completion feature to see a list of available services.

#### SEE ALSO

start, stop, sys service, tmsh

#### COPYRIGHT

## run

#### NAME

run command - Runs the specified program.

#### MODULE

All tmsh modules.

#### SYNTAX

Use the run command within tmsh to run a specified utility.

run

options:

```
/cli script [arguments]
/cm add-to-trust
/cm config-sync
/cm remove-from-trust
/cm sniff-updates
/cm watch-devicegroup-device
/cm watch-sys-device
/cm watch-trafficgroup-device
/gtm big3d_install [arguments]
/gtm bigip_add [arguments]
/gtm gtm_add [arguments]
/security anti-fraud engine-update
/security anti-fraud signatures-update [arguments]
/sys air-filter-reset
/util bash [arguments]
/util diadb [arguments]
/util dig [arguments]
/util dnat [arguments]
/util get-dossier [arguments]
/util get_ccn_dossier
/util ihealth [arguments]
/util ipsecalgdb [arguments]
/util lsndb [arguments]
/util netstat [arguments]
/util ping [arguments]
/util ping6 [arguments]
/util qkview [arguments]
/util racoonctl [arguments]
/util sipdb [arguments]
/util sys-icheck [arguments]
/util tcpdump [arguments]
/util tracepath [arguments]
/util tracepath6 [arguments]
/util traceroute [arguments]
/util traceroute6 [arguments]
/wom diagnose-conn
/wom verify-config
```

#### DESCRIPTION

You can use the run command to run the specified program, utility or process.

You can read about the arguments that are available for the utilities in the cm module using the following command sequence:

```
help /cm [utility name]
```

You can read about the arguments that are available for the utilities in the gtm module using the following command sequence:

```
help /gtm [big3d_install | bigip_add | gtm_add]
```

You can read about the arguments that are available for the utilities in the util module using the following command sequence:

help /util [utility name]

Note: Some tmsh features, such as tab completion, context-sensitive help, paging, and grep, are not available for utilities.

When you are building a batch mode transaction in tmsh, if you type the run command, the system runs the specified program immediately. It does not add the run command to the transaction that you are building.

#### EXAMPLES

help /util ping

Displays the help page for the ping utility.

#### OPTIONS

big3d\_install

Specifies to install the big3d daemon.

bigip\_add

Specifies the BIG-IP systems that you want to add to the Global Traffic Manager configuration.

bash Accesses the system shell.

add-to-trust

Add a device to a trust domain.

config-sync

Synchronize the configuration between devices.

remote-from-trust

Remove a device from a trust domain.

sniff-updates

Display the commit ID updates that occur over the CMI communications channel. When you troubleshoot a ConfigSync issue, it is helpful to determine which device group member has the latest commit ID update and contains the most recent configuration. You can then decide whether to replicate the newer configuration to the group, or perform a ConfigSync operation that replicates an older configuration to the group, thus overwriting a newer configuration.

watch-devicegroup-device

Display information about the devices in the device group to which the local device belongs.

watch-sys-device

Display information about the local device.

watch-trafficgroup-device

Display information about the traffic groups associated with devices in a device group.

diagnose-conn

Runs the specified diagnose-conn script, which detects the sources of network connection and performance problems in a WAN optimization configuration.

dig Runs the specified dig command. The dig utility queries DNS name servers.

dnat Runs the specified dnat command for the purpose of doing forward/reverse mapping of addresses for DNAT.

sipdb

Displays SIP persistence entries. The sipdb utility displays specific persistence entries and delete a particular persistence record.

diadb

Displays Diameter persistence entries. The diadb utility displays diameter persistence entries or delete a particular persistence entry.

get-dossier

Runs the get\_dossier utility for the purpose of displaying system license dossier information.

get-ccn-dossier

Runs the get\_ccn\_dossier utility for the purpose of displaying system information for dossier creation.

gtm add

Specifies the Global Traffic Manager systems that you want to add to the Global Traffic Manager configuration.

ihealth

Runs the ihealth utility for the purpose of uploading a new or existent qkview file to ihealth.

lsndb

Runs the lsndb utility to view Large Scale NAT persistence entries, inbound mappings, client connection counts, and PCP mappings.

ipsecalgdb

Runs the ipsecalgdb utility to view IPsecALG translation, and pending IKE connection count entries.

netstat

Displays network connections, routing tables, interface statistics, masquerade connections, and multicast memberships.

ping Runs the specified ping command. The ping utility sends ICMP echo requests to network hosts.

ping6  
Runs the specified ping6 command. The ping6 utility sends ICMPv6 echo requests to network hosts.

qkview  
Runs the specified qkview command. The qkview utility gathers diagnostic information from a BIG-IP system.

racoontl  
Runs the specified racoontl command. The racoontl utility is used to control operation of the racoon daemon.

ssh-keyswap  
Runs the keyswap.sh script for managing SSH keys on the BIG-IP.

sys-icheck  
Runs the specified sys-icheck command. The sys-icheck utility verifies all RPM packages and files.

tcpdump  
Runs the specified tcpdump command. The tcpdump utility prints headers and content of network traffic.

tracpath  
Displays the route packets take to a network host.

tracpath6  
Displays the route packets take to an IPv6 network host.

traceroute  
Displays the route packets take to a network host.

traceroute6  
Displays the route packets take to an IPv6 network host.

verify-config  
Runs the specified verify-config script, which detects errors in the configuration of the WAN Optimization Manager.

engine-update  
For the description and syntax see the help page for security anti-fraud engine-update.

signatures-update  
For the description and syntax see the help page for security anti-fraud signatures-update.

air-filter-reset  
Runs the command to reset the timer and the retry counter for air filter notifications.

## save

NAME

save - Writes the running configuration of the BIG-IP(r) system to the specified file.

MODULE

All tmsh modules.

DESCRIPTION

You can use the save command to write changes that you make to the running configuration of the BIG-IP system to the specified file. You can also use this command to save an analytics report to a file on the BIG-IP(r) system or to export an ASM policy to a file / standard output.

SEE ALSO

analytics report, asm policy, load, sys config, sys ucs, tmsh

## COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2012. All rights reserved.

BIG-IP 2012-10-16 save(1)

---

## send-mail

### NAME

send-mail - Send an e-mail to a list of recipients containing configuration or statistical information about the BIG-IP(r) system.

### MODULE

All tmsh modules.

### DESCRIPTION

You can use the send-mail command to send an analytics report from the BIG-IP system to a list of e-mail recipients.

### SEE ALSO

analytics report, tmsh

## COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-07-22 send-mail(1)

---

## show

### NAME

show command - Displays statistics for and the status of specified components.

### MODULE

All tmsh modules.

### SYNTAX

Use the show command within a tmsh module to display statistics for and the status of components in that module. To display statistics for and the status of components in another module, use the full path to the component.

```
show
show [component]
show [component] [name]
show / [module] [component] [name]
options:
  all-stats
  current-module
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  (detail | global | historical)
  field-fmt
  running-config
  recursive
```

### DESCRIPTION

You can use the show command to specify the unit value in which the system displays statistics and the type of statistics that you want the system to display.

After you reset statistics, when you run the command show, you may see a value of nan. This stands for not a number, which indicates that no data is currently available. Wait a few moments and run the show command again, and in most cases the nan value is replaced by an integer value. For more information, see help reset-stats.

## EXAMPLES

```
show / ltm current-module
```

From within the gtm module, displays statistics and status for all the components within the ltm module, but not the components in the ltm monitor, ltm persistence, and ltm profile modules.

```
show pool
```

From within the gtm module, displays statistics and status for all Global Traffic Manager pools.

```
show pool pool1
```

From within the gtm module, displays statistics and status for the Global Traffic Manager pool named pool1.

```
show / ltm pool
```

From within the gtm module, displays statistics and status for all Local Traffic Manager pools.

```
show / ltm profile tcp global
```

From within the gtm module, displays global statistics and status for all Local Traffic Manager TCP profiles in the system default unit.

## OPTIONS

all-stats

Displays all of the available system performance statistics.

component

Specifies the type of the component for which you want to show statistics and status.

current-module

Specifies to display only the components that reside in the specified module, not the components that reside in the sub-modules of that module.

For example, from within the ltm module to display only the components in the gtm module, and not the components in the gtm monitor and gtm settings sub-modules, use this command sequence:  
show / gtm current-module.

default

Displays data in the simplest units. For example, if the value of the data is 1,200,001, the system displays 1.20M; however, if the value of the data is 1,200, the system displays 1.2K.

detail

Displays detailed data for the specified component and associated components. Note that this option is available for only a partial set of tmsh components.

You can use the tab completion and context-sensitive help features to determine if this option is available. For more information about these features, see help.

field-fmt

Displays data as a list of options and their values. The option names can be used to retrieve statistics and status values in a shell script, see cli script.

gig Displays data in parts per billion.

global

Displays global statistics for the specified component that includes statistics for all components of the specified type. Note that this option is available for only a partial set of tmsh components. You can use the tab completion and context-sensitive help features to determine if this option is available.

historical

Displays historical statistics for the specified component. Note that this option is available only for a partial set of tmsh components. You can use the tab completion and context-sensitive help features to determine if this option is available.

kil Displays data in parts per thousand.

lines

Specifies how many lines of the log that you want the system to display.

meg Displays data in parts per million.

module

Specifies the module within which the component for which you want to show statistics and status resides.

Note: When you use the command show at the module level, by default, the system does not display all of the components that reside in the module. To display some components you must explicitly specify the component. For example, from the ltm module, to display the statistics for and status of the virtual addresses of the Local Traffic Manager, use the following command sequence:

```
show virtual-address
```

For more information about displaying statistics for and status of a component, see the man page for the component.

name Specifies the unique name of the component for which you want to show statistics and status.

range

Specifies a date range for the logs that you want the system to display, for example:

2d-4d

Specifies 2 - 4 days ago.

3d Specifies 3 days ago to now.

epoch--7/25:12:00:00

Specifies everything older than July 25th at noon.

2008-07-25--2008-07-28:13:30

Specifies between July 25th and 28th at 1:30 p.m.

raw Displays raw data.

recursive

Specifies to display the components not only from the current folder, but also from all sub-folders recursively.

running-config

Displays the running configuration of the components that you have permission to view within a tmsh module, if the default Read partition is All. If you specify a Read partition, this option displays only the components that you have permission to view in the current partition, all of the components that are not in partitions, and all of the components in partition Common. Note that this option is valid only for tmsh components you can configure.

The running-config option must be specified immediately after the show command, for example:

```
show running-config ltm pool
```

SEE ALSO

cli script, tmsh

## shutdown

NAME

shutdown command - Shuts down the system.

MODULE

All tmsh modules.

SYNTAX

```
shutdown
options:
slot [ [slot number] | all ]
```

DESCRIPTION

You can use the command shutdown to power down the system or cluster. If you do not specify an option, the local system shuts down.

For a cluster, you can use the slot option to shut down either a specific slot or all slots.

EXAMPLES

```
shutdown
```

Immediately shuts down the running system.

OPTIONS

slot [ [slot number] | all ]  
Shuts down either a specific slot or all slots in the cluster. This option is only available in a clustered environment.

SEE ALSO

reboot, install

## start

**NAME**  
start command - Starts a service on the BIG-IP(r) system.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the start command within tmsh to restart a specified service.

```
start
options:
/sys service [service name]
```

**DESCRIPTION**  
You can use the start command to start a specified service.

**EXAMPLES**

```
start /sys service mcpd

Starts the mcpd daemon.

start /sys service snmpd

Starts the snmpd daemon.
```

**OPTIONS**  
Tip: Use the tab completion feature to see a list of available services.

**SEE ALSO**  
restart, stop, sys service, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2013, 2016. All rights reserved.

BIG-IP 2016-03-14 start(1)

---

## stop

**NAME**  
stop command - Stops a service that is running on the BIG-IP(r) system.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the command stop within tmsh to stop a running service.

```
stop
options:
/sys service [service name]
```

**DESCRIPTION**  
You can use the command stop to stop a running service.

**EXAMPLES**

```
stop /sys service mcpd

Stops the mcpd daemon.

stop /sys service snmpd
```

Stops the snmpd daemon.

OPTIONS

Tip: Use the tab completion feature to see a list of available services.

SEE ALSO

restart, start, sys service, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 stop(1)

---

## submit

NAME

submit - Runs the transaction that you are creating.

MODULE

All tmsh modules.

SYNTAX

Use the submit command to run a transaction that you are creating.

submit transaction

DESCRIPTION

You can use the submit command to run a transaction, which is a series of commands that you enter in transaction mode.

For more information about creating transactions, see cli transaction.

SEE ALSO

cli transaction, tmsh

COPYRIGHT

## analytics

### analytics afm-sweeper report

NAME

report - Displays an afm-sweeper analytics report.

MODULE

analytics afm-sweeper

SYNTAX

Show, save or send an analytics afm-sweeper report using the syntax shown in the following sections.

DISPLAY

show report view-by [ policy-name | context-type | context-name | eviction-reason | client-ip ]

```

options:
  drilldown {
  {
entity [ policy-name | context-type | context-name | eviction-reason | client-ip ]
values
{
  [value ...]
}
} ...
}
field-fmt
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]

SAVE
save report view-by [ policy-name | context-type | context-name | eviction-reason | client-ip ]
options:
  drilldown {
  {
entity [ policy-name | context-type | context-name | eviction-reason | client-ip ]
values
{
  [value ...]
}
} ...
}
file [ file name ]
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]

SEND
send-mail report view-by [ policy-name | context-type | context-name | eviction-reason | client-ip ]
options:
  drilldown {
  {
entity [ policy-name | context-type | context-name | eviction-reason | client-ip ]
values
{
  [value ...]
}
} ...
}
email-addresses {
  [email address ...]
}
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate afm-sweeper analytics reports. You can generate an afm-sweeper analytics report for the following entities:

- o policy-name - Name of the sweeper policy.
- o context-type - The context type of the eviction. Can be one of three possible values: "Virtual Server", "Route Domain", "Global".
- o context-name - The name of the context. Depends on the context-type this value can be either a virtual server name (e.g. "my\_vs1"), route domain id (e.g. 317) or "Global".
- o eviction-reason - The algorithm used by sweeper that caused the eviction of a connection.
- o client-ip - The source IP of the evicted connection.

Different measures are collected for each of these entities and can be a part of the report request.

## EXAMPLES

```
show analytics afm-sweeper report view-by client-ip

show analytics afm-sweeper report view-by client-ip drilldown { {
entity context-type values { Global } } }

send-mail analytics afm-sweeper report view-by client-ip measures {
avg-connections-age } limit 15 order-by { { measure avg-connections-age
sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

## OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file**  
Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**avg-connections-age**  
The average time that the connections lasted before evicted for the selected filter (entity).

**evicted-connections**  
The total number of evicted connections for the selected filter (entity).

**total-bytes-in**  
The total number of bytes received for the selected filter (entity).

**total-bytes-out**  
The total number of bytes sent for the selected filter (entity).

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate application-security-anomalies analytics reports. You can generate an application-security-network analytics report for the following entities:

- o anomaly-type - Anomaly type (Brute Force/Web Scraping)
- o application - Application services.
- o policy - Security policy.
- o virtual - Virtual servers.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics application-security-network report view-by application
```

```
show analytics application-security-network report view-by application
drilldown { { entity virtual values { my_vip } } }
```

```
send-mail analytics application-security-anomalies report view-by
virtual measures { rejected-requests } limit 20 order-by { { measure
rejected-requests sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### rejected-requests

The total number of rejected requests for the selected filter (entity).

##### total-attacks

The total number of attacks for the selected filter (entity).

##### total-violations

The total number of violations for the selected filter (entity).

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

#### DESCRIPTION

Use this command to generate application-security-anomalies analytics reports. You can generate an application-security-network analytics report for the following entities:

- o anomaly-type - Anomaly type (Brute Force/Web Scraping)
- o application - Application services.
- o policy - Security policy.
- o virtual - Virtual servers.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics application-security-network report view-by application
```

```
show analytics application-security-network report view-by application
drilldown { { entity virtual values { my_vip } } }
```

```
send-mail analytics application-security-anomalies report view-by
virtual measures { rejected-requests } limit 20 order-by { { measure
rejected-requests sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**rejected-requests**  
The total number of rejected requests for the selected filter (entity).

**total-attacks**  
The total number of attacks for the selected filter (entity).

total-violations  
The total number of violations for the selected filter (entity).

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

#### DESCRIPTION

Use this command to generate application-security-network analytics reports. You can generate an application-security-network analytics report for the following entities:

- o application - Application services.
- o virtual - Virtual servers.
- o request-type - Request types (Legal/Alarmed/Blocked).
- o policy - Security policy.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics application-security-network report view-by violation

show analytics application-security-network report view-by violation
drilldown { { entity severity values { Error } } }

send-mail analytics application-security-network report view-by virtual
measures {events} limit 20 order-by { { measure events sort-type desc
} } format pdf email-addresses { some.one@someaddress.com }

```

For more syntactical examples see manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file**  
Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**events**  
The total number of events (requests) for the selected filter (entity).

**throughput**  
The average throughput (bits/s) for the selected filter (entity).

**tps** The average number of transactions per second for the selected filter (entity).

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

**SEE ALSO**

show, save, send-mail, tmsh, ltm profile analytics, analytics, analytics report

**COPYRIGHT**

```

#### DESCRIPTION

Use this command to generate application-security analytics reports. You can generate an application-security analytics report for the following entities:

- o application - Application services.
- o virtual - Virtual servers.
- o request-type - Request types (Legal/Alarmed/Blocked).
- o severity - Violation severities.
- o rating - Violation ratings.
- o username - User names.
- o attack-type - Attack type of the illegal request.
- o ip-address-intelligence - IP Address reputation categories.
- o policy - Security policy.
- o response-code - Response codes.
- o ip - Source IP addresses.
- o violation - Violation types.
- o country - Countries of the source IP address.
- o method - HTTP methods.
- o protocol - Protocols (HTTP/HTTPS).
- o session-id - IDs of sessions.
- o url - Requested URLs.
- o virus - Viruses that were detected by the system.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics application-security report view-by violation

show analytics application-security report view-by violation drilldown
{ { entity severity values { Error } } }

send-mail analytics application-security report view-by ip measures
{requests} limit 20 order-by { { measure requests sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples see manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### requests

The total number of requests for the selected filter (entity).

##### occurrences

Number of occurrences for the selected filter (relevant for attack-type, violation and ip-address-intelligence entities)

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### SEE ALSO

## analytics application-security scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for application security (ASM).

**MODULE**  
analytics application-security

**SYNTAX**  
Configure the scheduled-report component within the analytics application-security module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create scheduled-report [name]  
modify scheduled-report [name]  
options:  
  email-addresses [none | add | delete | modify |  
    replace-all-with] { email-address [string] }  
  first-time [date]  
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]  
  include-total [enabled | disabled]  
  multi-leveled-report {  
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }  
  limit [number of rows]  
  time-diff [last-hour | last-day | last-week | last-month | last-year]  
  view-by { entity name [string] }  
  }  
  predefined-report-name [name]  
  smtp-config [name]

**DISPLAY**  
list scheduled-report  
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]  
show running-config scheduled-report  
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

**DELETE**  
delete scheduled-report [name]

**DESCRIPTION**  
Use the scheduled-report component to create, modify or delete scheduled reports for the application security module.

**EXAMPLES**  
create scheduled-report myScheduledReport first-time now predefined-report-name "Top blocked URLs" frequency every-6-hours email-addresses add { person@domain.com } smtp-config asm\_smtp\_conf

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

modify scheduled-report myScheduledReport smtp-config none

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

create scheduled-report myCustomScheduledReport first-time now email-addresses add { person@domain.com } frequency every-6-hours smtp-config asm\_smtp\_conf multi-leveled-report { view-by url time-diff last-hour limit 5 chart-path add { policy violation } }

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the application security scheduled reports.

**OPTIONS**

**email-addresses**  
A list of the email addresses of the recipients that receive the scheduled report.

**first-time**  
First scheduled report time. Must be after current time and rounded up to the next round hour.

**frequency**  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

#### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics application-security report.

#### limit

The number of view-by entities displayed in the scheduled report.

#### time-diff

The time range for the report.

#### view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics application-security report.

#### measures

The measures which are available for the selected entities.

#### predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

#### smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

#### SEE ALSO

list, modify, show, tmsh, analytics application-security report, sys smtp-server

#### COPYRIGHT

```

#### DESCRIPTION

Use this command to generate asm-bypass analytics reports. You can generate an asm-bypass analytics report for the following entities:

- o slot - Blade Number
- o memory - BD memory

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics asm-bypass report view-by slot
```

```
show analytics asm-bypass report view-by slot drilldown { { entity slot
values { slot_index } } }
```

```
end-mail analytics asm-bypass report view-by slot measures { backlog-
messages } limit 20 order-by { { measure backlog-messages sort-type
desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**

Specifies a list of measures that can be used with the chosen entity type. The options are:

**backlog-messages**

The sum of backlog messages for the selected filter (entity).

**http-requests**

The sum of HTTP requests for the selected filter (entity).

**transactions-bypass**

The sum of transactions bypass for the selected filter (entity).

**order-by**

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

**SEE ALSO**

```

#### DESCRIPTION

Use this command to generate asm-cpu analytics reports. You can generate an asm-cpu analytics report for the following entities:

- o virtual - Virtual servers.
- o slot - Blade Number

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics asm-cpu report view-by slot
```

```
show analytics asm-cpu report view-by slot drilldown { { entity slot
values { slot_index } } }
```

```
send-mail analytics asm-cpu report view-by slot measures { bd-cpu-
utilization } limit 20 order-by { { measure bd-cpu-utilization sort-
type desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

bd-cpu-utilization

The BD CPU utilization for the selected filter (entity).

tmm-cpu-utilization

The TMM CPU utilization for the selected filter (entity).

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics asm-memory report

NAME

report - Displays an asm-memory analytics report.

MODULE

analytics asm-memory

SYNTAX

Show, save or send an analytics asm-memory report using the syntax shown in the following sections.

DISPLAY

```
show report view-by [ slot ]
options:
  drilldown {
  {
entity [ slot ]
values
{
```

```

    [value ...]
  }
  } ...
}
field-fmt
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]

SAVE
save report view-by [ slot ]
options:
  drilldown {
    {
      entity [ slot ]
      values
      {

    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate asm-memory analytics reports. You can generate a ASM memory analytics report for the following entities:

- o slot - Slot ID

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics asm-memory report view-by slot
```

```
show analytics asm-memory report view-by slot drilldown { { entity slot
values { slot_index } } }
```

```
send-mail analytics asm-memory report view-by slot measures { total-
swap-size } limit 20 order-by { { measure total-swap-size sort-type
desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**bd-memory-utilization**  
The BD memory utilization out of total assigned to BD (in percents) for the selected filter (entity).

**tmm-memory-util**  
The TMM memory utilization out of total assigned to TMM (in percents) for the selected filter (entity).

**bd-swap-size**  
The swap used by BD in MBs for the selected filter (entity).

**total-swap-size**  
The total swap used in MBs for the selected filter (entity).

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]
```

## DESCRIPTION

Use this command to generate cpu analytics reports. You can generate a IP-layer analytics report for the following entities:

- o slot - Slot ID
- o cpu - CPU number ID

Different measures are collected for each of these entities and can be a part of the report request.

## EXAMPLES

```
show analytics cpu report view-by cpu
```

```
show analytics cpu report view-by cpu drilldown { { entity cpu values {
1 } } }
```

```
send-mail analytics cpu report view-by slot measures { cpu-usage }
limit 20 order-by { { measure cpu-usage sort-type desc } } format pdf
email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### cpu-usage

The average time percentage of real CPU usage (user + system + nice) usage for the selected filter (entity).

**io** The average time percentage of (iowait + irq + softirq) for the selected filter (entity).

##### stolen

The average time percentage of virtual CPU waits for a real CPU while the hypervisor is servicing another virtual processor.

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

**DESCRIPTION** Use this command to generate disk-info analytics reports. You can generate a disk-info analytics report for the following entities:

o slot - Slot ID

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics disk-info report view-by slot
```

```
show analytics disk-info report view-by slot drilldown { { entity slot values { 7 } } }
```

```
send-mail analytics disk-info report view-by slot measures { total-ios } limit 20 order-by { { measure total-ios sort-type desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

total-ios

The total number of I/O for the selected filter (entity).

read-operations

The total number of read operations for the selected filter (entity).

read-merged

The total number of merged reads for the selected filter (entity).

write-operations

The total number of write operations for the selected filter (entity).

write-merged

The total number of merged writes for the selected filter (entity).

read-bytes

The total number of read bytes for the selected filter (entity).

write-bytes

The total number of write bytes for the selected filter (entity).

max-read-latency

The max value of read latency for the selected filter (entity).

average-read-latency

The average number of average read latency for the selected filter (entity).

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics dns report

NAME  
report - Displays a DNS analytics report.

MODULE  
analytics dns

SYNTAX  
Show, save or send an analytics dns report using the syntax shown in the following sections.

```
DISPLAY
show report view-by [ application | client-ip | domain-name | query-type | virtual | attack-id | transaction-outcome ]
options:
  drilldown {
  {
entity [ application | client-ip | domain-name | query-type | virtual | attack-id | transaction-outcome ]
values
{
  [value ...]
}
} ...
}
field-fmt
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc | desc ]
  } ...
}
range [date range]

SAVE
save report view-by [ application | client-ip | domain-name | query-type | virtual | attack-id | transaction-outcome ]
options:
  drilldown {
  {
entity [ application | client-ip | domain-name | query-type | virtual | attack-id | transaction-outcome ]
values
{
  [value ...]
}
} ...
}
file [ file name ]
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc | desc ]
  } ...
}
range [date range]

SEND
```

```

send-mail report view-by [ application | client-ip | domain-name | query-type | virtual | attack-id | transaction-outc
options:
  drilldown {
  {
entity [ application | client-ip | domain-name | query-type | virtual | attack-id | transaction-outcome ]
values
{
  [value ...]
}
} ...
}
email-addresses {
  [email address ...]
}
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc | desc ]
  } ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate DNS analytics reports. You can generate a DNS analytics report for the following entities:

- o application - Application services (iApps(tm)).
- o client-ip - DNS query source/client IP address.
- o domain-name - Queried domain name.
- o query-type - DNS query type.
- o virtual - Virtual server.
- o attack-id - (Only available with AFM is provisioned) DoS Attack ID.
- o transaction-outcome - Request outcome.

#### EXAMPLES

```

show analytics dns report view-by virtual

show analytics dns report view-by query-type drilldown { { entity
virtual values { /Common/v1 } } }

send-mail analytics dns report view-by client-ip limit 20 format pdf
email-addresses { some.one@someaddress.com }

For more syntactical examples see manual for analytics report.

```

#### OPTIONS

- device**  
Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)
- device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)
- drilldown**  
Specifies specific entities that are used as a filter.
- email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.
- file**  
Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).
- format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.
- include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.
- include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.
- limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.
- measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:
- packets

The total number of DNS packets for the specified view-by entity.

**order-by**

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

  {
    measure [ measure name ]
    sort-type [ asc | desc ]
  } ...
}
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate DoS (Layers 3-4) prevention analytics reports. You can generate a DoS prevention analytics report for the following entities:

- o action - Action taken (allowed/dropped).
- o application - Application services (iApps(tm)).
- o attack-id - DoS attack ID.
- o attack-type - DoS attack type.
- o category - Attack category.
- o source-ip - Source/client IP address.
- o virtual - Virtual server.
- o vlan - VLAN.
- o vlan-group - VLAN Group.

#### EXAMPLES

```

show analytics dos-13 report view-by virtual

show analytics dos-13 report view-by attack-type drilldown { { entity
virtual values { /Common/v1 } } }

send-mail analytics dos-13 report view-by source-ip limit 20 format pdf
email-addresses { some.one@someaddress.com }

For more syntactical examples see manual for analytics report.

```

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**

Specifies a list of measures that can be used with the chosen entity type. The options are:

**allowed-requests**

The total number of packets that were received by the virtual server(/s)s

**dropped-requests**

The total number of packets that were dropped by the virtual server(/s)s

**total-requests**

The total number of packets that were received or dropped by the virtual server(/s)s

**order-by**

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

**SEE ALSO**

show, save, send-mail, tmsh, analytics, analytics report

**COPYRIGHT**

#### DESCRIPTION

Use this command to generate HTTP analytics reports. You can generate an HTTP analytics report for the following entities:

- o application - Application services.
- o virtual - Virtual servers.
- o pool-member - Pool members.
- o url - A URL accessed by HTTP or HTTPS.
- o client-ip - A single client identified by an IP address.
- o country - A country from which HTTP/HTTPS traffic was sent to each of the virtual servers.
- o response-code - An HTTP response code that was sent back to the client.
- o method - An HTTP method used by the client (GET, CREATE, POST, DELETE, etc.).
- o user-agent - A browser identifier sent by the client's browser as part of the request for URL.

- o subnet - Client IP addresses classified into subnets.
- o attack-id - Application/L7 DoS Attack ID.
- o profile - DoS Layer 7 (Application) Profile.
- o transaction-outcome - Transaction outcomes (Blocked/Dropped/Passthrough/etc.)

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics http report view-by virtual measures {average-tps} limit 20
```

Gets the average tps of 20 virtual servers (unordered).

```
show analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } }
```

Gets the average tps of the top 20 virtual servers.

```
show analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } range now-3d--now
```

Gets the average tps of the top 20 virtual servers from the last three days.

```
show analytics http report view-by virtual drilldown { { entity application values { app } } { entity pool-member values { p1 p2 } } } range now-4d--now-2d measures {average-tps} limit 10 order-by { { measure average-tps sort-type DESC } }
```

Gets the average tps of the top 10 virtual servers (ordered by average tps) on app iApp (out of several monitored) on pool members p1 and p2 (out of five monitored p1-p5) in the interval ranging from two to four days ago.

```
show analytics http report view-by response-code drilldown { { entity virtual values { v1 } } } measures { transactions }
```

Gets a distribution of requests per response code on virtual v1.

```
show analytics http report view-by country drilldown { { entity application values { app } } } measures { average-concurrent-sessions average-sessions } order-by { { measure average-sessions sort-type DESC } } limit 5
```

Gets the new sessions and average concurrent sessions of the top five countries, ordered by the average concurrent sessions on the application app.

```
show analytics http report view-by client-ip drilldown { { entity virtual values { v1 } } } measures { max-page-load-time } limit 1
```

Gets the client IP address with the worst page load time.

```
show analytics http report view-by application drilldown { { entity pool-member values { p1 p2 } } } measures { transactions } order-by { { measure transactions } } range now-7d--now
```

Gets the distribution of requests per application on pool members p1 and p2 ordered by the number of requests during the last week.

```
save analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format pdf file report.pdf
```

Gets the average tps of the top 20 virtual servers and exports to a PDF file on the BIG-IP system.

```
save analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format csv-aggregated file report.csv
```

Gets the average tps of the top 20 virtual servers and exports to a CSV file on the BIG-IP system.

```
save analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format csv-time-series file report.csv
```

Gets the average tps over time of the top 10 virtual servers and exports to a CSV file on the BIG-IP system.

```
send-mail analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format pdf email-addresses { some.one@someaddress.com }
```

Gets the average tps over time of the top 10 virtual servers and sends out an email containing the report as a PDF.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The default value is transactions. The options are:

average-concurrent-sessions

The average number of concurrent sessions for each entity.

average-new-sessions

The average number of new sessions for each entity.

average-page-load-time

The average client page load time for each entity.

average-request-throughput

The average request throughput for each entity.

average-response-throughput

The average response throughput for each entity.

average-server-latency

The average server latency for each entity.

average-tps

The average number of transactions per second for each entity.

client-side-sampled-transactions

The number of transactions sampled for client side page load time.

max-page-load-time

The maximum client page load time for each entity.

max-request-throughput

The maximum request throughput for each entity.

max-response-throughput

The maximum response throughput for each entity.

max-server-latency

The maximum server latency for each entity.

max-tps

The maximum number of transactions per second for each entity.

transactions

The absolute number of transactions for each entity.

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The default value for measures is previously chosen measures. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

#### DESCRIPTION

Use this command to generate DoS Attacks analytics reports. You can generate a DoS Attacks analytics report for the following entities:

- o attack-id - Unique attack ID.
- o event-idx - Index of an event in an attack.
- o protocol - Attacked protocol (HTTP, DNS, SIP, Network).
- o virtual - Name of the attacked Virtual Server.
- o dos-profile - DoS profile that detects and mitigates the attack.
- o trigger - Threshold that was hit to indicate the attack.
- o vector - Attack vector (used by AFM, ASM has only 1 vector).
- o mitigation - Mitigation to the attack.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics dos-vis-attacks report view-by virtual
```

```
show analytics dos-vis-attacks report view-by virtual drilldown { {
entity protocol values { DNS } } }
```

```
send-mail analytics dos-vis-attacks report view-by virtual measures {
attack-severity } limit 15 order-by { { measure attack-severity sort-
type desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**event-start**  
The start moment of the event.

**event-end**  
The end moment of the event.

**total-blocked**  
Total number of blocked transactions.

**concurrent-ips**  
Maximum number of simultaneous attacking IPs per 10 second interval.

severity  
Calculated severity of the attack.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### DESCRIPTION

Use this command to generate HTTP analytics reports. You can generate an HTTP analytics report for the following entities:

- o application - Application services.
- o virtual - Virtual servers.
- o pool-member - Pool members.
- o url - A URL accessed by HTTP or HTTPS.
- o client-ip - A single client identified by an IP address.
- o country - A country from which HTTP/HTTPS traffic was sent to each of the virtual servers.
- o response-code - An HTTP response code that was sent back to the client.
- o method - An HTTP method used by the client (GET, CREATE, POST, DELETE, etc.).
- o user-agent - A browser identifier sent by the client's browser as part of the request for URL.
- o subnet - Client IP addresses classified into subnets.
- o attack-id - Application/L7 DoS Attack ID.
- o dosl7-profile - DoS Layer 7 (Application) Profile.
- o transaction-outcome - Transaction outcomes (Blocked/Dropped/Passthrough/etc.)
- o dosl7-bot-signature - DoS Layer 7 bot signature.
- o dosl7-bot-signature-category - DoS Layer 7 bot category.

Different measures are collected for each of these entities and can be a part of the report request.

## EXAMPLES

```
show analytics http report view-by virtual measures {average-tps} limit 20
```

Gets the average tps of 20 virtual servers (unordered).

```
show analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } }
```

Gets the average tps of the top 20 virtual servers.

```
show analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } range now-3d--now
```

Gets the average tps of the top 20 virtual servers from the last three days.

```
show analytics http report view-by virtual drilldown { { entity application values { app } } { entity pool-member values { p1 p2 } } } range now-4d--now-2d measures {average-tps} limit 10 order-by { { measure average-tps sort-type DESC } }
```

Gets the average tps of the top 10 virtual servers (ordered by average tps) on app iApp (out of several monitored) on pool members p1 and p2 (out of five monitored p1-p5) in the interval ranging from two to four days ago.

```
show analytics http report view-by response-code drilldown { { entity virtual values { v1 } } } measures { transactions }
```

Gets a distribution of requests per response code on virtual v1.

```
show analytics http report view-by country drilldown { { entity application values { app } } } measures { average-concurrent-sessions average-sessions } order-by { { measure average-sessions sort-type DESC } } limit 5
```

Gets the new sessions and average concurrent sessions of the top five countries, ordered by the average concurrent sessions on the application app.

```
show analytics http report view-by client-ip drilldown { { entity virtual values { v1 } } } measures { max-page-load-time } limit 1
```

Gets the client IP address with the worst page load time.

```
show analytics http report view-by application drilldown { { entity pool-member values { p1 p2 } } } measures { transactions } order-by { { measure transactions } } range now-7d--now
```

Gets the distribution of requests per application on pool members p1 and p2 ordered by the number of requests during the last week.

```
save analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format pdf file report.pdf
```

Gets the average tps of the top 20 virtual servers and exports to a PDF file on the BIG-IP system.

```
save analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format csv-aggregated file report.csv
```

Gets the average tps of the top 20 virtual servers and exports to a CSV file on the BIG-IP system.

```
save analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format csv-time-series file report.csv
```

Gets the average tps over time of the top 10 virtual servers and exports to a CSV file on the BIG-IP system.

```
send-mail analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format pdf email-addresses { some.one@someaddress.com }
```

Gets the average tps over time of the top 10 virtual servers and sends out an email containing the report as a PDF.

## OPTIONS

### device

Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)

### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

### drilldown

Specifies specific entities that are used as a filter.

### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

### format

Specifies the exported file format to be saved or sent. This

option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The default value is transactions. The options are:

average-concurrent-sessions

The average number of concurrent sessions for each entity.

average-new-sessions

The average number of new sessions for each entity.

average-page-load-time

The average client page load time for each entity.

average-request-throughput

The average request throughput for each entity.

average-response-throughput

The average response throughput for each entity.

average-server-latency

The average server latency for each entity.

average-tps

The average number of transactions per second for each entity.

client-side-sampled-transactions

The number of transactions sampled for client side page load time.

max-page-load-time

The maximum client page load time for each entity.

max-request-throughput

The maximum request throughput for each entity.

max-response-throughput

The maximum response throughput for each entity.

max-server-latency

The maximum server latency for each entity.

max-tps

The maximum number of transactions per second for each entity.

transactions

The absolute number of transactions for each entity.

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The default value for measures is previously chosen measures. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-lh).

smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

## DESCRIPTION

Use this command to generate ip-layer analytics reports. You can generate a IP-layer analytics report for the following entities:

- o ip - IP version (IPV4 / IPV6)

Different measures are collected for each of these entities and can be a part of the report request.

## EXAMPLES

```
show analytics ip-layer report view-by ip
```

```
show analytics ip-layer report view-by ip drilldown { { entity ip values { IP-V4 } } }
```

```
send-mail analytics ip-layer report view-by ip measures { dropped-pkts } limit 20 order-by { { measure dropped-pkts sort-type desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

## OPTIONS

### device

Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)

### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

### drilldown

Specifies specific entities that are used as a filter.

### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

### transmitted-pkts

The total number of transmitted packets for the selected filter (entity).

### received-pkts

The total number of received packets for the selected filter (entity).

### dropped-pkts

The total number of dropped packets for the selected filter (entity).

### err-invalid-len

The total number of error invalid length for the selected filter (entity).

### err-memory

The total number of error memory for the selected filter (entity).

### err-retransmitted

The total number of error retransmitted for the selected filter (entity).

### err-protocol

The total number of error protocol for the selected filter (entity).

### err-options

The total number of error options for the selected filter (entity).

### err-checksum

The total number of error checksum for the selected filter (entity).

### received-frags

The total number of received fragments for the selected filter (entity).

received-dropped-frags  
The total number of received dropped fragments for the selected filter (entity).

transmitted-frags  
The total number of transmitted fragments for the selected filter (entity).

transmitted-dropped-frags  
The total number of transmitted dropped fragment for the selected filter (entity).

reassembled-frags  
The total number of reassembled fragment for the selected filter (entity).

reassembled-dropped-frags  
The total number of 'too long' reassembled dropped fragment for the selected filter (entity).

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics lsn-pool report

NAME  
report - Displays an LSN Pool analytics report.

MODULE  
analytics lsn-pool

SYNTAX  
Show, save or send an analytics lsn-pool report using the syntax shown in the following sections.

```
DISPLAY
show report view-by [ lsn-pool ]
options:
  drilldown {
  {
entity [ none ]
values
{
  [value ...]
}
} ...
}
field-fmt
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
measure [ measure name ]
sort-type [ asc / desc ]
} ...
}
range [date range]
```

SAVE

```

save report view-by [ lsn-pool ]
options:
  drilldown {
    {
  entity [ none ]
  values
  {
    [value ...]
  }
  } ...
  }

  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate lsn-pool analytics reports. You can generate a LSN analytics report for the following entities:

- o lsn-pool - LSN Pool translation statistics

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics lsn-pool report view-by lsn-pool
```

```
send-mail analytics lsn-pool report view-by lsn-pool measures { active-
translations } limit 20 order-by { { measure active-translations sort-
type desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used

along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**active-translations**  
The average number of active LSN translations for the selected filter (entity).

**translation-request**  
The total number of LSN translation requests for the selected filter (entity).

**translation-failure**  
The total number of failed LSN translations for the selected filter (entity).

**translation-from-backup**  
The total number of LSN translations using the backup pool for selected filter (entity). Only applies to LSN Pool in Deterministic NAT mode.

**active-pb**  
The average number of active port-blocks for the selected filter (entity). Only applies to LSN Pool in PBA mode.

**pb-allocations**  
The total number of port-block allocations for the selected filter (entity). Only applies to LSN Pool in PBA mode.

**pb-freed**  
The total number of port-block deallocations for the selected filter (entity). Only applies to LSN Pool in PBA mode.

**zombie-block-created**  
The total number of zombie blocks created for the selected filter (entity). Only applies to LSN Pool in PBA mode.

**zombie-block-deleted**  
The total number of zombie blocks deleted for the selected filter (entity). Only applies to LSN Pool in PBA mode.

**active-pb-clients-reached-limit**  
The average number of port-block clients that have reached the port-block limit for the selected filter (entity). Only applies to LSN Pool in PBA mode.

**pb-client-reached-limit**  
The total number of port-block clients that have reached the port-block limit for the selected filter (entity). Only applies to LSN Pool in PBA mode.

**pcp-requests**  
The total number of PCP requests for the selected filter (entity). Only applies to LSN Pool with PCP profile.

**pcp-responses**  
The total number of PCP responses for the selected filter (entity). Only applies to LSN Pool with PCP profile.

**pcp-errors**  
The total number of PCP errors for the selected filter (entity). Only applies to LSN Pool with PCP profile.

**log-attempts**  
The total number of logging attempts for the selected filter (entity). Only applies to LSN Pool with Log publisher attached.

**log-failures**  
The total number of logging failures for the selected filter (entity). Only applies to LSN Pool with Log publisher attached.

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

#### DESCRIPTION

Use this command to generate memory analytics reports. You can generate a memory analytics report for the following entities:

- o slot - Slot ID

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics memory report view-by slot
```

```
show analytics memory report view-by slot drilldown { { entity slot
values { IP-V4 } } }
```

```
send-mail analytics memory report view-by slot measures { dropped-pkts
} limit 20 order-by { { measure host-usage sort-type desc } } format
pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**tmm-total-ram** The average of total TMM memory for the selected filter (entity).

**tmm-used-ram** The average of used TMM memory for the selected filter (entity).

**tmm-free-ram** The average of free TMM memory for the selected filter (entity).

**other-total-ram** The average of total other (daemons and kernel) memory for the selected filter (entity).

**other-used-ram** The average of used other (daemons and kernel) memory for the selected filter (entity).

**other-free-ram** The average of free other (daemons and kernel) memory for the selected filter (entity).

**system-total-ram** The average of total system memory for the selected filter (entity).

**system-used-ram** The average of used system memory for the selected filter (entity).

**system-free-ram** The average of free system memory for the selected filter (entity).

**swap-total-ram** The average of total swap memory for the selected filter (entity).

swap-used-ram The average of used swap memory for the selected filter (entity).  
swap-free-ram The average of free swap memory for the selected filter (entity).  
order-by Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### DESCRIPTION

Use this command to generate network firewall analytics reports. You can generate a network firewall analytics report for the following entities:

- o action - Action taken (allowed/dropped).
- o acl-enforced-application - Application services (ACL - Enforced).
- o acl-enforced-destination-ip - Destination IP Address (ACL - Enforced).
- o acl-enforced-destination-port - Destination IP Port (ACL - Enforced).

- o acl-enforced-policy - Policy (ACL - Enforced).
- o acl-enforced-rule-action - Rule Action (ACL - Enforced).
- o acl-enforced-rule-context - Rule Context (ACL - Enforced).
- o acl-enforced-rule-context-type - Rule Context Type (ACL - Enforced).
- o acl-enforced-rule - Rule (ACL - Enforced).
- o acl-enforced-self-ip - Self IP Address (ACL - Enforced).
- o acl-enforced-server-ip - Server IP Address (ACL - Enforced).
- o acl-enforced-source-ip - Source IP Address (ACL - Enforced).
- o acl-enforced-source-port - Source IP Port (ACL - Enforced).
- o acl-enforced-translation-pool - Translation Pool (ACL - Enforced).
- o acl-enforced-translation-type - Translation Type (ACL - Enforced).
- o acl-enforced-vlan - VLAN (ACL - Enforced).
- o acl-mgmt-application - Application services (ACL - Management).
- o acl-mgmt-destination-ip - Destination IP Address (ACL - Management).
- o acl-mgmt-destination-port - Destination IP Port (ACL - Management).
- o acl-mgmt-rule-action - Rule Action (ACL - Management).
- o acl-mgmt-rule-context - Rule Context (ACL - Management).
- o acl-mgmt-rule - Rule (ACL - Management).
- o acl-mgmt-source-ip - Source IP Address (ACL - Management).
- o acl-mgmt-source-port - Source IP Port (ACL - Management).
- o acl-staged-application - Application services (ACL - Staged).
- o acl-staged-destination-ip - Destination IP Address (ACL - Staged).
- o acl-staged-destination-port - Destination IP Port (ACL - Staged).
- o acl-staged-policy - Policy (ACL - Staged).
- o acl-staged-rule-action - Rule Action (ACL - Staged).
- o acl-staged-rule-context - Rule Context (ACL - Staged).
- o acl-staged-rule-context-type - Rule Context Type (ACL - Staged).
- o acl-staged-rule - Rule (ACL - Staged).
- o acl-staged-self-ip - Self IP Address (ACL - Staged).
- o acl-staged-server-ip - Server IP Address (ACL - Staged).
- o acl-staged-source-ip - Source IP Address (ACL - Staged).
- o acl-staged-source-port - Source IP Port (ACL - Staged).
- o acl-staged-translation-pool - Translation Reason (ACL - Staged).
- o acl-staged-translation-type - Translation Type (ACL - Staged).
- o acl-staged-vlan - VLAN (ACL - Staged).
- o 1314-errors-action - Network firewall errors action.
- o 1314-errors-destination-ip - Destination IP address (Network firewall errors).
- o 1314-errors-error-reason - Network firewall error reason.
- o 1314-errors-network-protocol - Destination port (Network protocol).
- o 1314-errors-source-ip - Source IP address (Network firewall errors).
- o 1314-errors-vlan - VLAN (Network firewall errors).

#### EXAMPLES

```
show analytics network report view-by acl-enforced-rule

show analytics network report view-by acl-staged-vlan drilldown { {
entity acl-staged-destination-port values { 80 } } }

send-mail analytics network report view-by acl-mgmt-source-ip limit 20
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples see manual for analytics report.

#### OPTIONS

```
device
Specifies a BIG-IP device on which to generate a report.
(Enterprise Manager only)
```

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**acl-matches**  
The total number of ACL rule matches. Applicable only to view-by entities starting with "acl-".

**errors**  
The total number of firewall errors. Applicable only to view-by entities starting with "l3l3-errors-".

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics network stale-rules

**NAME**  
stale-rules - Displays a network firewall stale rules report.

**MODULE**  
analytics network

**SYNTAX**  
Show an analytics network stale-rules report using the syntax shown in the following sections.

**DISPLAY**  
show stale-rules type [ enforced | staged ]

options:

```
drilldown {
  {
entity [ context | policy | rule-name ]
values
{
  [value ...]
}
} ...
}

field-fmt
first-rule-number [ value ]
number-of-rules [ value ]
range [ date range ]
```

#### DESCRIPTION

Use this command to generate network firewall stale rules reports. A stale rule is one that has had not hits, or very few hits, over a specified time period. The report is displayed in order from the least-hit rules (including rules with no hits) to the most hit rules. You can generate a stale rules report for either enforced or staged rules.

#### EXAMPLES

```
show analytics network stale-rules type enforced
```

Shows a stale rules report for enforced rules (either inline or not).

```
show analytics network stale-rules type staged drilldown { { entity
context values { /Common/virtual_server_1 } } }
```

Shows a stale rules report for staged rules in the context of the virtual server /Common/virtual\_server\_1

```
show analytics network stale-rules type enforced number-of-rules 100
range now-1w
```

Shows a stale rules report for enforced rules. 100 rules are shown in the report. This report is shown for the last week (including the last day).

```
show analytics network stale-rules type enforced first-rule-number 10
number-of-rules 100 range now-1w
```

Shows a stale rules report for enforced rules. The first least hit 9 rules are skipped, and 100 rules are shown in the report. This report is shown for the last week (including the last day).

```
show analytics network stale-rules type enforced first-rule-number 10
number-of-rules 100 range now-1d--now-1w
```

Shows a stale rules report for enforced rules. The first least hit 9 rules are skipped, and 100 rules are shown in the report. This report is shown for the last week, excluding the last day.

#### OPTIONS

**drilldown**  
Specifies specific entities that are used as a filter.

**field-fmt**  
Shows statistics in field format for the specified items.

**first-rule-number**  
Specifies the first rule number being displayed (rules are ordered by hit count in an ascending order).

**number-of-rules**  
Specifies the maximum number of firewall rules being displayed in the output result set. The default value is 10.

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

```

DESCRIPTION Use this command to generate pem analytics reports. You can generate a PEM analytics report for the following entities:

- o application - Classification application

- o category - Classification category
- o url-category - URL category
- o policy - Classification application policy
- o service - Forwarding service (endpoint)
- o action - PEM action (Gate, Forward, ICAP, Modify HTTP header, etc...)
- o tower - Tower the subscriber communicates from
- o subscribers - Subscriber summary statistics
- o subscriber-name - Subscriber name
- o ip-list - IP address list
- o device-name - Device name
- o device-os - Device operating system
- o called-station - Called station
- o calling-station - Calling station
- o subscriber-type - Subscriber type
- o user-name - User Name

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics pem report view-by category
```

```
show analytics pem report view-by category drilldown { { entity policy
values { Some_Policy_Name } } }
```

```
send-mail analytics pem report view-by tower measures { total_bytes_in
} limit 20 order-by { { measure total_bytes_in sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### hitcount

The total number of classified flows for the selected filter (entity).

##### total-bytes-in

The total number of bytes received for the selected filter (entity).

##### total-bytes-out

The total number of bytes sent for the selected filter (entity).

##### total-flows-opened

The total number of flows (classified and non-classified) for

the selected filter (entity).

**total-flows-closed**  
The total number of closed flows for the selected filter (entity).

**total-subscribers-login**  
The total number of login events for the selected filter (entity).

**total-subscribers-logout**  
The total number of logout events for the selected filter (entity).

**avg-distinct-apps**  
The average number of distinct applications for the selected filter (entity).

**avg-distinct-categories**  
The average number of distinct categories for the selected filter (entity).

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate protocol-security analytics reports. You can generate a protocol-security analytics report for the following entities:

- o application - Application services.
- o virtual-server - Virtual servers.
- o ip - Source IP addresses.
- o violation - Violation types.
- o protocol-type - Protocol type (HTTP/FTP/SMTP)
- o request-type - PRequest type (Legal or Alarmed/Blocked/Dropped)

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics protocol-security report view-by protocol-type

show analytics protocol-security report view-by request-type drilldown
{ { entity protocol-type values { HTTP } } }

send-mail analytics protocol-security report view-by protocol-type
measures {transactions} limit 20 order-by { { measure transactions
sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }

```

For more syntactical examples, see the manpage for analytics report.

#### OPTIONS

```

device
Specifies a BIG-IP device on which to generate a report.
(Enterprise Manager only)

device-list
Specifies a custom list of BIG-IP devices on which to generate a
report. (Enterprise Manager only)

drilldown
Specifies specific entities that are used as a filter.

```

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

requests

Request count.

occurrences

Number of occurrences for the selected filter (relevant for violation entity only)

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### DESCRIPTION

Use this command to generate HTTP analytics reports. You can generate an HTTP analytics report for the following entities:

- o application - Application services.
- o virtual - Virtual servers.

- o pool-member - Pool members.
- o url - A URL accessed by HTTP or HTTPS.
- o client-ip - A single client identified by an IP address.
- o country - A country from which HTTP/HTTPS traffic was sent to each of the virtual servers.
- o response-code - An HTTP response code that was sent back to the client.
- o method - An HTTP method used by the client (GET, CREATE, POST, DELETE, etc.).
- o user-agent - A browser identifier sent by the client's browser as part of the request for URL.
- o subnet - Client IP addresses classified into subnets.
- o attack-id - Application/L7 DoS Attack ID.
- o dosl7-profile - DoS Layer 7 (Application) Profile.
- o transaction-outcome - Transaction outcomes (Blocked/Dropped/Passthrough/etc.)
- o dosl7-bot-signature - DoS Layer 7 bot signature.
- o dosl7-bot-signature-category - DoS Layer 7 bot category.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics report view-by virtual measures {average-tps} limit 20
```

Gets the average tps of 20 virtual servers (unordered).

```
show analytics report view-by virtual measures {average-tps} limit 20
order-by { { measure average-tps sort-type desc } }
```

Gets the average tps of the top 20 virtual servers.

```
show analytics report view-by virtual measures {average-tps} limit 20
order-by { { measure average-tps sort-type desc } } range now-3d--now
```

Gets the average tps of the top 20 virtual servers from the last three days.

```
show analytics report view-by virtual drilldown { { entity application
values { app } } { entity pool-member values { p1 p2 } } } range
now-4d--now-2d measures {average-tps} limit 10 order-by { { measure
average-tps sort-type DESC } }
```

Gets the average tps of the top 10 virtual servers (ordered by average tps) on app iApp (out of several monitored) on pool members p1 and p2 (out of five monitored p1-p5) in the interval ranging from two to four days ago.

```
show analytics report view-by response-code drilldown { { entity
virtual values { v1 } } } measures { transactions }
```

Gets a distribution of requests per response code on virtual v1.

```
show analytics report view-by country drilldown { { entity application
values { app } } } measures { average-concurrent-sessions average-
sessions } order-by { { measure average-sessions sort-type DESC } }
limit 5
```

Gets the new sessions and average concurrent sessions of the top five countries, ordered by the average concurrent sessions on the application app.

```
show analytics report view-by client-ip drilldown { { entity virtual
values { v1 } } } measures { max-page-load-time } limit 1
```

Gets the client IP address with the worst page load time.

```
show analytics report view-by application drilldown { { entity pool-
member values { p1 p2 } } } measures { transactions } order-by { {
measure transactions } } range now-7d--now
```

Gets the distribution of requests per application on pool members p1 and p2 ordered by the number of requests during the last week.

```
save analytics report view-by virtual measures {average-tps} limit 20
order-by { { measure average-tps sort-type desc } } format pdf file
report.pdf
```

Gets the average tps of the top 20 virtual servers and exports to a PDF file on the BIG-IP system.

```
save analytics report view-by virtual measures {average-tps} limit 20
order-by { { measure average-tps sort-type desc } } format csv-
aggregated file report.csv
```

Gets the average tps of the top 20 virtual servers and exports to a CSV file on the BIG-IP system.

```
save analytics report view-by virtual measures {average-tps} limit 20
order-by { { measure average-tps sort-type desc } } format csv-time-
series file report.csv
```

Gets the average tps over time of the top 10 virtual servers and exports to a CSV file on the BIG-IP system.

```
send-mail analytics report view-by virtual measures {average-tps} limit  
20 order-by { { measure average-tps sort-type desc } } format pdf  
email-addresses { some.one@someaddress.com }
```

Gets the average tps over time of the top 10 virtual servers and sends out an email containing the report as a PDF.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The default value is transactions. The options are:

##### average-concurrent-sessions

The average number of concurrent sessions for each entity.

##### average-new-sessions

The average number of new sessions for each entity.

##### average-page-load-time

The average client page load time for each entity.

##### average-request-throughput

The average request throughput for each entity.

##### average-response-throughput

The average response throughput for each entity.

##### average-server-latency

The average server latency for each entity.

##### average-tps

The average number of transactions per second for each entity.

##### client-side-sampled-transactions

The number of transactions sampled for client side page load time.

##### max-page-load-time

The maximum client page load time for each entity.

##### max-request-throughput

The maximum request throughput for each entity.

##### max-response-throughput

The maximum response throughput for each entity.

##### max-server-latency

The maximum server latency for each entity.

##### max-tps

The maximum number of transactions per second for each entity.

##### transactions

The absolute number of transactions for each entity.

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The default value for measures is previously chosen measures. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

} ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate SIP DoS analytics reports. You can generate a SIP DoS prevention analytics report for the following entities:

- o application - Application services (iApp).
- o attack-id - DoS attack ID.
- o attack-type - DoS attack type.
- o callee - Callee.
- o caller - Caller.
- o method - Method.
- o src-ip - Source IP Address.
- o vlan - VLAN.
- o transaction-outcome - Transaction outcome.

#### EXAMPLES

```

show analytics sip report view-by attack-id

show analytics sip report view-by attack-type drilldown { { entity
method values { ACK } } }

send-mail analytics sip report view-by callee limit 20 format pdf
email-addresses { some.one@someaddress.com }

For more syntactical examples see manual for analytics report.

```

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. This option must be used with the drilldown option. You can also use it along with include-others.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result

set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

#### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

#### requests-count

The total number of requests that were received by the virtual server(/s)s

#### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

#### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

#### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### SEE ALSO

## analytics swg-blocked report

#### NAME

report - Displays an swg-blocked analytics report.

#### MODULE

analytics swg-blocked

#### SYNTAX

Show, save or send an analytics swg-blocked report using the syntax shown in the following sections.

#### DISPLAY

```
show report view-by [ ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | security-categ
options:
  drilldown {
    {
entity [ ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | security-category | host-n
values
{
  [value ...]
}
} ...
}
field-fmt
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
  measure [ measure name ]
  sort-type [ asc / desc ]
} ...
}
range [date range]
```

#### SAVE

```
save report view-by [ ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | security-categ
options:
  drilldown {
    {
entity [ ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | security-category | host-n
values
{
  [value ...]
}
} ...
}
```

```

}
file [ file name ]
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]

SEND
send-mail report view-by [ ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | security-
options:
  drilldown {
    {
entity [ ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | security-category | host-n
values
{
  [value ...]
}
} ...
}
email-addresses {
  [email address ...]
}
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate swg-blocked analytics reports. You can generate an application-security-network analytics report for the following entities:

- o ssl\_bypass - Is HTTP/HTTPS inspection bypassed
- o username - User name
- o client-ip - Client IP
- o host-name - Host name
- o url - URL
- o category - URL category
- o security-category - Categories which their parent is 'Security' category
- o url-filter - URL filter
- o scheme - Scheme

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics swg-blocked report view-by client-ip

show analytics swg-blocked report view-by client-ip drilldown { {
entity scheme values { my_scheme } } }

send-mail analytics swg-blocked report view-by category measures {
blocked-count } limit 20 order-by { { measure blocked-count sort-type
desc } } format pdf email-addresses { some.one@someaddress.com }

```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**blocked-count**  
The total number of blocked requests for the selected filter (entity).

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics swg report

**NAME**  
report - Displays an swg analytics report.

**MODULE**  
analytics swg

**SYNTAX**  
Show, save or send an analytics swg report using the syntax shown in the following sections.

```
DISPLAY
show report view-by [ action | ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | host-
options:
  drilldown {
  {
entity [ action | ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | host-name ]
values
{
  [value ...]
}
} ...
}
field-fmt
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
```

```

}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]

SAVE
save report view-by [ action | ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | host-
options:
  drilldown {
    {
entity [ action | ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | host-name ]
values
{
  [value ...]
}
} ...
}
file [ file name ]
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
}
range [date range]

SEND
send-mail report view-by [ action | ssl_bypass | username | client_ip | url | category | url_filter | filter_policy |
options:
  drilldown {
    {
entity [ action | ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | host-name ]
values
{
  [value ...]
}
} ...
}
email-addresses {
  [email address ...]
}
format [ csv-aggregated | csv-time-series | pdf ]

}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate swg analytics reports. You can generate an application-security-network analytics report for the following entities:

- o action - Transaction's action (Blocked / Allowed / Allowed with log)
- o ssl\_bypass - Is HTTP/HTTPS inspection bypassed
- o username - User name
- o client-ip - Client IP
- o host-name - Host name
- o url - URL
- o category - URL category
- o url-filter - URL filter
- o scheme - Scheme

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics swg report view-by client-ip

show analytics swg report view-by client-ip drilldown { { entity scheme
values { my_scheme } } }

send-mail analytics swg report view-by category measures { blocked-
count } limit 20 order-by { { measure blocked-count sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }

```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### request-count

The total number of requests for the selected filter (entity).

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-lh).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### SEE ALSO

order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]
```

#### DESCRIPTION

Use this command to generate tcp analytics reports. You can generate a TCP analytics report for the following entities:

- o application - Application services
- o city-postcode - City and postcode of remote host
- o continent-code - Continent of remote host
- o country-region - Country and region of remote host
- o nexthop - MAC address of next routing hop

- o remote-address - IP address of remote host
- o request-side - Client-side or server-side connection
- o subnet - /24 subnet of remote host
- o user-key - Key user-defined by TCP::analytics iRule.
- o virtual - Virtual Server

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics tcp-analytics report view-by virtual
```

```
show analytics tcp-analytics report view-by virtual drilldown { {
entity remote-address values { 10.10.2.2 } } }
```

```
send-mail analytics tcp-analytics report view-by remote-address
measures { goodput-rcv } limit 20 order-by { { measure goodput-rcv
sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### cs-dursum

The total duration of the active connection for the selected filter (entity).

##### cs-numendings

The total number of ending connections for the selected filter (entity).

##### cs-numstarts

The total number of starting connections for the selected filter (entity).

##### ds-3whs

The number of clock ticks spent by the connection in delay state three-way handshake (3WHS) for the selected filter (entity).

##### ds-app

The number of clock ticks spent by the connection in delay state limited by lack of application data for the selected filter (entity).

##### ds-closing

The number of clock ticks spent by the connection in delay state waiting for ack of FIN for the selected filter (entity).

##### ds-cwnd

The number of clock ticks spent by the connection in delay state limited by the congestion window for the selected filter (entity).

##### ds-nagle

The number of clock ticks spent by the connection in delay state where the app is limited, last packet held due to Nagle algorithm for the selected filter (entity).

**ds-ratepace**

The number of clock ticks spent by the connection in delay state where the app is limited, transmission delayed by rate pacing for the selected filter (entity).

**ds-retx**

The number of clock ticks spent by the connection in delay state retransmitting lost packets for the selected filter (entity).

**ds-rwnd**

The number of clock ticks spent by the connection in delay state where the client receive window is limited for the selected filter (entity).

**ds-sndbuf**

The number of clock ticks spent by the connection in delay state limited by send buffer configuration for the selected filter (entity).

**ds-waitforack**

The number of clock ticks spent by the connection in delay state waiting for acknowledgement for the selected filter (entity).

**goodput-rcv**

The total number of GoodPuts received for the selected filter (entity).

**goodput-snd**

The total number of GoodPuts sending for the selected filter (entity).

**pkts-lost**

The total number of packets lost for the selected filter (entity).

**pkts-sent**

The total number of packets sent for the selected filter (entity).

**rtt-avg**

The average round trip time for the selected filter (entity).

**rtt-count**

The number of measurements for round trip time for the selected filter (entity).

**rtt-max**

The maximum round trip time for the selected filter (entity).

**rtt-min**

The minimum round trip time for the selected filter (entity).

**rtt-sum**

The sum of round trip times for the selected filter (entity).

**rtt-var-sum**

The sum of variances of the round trip times for the selected filter (entity).

**SEE ALSO**

show, save, send-mail, tmsh, ltm profile analytics, analytics, analytics report

**COPYRIGHT**

```

#### DESCRIPTION

Use this command to generate tcp analytics reports. You can generate a TCP analytics report for the following entities:

- o virtual - Virtual Server
- o tcp - TCP Profile

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics tcp report view-by virtual

show analytics tcp report view-by virtual drilldown { { entity virtual
values { 172.12.34.56 } } }

```

```
send-mail analytics tcp report view-by tcp measures { max-active-conns
} limit 20 order-by { { measure max-active-conns sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### avg-active-conns

The average number of active connections for the selected filter (entity).

##### max-active-conns

The max number of active connections for the selected filter (entity).

##### total-accepts

The total number of accepted connections for the selected filter (entity).

##### total-accept\_fails

The total number of denied accept connections for the selected filter (entity).

##### total-new-conns

The total number of new connections for the selected filter (entity).

##### total-failed-conns

The total number of failed connections for the selected filter (entity).

##### total-expired-conns

The total number of expired connections for the selected filter (entity).

##### total-abandoned-connections

The total number of abandoned connections for the selected filter (entity).

##### total-rst-packets

The total number of RST connections for the selected filter (entity).

##### total-malformed-segments

The total number of malformed connections for the selected filter (entity).

##### total-oo-segs

The total number of out of ordered segments for the selected filter (entity).

##### total-rx-cookie

The total number of received SYN cookies for the selected filter (entity).

##### total-rxbadcookies

The total number of received bad SYN cookies for the selected filter (entity).

##### total-hw-cookies

The total number of received HW SYN cookies for the selected

filter (entity).

total-syncacheover  
The total number of SYN cache overflow for the selected filter (entity).

total-txrexmits  
The total number of retransmitted segments for the selected filter (entity).

total-sndpack  
The total number of sent packets for the selected filter (entity).

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics udp report

NAME  
report - Displays an udp analytics report.

MODULE  
analytics udp

SYNTAX  
Show, save or send an analytics udp report using the syntax shown in the following sections.

```
DISPLAY
show report view-by [ virtual | udp ]
options:
  drilldown {
  {
entity [ virtual | udp ]
values
{
  [value ...]
}
} ...
}
field-fmt
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
measure [ measure name ]
sort-type [ asc / desc ]
} ...
}
range [date range]
```

```
SAVE
save report view-by [ virtual | udp ]
options:
  drilldown {
  {
entity [ virtual | udp ]
values
{
```

```

    [value ...]
  }
} ...
}
file [ file name ]
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {

```

#### DESCRIPTION

Use this command to generate udp analytics reports. You can generate a UDP analytics report for the following entities:

- o virtual - Virtual Server
- o udp - UDP Profile

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics udp report view-by virtual

show analytics udp report view-by virtual drilldown { { entity virtual
values { 172.12.34.56 } } }

send-mail analytics udp report view-by udp measures { max-active-conns
} limit 20 order-by { { measure max-active-conns sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }

```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**avg-active-conns**  
The average number of active connections for the selected filter (entity).

**max-active-conns**  
The max number of active connections for the selected filter (entity).

**total-accepts**  
The total number of accepted connections for the selected filter (entity).

**total-accept\_fails**  
The total number of denied accept connections for the selected filter (entity).

**total-new-conns**  
The total number of new connections for the selected filter (entity).

**total-failed-conns**  
The total number of failed connections for the selected filter (entity).

**total-expired-conns**  
The total number of expired connections for the selected filter (entity).

**total-received-datagrams**  
The total number of received datagrams for the selected filter (entity).

**total-malformed-datagrams**  
The total number of malformed datagrams for the selected filter (entity).

**total-icmp-unreachable**  
The total number of ICMP unreachable for the selected filter (entity).

**total-bad-sum-datagrams**  
The total number of bad checksum datagrams for the selected filter (entity).

**total-no-sum-datagrams**  
The total number of 'no checksum' datagrams for the selected filter (entity).

**total-transmitted-datagrams**  
The total number of transmitted datagrams for the selected filter (entity).

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

**SEE ALSO**

show, save, send-mail, tmsh, ltm profile analytics, analytics, analytics report

  values  
    {  
      [value ...]  
    }  
  } ...  
  }  
  email-addresses {  
    [email address ...]  
  }  
  format [ csv-aggregated | csv-time-series | pdf ]  
  include-total  
  include-others  
  limit [number of rows]  
  measures {  
    [measure name ...]  
  }  
  order-by {  
    {  
      measure [ measure name ]  
      sort-type [ asc / desc ]  
    }  
  } ...  
  }  
  range [date range]  
  smtp-config-override [ smtp configuration object name ]

**DESCRIPTION**  
Use this command to generate vcmp analytics reports. You can generate a vCMP analytics report for the following entities:

- o slot - Slot ID
- o guest - vCMP Guest name
- o interface - vCMP Interface
- o process-name - Process name

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics vcmp report view-by slot
```

```
show analytics vcmp report view-by slot drilldown { { entity slot
values { 5 } } }
```

```
send-mail analytics vcmp report view-by guest measures { network-bytes-
in } limit 20 order-by { { measure network-bytes-in sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**network-bytes-in**  
The total number of external and internal bytes received for the selected filter (entity).

**network-bytes-out**  
The total number of external and internal bytes sent for the selected filter (entity).

**network-average-in-throughput**  
The average internal and external received throughput for the selected filter (entity).

**network-average-out-throughput**  
The average internal and external throughput sent for the selected filter (entity).

**average-guest-cpu-usage**  
The average number of CPU usage for the selected filter (entity) relative to host CPU.

**diskio-bytes-read**  
The average number of bytes read from disk for the selected filter (entity).

**diskio-bytes-written**  
The average number of bytes written to disk for the selected filter (entity).

**diskio-requests-read**  
The average number of read requests from disk for the selected filter (entity).

**diskio-requests-written**  
The average number of write requests from disk for the selected filter (entity).

average-process-cpu-usage  
The average number of CPU usage for the selected filter (entity) normalized relatively to guest CPU.

traffic-client-new-connections  
The total number of client-side new connections for the selected filter (entity).

traffic-client-avg-connections  
The average number of client-side connections opened for a selected filter (entity).

traffic-client-packets-in  
The total number of client-side received packets for a selected filter (entity).

traffic-client-packets-out  
The total number of client-side sent packets for a selected filter (entity).

traffic-client-bytes-in  
The total number of client-side received bytes for a selected filter (entity).

traffic-client-bytes-out  
The total number of client-side sent bytes for a selected filter (entity).

traffic-server-new-connections  
The total number of server-side new connections for the selected filter (entity).

traffic-server-avg-connections  
The average number of server-side connections opened for a selected filter (entity).

traffic-server-packets-in  
The total number of server-side received packets for a selected filter (entity).

traffic-server-packets-out  
The total number of server-side sent packets for a selected filter (entity).

traffic-server-bytes-in  
The total number of server-side received bytes for a selected filter (entity).

traffic-server-bytes-out  
The total number of server-side sent bytes for a selected filter (entity).

total-assisted-connections  
The total number of all hardware accelerated assisted connections for a selected filter (entity).

current-assisted-connections  
The average number of all hardware accelerated assisted connections for a selected filter (entity).

hardware-syncookies-generated  
The total number of SYN cookies generated for a selected filter (entity).

hardware-syncookies-detected  
The total number of SYN cookies detected for a selected filter (entity).

hw-accel-client-packets-in  
The total number of hardware accelerated client-side received packets for a selected filter (entity).

hw-accel-client-packets-out  
The total number of hardware accelerated client-side received sent for a selected filter (entity).

hw-accel-client-bytes-in  
The total number of hardware accelerated client-side received bytes for a selected filter (entity).

hw-accel-client-bytes-out  
The total number of hardware accelerated client-side sent bytes for a selected filter (entity).

hw-accel-client-max-connections  
The max number of hardware accelerated client-side connections for a selected filter (entity).

hw-accel-client-new-connections  
The total number of hardware accelerated client-side new connections for a selected filter (entity).

hw-accel-client-current-connections  
The average number of hardware accelerated client-side opened connections for a selected filter (entity).

hw-accel-server-packets-in  
The total number of hardware accelerated server-side received packets for a selected filter (entity).

hw-accel-server-packets-out  
The total number of hardware accelerated server-side received sent for a selected filter (entity).

hw-accel-server-bytes-in  
The total number of hardware accelerated server-side received bytes for a selected filter (entity).

hw-accel-server-bytes-out  
The total number of hardware accelerated server-side sent bytes for a selected filter (entity).

hw-accel-server-max-connections  
The max number of hardware accelerated server-side connections for a selected filter (entity).

hw-accel-server-new-connections  
The total number of hardware accelerated server-side new connections for a selected filter (entity).

hw-accel-server-current-connections  
The average number of hardware accelerated server-side opened connections for a selected filter (entity).

tmm-total-ram  
The average of total TMM memory for the selected filter (entity).

tmm-used-ram  
The average of used TMM memory for the selected filter (entity).

tmm-free-ram  
The average of free TMM memory for the selected filter (entity).

other-total-ram  
The average of total other (daemons and kernel) memory for the selected filter (entity).

other-used-ram  
The average of used other (daemons and kernel) memory for the selected filter (entity).

other-free-ram  
The average of free other (daemons and kernel) memory for the selected filter (entity).

system-total-ram  
The average of total system memory for the selected filter (entity).

system-used-ram  
The average of used system memory for the selected filter (entity).

system-free-ram  
The average of free system memory for the selected filter (entity).

swap-total-ram  
The average of total swap memory for the selected filter (entity).

swap-used-ram  
The average of used swap memory for the selected filter (entity).

swap-free-ram  
The average of free swap memory for the selected filter (entity).

#### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

#### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

#### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

## DESCRIPTION

Use this command to generate virtual analytics reports. You can generate a VIP analytics report for the following entities:

- o virtual - Virtual Server

Different measures are collected for each of these entities and can be a part of the report request.

## EXAMPLES

```
show analytics virtual report view-by virtual
```

```
show analytics virtual report view-by virtual drilldown { { entity  
virtual values { 172.12.34.67 } } }
```

```
send-mail analytics virtual report view-by virtual measures { total-  
server-packets-in } limit 20 order-by { { measure total-server-packets-  
in sort-type desc } } format pdf email-addresses {  
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

## OPTIONS

### device

Specifies a BIG-IP device on which to generate a report. (Enterprise Manager only)

### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

### drilldown

Specifies specific entities that are used as a filter.

### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

#### total-client-packets-in

The total number of client-side received packets for the selected filter (entity).

#### total-client-packets-out

The total number of client-side sent packets for the selected filter (entity).

#### total-server-packets-in

The total number of server-side received packets for the selected filter (entity).

#### total-server-packets-out

The total number of server-side sent packets for the selected filter (entity).

#### total-client-bits-in

The total number of client-side received bits for the selected filter (entity).

#### total-client-bits-out

The total number of client-side sent bits for the selected filter (entity).

#### total-server-bits-in

The total number of server-side received bits for the selected filter (entity).

#### total-server-bits-out

The total number of server-side sent bits for the selected filter (entity).

#### total-client-conns

The total number of client-side connections for the selected filter (entity).

#### avg-client-concurrent-conns

The average number of client-side concurrent connections for

the selected filter (entity).

**max-client-concurrent-conns**  
The max value of client-side concurrent connections for the selected filter (entity).

**total-server-conns**  
The total number of server-side connections for the selected filter (entity).

**avg-server-concurrent-conns**  
The average number of server-side concurrent connections for the selected filter (entity).

**max-server-concurrent-conns**  
The max value of server side concurrent connections for the selected filter (entity).

**total-syncookies**  
The total number of syncookies for the selected filter (entity).

**total-syncookies-accepts**  
The total number of accepted syncookies for the selected filter (entity).

**total-syncookies-rejects**  
The total number of rejected syncookies for the selected filter (entity).

**total-hw-syncookies**  
The total number of HW syncookies for the selected filter (entity).

**total-hw-syncookies-accepts**  
The total number of accepted HW syncookies for the selected filter (entity).

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

DELETE
delete active-directory-trusted-domains [name]

```

#### DESCRIPTION

You can use the active-directory-trusted-domains component to manage AAA Active Directory Trusted Domains. You can use this object to configure cross-domain authentication across a forest. It also allows to configure Active Directory(r) agents to work in a Route Domains environment.

#### EXAMPLES

```

create active-directory-trusted-domains MyTRD { trusted-domains {
  myDomain1 myDomain2 myDomain3 } root-domain /Common/myDomain2 }
Creates an object named MyTRD, sets domains myDomain1, myDomain2,
myDomain3 as trusted and the root-domain is set to myDomain2. To
use this example you need to have Active Directory servers
myDomain1, myDomain2 and myDomain3 pre-configured.

```

```

delete active-directory MyTRD
Deletes the AAA Active Directory Trusted Domains named MyTRD from
the system.

```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
Specifies a user-defined description for the Active Directory Trusted Domains.

**root-domain**  
Specifies an entry point to an Active Directory forest. An initial authentication request will always to be sent to root domain first. This setting is required.

**trusted-domains**  
Specifies a list of AAA Active Directory server components. Trust relationships should be defined for domains you add into this list. This setting is required.

## apm aaa active-directory

#### NAME

active-directory - Manages an authentication access policy (AAA) Active Directory(r) server.

#### MODULE

apm aaa

#### SYNTAX

Configure the active-directory component within the aaa module using

the syntax shown in the following sections.

```
CREATE/MODIFY
create active-directory [name]
modify active-directory [name]
options:
  admin-encrypted-password [[string] | none]
  admin-name [[string] | none]
  app-service [[string] | none]
  cleanup-cache [pso | group | none]
  description [[string] | none]
  domain [[string] | none]
  domain-controller [[string] | none]
  domain-controllers [add | delete | modify | replace-all-with] {
    [name] {
  ip [ip address]
    }
  }
  group-cache-ttl [integer]
  domain-controllers none
  location-specific [true | false]
  pool [name]
  pso-cache-ttl [integer]
  padata [encryption type]
  timeout [integer]
```

```
edit active-directory [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list active-directory
list active-directory [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

```
DELETE
delete active-directory [name]
```

#### DESCRIPTION

You can use the active-directory component to manage an AAA Active Directory server. The Active Directory is a network structure supported by Windows(r) 2000, or later, that provides support for tracking and locating any object on a network.

#### EXAMPLES

```
create active-directory MyADserver { domain-controller
  "server01.company.com domain "company.com " admin-name "administrator"
  admin-encrypted-password "!My123Password" }
Creates the AAA Active Directory server named MyADserver in the
company.dom domain, sets the administrator logon name to
administrator and the administrator password to !My123Password,
and sets the Key Distribution Center to company.com.
```

```
delete active-directory MyActiveDirectoryServer
Deletes the AAA Active Directory server named
MyActiveDirectoryServer from the system.
```

#### OPTIONS

**admin-encrypted-password**  
Specifies the password associated with admin name. This option is required only when you are using an Active Directory Query agent with this Active Directory server object.

**admin-name**  
Specifies the user name that has administrative permissions on an AAA Active Directory server. This option is required only when you are using an Active Directory Query agent with this Active Directory server object.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**cleanup-cache**  
Specifies if this is a cache cleanup request. You can cleanup Group cache or PSO cache.

**description**  
Specifies a description for the component. The default is none.

**domain**  
Specifies the Active Directory domain name. This setting is required.

**[name]**  
Specifies the name of an AAA Active Directory server. This setting is required.

**domain-controller**  
Specifies the fully qualified domain name (FQDN) of the domain controller for the domain specified in the domain option. The default is none.

**domain-controllers**  
Adds, deletes, or replaces a set of domain controllers, by

specifying an FQDN for each entry. You can configure the following options for each domain controller:

**ip** An IP address for specified domain controller entry.

**group-cache-ttl**  
Specifies group cache lifetime in days [0..1825]. The default value is 30. If you specify group cache lifetime 0, that means cache will be updated on every request.

**pso-cache-ttl**  
Specifies password security objects (PSO) Cache lifetime in days [0..1825]. The default value is 30. If you specify PSO cache lifetime 0, that means cache will be updated on every request.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**pool** Specifies the name of the pool with which the server is associated. The default is none.

**partition**  
Displays the partition within which the component resides. The default is Common.

**padata**  
Specifies a Kerberos preauthentication encryption type. If it is specified, the BIG-IP system includes Kerberos preauthentication data within the first AS-REQ. If you do not need to include preauthentication data, set this option to "none". Supported encryption types: none, des-cbc-crc, des-cbc-md5, aes128-cts-hmac-sha1-96, aes256-cts-hmac-sha1-96, rc4-hmac. The default is rc4-hmac.

**timeout**  
Specifies a timeout interval (in seconds) after which an AAA Active Directory server closes a connection. The default is 15.

## apm aaa crldp

**NAME**  
crldp - Configure a Certificate Revocation List Distribution Point (CRDLP) server object for implementing a CRDLP authentication module.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the crldp component within the aaa module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create crldp [name]  
modify crldp [name]  
options:  
address [ip addr]  
allow-nullcrl [true | false]  
app-service [[string] | none]  
base-dn [[string> | none]  
cache-expire [[integer] | none]  
connection-timeout [[integer] | none]  
description [[string> | none]  
location-specific [true | false]  
pool [name]  
port [[integer] | none]  
reverse-dn [true | false]  
use-issuer [true | false]  
use-pool [enabled | disabled]  
verify-sig [true | false]

edit crldp | [glob] | [regex] ] ... ]  
options:

all-properties  
non-default-properties

DISPLAY  
list crldp  
list crldp [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
app-service  
non-default-properties  
one-line  
partition

DELETE  
delete crldp [name]

DESCRIPTION  
Configure a CRLDP authentication server, and then assign the server to the CRLDP auth agent in your access policy.

EXAMPLES  
create crldp aaa-ldap-2027 { address 172.27.32.60 allow-nullcrl false  
base-dn DC=net,DC=aina,DC=test cache-expire 1000 connection-timeout 15  
description none partition Common pool aaa-ldap-2027-pool port ldap  
reverse-dn true use-issuer false use-pool disabled verify-sig true }  
Creates a CRLDP server named aaa-ldap-2027.

delete crldp server my\_crldp\_server  
Deletes the CRLDP server named my\_crldp\_server.

OPTIONS  
address  
Specifies the IP address of the server. This option is required.  
allow-nullcrl  
Specifies whether to consider a null CRL from the CRLDP server a successful authentication. The default is false.  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
base-dn  
Specifies the LDAP base directory name for certificates that specify the CRL distribution point in directory name (dirName) format. Used when the value of the X509v3 attribute crlDistributionPoints is of type dirName. In this case, the BIG-IP system attempts to match the value of the crlDistributionPoints attribute to the Base DN value. An example of a Base DN value is cn=lxxx,dc=f5,dc=com.  
cache-expire  
Specifies (in seconds) an update interval for CRL distribution points. The update interval for distribution points ensures that CRL status is checked at regular intervals, regardless of the CRL timeout value. This helps prevent CRL information from becoming outdated before the Access Policy Manager checks the status of a certificate.  
connection-timeout  
Specifies the number of seconds of inactivity the system allows before the connection times out. The default is 15.  
description  
Specifies a unique description for the server. The default is none.  
partition  
Displays the partition within which the component resides.  
location-specific  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.  
pool  
Specifies the name of the pool with which the server is associated.  
port  
Specifies the CRLDP service port. The default is 389.  
reverse-dn  
Specifies in which order the system is to attempt to match the Base DN value to the value of the X509v3 attribute crlDistributionPoints. Possible values are enabled and disabled. When set to enabled, the system matches the base DN from left to right, or from the beginning of the DN string, to accommodate dirName strings in certificates such as C=US,ST=WA,L=SEA,OU=F5,CN=xxx. The default value is false.  
use-issuer  
Specifies whether the CRL distribution point is extracted from the certificate of the client certificate issuer. The default is false.  
use-pool  
Enables or disables high availability between CRLDP servers. When enabled, Access Policy Manager sends CRLDP authentication requests

for the associated CRLDP auth agent to the virtual server, and standard pool behavior is used to implement high availability for CRDLP.

**verify-sig**  
Specifies whether the signature on the received CRL is verified.  
The default is true.

### DISPLAY

list endpoint-management-system

list endpoint-management-system [ [name] | [glob] | [regex] ] ... ]

options:

all-properties  
app-service  
non-default-properties  
one-line  
partition

### DELETE

delete endpoint-management-system [name]

### DESCRIPTION

You can use the endpoint-management-system component to manage an integration with remote Mobile Device Management (MDM) server.

## EXAMPLES

```
create endpoint-management-system MyEndpointManagementSystem { type
airwatch fqdn "server01.company.com" port 443 serverssl-profile
serverssl username "administrator" password "!My123Password" mdm-token
"token" }
```

Creates the endpoint management system named MyEndpointManagementSystem with MDM API URL server01.company.com:port, sets serverssl-profile to serverssl, sets the MDM administrator user name to administrator and the password to !My123Password, and sets the API token to token.

```
delete endpoint-management-system MyEndpointManagementSystem
Deletes the endpoint management system named
MyEndpointManagementSystem from the system.
```

## OPTIONS

[name]

Specifies the name for the endpoint management system. This setting is required.

type Specifies the type of endpoint management system: airwatch or maas360. This setting is required.

fqdn Specifies the fully qualified domain name. This setting is required.

port Specifies the port number. Default is 443

serverssl-profile

Specifies the server SSL profile. This setting is required.

description

Specifies a description for the component. The default is none.

username

Specifies the user name of the MDM administrator. This setting is required.

password

Specifies the password the MDM administrator uses to log in. This setting is required.

mdm-token

Specifies the API token.

billing-id

Specifies the billing ID for the user's IBM Maas360 account.

application-id

Specifies the application ID provided by IBM Maas360.

access-key

Specifies the access key provided by IBM Maas360.

platform

Specifies the platform version of the IBM Maas360 console.

app-version

Specifies the current version number of the application that corresponds to the account.

sync-interval

Specifies the length of time it takes for the synchronization to complete. The default is 240 minutes.

location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

## apm aaa http

### NAME

http - Specify an http server configuration used for authentication.

## MODULE

apm aaa

## SYNTAX

Configure the http component within the aaa module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create http [name]
modify http [name]
options:
  app-service [[string] | none]
  auth-type [form-based | basic-ntlm | custom-post]
  content-type [xml-utf8 | url-encoded-utf8 | none]
  custom-body [[string] | none]
  description [[string] | none]
  follow-redirect [integer]
  form-action [[string] | none]
  form-fields [[string] | none]
  form-method [get | post]
  form-params [[string] | none]
  form-password [[string] | none]
  form-username [[string] | none]
  headers [add | delete | modify | replace-all-with | none] {
[name] {
  app-service [[string] | none]
  hname [[string] | none]
  hvalue [[string] | none]
}
}
  location-specific [true | false]
  start-uri [[string] | none]
  success-match-type [url | cookie | string | exact-cookie]
  success-match-value [[string] | none]
```

```
edit http [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
```

### DISPLAY

```
list http
list http [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete http [name]
```

## DESCRIPTION

You can use the http component to create and manage AAA HTTP servers.

## EXAMPLES

```
create http myHttpServer { start-uri "http://mycompany.com/" auth-type
basic-ntlm }
Creates an HTTP authentication server named "myHttpServer" with a
starting URI of http://mycompany.com.
```

```
delete http myHttpServer
Deletes the myHttpServer AAA HTTP server.
```

## OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**auth-type**  
Specifies the type of authentication you want to use.

**form-based**  
Specifies the authentication type to be form-based.

**basic-ntlm**  
Specifies the authentication type to be basic-ntlm.

**custom-post**  
Specifies the authentication type to be custom-post.

**content-type**  
Specifies the encoding (xml-utf8, url-encoded-utf8, or none) for an HTTP custom post. If you specify 'none', you must use the headers option to add a custom header. In addition to specifying a custom header, you must apply your own encoding through an iRule.

**custom-body**  
Specifies the body for a HTTP Custom Post.

**description**  
Specifies a unique description for the server. The default is none.

**follow-redirect**  
Specifies the number of pages away from the landing page the request should travel before failing.

**form-action**  
Specifies the complete destination URL to process the form using

HTTP form-based authentication. This is optional. If you do not specify a form action, then Access Policy Manager will use the URI from the request to perform HTTP form-based authentication.

**form-fields**

Specifies the hidden form parameters that are required by the authentication server logon form at your location. The default is none. Specify a parameter name, a space, and the parameter value, if any. Multiple parameters can be configured with each "name value" pair in one line. Use edit to add multiple parameters. Please note that create and modify do not allow using new line on the terminal.

**form-method**

Specifies the form method you want to use for the form-based HTTP authentication. The value is either Get or POST. The default is POST. However, if you specify GET, the Access Policy Manager will force the authentication using HTTP GET rather than perform authentication using form-based POST.

**form-password**

Specifies the parameter names used by the form you are sending the POST request to.

**form-username**

Specifies the parameter names used by the form you are sending the POST request to.

**headers**

Specifies the name and value of the header content to be inserted in an HTTP Post. The options are:

**app-service**

Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

**hname**

The name of the HTTP header.

**hvalue**

The value of the HTTP header.

**location-specific**

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**

Specifies the name of the aaa http server. This option is required.

**partition**

Displays the partition within which the component resides. The default is Common.

**start-uri**

Specifies a URL resource, for example, <http://plum.tree.lab2.sp.companynet.com/>. This resource must respond with a challenge to a non-authenticated request.

**success-match-type**

Specifies the method your authentication server uses and determines the option definition used for this field. The field toggles according to your selection.

**cookie**

Specifies any string in cookie is required.

**exact-cookie**

Specifies key fields in cookie is required.

**string**

Specifies a specific string is required.

**url**

Specifies a URL is required.

**success-match-value**

Specifies the URL, any string in cookie, exact cookie or specific string used for the specific success match type you see.

**SEE ALSO**  
**COPYRIGHT**

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

options:  
  all-properties  
  app-service  
  non-default-properties  
  one-line  
  partition

**DELETE**  
delete kerberos-keytab-file [name]

**DESCRIPTION**  
You can use the kerberos-keytab-file component to create and manage a Kerberos Keytab file.

**EXAMPLES**  
create kerberos-keytab-file my\_keytab { source-path  
  file:/root/apmkeytab }  
Creates a Kerberos Keytab file name my\_keytab located at root/apmkeytab.

delete kerberos-keytab-file my\_keytab  
Deletes the Kerberos Keytab file name my\_keytab.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

source-path  
Specifies the location of the Kerberos Keytab file.

partition  
Displays the partition within which the component resides.

---

NAME  
kerberos - Configures a Kerberos server.

MODULE  
apm aaa

SYNTAX  
Configure the kerberos component within the aaa module using the syntax shown in the following sections.

CREATE/MODIFY  
create kerberos [name]  
modify kerberos [name]  
options  
auth-realm [[string] | none]  
app-service [[string] | none]  
keytab-file-obj [[string] | none]  
location-specific [true | false]  
service-name [[string] | none]

edit kerberos [ [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

DISPLAY  
list kerberos  
list kerberos [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
app-service  
non-default-properties  
one-line  
partition

DELETE  
delete kerberos [name]

DESCRIPTION  
You can use the kerberos component to create and manage AAA Kerberos servers. Use the Kerberos authentication server to configure authentication for the Access Policy Manager. A client retrieves credentials from the domain controller and passes those credentials to the Access Policy Manager. Then Access Policy Manager uses the value in the keytab-file-obj option of the Kerberos AAA server object to verify the credentials. Access Policy Manager system does not have to reside in the domain.

EXAMPLES  
delete kerberos my\_kerberos  
Deletes the server named my\_kerberos.

OPTIONS

auth-realm  
Specifies a Kerberos auth realm name (administrative name), such as user@realm.com to establish the boundaries within which an authentication server has the authority to authenticate a user, host, or service. Kerberos clients manually map DNS domain names to Kerberos realm names. This option is required.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

keytab-file-obj  
Specifies a keytab file that contains the keys (derived from the Kerberos password) that the server uses to authenticate the client. This option is required.

location-specific  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]  
Specifies the name of an AAA Kerberos server. This option is required.

partition  
Displays the partition within which the component resides.

service-name  
Specifies the Kerberos service name defined inside KDC in the format service name/hostname@kerberosrealm. This option is required, for example, HTTP.

## apm aaa ldap

**NAME**  
ldap - Manages an AAA LDAP server.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the ldap component within the aaa module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create ldap [name]
modify ldap [name]
options:
  address [[ip addr] | none]
  admin-dn [[string] | none]
  admin-encrypted-password [[string] | none]
  app-service [[string] | none]
  base-dn [string]
  description [[string] | none]
  is-ldaps [false | true]
  location-specific [true | false]
  pool [name]
  port [[service] | none]
  schema-attr {
    group-member [[string] | none]
    group-member-value [[string] | none]
    group-memberof [[string] | none]
    group-object-class [[string]]
    user-memberof [[string] | none]
    user-object-class [string]
  }
  serverssl-profile [none | serverssl | serverssl-insecure-compatible | wom-default-serverssl]
  timeout [integer]
  use-pool [enabled | disabled]
```

```
edit ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

### DISPLAY

```
list ldap
list ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete ldap [name]
```

### DESCRIPTION

You can use the ldap component to create and manage an AAA LDAP server.

### EXAMPLES

```
create ldap MyLDAPserver { address 172.30.6.144 admin-dn
  "cn=administrator,cn=users,dc=company,dc=companynet,dc=com" admin-
  encrypted-password "!MyPassword" }
Creates the AAA LDAP server named MyLDAPserver that is assigned
the IP address 172.30.6.144 and the
cn=administrator,cn=users,dc=company,dc=companynet,dc=com admin dn
with a password of !MyPassword.
```

```
delete ldap MyLDAPServer
Deletes the AAA LDAP server named MyLDAPServer from the system.
```

### OPTIONS

**address**  
Specifies the IP address of an AAA LDAP server. This option is required.

**admin-dn**  
Specifies the Container Distinguished Name (DN) to use for authentication. This option is required.

**admin-encrypted-password**  
Specifies the password for admin name. This option is required.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**base-dn**  
Specifies the base DN from which to search. This search DN is used to search groups across a whole directory.

**group-cache-ttl**  
Specifies a lifetime for the group cache (days).

**cleanup-cache**  
Specifies whether cache invalidation is required. The default is none. The options are:

none  
group  
description  
Specifies a unique description for the server. The default is none.

**is-ldaps**  
Specifies whether to use the LDAPS protocol during authentication. If true, you must also specify the option `serverssl-profile`.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]  
Specifies the name of the AAA server. This option is required.

partition  
Displays the partition within which the component resides.

pool Specifies the name of the pool with which the server is associated. The default is none.

port Specifies the port number of the AAA LDAP server. The default is ldap. This option is required.

schema-attr  
Specifies LDAP schema-specific attribute names.

user-object-class The value of the objectClass attribute for a user object. The default is "user".

user-memberof If the user object maintains a group membership, you should specify the membership attribute name here. The default is "memberOf".

group-object-class The value of the objectClass attribute for a group object. The default is "group".

group-memberof If the group object maintains a group membership in other groups, you should specify a membership attribute name here. The default is "memberOf".

group-member If the group object maintains a list of users that belong to the group, you should specify the attribute here. The default is "member".

group-member-value If the "group-member" attribute is specified, you should specify the attribute that is used to add users into a group. The default is "dn".

serverssl-profile  
Specifies the server side SSL profile. LDAPS is achieved by directing LDAP traffic over a virtual server that uses a server side SSL to communicate with the LDAP server.

The options are:

serverssl  
serverssl-insecure-compatible  
wom-default-serverssl  
timeout  
Specifies a timeout interval (in seconds) for the AAA server after which the server closes a connection. The default is 15.

use-pool  
Enables or disables high availability between pool members. When enabled, the Access Policy Manager sends AAA requests for the associated policy item to the virtual server, and standard pool behavior is used to implement high availability for CRDLP.

## apm aaa oam

**NAME**  
oam - Manages an AAA Oracle Access Manager server.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the oam component within the aaa module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create oam [name]  
modify oam [name]  
options:  
  access-server-hostname [[string] | none]  
  access-server-name [[string] | none]  
  access-server-port [[integer] | none]  
  access-server-retries [integer]  
  accessgate-encrypted-password [[string] | none]  
  accessgates [add | delete | modify | replace-all-with] {  
    [name]  
  }  
  action [config-accessgate | noop]  
  admin-id [[string] | none]  
  admin-password [[string] | none]  
  app-service [[string] | none]  
  description [[string] | none]  
  enable [false | true]  
  global-access-protocol-passphrase [[string] | none]  
  location-specific [true | false]  
  transport-security-mode [cert | open | simple]

edit oam | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

**DISPLAY**  
list oam  
list oam [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  app-service  
  non-default-properties  
  one-line  
  partition

**DELETE**  
delete oam [name]

**DESCRIPTION**  
You can use the oam component to create and manage an AAA Oracle Access Manager server.

**EXAMPLES**  
create oam oam10g { access-server-hostname www.localcorp.biz access-server-name accessSrv1 access-server-port 6021 access-server-retries 0 accessgates { oam10gwebgate1 { encrypted-password [string] } } admin-id firstname.lastname admin-password "[string]" global-access-protocol-passphrase "[string]" transport-security-mode simple }  
Creates the AAA OAM server named oam10g accessing the web gate oam10gwebgate1 on the Access Server accessSrv1 at host name www.localcorp.biz on port 6021. The server retries connections zero times.  
  
delete aaa oam MyOAMServer  
Deletes the AAA Oracle Access Manager server named MyOAMServer from the system.

**OPTIONS**  
  access-server-hostname  
Specifies the IP address or FQDN of the Oracle Access Manager server. This option is required.  
  
  access-server-name  
Specifies the name of the Oracle Access Manager server. This option is required.  
  
  access-server-port  
Specifies the port of the Oracle Access Manager server. The default is 6021.  
  
  access-server-retries  
Specify the number of times you want the access gate to attempt to connect to the Oracle Access Manager server when the action option is set to config-accessgate. The default is 0 (zero).  
  
  accessgates  
Specifies the ID of the access gate or web gate on the OAM Server. The system supports the use of multiple access gates/web gates as long as they are from the same OAM server.  
  
  action  
Specifies the Oracle Access Manager action type. Actions allow you to pass user profile information or to redirect the user's browser to another site. For more information on Actions, refer to the Access Administration Guide provided by Oracle. The options are:  
config-accessgate

Specifies that you want the system to use the configureAccessGate tool.

noop Specifies "no operation performed." This is the default.

admin-id  
Specifies the administrator ID required by the Oracle Access Manager server. This option is required.

admin-password  
Specifies the administrator password required by the Oracle Access Manager server. The default is none.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description  
Specifies a unique description for the Oracle Access Manager server. The default is none.

enable  
Specifies whether you want to enable the server. The default is true.

global-access-protocol-passphrase  
Specifies a global passphrase for all Oracle components. The default is none.

location-specific  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]  
Specifies the name of an AAA Oracle Access Manager server. This setting is required.

transport-security-mode  
Specifies the transport security level for the communication between Oracle components and Access Policy Manager. The options are:

open Communication is not encrypted for protection. Use this mode when security is not an issue

simple  
Communication is encrypted with Oracle Access Manager's internal CA. Simple mode encrypts communications using Transport Layer Security, RFC 2246 (TLS v1). This mode is less secure than Cert mode. Use this mode if you have some security concerns but do not want to manage your own CA.

cert Communication is encrypted with an external CA. Use cert mode if you want different certificates on OAM servers and webgates and you have a trusted 3rd party CA. Oracle Access Manager components use X.509 digital certificates in PEM format only.

## apm aaa oauth-provider

NAME  
oauth-provider - Manages an OAuth Provider.

MODULE  
apm aaa

SYNTAX  
Configure the oauth-provider component within the aaa module using the syntax shown in the following sections.

CREATE/MODIFY

```
create oauth-provider [name]
modify oauth-provider [name]
options:
  app-service [[string] | none]
  authentication-uri [[string] | none]
  description [[string] | none]
  token-uri [[string] | none]
  token-validation-scope-uri [[string] | none]
  type [custom | f5 | facebook | google | ping]
```

```
edit oauth-provider[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list oauth-provider
list oauth-provider [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

```
DELETE
delete oauth-provider [name]
```

**DESCRIPTION**  
You can use the `oauth-provider` component to manage an OAuth Provider. The OAuth Provider specifies endpoint URIs to retrieve token, refresh token, validate token, get a list of scopes associated with token and redirect user to obtain `authorization_code`.

**EXAMPLES**

```
create oauth-provider f5Provider { authentication-uri
  https://local.f5.com/f5-oauth2/v1/authorize description "OAuth provider
  defines F5 AS" token-uri https://local.f5.com/f5-oauth2/v1/token token-
  validation-scope-uri https://local.f5.com/f5-oauth2/v1/validate type f5
}
```

Creates the OAuth Provider named `f5Provider` of type `f5`, defines all endpoint URIs to the local Authorization Server.

```
delete oauth-provider f5Provider
Deletes the OAuth Provider named f5Provider from the system.
```

**OPTIONS**

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**authentication-uri**  
The endpoint URI that is used to redirect user for authentication in order to get `authorization_code`. This endpoint is used by OAuth Client agent, when `grant type` is configured to `Authorization Code`.

**description**  
Specifies a description for the component. The default is `none`.

**partition**  
Displays the partition within which the component resides. The default is `Common`.

**token-uri**  
The endpoint URI that is used to retrieve an `access_token`. This endpoint is used by OAuth Client agent.

**token-validation-scope-uri**  
The endpoint URI that is used by OAuth Scope agent, in order to retrieve a list of scopes associated with an `access_token`. The same URI is used to validate an `access_token` by OAuth Client agent.

**type** The type of the provider.

**custom** The provider is using a custom Authorization Server.

**f5** The provider is using an F5 Authorization Server.

**facebook** The provider is Facebook Authorization Server.

**google** The provider is Google Authorization Server.

**ping** The provider is Ping Identity Authorization Server.

Default value for provider type is `f5`.

**SEE ALSO**  
**COPYRIGHT**

## apm aaa oauth-request

**NAME**  
oauth-request - Manages an OAuth Request.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the oauth-request component within the aaa module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create oauth-request [name]  
modify oauth-request [name]  
options:  
  app-service [[string] | none]  
  description [[string] | none]  
  headers [add | delete | modify | replace-all-with] {  
    [name] {  
      value [value]  
    }  
  method [get | post]  
  parameters [add | delete | modify | replace-all-with] {  
    [name] {  
      type [parameter type]  
      value [[string] | none]  
    }  
  }  
  type [request type]  
  uri [[string] | none]

edit oauth-request [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

**DISPLAY**  
list oauth-request  
list oauth-request [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  app-service  
  non-default-properties  
  one-line  
  partition

**DELETE**  
delete oauth-request [name]

**DESCRIPTION**  
You can use the oauth-request component to manage an OAuth Request. The OAuth Request is an HTTP request that is used during communication between the BIG-IP system and an OAuth Authorization Server (AS). Different types of OAuth Requests can be configured for both OAuth Client and OAuth Scope agents.

**EXAMPLES**  
create oauth-request F5AuthRedirectRequest { description "F5 Authentication Redirect request" method get parameters add { client\_id { type client-id } redirect\_uri { type redirect-uri } response\_type { value "code" } } type auth-redirect-request }  
Creates the OAuth Request named F5AuthRedirectRequest of type auth-redirect-request, sets HTTP method to get and specifies the list of GET parameters to be sent: client-id, redirect\_uri, response\_type.  
  
delete oauth-request F5AuthRedirectRequest  
Deletes the OAuth Request named F5AuthRedirectRequest from the system.

**OPTIONS**  
**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
Specifies a description for the component. The default is none.

**headers**  
Adds, deletes, or replaces a set of headers, by specifying a header name and value for each entry.

**value**  
The value of the header.

**method**  
Specifies the HTTP method for the OAuth Request. The options are:  
get Configures the system to make HTTP request using GET method.  
post Configures the system to make HTTP request using POST method.

**parameters**  
Adds, deletes, or replaces a set of parameters, by specifying a parameter name for each entry. You can configure the following options for each parameter:

**type** The type of the parameter. For a custom type of parameter, you must provide a value. For other parameter types, the value is taken from other configurations. The options for the type of a parameter are:

**access-token** The value for the parameter is `access_token`. Value assigned from session variable `session.oauth.client..access_token`  
**client-id** The value for this parameter type is the Client Id that is configured in the OAuth Server object.  
**client-secret** The value for this parameter type is the Client Secret that is configured in the OAuth Server object.  
**grant-type** The value for this parameter type is the Grant Type that is configured in the OAuth Client agent.  
**redirect-uri** The value for this parameter type is the Redirect URI that is configured in the OAuth Client agent.  
**resource-server-id** The value for this parameter is the Resource Server Id that is configured in the OAuth Server object.  
**resource-server-secret** The value for this parameter is the Resource Server Secret that is configured in the OAuth Server object.  
**scope** The value for this parameter is the Scope that is configured in the OAuth Client agent.  
**custom** Custom parameter value; you can specify any custom value for the parameter.

Default value for parameter type is `custom`.

**value**  
The value of the parameter. A value is required for parameters of type `custom` only.

**partition**  
Displays the partition within which the component resides. The default is `Common`.

**type** Type of the request. The options for the type of a request are:

**auth-redirect-request** The Authentication Redirect request. This type of request is used to redirect user to an Authorization Server, when OAuth Client agent is configured to use "Authorization Code" grant type.  
**token-request** The Token request. This type of request is used to access an Authorization Server in order to obtain an `access_token` or exchange an `authorization_code` for an `access_token`.  
**token-refresh-request** The Refresh Token request. This type of request is used to refresh an expired `access_token`.  
**token-revocation-request** The Revocation request. This type of request is used to revoke an `access_token`.  
**validation-scopes-request** The Validation and Scopes request. This type of request is used in OAuth Client agent to validate an existing token. The same type of request is used to get a list of scopes associated with an existing token.  
**scope-data-request** The Scope Data request. This type of request is used to obtain additional information from an Authorization Server.

Default value for request type is `scope-data-request`.

**uri** Request URI. This option is required for request of type `scope-data-request` only. All other types of requests use endpoint URIs configured at OAuth Provider component.

---

## apm aaa oauth-server

**NAME**  
oauth-server - Manages an OAuth Server.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the `oauth-server` component within the `aaa` module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create oauth-server [name]

```
modify oauth-server [name]
options:
  app-service [[string] | none]
  client-id [string]
  client-secret [[string] | none]
  client-serverssl-profile-name [name]
  dns-resolver-name [name]
  mode [client | rs | client-rs]
  provider-name [name]
  resource-server-id [string]
  resource-server-secret [[string] | none]
  resource-serverssl-profile-name [name]
  rules [[string] | none]
  token-validation-interval [[integer] | none]
```

```
edit oauth-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list oauth-server
list oauth-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

```
DELETE
delete oauth-server [name]
```

#### DESCRIPTION

You can use the `oauth-server` component to manage an OAuth Server. The OAuth Server specifies the configuration of an OAuth Authorization server for use by the OAuth Client or OAuth Scope agents.

#### EXAMPLES

```
create oauth-server f5Server { provider-name Google mode client client-id myClientApplicationId client-secret e939e2lead60c0406341c9be587a005056890213d480f456 client-serverssl-profile-name serverssl dns-resolver-name myResolver}
Creates the OAuth Server named f5Server and defines all required options. In this example, the BIG-IP system is supposed to only acquire an access token from Google. The server mode is set to client and resource server credentials are not needed.
```

```
delete oauth-server f5Server
Deletes the OAuth Server named f5Server from the system.
```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**client-id**  
Specifies the client application ID. The client application must be configured before configuring the OAuth Server on the BIG-IP system.

**client-secret**  
Specifies the client application secret. The client application must be configured at the authorization server before configuring the OAuth Server on the BIG-IP system.

**client-serverssl-profile-name**  
SSL profile to be used by the BIG-IP system when connecting to authorization server.

**dns-resolver-name**  
DNS resolver object to be used by OAuth Server to resolve DNS names for endpoint URIs.

**mode** The mode of operation for the OAuth Server. The options for the mode of operation are:

**client** The OAuth Server can be used by OAuth Client agent only. In this mode, you do not need to specify Resource Server credentials.  
**rs** The OAuth Server can be used by OAuth Scope agent only. In this mode, you do not need to specify Client Application credentials.  
**client-rs** The OAuth Server can be used by either OAuth Client or OAuth Scope agent. Client Application credentials and Resource Server credentials are required.

**partition**  
Displays the partition within which the component resides. The default is `Common`.

**resource-server-id**  
Specifies the Resource Server ID. The Resource Server must be configured before configuring OAuth Server on the BIG-IP system.

**resource-server-secret**  
Specifies the Resource Server Secret. The Resource Server must be configured before configuring OAuth Server on the BIG-IP system.

**resource-serverssl-profile-name**  
SSL profile to be used by the BIG-IP system when connecting to resource server.

#### rules

The list of iRule events. You can apply an iRule event to modify a request or a response (except an authorization code request from the BIG-IP OAuth client to the OAuth authentication server).

#### token-validation-interval

Specifies the number of minutes that the token can remain valid. The token becomes invalid when this interval elapses or at the token expiry that the authentication server specifies, whichever is shorter. When the token expires, the subsession times out. (This setting applies only to a per-request policy).

## apm aaa ocsdp

#### NAME

ocsp - Configure Online Certificate System Protocol (OCSP) responder objects.

#### MODULE

apm aaa

#### SYNTAX

Configure the ocsdp component within the aaa module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create ocsdp [name]
modify ocsdp [name]
options:
  allow-certs [true | false]
  app-service [[string] | none]
  ca-file ( | none)
  ca-path ( | none)
  cert-id-digest (sha1 | md5)
  chain [true | false]
  check-certs [true | false]
  explicit-ocsp [true | false]
  ignore-aia [true | false]
  intern [true | false]
  location-specific [true | false]
  nonce [true | false]
  sign-digest (sha1 | md5)
  sign-key ( | none)
  sign-key-passphrase ( | none)
  sign-other ( | none)
  signer ( | none)
  status-age
  trust-other [true | false]
  url ( | none)
  va-file ( | none)
  validity-period
  verify [true | false]
  verify-cert [true | false]
  verify-other ( | none)
  verify-sig [true | false]
```

```
edit ocsdp | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list ocsdp
list ocsdp [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

#### DELETE

```
delete ocsdp [name]
```

#### DESCRIPTION

To implement the SSL OCSP authentication module, create an OCSP responder object and assign it to the OCSP auth agent in your access policy.

## OPTIONS

### allow-certs

Specifies whether the addition of certificates to an OCSF request is enabled. The default is true.

### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

### ca-file

Specifies the name of the certificate file object containing trusted CA certificates used to verify the signature on the OCSF response. The default is none.

### ca-path

Specifies the path to the trusted CA certificates used to verify the signature on the OCSF response. The default is none.

### cert-id-digest

The cert ID digest is part of the OCSF protocol. The OCSF client (in this case, the BIG-IP system) calculates the cert ID using a hash of the Issuer and serial number for the certificate that it is trying to verify. The options are:

shal Newer algorithm that provides a higher security level with a 160 bit hash length. This is the default.

md5 Older algorithm with a 128 bit hash length.

### chain

Specifies whether the system constructs a chain from certificates in the OCSF response. The default is true.

### check-certs

Specifies whether the LTM system makes additional checks to see if the signer's certificate is authorized to provide the necessary status information. Use this option only for testing purposes. The default is true.

### explicit-ocsp

Specifies whether the BIG-IP system explicitly trusts that the OCSF response signer's certificate is authorized for OCSF response signing. If the signer's certificate does not contain the OCSF signing extension, setting this option to true causes a response to be untrusted. The default is true.

### ignore-aia

Specifies whether to ignore the URL contained in the certificate's AIA fields, and to always use the URL specified by the responder instead. The default is false.

### intern

Specifies whether to ignore certificates contained in an OCSF response when searching for the signer's certificate. When you set this option to true, you must also specify the signer's certificate using either the verify-other or va-file option. The default is true.

### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

### [name]

Specifies a unique name for the component. This option is required.

### nonce

Specifies whether a nonce will be sent in an OCSF request. When set to false, the request is sent without a nonce. The default is true.

### partition

Displays the partition within which the OCSF responder object resides.

### sign-digest

Specifies the algorithm (md5 or sha1) used to sign a request using a signing certificate and key. The default is sha1. If you use this option, you must also set the sign-key and sign-key-passphrase options.

### sign-key

Specifies the key used to sign an OCSF request. If you use this option, you must also set the sign-digest and sign-key-passphrase options. The default is none.

### sign-key-passphrase

Specifies the passphrase for the signing key. If you use this option, you must also set the sign-digest and sign-key options. The default is none.

### sign-other

Specifies additional certificates to add to an OCSF request. The options are default.crt and ca-bundle.crt. The default is none.

**signer**  
Specifies the certificate used to sign an OSCP request. If the certificate is specified but the key is not specified, then the private key is read from the same file as the certificate. If neither the certificate nor the key is specified, then the request is not signed. If the certificate is not specified and the key is specified, then the configuration is considered to be invalid. The default is none.

**status-age**  
Specifies the amount of time (in seconds) to compare to the notBefore value of a status response. Use this option only when a status response does not include the notAfter field. The default is 0 (zero).

**trust-other**  
Specifies whether the BIG-IP system trusts the certificates specified using the verify-other option. The default is false.

**url** Specifies the URL used to contact the OSCP service on the responder. This option is required. The default is none.

**va-file**  
Specifies the name of the file containing explicitly-trusted responder certificates. Use this option when the responder is not covered by the certificates already loaded into the responder's CA store. The default is none.

**validity-period**  
Specifies an acceptable error range in seconds. Use this option when the OSCP responder clock and a client clock are not synchronized, which could cause a certificate status check to fail. This value must be a positive number. This option is required. The default is 300.

**verify**  
Specifies whether verification of an OSCP response signature or the nonce values is enabled. Use this option only for debugging purposes. The default is true.

**verify-cert**  
Specifies whether the BIG-IP system verifies the certificate in the OSCP response. The default is true.

**verify-other**  
Specifies the name of the file used to search for an OSCP response signing certificate when the certificate has been omitted from the response. The default is none.

**verify-sig**  
Specifies whether the BIG-IP system checks the signature on the OSCP response. Use this option only for testing purposes. The default is true.

## apm aaa radius

**NAME**  
radius - Manages an AAA RADIUS server.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the radius component within the aaa module using the syntax shown in the following sections.

```
CREATE/MODIFY
create radius [name]
modify radius [name]
options:
  acct-port [integer]
  address [[ip addr] | none]
  auth-port [integer]
  app-service [[string] | none]
  description [[string] | none]
  mode [acct | auth | both]
  nas-ip-address [[ip addr] | none]
  nas-ipv6-address [[ip addr] | none]
  location-specific [true | false]
```

```

    pool [[string] | none]
    retries [integer]
    secret [string]
    service-type [default | login | framed | callback-login | callback-framed | outbound | administrative | nas-promp
    timeout [integer]
    use-pool [enabled | disabled]

edit radius | [glob] | [regex] ] ... ]

options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

DELETE
delete radius [name]

```

#### DESCRIPTION

You can use the radius component to create and manage an AAA RADIUS server.

#### EXAMPLES

```

create rad_auth { address 172.30.6.144 secret "test" use-pool
"disabled"}
Creates the AAA RADIUS server named rad_auth that has an IP
address of 172.30.6.144 and has a shared secret of test.

```

```

delete radius MyRadiusServer
Deletes the AAA RADIUS server named MyRadiusServer from the
system.

```

#### OPTIONS

**acct-port**  
Specifies the port number of the external AAA RADIUS accounting server. The default is radius-acct.

**address**  
Specifies the IP address of the AAA RADIUS server. This option is required.

**auth-port**  
Specifies the port number for the service. The default is radius. This option is required.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
Specifies a unique description for the AAA RADIUS server. The default is none.

**mode** Specifies the configuration mode you want to use for RADIUS authentication. Note that you cannot modify the mode once you create the server. The options are:

**acct** Configures the system to perform only RADIUS accounting. Use this option to pass accounting information about your users to the external RADIUS accounting server.

**auth** Configures the system to perform only RADIUS authentication. Use this option to authenticate your users through a RADIUS server.

**both** Configures the system to perform both RADIUS authentication and RADIUS accounting simultaneously.

**[name]**  
Specifies the name of an AAA RADIUS server. This option is required.

**nas-ip-address**  
Specifies an IP address as RADIUS attribute 4 that you can configure without changing the source IP address in the IP header of the RADIUS packets. Use this option in situations where you are using an NAS cluster to be recognized as a single RADIUS client.

**nas-ipv6-address**  
Specifies an IPv6 address as RADIUS attribute 4 that you can configure without changing the source IP address in the IP header of the RADIUS packets. Use this option in situations where you are using an NAS cluster to be recognized as a single RADIUS client.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**partition**

Displays the partition within which the component resides.

**pool** Specifies the name of the pool to which this server belongs. The default is none.

**retries**  
Specifies the number of times the BIG-IP system tries to make a connection to the RADIUS AAA server after the first attempt fails. The default is 3.

**secret**  
Specifies the shared secret password of the AAA RADIUS server. This option is required.

**service-type**  
Specifies the type of service used for the RADIUS server. The default is default, which behaves as authenticate-only.

**timeout**  
Specifies a timeout interval (in seconds) for the AAA RADIUS server after which the server closes a connection. The default is 5.

**use-pool**  
Enables or disables the use of the pool specified using the pool option. The default is none.

## apm aaa saml-idp-connector

**NAME**  
saml-idp-connector - Specify saml idp connector configuration used for SAML authentication.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the saml-idp-connector component within the aaa module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create saml-idp-connector [name]
modify saml-idp-connector [name]
options:
  app-service [[string] | none]
  artifact-resolution-service-addr [IP address]
  artifact-resolution-service-port [integer]
  artifact-resolution-service-url [[string] | none]
  basic-auth-password [[string] | none]
  basic-auth-username [[string] | none]
  description [[string] | none]
  entity-id [string]
  identity-location [attribute | subject]
  identity-location-attribute [[string] | none]
  idp-certificate [[string] | none]
  import-metadata [[metadata-file] | none]
  location-specific [ true | false ]
  metadata-cert [[string] | none]
  serverssl-profile-name [profile name | none]
  sign-artifact-resolution-rq [true | false]
  single-logout-binding
  single-logout-response-uri [[string] | none]
  single-logout-uri [[string] | none]
  sso-binding [http-post | http-redirect]
  sso-uri [[string] | none]
  want-authn-request-signed [true | false]
  want-detached-signature [true | false]
```

```
edit saml-idp-connector [ [ name ] | [ glob ] | [ regex ] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list saml-idp-connector
list saml-idp-connector [ [ name ] | [ glob ] | [ regex ] ] ... ]
show running-config saml-idp-connector
show running-config saml-idp-connector [ [ name ] | [ glob ] | [ regex ] ] ... ]
```

options:  
all-properties  
app-service  
non-default-properties  
one-line  
partition

DELETE  
delete saml-idp-connector [name]

DESCRIPTION  
You can use the saml-idp-connector to create and manage saml idp connectors.

EXAMPLES  
create saml-idp-connector my\_idp\_connector { import-metadata  
/shared/tmp/meta\_data\_idp.xml}  
Creates saml idp connector named my\_idp\_connector from metadata.  
In this example "/shared/tmp/meta\_data\_idp.xml" is a file  
containing saml identity provider metadata.

```
create saml-idp-connector my_idp_connector1 { entity-id  
"https://www.secureauth.com/dom1" identity-location subject sso-binding  
http-post sso-uri "https://www.secureauth.com/dom1/acs/" idp-  
certificate my_company.crt}  
Creates a saml idp connector named my_idp_connector1 with  
certificate "my_company.crt" with identity-location "subject".
```

```
list saml-idp-connector  
Displays a list of saml idp connectors.
```

```
delete saml-idp-connector my_idp_connector  
Deletes the my_idp_connector saml idp connector.
```

OPTIONS  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

artifact-resolution-service-addr  
Specifies the IP address that this BIG-IP as SP will use to connect to the IdP artifact resolution service. Value must be a valid IPv4 or IPv6 address.

artifact-resolution-service-port  
Specifies the port that this BIG-IP as SP will use to connect to the IdP artifact resolution service.

artifact-resolution-service-url  
Specifies the URI of the IdP artifact resolution service. The URI must include protocol, hostname, and full path.

basic-auth-password  
Specifies the password for basic authentication. When configured, basic authentication is used for the artifact resolve request sent to the IdP.

basic-auth-username  
Specifies username for basic authentication. When configured, basic authentication is used for the artifact resolve request sent to the IdP.

description  
Specifies a unique description for the saml idp connector. The default is none.

entity-id  
Specifies unique URI to represent the IdP pointed by idp connector.

identity-location  
Specifies location of user identity inside SAML assertion. It can be either one of the attributes or the subject.

identity-location-attribute  
If the location of user identity is set to attribute then attribute name should be specified as part of this attribute.

idp-certificate  
This is IdP's certificate and is used by BIG-IP as SP to verify the signature of the assertion.

import-metadata  
This attribute specifies the metadata file from an external IdP system used for creating idp connector object.

For example: create saml-idp-connector my\_idp\_connector { import-metadata /shared/tmp/meta\_data\_idp.xml}

location-specific  
Objects of this class might have location specific attribute(s). Admin can indicate if object is location specific by setting it to true.

metadata-cert  
This specifies the certificate to use to verify the signature of metadata imported from a file.

For example: create saml-idp-connector my\_idp\_connector2 {import-metadata /shared/tmp/meta\_data\_signed\_idp.xml metadata-cert default.crt}

`serverssl-profile-name`  
Specifies the SSL profile used when this BIG-IP as SP connects to the IdP artifact resolution service.

`sign-artifact-resolution-rq`  
Specifies whether the IdP requires artifact resolve requests to be signed. Default value is true.

`single-logout-binding`  
This attribute is reserved for future functionality.

`single-logout-response-uri`  
A URI where this BIG-IP as SP will send single logout (SLO) responses.

`single-logout-uri`  
A URI where this BIG-IP as SP will send single logout (SLO) requests.

`sso-binding`  
This specifies the method the IdP uses to receive authentication request from BIG-IP as SP. Default value is http-post

`sso-uri`  
This specifies the URL of IdP's SSO service where BIG-IP as SP sends an authentication request to IdP.

`want-authn-request-signed`  
This property specifies whether IdP requires signed authentication request. Set it to true if this BIG-IP as SP is required to send signed authentication request to IdP. Default value is false.

`want-detached-signature`  
This property specifies signature type for messages sent by BIG-IP via HTTP Redirect binding. To use detached signatures set this property to true. Enveloped signatures are used by default.

options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

DELETE
delete saml [name]

DESCRIPTION
  You can use the saml component to create and manage saml aaa servers.

EXAMPLES
  create saml my_saml_server { entity-id "https://spvs1.mycompany.com/id"
  want-assertion-signed true want-assertion-encrypted false is-authn-
  request-signed true sp-certificate my_company.crt sp-signkey
  my_company.key}
  Creates a SAML authentication server named my_saml_server with
  certificate my_company.crt and key my_company.key and security
  options requiring signed assertion and want to send signed
  authentication request.

  list saml
  Displays a list of aaa saml servers.

  delete saml my_saml_server
  Deletes the my_saml_server aaa saml server.

OPTIONS
  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  assertion-consumer-binding
  Specifies method this BIG-IP as SP uses to receive assertions.
  Default value is http-post.

  auth-context-class-list
  Specifies an ordered list of authentication context classes. The
  BIG-IP as SP uses this list to validate the authentication context
  (in the assertion from the IdP) against locally configured context
  methods (auth-context-methods) using the specified comparison
  method (auth-context-comparison-method).

  This property is required if you use a comparison method (auth-
  context-comparison-method) other than the default ('exact'). You
  can specify any auth-context-class-list list that you have
  configured on the BIG-IP system. Or, you can specify the
  predefined auth-context-class-list list
  (authentication_contexts_list) that the BIG-IP system provides.

  auth-context-comparison-method
  Specifies the comparison method that the IdP must use to evaluate
  the requested context classes auth-context-methods, one of
  "exact", "minimum", "maximum", or "better". The default is exact.
  If non-default comparison method is configured, all context
  classes from auth-context-methods must be present in the
  configured priority list of classes auth-context-class-list.

  auth-context-methods
  Specifies a list of authentication context classes that this BIG-
  IP as SP will request from an IdP. As a response, the IdP must
  return an assertion containing one of the requested authentication
  contexts. Each value can be a session variable if the comparison
  method is set to 'exact', which is the default value.

  description
  Specifies a unique description for the server. The default is
  none.

  entity-id
  Specifies a unique identifier for BIG-IP as SP. Typically
  'entity-id' is a URI that points to the BIG-IP virtual server that
  is going to act as SAML SP. In case 'entity-id' is not a valid
  URL, the sp-host attribute is required. Examples of valid
  configuration include "https://mycompany-sp", "sp:my:company", and
  "sp.my.company.com".

  force-authn
  If enabled, this BIG-IP as SP requests the IdP to authenticate the
  principal directly rather than rely on a previous security

```

context.

#### export-metadata

You can simplify SAML configuration using metadata files. When you use BIG-IP as an SP, you can export metadata for an SP to a file. Then you can use the file to configure SP metadata on an IdP system by importing the file or using the information in the file to configure the SP. You can choose to sign metadata while exporting it for better security.

For example:

1. Exporting metadata with signing. This requires metadata-cert and metadata-signkey files.

```
modify saml aaa_obj {export-metadata with-signing metadata-file /shared/sp_signed_metadata.xml metadata-cert defa
```

2. Exporting metadata with no signing.

```
modify saml aaa_obj {export-metadata no-signing metadata-file /shared/sp_metadata.xml}
```

#### idp-connectors

Add one or more IdP connectors to this SP service. BIG-IP SP redirect users to associated IdPs for authentication. If more IdP connectors associated with the SP, BIG-IP SP selects one of the IdP based on the specified selection criteria.

For example:

1. The following command associates one IdP connect to an SP

```
modify saml my_saml_server idp-connectors add { my_idp_connector1 }
```

2. Following associates multiple IdP connectors to SP with selection criteria based on landing URI. If the landing URI is /google, the user is sent to IdP as specified by my\_idp\_connector\_google\_app and if the landing URI is /salesforce, the user is sent to IdP as specified by my\_idp\_connector\_for\_salesforce.

```
modify saml my_saml_server idp-connectors add { my_idp_connector_google_app { idp-matching-source "%{session.serv
```

#### is-authn-request-signed

This property specifies whether the SP signs authentication requests while sending them to the IdP. Set it to true if this BIG-IP SP should sign authentication requests. The default value for this is false.

#### location-specific

Objects of this class might have location specific attributes. Admin can indicate if object is location specific by setting it to true.

#### metadata-cert

Specifies the certificate with public key of the key pair used in signing the metadata. See export-metadata for more information on metadata export functionality. This is the certificate to be included in signed metadata when we export metadata. This might or might not be SP certificate.

#### metadata-file

Specifies the file to which metadata is saved. See export-metadata for more information on metadata export functionality.

#### metadata-signkey

Specifies the key that is used to sign SP's metadata. See export-metadata for more information on metadata export functionality.

#### name-id-policy-allow-create

A Boolean value used to indicate whether external IdP is allowed, when processing requests from this BIG-IP as SP, to create a new identifier to represent the principal. Default value is false

#### name-id-policy-format

A URI reference representing the classification of string-based identifier information. For example, if a Service Provider (SP) initiates SSO by sending an AuthnRequest to the IDP with format "urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress", then the IdP response should contain subject identity in email format. This attribute can be a session variable.

#### name-id-policy-sp-name-qualifier

Optionally specifies that the assertion subject's identifier be returned in the namespace of an SP other than the requester, or in the namespace of a SAML affiliation group of SPs. This attribute can be a session variable.

#### relay-state

Specifies the value where the BIG-IP as SP redirects users after they are successfully authenticated and have been allowed by access policy. When BIG-IP receives the relay state from the IdP in addition to assertion, then it uses the value received from IdP to redirect the user to after authentication. Otherwise, BIG-IP uses the value from this configuration.

#### sp-certificate

BIG-IP includes this certificate in the SAML SP metadata that you export. After the SAML SP metadata is imported on the IdP, the IdP can use this certificate to verify signed authentication request and to encrypt assertion.

#### sp-host

Hostname of this BIG-IP as SP. This attribute is required when "entity-id" is not a valid URL.

sp-scheme  
Scheme used by this BIG-IP as SP. This attribute is only used when sp-host is not empty. Default value is https.

sp-signkey  
This specifies the private key used to sign authentication requests if "is-authn-request-signed" is set to true or to decrypt assertions when "want-assertion-encrypted" is set to true.

want-assertion-encrypted  
This property specifies whether SP requires encrypted assertions. Set it to true if this BIG-IP SP requires encrypted assertions from the SAML IdP. The default value for this is false.

want-assertion-signed  
This property specifies whether SP requires signed assertions. Set it to true if this BIG-IP SP requires signed assertions from the SAML IdP. The default value for this is true.

## apm aaa securid

NAME  
securid - Manages an RSA SecurID authentication server.

MODULE  
apm aaa

SYNTAX  
Configure the securid component within the aaa module using the syntax shown in the following sections.

```
CREATE/MODIFY
create securid [name]
modify securid [name]
options:
  app-service [[string] | none]
  config-files [[string] | none]
  description [[string] | none]
  location-specific [true | false]
  source-ip [ip addr]

edit securid | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list securid
list securid [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

DELETE
delete securid [name]
```

DESCRIPTION  
You can use the securid component to create and manage an RSA SecurID authentication server.

EXAMPLES  
create securid mySecuridServer { config-files add { sdconf.rec { local-path /shared/tmp/1 } } source-ip 172.31.54.138 }  
Creates the mySecuridServer AAA RSA SecurID server.

list securid all  
Displays a list of AAA RSA SecurID servers on the system.

delete securid mySecuridServer  
Deletes the mySecuridServer AAA RSA SecurID server from the system.

OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**config-files**  
Specifies which files to use for SecurID authentication. Upload a copy of the sdconf.rec file from your RSA Authentication Manager server.

**description**  
Specifies a description for the configuration file you are uploading.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**source-ip**  
Specifies the source IP address of the RSA SecurID agent. This option is required when authenticating to the RSA Authentication Manager server.

**partition**  
Displays the partition within which the component resides.

## apm aaa tacacsplus

**NAME**  
tacacsplus - Configure a TACACS+ server for implementing remote TACACS+-based client authentication.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the tacacsplus component within the apm aaa module using the syntax shown in the following sections.

```
CREATE/MODIFY
create tacacsplus
modify tacacsplus
options:
address [ip addr]
auth-service [arap | enable | fwproxy | login | nasi | none | ppp | pt | rcmd | x25]
auth-type [arap | ascii | chap | mschap | pap]
app-service [[string] | none]
description [[string] | none]
encrypt [enabled | disabled]
location-specific [true | false]
pool [[string] | none]
port [[string] | none]
priv-lvl [max | min | user]
protocol [atalk | deccp | ftp | http | ip | ipx | lat | lcp | osicp | pad | rlogin | telnet | tn3270 | unknown | v]
secret [[string] | none]
service [none | arap | connection | firewall | ppp | shell | slip | system | tty-daemon]
use-pool [[string] | none]
```

```
edit tacacsplus [ [glob] | [regex] ] ... ]
options:
all-properties
non-default-properties
```

```
DISPLAY
list tacacsplus
list tacacsplus [ [name] | [glob] | [regex] ] ... ]
options:
all-properties
app-service
non-default-properties
one-line
```

partition

DELETE  
delete tacacsplus [name]

DESCRIPTION

You can use the tacacsplus component to create and manage a TACACS+ authentication server.

EXAMPLES

create tacacsplus mytacacs auth-service enable encrypt enabled  
Creates a TACACS server named mytacacs with encryption enabled.

OPTIONS

address

Specifies the IP address of the TACACS+ server. This option is required.

auth-service

Specifies the name of the service that the user is requesting to be authenticated to use. This enables the TACACS+ server to behave differently for different types of authentication requests. This option is required.

auth-type

Specifies the type of authentication to be used for authenticating the user.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

Specifies a unique description for the component. The default is none.

encrypt

Enables or disables encryption of TACACS+ packets. Recommended for normal use. The default is enabled.

location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]

Specifies the name of an AAA TACACS+ server. This option is required.

partition

Displays the partition within which the component resides.

pool

Specifies the name of the pool to which this server belongs. The default is none.

port

Specifies the port number of the server. The default is 49.

priv-lvl

Specifies the privilege level at which the user is authenticating. The options are:

max

min This is the default.

user

protocol

Specifies the protocol associated with the value specified in the service option, which is a subset of the associated service being used for client authorization or system accounting. The default is unknown.

secret

Sets the secret key used to encrypt and decrypt packets sent or received from the server. This option is required.

service

use-pool

Enables or disables the use of the pool specified using the pool option. The default is none.

SEE ALSO

## apm access-info

**NAME**  
access-info - Shows session related information such as session id, client ip, logon user and access profile name.

**MODULE**  
apm access-info

**SYNTAX**  
Shows the access-info component using the syntax shown in the following sections.

**DISPLAY**  
show access-info  
options:  
all-properties  
save-to-file

show access-info all  
show access-info logon-user username  
show access-info client-ip ip-address

**EXAMPLES**  
show access-info  
Displays the session id, client ip and logon user.

show access-info logon-user username  
Displays the session id, and the corresponding client ip.

show access-info client-ip ip-address  
Displays the session id and the corresponding logon user.

show access-info all-properties  
The output of this command looks like this:

session	session id
partition	partition Name
status	status of the session such as established and active
logon user	username
client IP	client ip address
profile access type	profile access type
access profile	access profile name
start time	start time of the session
expiration time	expiration time of the session
bytes(rx,tx)	session traffic bytes in and out
packets(rx,tx)	session traffic packets in and out
ingress(raw, compressed)	ingress raw bytes and compressed bytes
egress(raw, compressed)	egress raw bytes and compressed bytes
slot	slot number (applicable only in the cluster environment)
tmm	tmm number for the session

Displays the session id, client ip, logon user and other information of session as shown above.

**OPTIONS**  
session  
Specifies the session id.

partition  
Specifies the virtual server partition name.

status  
Specifies the access status and valid values are established or pending.

logon user  
Specifies the logged in user name for the session.

client IP  
Specifies the client IP from which the session is established.

profile access type  
Specifies access profile type; examples of valid values are: all, ltm-apm, ssl-vpn, sso, swg-explicit and swg-transparent.

access profile  
Specifies the access profile name.

start time  
Specifies the start time of the session.

expiration time  
Specifies the expiration time of the session.

bytes:(rx,tx)  
Specifies the traffic bytes in and out for the session.

packets:(rx,tx)  
Specifies the traffic packets in and out for the session.

ingress:(raw,compressed)  
Specifies the ingress raw and compressed bytes for the session.

egress:(raw,compressed)  
Specifies the egress raw and compressed bytes for the session.

slot  
Specifies the slot number for the session. Applicable only in the

cluster environment.

tmm Specifies the tmm number that holds the session.

SEE ALSO

## apm acl

NAME

acl - Manages an access control list (ACL).

MODULE

apm

SYNTAX

Configure the acl component within the apm module using the syntax shown in the following sections.

CREATE/MODIFY

```
create acl [name]
modify acl [name]
options:
  acl-order [integer]
  app-service [[string] | none]
  description [[string] | none]
  entries {
  {
  options:
    action [allow | continue | discard | reject | unspec]
    dst-end-port [[service] | none]
    dst-start-port [[service] | none]
    dst-subnet [[ip addr] | [[ip addr] [mask]]
    host [[string] | none]
    log [config | none | packet | summary | verbose]
    paths [[string] | none]
    protocol [integer]
    scheme [any | http | https]
    src-end-port [[service] | none]
    src-start-port [[service] | none]
    src-subnet [[ip addr] | [[ip addr] [mask]]
  }
  }
  location-specific [true | false]
  path-match-case [false | true]
  type [dynamic | static]
```

DISPLAY

```
list acl
list acl [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show acl
show acl [ [ [name] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

DELETE

```
delete acl [name]
```

DESCRIPTION

You can use the acl component to configure a set of restrictions associated with a resource or favorite that defines access for users and groups.

EXAMPLES

```
create acl MyACL { acl-order 3 entries src-start-port ip default inet
dst-end-port ip default inet action allow }
Creates the static access control list named MyACL that is the third ACL in the list of ACLs in the visual policy editor, and adds an access control entry that allows traffic using the default source IP address and the default destination IP address.
```

```
list acl all-properties
Displays a list of ACLs that includes the attributes of each ACL.
```

delete acl MyACL  
Deletes the MyACL access control list.

#### OPTIONS

acl-order  
Specifies the order of the access control entries in this access control list. This option is required.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description  
Describes the access control list.

entries  
Configures an entry for an access control list.

action  
Specifies the action that an access control list takes when this access control list entry is encountered. This option is required. You can specify one of the following actions:

allow  
Allows traffic.

continue  
Skips checking against the remaining access control list entries in this access control list, and continues evaluation at the next access control list.

discard  
Drops packets silently.

reject  
Drops a packet and sends TCP RST on TCP flows or proper ICMP messages on UDP flows. Silently drops a packet on other protocols.

dst-end-port  
Specifies the destination IP address and network mask of the access control list entry. The default is 0.

dst-start-port  
Specifies the source port or range of ports of the access control list entry.

dst-subnet  
Specifies the destination subnet.

host Specifies the host name of the access control list entry.

location-specific  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

log Specifies the log level that is logged when actions of this type occur. Your options are:

config  
Logs the configuration of a matched entry.

none Logs nothing. This is the default value.

packet  
Logs a matched packet.

summary  
Logs the name and entry number of a matched access control list and access control list entry.

verbose  
Logs everything.

paths  
Specifies an L7 access control list of matching URL paths.

protocol  
Specifies the protocol number (TCP=6, UDP=17) of the access control list entry. The default is 0.

src-end-port  
Specifies the source IP address and network mask of the access control list entry.

src-start-port  
Specifies the source port or range of ports of the access control list entry.

src-subnet  
Specifies the source subnet.

[name]  
Specifies the name of the access control list. This setting is

required.

**partition**  
Displays the partition within which the object resides. The default is Common.

**path-match-case**  
Indicates whether the path is case sensitive. The default is true.

**type** Specifies the type of access control list. The default is static. The available types are static and dynamic.

## apm apm-avr-config

NAME

apm-avr-config - Configures AVR overview/statistics settings for Secure Web Gateway Functionality

MODULE

apm

SYNTAX

Configure an apm-avr-config component within the apm module using the syntax shown in the following sections.

MODIFY

The AVR Configuration consists of the following information: boolean flag to turn off data collection by AVR; Boolean flag to turn off sampling by AVR; Both are on by default. No create or delete function is allowed.

```
modify apm-avr-config apm-avr-config {  
  avr-collect-data [true | false]  
  avr-sampling [true | false]  
}
```

DISPLAY

```
list apm-avr-config  
list apm-avr-config [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  one-line  
  partition
```

DESCRIPTION

Configures AVR Configuration for SWG Statistical Reporting

EXAMPLES

```
modify apm-avr-config apm-avr-config { avr-collect-data false }
```

Modify apm-avr-config by setting avr collect data to false.

OPTIONS

**avr-collect-data**

Specifies whether data should be collected or not for statistical reporting.

**avr-sampling**

Specifies whether sampling should be turned on or off.

## apm configuration captcha

### NAME

captcha - Manages CAPTCHA version 2 configuration

### MODULE

apm configuration

### SYNTAX

Configure the captcha component within the configuration module using the syntax shown in the following sections.

#### CREATE/MODIFY

create captcha [name]

modify captcha [name]

#### options:

captcha-data-size [data-size-compact | data-size-normal]

captcha-data-theme [data-theme-dark | data-theme-light]

captcha-data-type [data-type-audio | data-type-image]

captcha-theme [theme-red | theme-white | theme-blackglass | theme-clean | theme-custom]

challenge-url [string]

description [string]

exposition-threshold [integer]

noscript-url [string]

private-key [hexadecimal string]

proceed-on-verification-error [false | true]

public-key [hexadecimal string]

secret [hexadecimal string]

site-key [hexadecimal string]

track-by-ip [false | true]

track-by-username [false | true]

verification-url [string]

edit captcha [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties

non-default-properties

#### DISPLAY

list captcha

list captcha [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties

app-service

non-default-properties

one-line

partition

#### DELETE

delete captcha [name]

### DESCRIPTION

You can use the captcha component to create and manage CAPTCHA configuration.

### EXAMPLES

```
create captcha mycaptcha {secret 123456789abcdef site-key
fedcba987654321 }
```

Creates a CAPTCHA version 2 configuration named mycaptcha that uses site secret 123456789abcdef and site key fedcba987654321.

```
delete captcha mycaptcha
```

Deletes the CAPTCHA version 2 configuration named mycaptcha from the system.

### OPTIONS

captcha-data-size

Specifies the size of the reCAPTCHA widget. The default is data-size-normal.

captcha-data-theme

Specifies the color theme of the reCAPTCHA widget. The default is data-theme-light.

captcha-data-type

Specifies the type of CAPTCHA to server. The default is data-type-image.

captcha-theme

This option is specific to reCAPTCHA v1 and is deprecated in version 13.0.0.

challenge-url

Specifies the URL of the service that provides the CAPTCHA challenge. The default is [www.google.com/recaptcha/api.js](http://www.google.com/recaptcha/api.js).

description

Specifies a unique description for the CAPTCHA configuration.

exposition-threshold

Specifies the number of logon attempts to allow before issuing a CAPTCHA challenge. The default is 0.

noscript-url

Specifies the URL to use for obtaining the challenge if JavaScript is disabled. The default is [www.google.com/recaptcha/api/fallback](http://www.google.com/recaptcha/api/fallback).

private-key

This option is specific to reCAPTCHA v1 and is deprecated in version 13.0.0.

`proceed-on-verification-error`  
Specifies whether to allow user access when CAPTCHA verification cannot be completed for some reason. The default is true.

`public-key`  
This option is specific to reCAPTCHA v1 and is deprecated in version 13.0.0.

`secret`  
Specifies the secret provided by the CAPTCHA service provider. This option is required.

`site-key`  
Specifies the site key provided by the CAPTCHA service provider. This option is required.

`track-by-ip`  
Specifies whether to track logon failures using IP address. The default is true.

`track-by-username`  
Specifies whether to track logon failures using username. The default is true.

`verification-url`  
Specifies the URL of the service that verifies the response to the CAPTCHA challenge. The default is `www.google.com/recaptcha/api/siteverify`.

SEE ALSO

## apm epsec epsec-package

**NAME**  
epsec-package - Manages an EPSEC package.

**MODULE**  
apm epsec

**SYNTAX**  
Configure the epsec-package component within the apm epsec module using the syntax shown in the following sections.

**CREATE**  
create epsec-package  
options:  
local-path [string]  
server [[string] | none]

**DISPLAY**  
list epsec-package  
options:  
all-properties  
non-default-properties  
recursive

list epsec-package [name]

**INSTALL**  
install epsec-package [name]  
options:  
device-group [string]

**DELETE**  
delete epsec-package [name]

**DESCRIPTION**  
You can use the epsec-package component to create, install and manage an EPSEC package.

**EXAMPLES**  
create epsec-package my\_epsec\_package local-path /tmp/my\_epsec\_package  
Creates an EPSEC package named my\_epsec\_package under the /Common/EPSEC/Upload folder.

list epsec-package  
Displays a list of EPSEC packages under the specific folder. To list all EPSEC packages use the recursive option.

```
install epsec-package my_epsec_package
Installs the EPSEC package named my_epsec_package on this device.
You cannot install a package from the /Common folder as it is a
pre-installed package.
```

```
install epsec-package my_epsec_package device-group /Common/my_epsec_dg
Installs the EPSEC package named my_epsec_package on the devices
in the device group /Common/my_epsec_dg. You cannot install a
package from the /Common folder as it is a pre-installed package.
```

```
delete epsec-package my_epsec_package
Deletes the EPSEC package named my_epsec_package.
```

#### OPTIONS

```
[name]
Specifies the name of the component. This option is required.
```

```
local-path
Specifies the local path of the package to be uploaded. This
option is valid only with CREATE command and is a required option.
```

```
device-group
Specifies the device group on which the package will be installed.
This option is valid only with INSTALL command
```

## apm epsec software-status

#### NAME

software-status - Displays the status of the EPSEC software installation.

#### MODULE

apm epsec

#### SYNTAX

Display information about the software-status component within the apm epsec module using the following syntax.

#### DISPLAY

```
show software-status
```

#### DESCRIPTION

You can use the software-status component to display the status of the EPSEC software installation, including the version of the EPSEC package being installed and the OESIS software version.

#### EXAMPLES

```
show software-status
```

Displays the status of the EPSEC software installation in a table.

#### OPTIONS

#### SEE ALSO

epsec-package

#### COPYRIGHT

## apm license

NAME  
license - Shows the session information related to apm license.

MODULE  
apm

SYNTAX  
Displays the apm license information.

DISPLAY  
show apm license

DESCRIPTION  
APM module license is based on the session count depending on the platform. This module shows the total session information for access, ccu (connectivity), swg, swg limited and the currently used sessions for access, ccu, swg, swg limited. In addition, the statistics include the threshold percent for all the sessions.

EXAMPLES  
show apm license

Displays the apm license usage information.

total access sessions  
Total access sessions for BIG-IP. This number is based on the license and platform type.

current active sessions  
The number of access sessions that are currently in use.

current established sessions  
Total number of currently established sessions.

access sessions threshold percent  
Access sessions threshold warning percent set by the user. The default is 75%.

total connectivity sessions  
Total connectivity sessions (ccu) for BIG-IP. This number is based on the license and platform type.

current connectivity sessions  
The number of connectivity sessions (ccu) that are currently in use.

connectivity sessions threshold percent  
Connectivity sessions threshold warning percent set by the user. The default is 75%.

total swg sessions  
Total swg sessions for BIG-IP. This number is based on the subscription-based swg license.

current swg sessions  
The number of swg sessions that are currently in use.

swg sessions threshold percent  
SWG sessions threshold warning percent set by the user. The default is 75%.

total swg limited sessions  
Total swg limited sessions for BIG-IP. This number is based on the license and platform type.

current swg limited sessions  
The number of swg limited sessions that are currently in use.

swg limited sessions threshold percent  
SWG limited sessions threshold warning percent set by the user. The default is 75%.

COPYRIGHT  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

---

## apm log-setting

**NAME**  
log-setting - Configures log configurations for various features in APM, such as URL Filter/Classification (URL Filter).

**MODULE**  
apm

**SYNTAX**  
Configure the log-setting component within the module using the syntax shown in the following sections.

**CREATE/MODIFY**  
Consider log-setting as a container for log configurations belonging to different features. At this time URL Filter is the only feature with a log setting.

```
create log-setting [name]
modify log-setting [name]
options:
  description
  url-filters [add | delete | modify | replace-all-with] {
    [item name] {
  filter { log-allowed-url [true|false] log-blocked-url [true|false] }
  publisher [string]
    }
  }
  access [add | delete | modify | replace-all-with] {
    [item name] {
  log-level {
    access-control [emerg|alert|crit|err|warn|notice|info|debug]
    access-per-request [emerg|alert|crit|err|warn|notice|info|debug]
    apm-acl [emerg|alert|crit|err|warn|notice|info|debug]
    eca [emerg|alert|crit|err|warn|notice|info|debug]
    paa [emerg|alert|crit|err|warn|notice|info|debug]
    sso [emerg|alert|crit|err|warn|notice|info|debug]
    swg [emerg|alert|crit|err|warn|notice|info|debug]
  }
  publisher [string]
    }
  }
}
```

**DISPLAY**  
list log-setting  
list log-setting [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DESCRIPTION**  
Configures a container for log configurations.

**NOTE:** Each container can enclose log configurations for many different features. However, each feature can only have one log configuration in a container.

**NOTE:** For the log configuration to take effect, the log-setting must be associated with an access profile (See man page for apm access profile).

**NOTE:** A log-setting container cannot be deleted if it is associated with an access profile.

**EXAMPLES**  
create log-setting my-log-cfg  
  
Creates a container without any log configuration.  
  
create log-setting my-log-cfg url-filters add { my-urlf { filter { log-allowed-url true } publisher my-publisher } }  
  
Creates a container with a log configuration for the URL Filter feature. At this version, URL Filter is the only feature with a log configuration.  
  
modify log-setting my-log-cfg url-filters modify { my-urlf { publisher my-other-publisher } }  
  
Modify the publisher of a log configuration.  
  
modify log-setting my-log-cfg url-filters modify { my-urlf { filter { log-allowed-url false } } }  
  
Modify the setting of a log filter  
  
create log-setting my-log-cfg access add { my-access { publisher my-publisher } }  
  
Creates a container with a log configuration for APM logging.  
  
modify log-setting my-log-cfg access modify { my-access { log-level { access-control debug } } }  
  
Modify the log level for module access-control.

**OPTIONS**  
description  
Specifies a unique description for the log-setting container.  
  
url-filters  
This is the list to store log configurations for the URL Filter feature.  
  
item name

Specifies the name of the log configuration to be added to the list url-filters. Currently, the list supports only one item.

#### filter

Specifies the value for different log filters. In particular, URL Filter log configuration has two filters:  
log-allowed-url [true|false]  
log-blocked-url [true|false]

#### publisher

Specifies the publisher of the log configuration. See sys log-config publisher.

#### access

This is the list to store log configurations for APM logging.

#### log-level

## apm ntlm machine-account

#### NAME

machine-account - Configures an APM NTLM machine account object.

#### MODULE

apm ntlm

#### SYNTAX

Configure the ntlm machine account using the syntax shown in the following sections.

##### CREATE/MODIFY

create machine-account [name]

##### options:

action [noop]  
administrator-name [[string] | none]  
administrator-password [[string] | none]  
app-service [[string] | none]  
domain-controller-fqdn [fqdn]  
domain-fqdn [fqdn]  
machine-account-name [[string] | none]

modify machine-account [name]

##### options:

action [change-password | noop]  
app-service [[string] | none]  
domain-controller-fqdn [fqdn]

edit machine-account [ [ [name] | [glob] | [regex] ] ... ]

##### options:

all-properties  
non-default-properties

##### DISPLAY

list machine-account

list machine-account [ [ [name] | [glob] | [regex] ] ... ]

##### DELETE

delete machine-account [name]

#### DESCRIPTION

You can use the machine-account component to configure a NTLM machine account.

#### EXAMPLES

```
create machine-account myaccount { machine-account-name
"my_account_name" domain-fqdn "company.com" domain-controller-fqdn
"server01.company.com" administrator-name "administrator"
administrator-password "!My123Password" }
```

Creates a NTLM machine account named myaccount in the company.com domain, with domain controller server01.company.com, administrator name administrator and administrator password !My123Password.

```
list machine-account
```

Displays a list of all NTLM machine accounts created on the

system.

delete machine-account myaccount  
Deletes the NTLM machine account named myaccount the system.

#### OPTIONS

machine-account-name  
Specifies the name of the machine account.

domain-fqdn  
Specifies the Fully Qualified Domain Name. This setting is required.

domain-controller  
Specifies the Fully Qualified Domain Name (FQDN) of the domain controller for the domain specified in the domain-fqdn option. The default is none.

administrator-name  
Specifies the name of a user that has administrative permissions on an Active Directory server. This setting is required only when a new machine account is being created.

administrator-password  
Specifies the password associated with administrator-name. This setting is required only when a new machine account is being created.

action  
Specifies the action type. To change the machine account password, type this action: change-password else noop

change-password  
Specifies that you want to change the machine account password.

noop Specifies "no operation performed". This is the default.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

## apm ntlm ntlm-auth

NAME  
ntlm-auth - Configures an APM NTLM authentication object.

MODULE  
apm ntlm

SYNTAX  
Configure the ntlm-auth using the syntax shown in the following sections.

```
CREATE/MODIFY
create ntlm-auth [name]
options:
  app-service [[string] | none]
  dc-fqdn-list [add | delete | modify | replace-all-with] {
[[string]]
}
  machine-account-name [[string] | none]

modify ntlm-auth [name]
options:
  app-service [[string] | none]
  dc-fqdn-list [add | delete | modify | replace-all-with] {
[[string]]
}
  machine-account-name [[string] | none]

edit ntlm-auth [ [name] | [glob] | [regex] ] ... ]
options:
```

```
all-properties
non-default-properties

DISPLAY
list ntlm-auth
list ntlm-auth [ [ [name] | [glob] | [regex] ] ... ]

DELETE
delete ntlm-auth [name]

DESCRIPTION
You can use the ntlm-auth component to configure an NTLM authentication
object.

EXAMPLES
create ntlm-auth myaccount { dc-fqdn-list add { server01.company.com }
machine-account-name "my_account" }
Creates a NTLM authentication object named myaccount with machine
account my_account, and the list of domain controllers specified
by dc-fqdn-list

list ntlm-auth
Displays a list of all NTLM authentication objects created on the
system.

delete ntlm-auth myaccount
Deletes the NTLM authentication object named myaccount from the
system.

OPTIONS
dc-fqdn-list
Specifies a list of Fully Qualified Domain Names (FQDNs) for the
domain controllers to use for NTLM authentication.

machine-account-name
Specifies the NTLM machine account object name to use for this
NTLM authentication

app-service
Specifies the name of the application service to which the object
belongs. The default value is none. Note: If the strict-updates
option is enabled on the application service that owns the object,
you cannot modify or delete the object. Only the application
service can modify or delete the object.

SEE ALSO

## apm oauth db-instance

```
NAME
db-instance - Manages various OAuth database instances for this
partition.

MODULE
apm oauth

SYNTAX
Configure the db-instance component within the oauth module using the
following syntax.

CREATE/MODIFY
create db-instance [name]
modify db-instance [name]
options:
app-service [[string] | none]
description [[string] | none]
purge-frequency [daily | hourly | monthly | never | weekly]
purge-now
purge-time [string]
edit db-instance [ [ [name] | [glob] | [regex] ] ... ]
options:
all-properties
non-default-properties
one-line

DISPLAY
list db-instance
list db-instance [ [ [name] | [glob] | [regex] ] ... ]
show running-config db-instance
```

```
show running-config db-instance [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

```
DELETE
delete db-instance [name]
```

#### DESCRIPTION

OAuth authorization server supports persistence for OAuth tokens and related data using on-disk databases. This data can be grouped into separate logical entities using database instances. The db-instance component can be used to manage such database instances within a partition.

Because disk size is a limited resource, expired/obsolete tokens need to be purged in order to make space for newly issued tokens. The db-instance component provides options to purge either periodically, using combination of purge-frequency and purge-time or on-demand, using purge-now. The default setting for purge-frequency is daily and for purge-time is 02:00 hours for a newly created database instance. When executed, database instance purging removes revoked, expired access tokens, refresh tokens, auth code and associated entries from the particular instance. Expired access tokens will not be removed if the reuse-access-token setting is enabled in the corresponding OAuth profile.

#### EXAMPLES

```
create db-instance myDbInstance {
description "Sales Team"
purge-frequency weekly
purge-time "00:00"
}
```

Creates a database instance named myDbInstance that, when associated with an OAuth profile, stores tokens related to the OAuth profile in a separate database. This database instance is for the Sales team within the company. Stored data is purged weekly at 12AM.

```
list db-instance
```

Displays a list of all DB instances on the Authorization server.

```
delete db-instance myDbInstance
```

Deletes the database instance myDbInstance.

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
Specifies a user-defined description for the database instance. The default value is none.

**[name]**  
Specifies the name of the OAuth database instance. This setting is required.

**partition**  
Displays the partition within which the component resides.

**purge-frequency**  
Specifies the frequency at which data should be purged. The default value is daily. Other possible values are hourly, monthly, never and weekly.

**purge-now**  
Indicates a request to purge the data right now.

**purge-time**  
Specifies the time at which data should be purged. The default value is 02:00. HH:MM format must be used to specify time value.

## apm oauth oauth-client-app

**NAME**  
oauth-client-app - Manages client applications to use with OAuth Authorization Server.

**MODULE**  
apm oauth

**SYNTAX**  
Configure the oauth-client-app component within the oauth module using the following syntax.

**CREATE/MODIFY**  
create oauth-client-app [name]  
modify oauth-client-app [name]  
options:  
  access-token-lifetime [integer]  
  app-description [[string] | none]  
  app-name [string]  
  app-service [[string] | none]  
  auth-code-lifetime [integer]  
  auth-type [none | secret | certificate]  
  client-cert-dn [[string] | none]  
  contact [[string] | none]  
  customization-group [[string] | none]  
  generate-refresh-token [true | false]  
  grant-code [enabled | disabled]  
  grant-password [enabled | disabled]  
  grant-token [enabled | disabled]  
  logo-url [[string] | none]  
  redirect-uris [add | delete | none | replace-all-with] {  
    [URI]  
  }  
  refresh-token-lifetime [integer]  
  refresh-token-usage-limit [integer]  
  regenerate-client-secret  
  reuse-access-token [true | false]  
  reuse-refresh-token [true | false]  
  scopes [add | delete | replace-all-with] {  
    [scope-name]  
  }  
  use-profile-token-mgmt-settings [true | false]  
  website-url [[string] | none]  
edit oauth-client-app [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  one-line

**DISPLAY**  
list oauth-client-app  
list oauth-client-app [ [ [name] | [glob] | [regex] ] ... ]  
show running-config oauth-client-app  
show running-config oauth-client-app [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  one-line

**DELETE**  
delete oauth-client-app [name]

**DESCRIPTION**  
You can use the oauth-client-app component to register and manage client applications that will make protected resource requests to the OAuth Authorization server on behalf of the resource owner and with its authorization.

**EXAMPLES**

```
create oauth-client-app myClientApplication {
  app-description "Test App is an application that tests all grant types."
  app-name "Test App"
  grant-code enabled
  grant-password enabled
  grant-token enabled
  logo-url "https://abc.cloud.net/www/public/assets/images/logos/testapp.png"
  redirect-uris add { https://vm1.lab.fp.f5net.com/oauth2/f5_test.php }
  scopes add { scope1 scope2 }
  website-url "https://www.test.com"
}
```

Creates a client application named myClientApplication that will use the generated client credentials to send requests to this Authorization server. It can send token requests using any of the three supported grant types (authorization code, resource owner password credentials or implicit) and uses the default authentication type "secret".

The authorization server will use the configured redirect uri to re-direct back to the client. The client application is associated with configured scopes named scope1 and scope2.

```
list oauth-client-app
```

Displays a list of registered client-apps.

```
delete oauth-client-app myClientApplication
```

Deletes the OAuth client application myClientApplication

## OPTIONS

### access-token-lifetime

Specifies the number of minutes for which the access token should be valid. The default is 5 minutes.

### app-description

Specifies a user-defined description for the client-app. The default value is none.

### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

### auth-code-lifetime

Specifies the number of minutes for which the authorization code should be valid. The default is 5 minutes.

### auth-type

Specifies the authentication type the client will use when it makes requests to the Authorization Server. The default value is secret and other possible values are none and certificate.

### client-cert-dn

Specifies the distinguished name of the client certificate that is used to validate a request from client when authentication type is set to certificate.

### client-id

Specifies the client ID that uniquely identifies the client application. This field will be auto-generated and should not be specified or modified. Also, this entry cannot be edited once it has been generated.

### client-secret

Specifies the client secret that is used to validate a request from client when authentication type is set to secret. This field will be auto-generated and should not be specified or modified.

### contact

Specifies a means to contact the developer of the client application.

### customization-group

Specifies the customization settings for the client application.

### generate-refresh-token

Specifies whether a refresh token should be generated along with the access token. This is applicable only for "Authorization Code" and "Resource Owner Password Credentials" grant types.

### grant-code

Specifies whether the client application will use the "authorization code" grant type. The default value is disabled. At least one grant type must be set to enabled.

### grant-password

Specifies whether the client application will use the "resource owner password credentials" grant type. The default value is disabled.

### grant-token

Specifies whether the client application will use the "implicit" grant type. The default value is disabled.

### logo-url

Specifies the path from which the logo of the client application can be displayed.

### [name]

Specifies the name of the OAuth Client Application. This setting is required.

### partition

Displays the partition within which the component resides.

### redirect-uris

Specifies the list of re-direct URIs that the Authorization Server will use to re-direct back to the client after processing a request. This setting should have at least one entry if the client application uses the authorization code grant type or the implicit grant type.

### refresh-token-lifetime

Specifies the number of minutes for which the refresh token should be valid. The default is 480 minutes.

### refresh-token-usage-limit

Specifies the maximum number of times the access token can be obtained using the refresh token request. The default value is 0, which represents unlimited number of times.

### regenerate-client-secret

Indicates a request to regenerate the client secret. Do not use other means to modify the secret.

### reuse-access-token

Specifies whether an access token is reused or a new access token is generated when it is obtained using refresh token request. When the access token is reused, its expiry time is extended.

### reuse-refresh-token

Specifies whether a refresh token is reused or a new refresh token is generated when it is obtained using refresh token request.

**scopes**

Specifies the list of scopes that is to be associated with the client application.

**use-profile-token-mgmt-settings**

Specifies whether the default settings that come from OAuth profile must be used or not.

**website-url**

Specifies the website URL of the client application.

## apm oauth oauth-resource-server

**NAME**

oauth-resource-server - Manages resource servers to use with OAuth Authorization Server.

**MODULE**

apm oauth

**SYNTAX**

Configure the oauth-resource-server component within the oauth module using the following syntax.

**CREATE/MODIFY**

create oauth-resource-server [name]

modify oauth-resource-server [name]

**options:**

app-service [[string] | none]

description [[string] | none]

auth-type [none | secret | certificate]

regenerate-resource-server-secret

resource-server-cert-dn [[string] | none]

edit oauth-resource-server [ [ [name] | [glob] | [regex] ] ... ]

**options:**

all-properties

non-default-properties

one-line

**DISPLAY**

list oauth-resource-server

list oauth-resource-server [ [ [name] | [glob] | [regex] ] ... ]

show running-config oauth-resource-server

show running-config oauth-resource-server [ [ [name] | [glob] | [regex] ] ... ]

**options:**

all-properties

non-default-properties

one-line

**DELETE**

delete oauth-resource-server [name]

**DESCRIPTION**

You can use the oauth-resource-server component to register and manage resource servers that host resources that will be accessed by the user. Resource servers can accept and respond to protected resource requests using access tokens.

**EXAMPLES**

```
create oauth-resource-server myResourceServer {
resource-server-cert-dn "/C=US/ST=CA/L=SJ/O=Company Name,Inc/OU=Engg/CN=user-name/emailAddress=username@company-doma
}
```

Creates a resource server named myResourceServer that will use the generated resource server credentials to send requests to the Authorization server. It uses the default authentication type "certificate".

```
list oauth-resource-server
```

Displays a list of registered resource servers.

```
delete oauth-resource-server myResourceServer
```

Deletes the OAuth resource server myResourceServer.

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**auth-type**  
Specifies the authentication type the resource server will use when it makes requests to the Authorization Server. The default value is certificate and other possible values are none and secret.

**[name]**  
Specifies the name of the OAuth Resource Server. This setting is required.

**description**  
Specifies the description of the OAuth Resource Server Object.

**partition**  
Displays the partition within which the component resides.

**regenerate-resource-server-secret**  
Indicates a request to regenerate the resource server secret. Do not use other means to modify the secret.

**resource-server-cert-dn**  
Specifies the distinguished name of the resource server certificate that is used to validate a request from the resource server when authentication type is set to certificate.

**resource-server-id**  
Specifies the resource server ID that uniquely identifies the resource server. This field will be auto-generated and should not be specified or modified. Also, this entry cannot be edited after it has been generated.

**resource-server-secret**  
Specifies the resource server secret that is used to validate a request from the resource server when authentication type is set to secret. This field will be auto-generated and should not be specified or modified.

## apm oauth oauth-scope

#### NAME

oauth-scope - Manages scopes for OAuth Authorization Server.

#### MODULE

apm oauth

#### SYNTAX

Configure the oauth-scope component within the oauth module using the following syntax.

##### CREATE/MODIFY

create oauth-scope [name]

modify oauth-scope [name]

##### options

app-service [[string] | none]

customization-group [[string] | none]

scope-description [[string] | none]

scope-name [string]

scope-value [[string] | none]

edit oauth-scope [ [ [name] | [glob] | [regex] ] ... ]

##### options:

all-properties

non-default-properties

one-line

##### DISPLAY

list oauth-scope

```
list oauth-scope [ [ [name] | [glob] | [regex] ] ... ]
show running-config oauth-scope
show running-config oauth-scope [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

```
DELETE
delete oauth-scope [name]
```

#### DESCRIPTION

You can use the oauth-scope component to create and manage scopes that provide different levels of access control based on end user's role or any other criteria.

#### EXAMPLES

```
create oauth-scope myOAuthScope {
  customization-group "company_my_oauth_scope"
  scope-description "Group in company"
  scope-name "profile"
  scope-value "Product Development"
}
```

Creates a scope named myOAuthScope that uses customization group company\_my\_oauth\_scope to customize scope information in the OAuth Authorization page. It is configured with profile and Product Development as its name and value respectively.

```
list oauth-scope
```

Displays a list of OAuth Scopes.

```
delete oauth-scope myOAuthScope
```

Deletes the OAuth Scope named myOAuthScope.

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**customization-group**  
Specifies the customization settings for the scope.

**[name]**  
Specifies the name of the OAuth Scope. This setting is required.

**partition**  
Displays the partition within which the component resides.

**scope-description**  
Specifies the description of the scope.

**scope-name**  
Specifies the name of the scope.

**scope-value**  
Specifies the value of the scope. This value can be any string or session variable.

#### SEE ALSO

## apm oauth purged-entries

**NAME**  
Purged-Entries - Displays OAuth records purged from the respective database instance.

**MODULE**  
apm oauth purged-entries

**SYNTAX**  
Displays all the purged-entries within the oauth module using the syntax shown below.

```
DISPLAY
show purged-entries
show purged-entries [db-instance]
options:
  all-properties
  non-default-properties
  one-line
  recursive
output only properties:
  oauth_id [string]
  purged_time [string]
```

DESCRIPTION  
You can use the purged-entries component to manage purged records.

EXAMPLES  
show apm oauth purged-entries  
Lists all the OAuth purged entries for the oauth default db instance oauthdb. Also displays the total number of records purged.  
  
show apm oauth purged-entries db-instance test  
Lists all the purged entries for the oauth db instance test. Also displays the total number of records purged.

OPTIONS  
db-instance  
This specifies the db instance. If no value is specified, the default db instance, oauthdb, is used.  
  
oauth-id  
Specifies oauth id. Displays in the output of the show command.  
  
purged\_time  
Specifies the timestamp at which each record was purged. The format is "YYYY-MM-DD HH:MM:SS". Displays in the output of the show command.

SEE ALSO  
apm oauth db-instance

## apm oauth token-details

NAME  
Token-Details - Displays OAuth token properties and revokes access tokens and refresh tokens.

MODULE  
apm oauth token-details

SYNTAX  
Lists the token-details within the oauth module using the syntax shown in the following sections.

```
DISPLAY
list token-details
list token-details [ [ [oauth-id] | [app-name] | [client-id] | [offset] | [db-instance] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  recursive
output only properties:
  access-token-status [[string] | none]
  access-token-issued-at [[string] | none]
  access-token-expires-at [[string] | none]
  refresh-token-status [[string] | none]
  refresh-token-issued-at [[string] | none]
  refresh-token-expires-at [[string] | none]
  grant-type [[string] | none]
  user-agent [[string] | none]

show token-details
show token-details [ [ [app-name] | [client-id] | [offset] | [db-instance] ] ... ]
options:
  field-fmt
  recursive

REVOKE
revoke token-details [ [oauth-id client-id] ]
```

## DESCRIPTION

You can use the token-details component to manage oauth tokens.

## EXAMPLES

```
list apm oauth token-details
```

Lists all the token details for the oauth default db instance of oauthdb.

```
list apm oauth token-details db-instance test
```

Lists all the token details for the oauth db instance test.

```
list apm oauth token-details client-app myapp
```

Lists all the token details for the client app myapp in the default db instance.

```
show apm oauth token-details
```

Shows the number of tokens in the oauth default db instance of oauthdb.

```
show apm oauth token-details db-instance test
```

Shows the number of tokens in oauth db instance test.

```
show apm oauth token-details client-app myapp
```

Shows the number of token for the client app myapp in default db instance.

```
revoke apm oauth token-details
```

```
93b225478484f0fa0addc527b2c50001d7e3yyb70c3eda99e56 client-id  
ae8b6cd3708a5805e84ae48369ab0001d7eb70c1325c8d56
```

Revokes the access/refresh token for oauth id 93b225478484f0fa0addc527b2c50001d7eb70c3eda99e56 and client id ae8b6cd3708a5805e84ae48369ab0001d7eb70c1325c8d56.

```
revoke apm oauth token-details
```

```
93b225478484f0fa0addc527b2c50001d7e3yyb70c3eda99e56 db-instance test  
client-id ae8b6cd3708a5805e84ae48369ab0001d7eb70c1325c8d56
```

Revokes the access/refresh token for oauth id 93b225478484f0fa0addc527b2c50001d7eb70c3eda99e56 and client id ae8b6cd3708a5805e84ae48369ab0001d7eb70c1325c8d56 in the db instance test.

## OPTIONS

**client-id**

Specifies the client id for which the token is generated. Must be specified for revoke command.

**app-name**

Specifies the app name for which the token is generated. This is an optional parameter for list and show commands.

**offset**

Specifies the number of tokens to skip before beginning to display the remaining tokens.

Example: list apm oauth token-details offset 10

This will return the tokens from the count of 11 and will skip the first 10.

**db-instance**

This specifies the db instance. If no value is specified, oauthdb (the default db instance) is used.

**user-id**

Specifies the user id for which the token is generated.

**oauth-id**

Specifies oauth id. Displays in the output of the list command.

**access-token-status**

Specifies the access token status, such as active,inactive,expired and revoked. Displays in the output of the list command. Access token status changes from active to expired only when a token validate request is attempted after the expiry time.

**access-token-issued-at**

Specifies the access token issued timestamp. The format is "YYYY-MM-DD HH:MM:SS". Displays in the output of the list command.

**access-token-expires-at**

Specifies the access token expiry timestamp. The format is "YYYY-MM-DD HH:MM:SS". Displays in the output of the list command.

**refresh-token-status**

Specifies the refresh token status such as active,inactive,expired and revoked. Displays in the output of the list command.

**refresh-token-issued-at**

Specifies the refresh token issued timestamp. The format is "YYYY-MM-DD HH:MM:SS". Displays in the output of the list command.

**refresh-token-expires-at**

Specifies the refresh token expiry timestamp. The format is "YYYY-MM-DD HH:MM:SS". Displays in the output of the list command.

**grant-type**

Specifies the grant type; valid values are ropc, implicit and auth-code. Displays in the output of the list command.

**user-agent**

Specifies the user agent information for the token. Displays in the output of the list command.

## apm policy access-policy

NAME  
access-policy - Manages an access policy.

MODULE  
apm policy

SYNTAX  
Warning: F5 Networks recommends that you use the visual policy editor in the Configuration utility to create and manage access policies. If you are using tmsh scripts to create an access policy, please do the following:

1. Create transaction.
2. Create policy agents; each policy must include an ending agent type.
3. Create access policy items for start and end and attach the corresponding agents.
4. Create access policy and add all the policy items.
5. Create access profile with the corresponding access policy.
6. Submit transaction.

Failure to follow the above mentioned steps will result in error messages or invalid configuration. This sample script creates a policy with start and end agents only:

1. create cli transaction
2. create apm policy agent ending-allow /Common/rest\_end\_allow\_ag { }
- 3a. create apm policy policy-item /Common/rest\_end\_allow { agents add { /Common/rest\_end\_allow\_ag { type ending-allow
- 3b. create apm policy policy-item /Common/rest\_end { caption Start color 1 rules { { caption fallback next-item /Commo
4. create apm policy access-policy /Common/rest { default-ending /Common/rest\_end\_allow items add { rest\_end\_allow { }
5. create apm profile access /Common/rest { accept-languages add { en } access-policy /Common/rest log-settings add {
6. submit cli transaction

## apm policy agent aaa-active-directory

NAME  
aaa-active-directory - Manages an AAA Active Directory(r) agent.

MODULE  
apm policy agent

SYNTAX  
Configure the aaa-active-directory component within the policy agent module using the following syntax.

CREATE/MODIFY  
create aaa-active-directory [name]  
modify aaa-active-directory [name]  
options  
app-service [[string] | none]  
auth-max-logon-attempt [integer]  
fetch-nested-groups [true | false]  
fetch-primary-groups [true | false]  
hints [true | false]

```
query-attrname [[string] | none]
query-filter [[string] | none]
server [[string] | none]
trusted-domains [[string | none]]
show-extended-error [true | false]
type [query | auth | last]
upn [true | false]
```

#### DISPLAY

```
list aaa-ldap
list aaa-ldap [ [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-ldap
show running-config aaa-ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition
```

#### DELETE

```
delete aaa-active-directory ([name] | all)
```

#### DESCRIPTION

You can use the aaa-active-directory component to configure an AAA Active Directory agent.

#### EXAMPLES

```
create aaa-active-directory MyADQueryagent {query-filter "(be
sAMAccountName=%{session.logon.last.username})" type query server
"companyAD" }
```

Creates the query type AAA Active Directory agent named MyADQueryagent that uses the (be sAMAccountName=%{session.logon.last.username}) filter and the companyAD AAA AD Server.

```
create agent aaa active MyADAuthagent { type auth server "companyAD" }
```

Creates the authorization type AAA Active Directory agent named MyADAuthagent that uses the companyAD AAA AD server.

```
list aaa-active-directory all
```

Displays a list of AAA Active Directory agents and their properties.

```
delete aaa-active-directory MyADagent
```

Deletes the MyADagent AAA Active Directory agent.

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**auth-max-logon-attempt**  
Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

**fetch-nested-groups**  
When enabled, the system administrator can retrieve the full list of groups that user belongs to, even if the retrieval privileges are nested through other groups to which the user belongs to directly. The default value is false.

**fetch-primary-groups**  
When enabled, the system administrator can retrieve the primary group of a user, and use that name as a group in access policy item rules. The default value is false.

**hints**  
When enabled, the system offers the user an option to create a hint that assists in remembering a password. The default value is false.

**query-attrname**  
Specifies the attribute name that you are adding or deleting for the agent.

**query-filter**  
Specifies the search criteria the system uses when querying an AAA Active Directory(r) server for authentication information. The system supports session variables as part of search query string.

**[name]**  
Specifies the name of an AAA Active Directory agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

**server**  
Specifies an AAA Active Directory server the system uses for Active Directory queries and authentication.

**server**  
Specifies an AAA Active Directory Trusted Domains object that the

system uses for Active Directory queries and authentication. This option requires upn option to be enabled

**show-extended-error**  
Specifies to display a verbose error message. The default value is false.

**type** Specifies the type of AAA Active Directory agent. The default value is last.

**query**  
Specifies that the agent makes a query against the AAA Active Directory Server to retrieve information in accordance with the query-filter and query-attributes options.

**auth** Specifies that the agent is an authentication agent only. It uses the AAA Active Directory Server, but only for authentication purposes. APM does not get any information from the Domain.

**last**  
**upn** When enabled, APM supports the user principal name (UPN) naming style and process cross-domain authentication requests. Some examples of UPNs are: user@fqdn.of.domain.com, user@upnsuffix.com, and user@domain. The default value is false.

## apm policy agent aaa-client-cert

**NAME**  
aaa-client-cert - Manages an AAA Client Certification agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the aaa-client-cert component within the policy-agent module using the following syntax.

**CREATE/MODIFY**  
modify aaa-client-cert [name]  
create aaa-client-cert [name]  
options:  
app-service [[string] | none]  
mode [request | require]

**DISPLAY**  
list aaa-client-cert  
list aaa-client-cert [ [ [name] | [glob] | [regex] ] ... ]  
show running-config aaa-client-cert  
show running-config aaa-client-cert [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
all-properties  
current-module  
non-default-properties  
one-line  
app-service  
partition

**DELETE**  
delete aaa-client-cert [name]

**DESCRIPTION**  
You can use this component to configure an AAA Client Certification agent.

**EXAMPLES**  
create aaa-client-cert MyCCagent  
Creates the AAA Client Certification agent named MyCCagent in the Common partition.

list aaa-client-cert all  
Displays a list of AAA Client Certification agents.

delete aaa-client-cert MyCCagent  
Deletes the MyCCagent AAA Client Certification agent.

## OPTIONS

[name]

Specifies the name of an AAA client cert agent. This setting is required.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

mode Specifies the mode (request/require) for this certificate. The options are:

request

Specifies that the system requests a valid certificate from a client, but always authenticates the client.

require

Specifies that the system requires a client to present a valid certificate.

partition

Displays the partition within which the component resides.

## apm policy agent aaa-crldp

### NAME

aaa-crldp - Manages an AAA CRLDP (Constraint-Based Routed Label Distributed Protocol) agent.

### MODULE

apm policy agent

### SYNTAX

Configure the aaa-crldp component within the policy agent module using the following syntax.

#### CREATE/MODIFY

```
create aaa-crldp [name]
modify aaa-crldp [name]
options:
  app-service [[string] | none]
  server ( | none)
```

#### DISPLAY

```
list aaa-crldp
list aaa-crldp [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-crldp
show running-config aaa-crldp [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  app-service
  current-module
  non-default-properties
  one-line
  partition
```

#### DELETE

```
delete aaa-crldp [name]
```

### DESCRIPTION

You can use the aaa-crldp component to create and manage an AAA CRLDP agent.

### EXAMPLES

```
create aaa-crldp MyCCagent
Creates an AAA CRLDP agent named MyCCagent in the Common partition.
```

```
list aaa-crldp all
Displays a list of AAA CRLDP agents.
```

```
delete aaa-crldp MyCCagent
Deletes the MyCCagent AAA CRLDP agent.
```

## OPTIONS

`[name]`  
Specifies the name of an agent that you want to display or delete. This setting is required.

`partition`  
Displays the partition within which the component resides.

`app-service`  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`server`  
Specifies the name of the server on which this agent resides. This option is required.

## apm policy agent aaa-http

### NAME

`aaa-http` - Manages an AAA HTTP agent.

### MODULE

`apm policy agent`

### SYNTAX

Configure the `aaa-http` component within the policy agent module using the following syntax.

#### CREATE/MODIFY

```
create aaa-http [name]
modify aaa-http [name]
options
  app-service [[string] | none]
  max-logon-attempt [integer]
  server [[string] | none]
```

#### DISPLAY

```
list aaa-http
list aaa-http [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-http
show running-config aaa-http [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition
```

#### DELETE

```
delete aaa-http [name]
```

### DESCRIPTION

You can use the `aaa-http` component to configure an AAA HTTP agent.

### EXAMPLES

```
create aaa-http MyCCagent
Creates the aaa-http agent named MyCCagent in the Common partition.
```

```
list all aaa-http
Displays a list of aaa-http agents.
```

```
delete aaa-http MyCCagent
Deletes the MyCCagent aaa-http agent.
```

### OPTIONS

`app-service`  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application

service can modify or delete the object.

**max-logon-attempt**  
Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

**[name]**  
Specifies the name of an AAA HTTP agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

**server**  
Specifies which AAA HTTP server the system uses for Active Directory queries and authentication.

SEE ALSO

## apm policy agent aaa-ldap

**NAME**  
aaa-ldap - Manages an AAA LDAP(r) agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the aaa-ldap component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create aaa-ldap [name]  
modify aaa-ldap [name]  
options:  
app-service [[string] | none]  
attr-name ( | none) [add | delete]  
filter [[string] | none]  
group-member-scope [none | direct | all]  
group-membership-scope [none | direct | all]  
max-logon-attempt [integer]  
search-dn [[string] | none]  
server [[string] | none]  
show-extended-error [true | false]  
type [query | auth | modify | last]  
user-dn [[string] | none]  
modify-type [add | modify | delete | modify-last]  
ldapmod-attributes ( | none) [add | delete]

**DISPLAY**  
list aaa-ldap  
list aaa-ldap [ [ [name] | [glob] | [regex] ] ... ]  
show running-config aaa-ldap  
show running-config aaa-ldap [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
all-properties  
current-module  
non-default-properties  
one-line  
app-service  
partition

**DELETE**  
delete aaa-ldap [name]

**DESCRIPTION**  
Use this component to create, modify, display, or delete an AAA LDAP agent.

**EXAMPLES**  
create aaa-ldap MyLDAPagent { user-dn  
"cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=com" type  
auth server "companyLDAP" } aaa-ldap MyLDAPagent { search-dn  
"cn=users,dc=lab,dc=fp,dc=com" filter

```
"(SAMAccountName=%{{session.logon.last.username}})" type auth server
"companyLDAP" }
```

Creates the authorization type AAA LDAP agent named MyLDAPagent that is associated with the companyLDAP server that uses the cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=f5net,dc=com user domain name, the cn=users,dc=lab,dc=fp,dc=com search domain, and the (SAMAccountName=%{{session.logon.last.username}}) filter.

```
create aaa-ldap MyLDAPagent { search-dn "cn=users,dc=lab,dc=fp,dc=com"
filter "(SAMAccountName=%{{session.logon.last.username}})" type query
server "companyLDAP" }
```

Creates the query type AAA LDAP agent named MyLDAPagent that is associated with the companyLDAP server that uses the cn=users,dc=lab,dc=fp,dc=com search domain and the (SAMAccountName=%{{session.logon.last.username}}) filter.

```
create aaa-ldap MyLDAPagent { user-dn
"cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=com" type
modify modify-type add server "companyLDAP" ldapmod-attributes add {
objectClass { mod-op add mod-values add { top person
organizationalPerson user } } cn { mod-op add mod-values add { demo } }
} }
```

Creates the modify type AAA LDAP agent named MyLDAPagent that is associated with the companyLDAP server that uses the cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=f5net,dc=com user domain name, the add modify type, and the ldapmod attributes

```
create aaa-ldap MyLDAPagent { user-dn
"cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=com" type
modify modify-type modify server "companyLDAP" ldapmod-attributes add {
givenName { mod-op replace mod-values add { demo } } } }
```

Creates the modify type AAA LDAP agent named MyLDAPagent that is associated with the companyLDAP server that uses the cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=f5net,dc=com user domain name, the modify modify type, and the ldapmod attributes which uses givenName modify attribute replace mod operation and the demo mod values

```
create aaa-ldap MyLDAPagent { user-dn
"cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=com" type
modify modify-type delete server "companyLDAP" }
```

Creates the modify type AAA LDAP agent named MyLDAPagent that is associated with the companyLDAP server that uses the cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=f5net,dc=com user domain name, the delete modify type

```
list aaa-ldap
```

Displays a list of AAA LDAP agents.

```
delete aaa-ldap MyLDAPagent
```

Deletes the MyLDAPagent AAA LDAP agent.

## OPTIONS

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**attr-name**

Adds an attribute name to the agent or deletes an attribute name from the agent.

**group-member-scope**

Specifies the scope of user lookup for a group. When the search returns a group, this attribute specifies whether to also look up the members of the group. The options are:

none No members required.

direct Only direct members required.

all All members required. This includes those that derive membership in this group through membership in other groups and those that are direct members.

**group-membership-scope**

Specifies the scope of group lookup for a user or a group. When the search returns a user or a group, this attribute specifies whether to also look up the groups to which this user or group belong. The options are:

none No groups required.

direct Only the groups to which the current user or group belong directly are required.

all All groups required. This includes the groups to which the user or the group belong directly and the groups to which the user or group belong indirectly (through membership in another group).

**filter**

Specifies the LDAP filter that APM uses when querying an AAA LDAP server for authentication information. You must use the filter option with the search-dn option.

**max-logon-attempt**

Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

**[name]**

Specifies the name of an AAA LDAP agent. This setting is required.

**partition**

Displays the partition within which the component resides.

**search-dn**  
Specifies the base domain name that APM uses for internal LDAP search operations. You must use the search-dn option with the filter option.

**server**  
Specifies the AAA LDAP server that the system uses for LDAP queries and authentication.

**show-extended-error**  
Specifies to display a verbose error message. The default value is false.

**type** Specifies a type of AAA LDAP agent. This setting is required. The default is last.

**user-dn**  
Specifies the fully qualified domain name of the Access Policy Manager. F5 Networks recommends that you specify this value in lower case and without spaces for compatibility with some specific LDAP servers. The specific content of this string depends on your directory layout.

## apm policy agent aaa-oauth

**NAME**  
aaa-oauth - Manages an AAA OAuth(r) agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the aaa-oauth component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create aaa-oauth[name]  
modify aaa-oauth [name]  
options:  
app-service [[string] | none]  
auth-redirect-request [name]  
grant-type [authorization-code | password]  
redirection-uri [string]  
scope [[string] | none]  
scope-data-request [name]  
server [name]  
token-refresh-request [name]  
token-request [name]  
type [client | scope]  
validation-scopes-request [name]

**DISPLAY**  
list aaa-oauth  
list aaa-oauth [ [ [name] | [glob] | [regex] ] ... ]  
show running-config aaa-oauth  
show running-config aaa-oauth [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
all-properties  
current-module  
non-default-properties  
one-line  
app-service  
partition

**DELETE**  
delete aaa-oauth [name]

**DESCRIPTION**  
Use this component to create, modify, display, or delete an OAuth Client or OAuth Scope agent.

**EXAMPLES**  
create aaa-oauth MyGoogleClient { auth-redirect-request

```
GoogleAuthRedirectRequest grant-type authorization-code scope
"https://www.googleapis.com/auth/userinfo.email
https://www.googleapis.com/auth/userinfo.profile" server myGoogleServer
token-request GoogleTokenRequest type client validation-scopes-request
GoogleValidationScopesRequest } Creates the OAuth Client agent to
acquire an access_token from Google authorization server using
authorization-code grant type. Defines two scopes. The user's
permission will be requested for the scopes.
create aaa-oauth MyGoogleScope { scope-data-request {
https://www.googleapis.com/auth/userinfo.profile { request
GoogleScopeUserInfoProfileRequest } } server myGoogleServer type scope
validation-scopes-request GoogleValidationScopesRequest }
Creates OAuth Scope agent to get the list of scopes associated
with the access_token, and defines the scope-data-request to
retrieve more information about user identity if the access_token
contains the scope
"https://www.googleapis.com/auth/userinfo.profile".
```

```
list aaa-oauth
Displays a list of OAuth agents.
```

```
delete aaa-oauth MyGoogleScope
Deletes the MyGoogleScope OAuth agent.
```

#### OPTIONS

```
app-service
Specifies the name of the application service to which the object
belongs. The default value is none. Note: If the strict-updates
option is enabled on the application service that owns the object,
you cannot modify or delete the object. Only the application
service can modify or delete the object.
```

```
auth-redirect-request
OAuth Request name to be used for user redirect in order to obtain
authorization code.
```

```
grant-type
Specifies grant type that should be used to request an
access_token.
```

```
redirection-uri
Specifies redirection URI. The redirection URI is used by the
Authorization Server to redirect user back after authentication.
The URI is a property of client application registered at
authorization server. This option is used along with
'authorization-code' grant type only.
```

```
scope
The list of scopes to request user's permission for.
```

```
scope-data-request
Defines OAuth Request to obtain additional information from the
resource server for the specified scope, using access_token.
```

```
server
Specifies OAuth Server that represents the authorization server to
work with.
```

```
token-refresh-request
Specifies OAuth Request to refresh an expired access_token.
```

```
token-request
Specifies OAuth Request to request an access_token.
```

```
type Type of the OAuth agent. Available options are: client or scope.
Default value client. The type cannot be changed for an existing
OAuth agent.
```

```
validation-scopes-request
Specifies OAuth Request to validate the access token (when agent
type is client) or to retrieve list of scopes associated with the
access_token (when agent type is scope).
```

## apm policy agent aaa-ocsp

NAME

aaa-ocsp - Manages an AAA OCSF (Online Certificate Status Protocol) agent.

#### MODULE

apm policy agent

#### SYNTAX

Configure the aaa-ocsp component within the policy agent module using the following syntax.

#### CREATE/MODIFY

```
create aaa-ocsp [name]
modify aaa-ocsp [name]
options:
  app-service [[string] | none]
  certificate-type
  ocsf-responder
```

#### DISPLAY

```
list aaa-ocsp
list aaa-ocsp [ [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-ocsp
show running-config aaa-ocsp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition
```

#### DELETE

```
delete aaa-ocsp [name]
```

#### DESCRIPTION

Use this command to create, modify, display, or delete an AAA OCSF agent.

#### EXAMPLES

```
create aaa-ocsp MyCCagent
Creates the AAA OCSF agent named MyCCagent in the Common partition.
```

```
list aaa-ocsp all
Displays a list of AAA OCSF agents.
```

```
delete aaa-ocsp MyCCagent
Deletes the MyCCagent AAA OCSF agent.
```

#### OPTIONS

[name]  
Specifies the name of an agent that you want to display or delete. This setting is required.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

certificate-type  
Specifies the type of certificate to check against OCSF responder. The value can be either user or machine. The default value is user.

ocsf-responder  
Specifies which OCSF responder object to use to validate a certificate.

partition  
Displays the partition within which the object resides.

## apm policy agent aaa-radius

#### NAME

aaa-radius - Manages an AAA RADIUS agent.

MODULE  
apm policy agent

SYNTAX  
Configure the aaa-radius component within the policy agent module using the following syntax.

CREATE/MODIFY

```
create aaa-radius [name]
modify aaa-radius [name]
options:
  app-service [[string] | none]
  max-logon-attempt
  server ( | none)
  show-extended-error (true | false)
```

DISPLAY

```
list aaa-radius
list aaa-radius [ [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-radius
show running-config aaa-radius [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition
```

DELETE

```
delete aaa-radius [name]
```

DESCRIPTION

Use this command to create, modify, display, or delete an AAA RADIUS agent.

EXAMPLES

```
create aaa-radius Myradiusagent {server "companyradius"}
Creates an AAA RADIUS agent named Myradiusagent that is associated with the companyradius server.
```

```
list aaa-radius
Displays a list of AAA RADIUS agents.
```

```
delete aaa-radius Myradiusagent
Deletes the Myradiusagent AAA RADIUS agent.
```

OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**max-logon-attempt**  
Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

**[name]**  
Specifies the name of an aaa radius agent. This setting is required.

**partition**  
Displays the partition within which the object resides.

**server**  
Specifies the AAA RADIUS server that the system uses for RADIUS queries and authentication.

**show-extended-error**  
Specifies to display a verbose error message. The default value is false.

# apm policy agent aaa-securid

**NAME**  
aaa-securid - Manages an AAA SecurID agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the aaa-securid component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create aaa-securid [name]  
modify aaa-securid [name]  
options:  
  app-service [[string] | none]  
  max-logon-attempt [integer]  
  server [[string] | none]  
  show-extended-error [true | false]

edit aaa-securid | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

**DISPLAY**  
list aaa-securid  
list aaa-securid [ [name] | [glob] | [regex] ] ... ]  
show running-config aaa-securid  
show running-config aaa-securid [ [name] | [glob] | [regex] ] ... ]  
options:  
  all  
  all-properties  
  current-module  
  non-default-properties  
  one-line  
  app-service  
  partition

**DELETE**  
delete aaa-securid [name]

**DESCRIPTION**  
You can use the aaa-securid component to create and manage an AAA SecurID agent.

**EXAMPLES**  
create aaa-securid mySecuridAgent { server rsal\_106 }  
Creates an AAA SecurID agent named mySecuridAgent that is associated to AAA RSA Server rsal\_106.

list all aaa-securid  
Displays a list of AAA SecurID agents.

delete aaa-securid MyCCagent  
Deletes the MyCCagent AAA Client Certification agent.

**OPTIONS**

[name]  
Specifies the name of an agent that you want to display or delete. This setting is required.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

max-logon-attempt  
Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

server  
Specifies the AAA RSA SecurID server that the system uses for LDAP queries and authentication.

show-extended-error  
Specifies to display a verbose error message. The default value is false.

## apm policy agent acct-radius

**NAME**  
acct-radius - Manages a RADIUS Account agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the acct-radius component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create acct-radius [name]  
modify acct-radius [name]  
options:  
  app-service [[string] | none]  
  server [[string] | none]

edit acct-radius | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

**DISPLAY**  
list acct-radius  
list acct-radius [ [name] | [glob] | [regex] ] ... ]  
show running-config acct-radius  
show running-config acct-radius [ [name] | [glob] | [regex] ] ... ]  
options:  
  all  
  all-properties  
  current-module  
  non-default-properties  
  one-line  
  app-service  
  partition

**DELETE**  
delete acct-radius [name]

**DESCRIPTION**  
You can use the acct-radius component to create and manage an RADIUS Account agent.

**EXAMPLES**  
create acct-radius MyRADIUSagent { server "MyRADIUS" }  
Creates the MyRADIUSagent RADIUS Account agent that is associated with the MyRADIUS server.

list acct-radius  
Displays a list of RADIUS Account agents and the servers associated with the agents.

delete acct-radius MyRADIUSagent  
Deletes the MyRADIUSagent RADIUS Account agent.

**OPTIONS**  
[name]  
Specifies the name of an RADIUS Account server. This setting is required.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

server  
Specifies an RADIUS Account server the system uses for RADIUS queries and authentication. This option is required.

## apm policy agent acct-tacacsplus

**NAME**  
acct-tacacsplus - Manages a TACACS+(r) Account agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the acct-tacacsplus component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create acct-tacacsplus [name]  
modify acct-tacacsplus [name]  
options  
app-service [[string] | none]  
server [[string] | none]

**DISPLAY**  
list acct-tacacsplus  
list acct-tacacsplus [ [ [name] | [glob] | [regex] ] ... ]  
show running-config acct-tacacsplus  
show running-config acct-tacacsplus [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
all-properties  
current-module  
non-default-properties  
app-service  
partition

**DELETE**  
delete acct-tacacsplus [name]

**DESCRIPTION**  
You can use the acct-tacacsplus component to configure a TACACS+ Account agent.

**EXAMPLES**  
create acct-tacacsplus MyADQueryagent { server "companyAD" }  
Creates the agent type TACACS+ Account named MyADQueryagent that uses the companyAD server.  
  
list acct-tacacsplus all  
Displays a list of TACACS+ Account agents and the server associated with each agent.  
  
delete acct-tacacsplus MyADagent  
Deletes the MyADagent TACACS+ Account agent.

**OPTIONS**  
[name]  
Specifies the name of an acct-tacacsplus agent. This setting is required.  
  
partition  
Displays the partition within which the component resides.  
  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
  
server  
Specifies the TACACS+ Account server that the system uses for queries and authentication.

## apm policy agent decision-box

**NAME**  
decision-box - Manages a Decision Box agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the decision-box component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create decision-box [name]  
modify decision-box [name]  
options  
  app-service [[string] | none]  
  customization-group [name]

**DISPLAY**  
list decision-box  
list decision-box [ [ [name] | [glob] | [regex] ] ... ]  
show running-config decision-box  
show running-config decision-box [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all  
  all-properties  
  app-service  
  current-module  
  non-default-properties  
  one-line  
  partition

**DELETE**  
delete decision-box ([name] | all)

**DESCRIPTION**  
You can use the decision-box component to configure a Decision Box agent.

**EXAMPLES**  
create dynamic-acl MyADQueryagent  
Creates the Decision Box agent named MyADQueryagent.  
  
list decision-box all  
Displays a list of Decision Box agents.  
  
delete decision-box MyADagent  
Deletes the MyADagent Decision Box agent.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
  
customization-group  
Specifies the name of the existing customization group to which the agent belongs.  
  
[name]  
Specifies the name of a Decision Box agent. This setting is required.  
  
partition  
Displays the partition within which the component resides.

## apm policy agent dynamic-acl

NAME  
dynamic-acl - Manages a Dynamic ACL agent.

MODULE  
apm policy agent

SYNTAX  
Configure the dynamic-acl component within the policy agent module using the following syntax.

CREATE/MODIFY  
create dynamic-acl [name]  
modify dynamic-acl [name]  
options  
  app-service [[string] | none]  
  entries [ add | delete | modify | none | replace-all-with]

DISPLAY  
list dynamic-acl  
list dynamic-acl [ [name] | [glob] | [regex] ] ... ]  
show running-config dynamic-acl  
show running-config dynamic-acl [ [name] | [glob] | [regex] ] ... ]  
options:  
  all  
  all-properties  
  app-service  
  current-module  
  non-default-properties  
  one-line  
  partition

DELETE  
delete dynamic-acl [name]

DESCRIPTION  
You can use the dynamic-acl component to create and manage a Dynamic access control list (acl) agent that parses ACL text input with a specified format from a specified session variable, assigns the parsed entry into a Dynamic ACL object, and assigns it into a current user session. An ACL is a set of restrictions associated with a resource or favorite that defines access for users and groups.

EXAMPLES  
create dynamic-acl {  
  { acl [ format [f5 | cisco] ] source  
  } } }>  
Creates the Dynamic ACL agent named MyDynamicAclAgent.  
  
list dynamic-acl  
Displays a list of Dynamic ACL agents.  
  
delete dynamic-acl MyDynamicAclAgent  
Deletes the Dynamic ACL agent named MyDynamicAclAgent.

OPTIONS  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
  
entries  
Specifies the name of the entry to assign this dynamic access control list.  
  
[name]  
Specifies the name of the Dynamic Acl agent. This setting is required.  
  
partition  
Displays the partition within which the component resides.

BIG-IP      2012-10-19    apm policy agent dynamic-acl(1)

NAME ending-allow - Manages an Ending Allow agent.

MODULE apm policy agent

SYNTAX Configure the ending-allow component within the policy agent module using the following syntax.

CREATE/MODIFY

```
create ending-allow [name]
modify ending-allow [name]
options:
  app-service [[string] | none]
```

DISPLAY

```
list ending-allow
list ending-allow [ [name] | [glob] | [regex] ] ... ]
show running-config ending-allow
show running-config ending-allow [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  app-service
  current-module
  non-default-properties
  one-line
  partition
```

DELETE

```
delete ending-allow ([name] | all)
```

DESCRIPTION

Access policy endings indicate the final outcome of a branch of an access policy. An Allow ending is a successful ending in which the system displays the user's home page and grants access to a webtop connection.

EXAMPLES

```
create ending-allow MyEndingAllowAgent { }
Creates the Ending Allow agent named MyEndingAllowAgent.

list ending-allow
Displays a list of Ending Allow agents.

delete ending-allow MyEndingAllowAgent
Deletes the Ending Allow agent named MyEndingDeniedAgent.
```

OPTIONS

[name]  
Specifies the name of an Ending Allow agent. This option is required.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

partition  
Displays the partition within which the component resides.

---

## apm policy agent ending-deny

NAME ending-deny - Manages an Ending Deny agent.

MODULE apm policy agent

SYNTAX Configure the ending-deny component within the policy agent module using the following syntax.

CREATE/MODIFY

```

create ending-deny [name]
modify ending-deny [name]
  options
    app-service [[string] | none]
    customization-group [name]

DISPLAY
list ending-deny
list ending-deny [ [ [name] | [glob] | [regex] ] ... ]
show running-config ending-deny
show running-config ending-deny [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all
    all-properties
    app-service
    current-module
    non-default-properties
    one-line
    partition

DELETE
delete ending-deny ([name] | all)

```

#### DESCRIPTION

Access policy endings indicate the final outcome of a branch of an access policy. The Logon Deny ending is the final result of an unsuccessful logon attempt (the failure could be caused by an incorrect logon attempt, a security requirement incompatibility, or the use of an unsupported device). Upon reaching a Logon Deny ending, the user sees an error message. You can use the ending-deny component to create and manage an Ending Deny agent.

#### EXAMPLES

```

create ending-deny MyEndingDenyAgent customization-group MyLogOffCG
Creates the Ending Deny agent named MyEndingDenyAgent that is
associated with the MyLogOffCG customization group.

```

```

list ending-deny
Displays a list of Ending Deny agents.

```

```

delete ending-deny MyEndingDenyAgent
Deletes the Ending Deny agent named MyEndingDenyAgent.

```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**customization-group**  
Specifies the name of the existing customization-group to which the agent belongs. It enables you to customize the logon deny page. For example, you can indicate a specific reason for the denial of access. This setting is required, and the customization group that you assign must be of the type logout.

**[name]**  
Specifies the name of an Ending Deny agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

#### SEE ALSO

tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2011-2012. All rights reserved.

## apm policy agent ending-redirect

**NAME**  
ending-redirect - Manages an Ending Redirect agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the ending-redirect component within the policy agent module using the following syntax.

```

CREATE/MODIFY
create ending-redirect [name]
modify ending-redirect [name]
  options
    app-service [[string] | none]
    close-session [true | false]
    url [value]

DISPLAY
list ending-redirect
list ending-redirect [ [ [name] | [glob] | [regex] ] ... ]
show running-config ending-redirect
show running-config ending-redirect [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all
    all-properties
    app-service
    current-module
    non-default-properties
    one-line
    partition

DELETE
delete ending-redirect ([name] | all)

```

#### DESCRIPTION

The Redirect ending can be used to redirect the user, rather than allowing or denying a connection. It can also send a user directly to an update script or to different server or landing URI. Upon reaching a Redirect ending, the user sees a screen indicating that they are being redirected to a different URL. You can use the ending-redirect component to create and manage an Ending Redirect agent.

#### EXAMPLES

```

create ending-redirect MyEndingRedirectAgent { url
  "http://www.myweb.com" }
Creates the Ending Redirect agent named MyEndingRedirectAgent that
redirects a connection to http://www.myweb.com.

```

=item

Creates an agent using the current protocol and the session variable `%(session.server.network.protocol)`

```

list ending-redirect
Displays a list of Ending Redirect agents.

```

```

delete ending-redirect MyEndingRedirectAgent
Deletes the Ending Redirect agent named MyEndingRedirectAgent.

```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**close-session**  
Redirects to the specified URI after closing the session if enabled. Otherwise, redirect to the specified URI without closing the session. The default is enabled.

**[name]**  
Specifies the name of an Ending Redirect agent. This option is required.

**url** Specifies the URL to which the system redirects the original request. This option is required, and you must specify an absolute URL.

An absolute URL specifies the exact location of a file or directory on the Internet.

#### SEE ALSO

 partition

**DELETE**  
 delete endpoint-check-machine-cert [name]

**DESCRIPTION**  
 Endpoint security is a centrally-managed method of monitoring and maintaining client-system security.

The endpoint-check-machine-cert component checks for the presence of a valid machine certificate on Windows/Mac client systems during access policy validation.

**EXAMPLES**  
 create endpoint-check-machine-cert MyMCagent  
 Creates the Endpoint Check Machine certificate agent named MyMCagent in the Common partition.

list endpoint-check-machine-cert  
 Displays a list of Endpoint Check Machine certificate agents.

delete endpoint-check-machine-cert MyMCagent  
 Deletes the MyMCagent Endpoint Check Machine certificate agent.

**OPTIONS**  
 allow-elevation  
 Specifies that User Account Control (UAC) prompts are allowed during private key checking.

app-service  
 Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

ca-profile-name  
 Specifies the name of the certificate authority profile to validate the certificate.

issuer  
 Specifies the name used to match the issuer name in the machine certificate.

[name]  
 Specifies the name of an external logon page agent. This option is required.

partition  
 Displays the partition within which the component resides.

save-cert  
 Specifies to store the entire machine certificate in a session variable.

serial-number  
 Specifies the serial number used to match the serial number of the machine certificate.

store-location  
 Specifies the location of the certificate store on the client

machine.

**store-name**  
Specifies the name of the certificate store on the client machine.

**subject-alt-name**  
Specifies the name used to match the subject-alt-name in the machine certificate.

**subject-match-fqdn**  
Specifies if lookup must match fully qualified domain name (FQDN) in the machine certificate.

## apm policy agent endpoint-check-software

**NAME**  
endpoint-check-software - Manages an Endpoint Software Check agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the endpoint-check-software component within the apm policy agent module using the following syntax.

```
CREATE/MODIFY
create endpoint-check-software [name]
modify endpoint-check-software [name]
options:
  collect [ true | false ]
  continuous-check [ true | false ]
  type [ antivirus | firewall | patch-management | antispyware | peer-to-peer | hard-disk-encryption | health-agent
  check-list-type [ required | allow | deny ]
  items [ vendor_id | product_id | state | version | db-age | db-version | last-scan | missing-updates | platform ]

edit endpoint-check-software [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list endpoint-check-software
list endpoint-check-software [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-check-software
show running-config endpoint-check-software [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  app-service
  current-module
  non-default-properties
  one-line
  partition

DELETE
delete endpoint-check-software ([name] | all)
```

#### DESCRIPTION

Endpoint security is a centrally-managed method of monitoring and maintaining client-system security. You can use the endpoint-check-software component to create and manage an agent that enforces monitoring of various client-system security third party software. Different types of third party software supported are described below in options.

The configuration attributes in the items option are generic and therefore for a given software type only certain items attributes are useful, rest of the attributes are ignored even if they are configured.

For example: for type=peer-to-peer only vendor\_id, product\_id, state and version are considered and rest of the items like db-age, db-version etc are ignored. Following is the list of useful attributes corresponding to the software type:

Common to all software type:  
vendor\_id, product\_id, version, platform, state

antivirus & antispysware:  
db-age, db-version, last-scan

patch-management:  
missing-updates

#### EXAMPLES

```
create endpoint-check-software MyEndpointWCagent items state enabled
add
Creates the Endpoint Check Software agent named MyEndpointWCagent,
which verifies that the specified third party software on the
client is compliant with system administrators configuration,
which my just check for the installation or monitor the state of
the software
```

```
list endpoint-check-software
Displays a list of Endpoint Software Check agents.
```

```
delete endpoint-check-software MyEndpointWCagent
Deletes the Endpoint Software Check agent named MyEndpointWCagent.
```

#### OPTIONS

items  
Adds items to or deletes items from an Endpoint Software Check agent. You can specify the following attributes for the software:

check-list-type Specifies how the list of software should be checked  
required:

Client is required to have at least one of the software configured in the list in order to pass the access policy. And that software should satisfy all the configuration fields e.g. state, version etc.

allow: Client is allowed to have any of the software configured in the list but NOT any other than that, in order to pass the access policy. List is treated as whitelist. A given client software will not match unless it satisfies all the configuration fields (e.g. state, version etc). NOTE: The check will also be successful if client has no software installed at all. List of software is treated as whitelist.

deny: Client should NOT have any software configured in the list in order to pass the access policy. And that software should satisfy all the configuration fields (e.g. state, version etc). NOTE: The check will also be successful if client has no software installed at all. List of software is treated as blacklist.

db-age  
Specifies the maximum age of the anti-virus/anti-spyware database that you want an Endpoint Software Check agent to verify the presence of on the client in order to allow the access policy to pass.

db-version  
Specifies the version of the anti-virus/anti-spyware database that you want an Endpoint Software Check agent to verify the presence of on the client in order to allow the access policy to pass.

product\_id  
Specifies the product ID of the software that you want an Endpoint Software Check agent to verify the presence of on the client in order to allow the access policy to pass.

vendor\_id  
Specifies the vendor ID of the software that you want an Endpoint Software Check agent to verify the presence of on the client in order to allow the access policy to pass.

NOTE: If none of the vendor id or product id is defined then check is performed for any of the software of given type If both vendor id and product id are configured then, product id is ignored and only vendor id is considered. Vendor ID always takes precedence. A vendor can have many products. Each product (of every vendor) has unique ID assigned to them. Similarly, every vendor is assigned a unique ID too which is separate from product ID. If you want to check every software from a vendor then specify vendor\_id only.

state  
State means different things to different software type. The state can be enabled, disabled or unspecified. The default is unspecified.

antivirus and antispysware:  
When the state is set to enabled or disabled, agent verifies that the specified antivirus/antispysware software has real time protection enabled or disabled on the client that is attempting to connect. When state is unspecified, it ignores the state.

patch-management:  
When the state is set to enabled, agent verifies that the specified PM software is running on the client that

is attempting to connect. When its set to unspecified, state of the software is ignored.

**firewall:**

When the state is enabled or disabled, agent verifies that the specified firewall software has real time protection enabled or disabled on the client that is attempting to connect. When state is unspecified, the software state is ignored.

**peer-to-peer:**

When the state is set to enabled agent verifies that the peer-to-peer software is running on the client that is attempting to connect. When state is unspecified, the agent only verifies that the software is installed or not.

**hard-disk-encryption:**

When the state is set to enabled agent verifies that all disk volumes are encrypted on the client that is attempting to connect. When the state is set to disabled agent verifies that system disk volume is encrypted on the client that is attempting to connect. When state is unspecified, the agent only verifies that the software is installed or not.

**health-agent:**

When the state is set to enabled agent verifies that endpoint client is compliant with the health policy set out by the site administrator.

**version**

Specifies the version of the software that you want an Endpoint Software Check agent to verify the presence of on the client in order to allow the access policy to pass.

**last-scan**

Specifies the maximum allowed duration without the full system scan of endpoint client that software agent can accept in order to allow the access policy to pass. It is specified in number of days.

**missingupdates**

Specifies the maximum number of allowed missing critical updates of the PM software at the endpoint client in order to allow the access policy to pass. Leave blank to ignore number of missing critical updates. Specify 0 to make sure endpoint client is up-to-date

**platform**

Specifies the platform. It could be any of the following: windows, linux, mac or any. The default is any.

**type** Its the type of the third party software to be monitored on the client system. It could be any of the following: antivirus, firewall, patch-management, antispysware, peer-to-peer, hard-disk-encryption, health-agent

**collect**

This setting is ignored.

**continuous-check**

Continuously check the items, and end the session if the result changes. The default is false.

**[name]**

Specifies the name of an Endpoint Software Check agent. This option is required.

**partition**

Displays the partition within which the component resides.

**SEE ALSO**

apm policy agent endpoint-linux-check-file, apm policy agent endpoint-linux-check-process, apm policy agent endpoint-mac-check-file, apm policy agent endpoint-mac-check-process, apm policy agent endpoint-windows-browser-cache-cleaner, apm policy agent endpoint-windows-check-file, apm policy agent endpoint-check-machine-cert, apm policy agent endpoint-windows-check-process, apm policy agent endpoint-windows-check-registry, apm policy agent endpoint-windows-group-policy, apm policy agent endpoint-windows-info-os, apm policy agent endpoint-machine-info, apm policy agent endpoint-windows-protected-workspace

# apm policy agent endpoint-linux-check-file

**NAME**  
endpoint-linux-check-file - Manages an Endpoint Linux Check File agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the endpoint-linux-check-file component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create endpoint-linux-check-file [name]  
modify endpoint-linux-check-file [name]  
options:  
  continuous-check [ true | false ]  
  app-service [[string] | none]  
  files [ filename | md5 | modified | size ]

edit endpoint-linux-check-file [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

**DISPLAY**  
list endpoint-linux-check-file  
list endpoint-linux-check-file [ [ [name] | [glob] | [regex] ] ... ]  
show running-config endpoint-linux-check-file  
show running-config endpoint-linux-check-file [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all  
  all-properties  
  app-service  
  current-module  
  non-default-properties  
  one-line  
  partition

**DELETE**  
delete endpoint-linux-check-file ([name] | all)

**DESCRIPTION**  
Access Policy Manager checks for the presence of one or more files on a client that is attempting to connect. If a file with the described properties exists, the action goes to the successful branch. If the file does not exist, or a file exists but one or more properties are not correct, the action goes to the fallback branch.

You can use the endpoint-linux-check-file component to create or manage an Endpoint Linux Check File agent that verifies the presence of specified Linux files on a client.

**EXAMPLES**  
create endpoint-linux-check-file Myprofile\_act\_file\_check\_ag { files { filename "/tmp/demo/demofile" md5 "6b61ad518c23650b17e738e1fa2bb04e" modified 2007-06-01 10:30:10 size 12 } { filename "/tmp/demo/testfile" md5 "f20d9f2072bbeb6691c0f9c5099b01f3" size 9 } }  
Creates the Endpoint Linux Check File agent named Myprofile\_act\_file\_check\_ag that checks that the client contains two files located in the /tmp/demo directory: a 12 byte file named demofile that was modified no later than January 6, 2007 at 10:30 and has an MD5 checksum of 6b61ad518c23650b17e738e1fa2bb04e, and a 9-byte file named testfile that has an MD5 check sum of f20d9f2072bbeb6691c0f9c5099b01f3.

list all endpoint-linux-check-file Company8profile\_act\_file\_check\_ag  
Displays information about the Endpoint Linux Check File agent named Company8profile\_act\_file\_check\_ag.

delete endpoint-linux-check-file Company8profile\_act\_check\_file { files { filename "/tmp/demo/demofile" } }  
Deletes the /tmp/demo/demofile file from the Endpoint Linux Check File agent named Company8profile\_act\_file\_check\_ag.

**OPTIONS**  
**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**files**  
Adds files to or deletes files from an Endpoint Linux Check File agent. You can specify the following attributes of the files that you want an Endpoint Linux Check File agent to verify the presence of on the client in order to allow the access policy to pass.

**filename**  
Specifies the name of the file and includes the full path. The Endpoint linux Check File agent that you are creating must be able to verify the file's presence on the client for the access policy to pass. When you add a file to or delete a file from the agent, this setting is required.

**md5** Specifies the value of an MD5 checksum. The Endpoint Linux Check File agent you are creating must be able to match the checksum on the client for the access policy to pass. The default is none.

modified  
Specifies the last modified date of the specified file. The Endpoint Linux Check File agent you are creating must verify this date on the client for the access policy to pass. The default is 1970-01-01 00:00:00.

size Specifies the size, in bytes, of the specified file. The Endpoint Linux Check File agent you are creating must verify this size on the client for the access policy to pass. The default is 0.

continuous-check  
Continuously check the files, and end the session if the result changes. The default is false.

[name]  
Specifies the name of an Endpoint Linux Check File agent. This setting is required.

partition  
Displays the partition within which the component resides.

## apm policy agent endpoint-linux-check-process

NAME  
endpoint-linux-check-process - Manages an Endpoint Linux Check Process agent.

MODULE  
apm policy agent

SYNTAX  
Configure the endpoint-linux-check-process component within the policy agent module using the following syntax.

```
CREATE/MODIFY
create endpoint-linux-check-process [name]
modify endpoint-linux-check-process [name]
options
  continuous-check [ true | false ]
  app-service [[string] | none]
  expression [ string | none ]

edit endpoint-linux-check-process [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list endpoint-linux-check-process
list endpoint-linux-check-process [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-linux-check-process
show running-config endpoint-linux-check-process [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  app-service
  current-module
  non-default-properties
  one-line
  partition

DELETE
delete endpoint-linux-check-process [name]
```

DESCRIPTION  
You can use the endpoint-linux-check-process component to create and manage an Endpoint Linux Check Process agent that collects information about the Linux processes running on the client.

#### EXAMPLES

```
create endpoint-linux-check-process MyEndpointWCPagent { (bash OR top)
AND firefox }
Creates the Endpoint Linux Check Process agent named
MyEndpointWCPagent that checks that the client has either bash or
top, and firefox launched.

list endpoint-linux-check-process
Displays a list of Endpoint Linux Check Process agents.

delete endpoint-linux-check-process MyEndpointWCPagent
Deletes the Endpoint Linux Check Process agent named
MyEndpointWCPagent.
```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**expression**  
Specifies the expression that you want an Endpoint Linux Check Process agent to use to verify the processes that are running on the client to allow the access policy to pass. You can use the following operators: AND, OR, NOT, (and). You can use wildcards in the process name, for example, navapvc.\*.

If the check is successful, the system returns 1. If the check fails, the system returns 0. If the expression is incorrect, the system returns -1.

**continuous-check**  
Continuously check the expression, and end the session if the result changes. The default is false.

**[name]**  
Specifies the name of an Endpoint Linux Check Process agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

#### SEE ALSO

## apm policy agent endpoint-mac-check-file

**NAME**  
endpoint-mac-check-file - Manages an Endpoint Macintosh Check File agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the endpoint-mac-check-file component within the policy agent module using the following syntax.

```
CREATE/MODIFY
create endpoint-mac-check-file [name]
modify endpoint-mac-check-file [name]
options
  continuous-check [ true | false ]
  app-service [[string] | none]
  files [ filename | md5 | modified | size ]
```

```
edit endpoint-mac-check-file [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list endpoint-mac-check-file
list endpoint-mac-check-file [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config endpoint-mac-check-file
show running-config endpoint-mac-check-file [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  app-service
  current-module
  non-default-properties
  one-line
  partition
```

```
DELETE
delete endpoint-mac-check-file ([name] | all)
```

#### DESCRIPTION

Access Policy Manager checks for the presence of one or more files on a client that is attempting to connect. If a file with the described properties exists, the action goes to the successful branch. If the file does not exist, or a file exists but one or more properties are not correct, the action goes to the fallback branch.

You can use the endpoint-mac-check-file component to create or manage an Endpoint Macintosh Check File agent that verifies the presence of specified Macintosh files on a client.

#### EXAMPLES

```
create endpoint-mac-check-file Myprofile act_file_check_ag { files {
  filename "/tmp/demo/demofile" md5 "6b61ad518c23650b17e738e1fa2bb04e"
  modified 2007-06-01 10:30:10 size 12 } { filename "/tmp/demo/testfile"
  md5 "f20d9f2072bbeb6691c0f9c5099b01f3" size 9 } }
Creates the Endpoint Macintosh Check File agent named
Myprofile_act_file_check_ag that checks that the client contains
two files located in the /tmp/demo directory: a 12 byte file named
demofile that was modified no later than January 6, 2007 at 10:30
and has an MD5 checksum of 6b61ad518c23650b17e738e1fa2bb04e, and a
9 byte file named testfile that has an MD5 check sum of
f20d9f2072bbeb6691c0f9c5099b01f3.
```

```
list all endpoint-mac-check-file Company8profile act_file_check_ag
Displays information about the Endpoint Macintosh Check File agent
named Company8profile_act_file_check_ag.
```

```
delete endpoint-mac-check-file Company8profile_act_check_file { files {
  filename "/tmp/demo/demofile" } }
Deletes the /tmp/demo/demofile file from the Endpoint Macintosh
Check File agent named Company8profile_act_file_check_ag.
```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**files**  
Adds files to or deletes files from an Endpoint Macintosh Check File agent. You can specify the following attributes of the files that you want an Endpoint Macintosh Check File agent to verify the presence of on the client to allow the access policy to pass:

**filename**  
Specifies the name of the file and includes the full path. The Endpoint Macintosh Check File agent that you are creating must be able to verify the file's presence on the client for the access policy to pass. When you add a file to or delete a file from the agent, this setting is required.

**md5** Specifies the value of an MD5 checksum. The Endpoint Macintosh Check File agent you are creating must be able to match the checksum on the client for the access policy to pass. The default is none.

**modified**  
Specifies the last modified date of the specified file. The Endpoint Macintosh Check File agent you are creating must verify this date on the client for the access policy to pass. The default is 1970-01-01 00:00:00.

**size** Specifies the size, in bytes, of the specified file. The Endpoint Macintosh Check File agent you are creating must verify this size on the client for the access policy to pass. The default is 0.

**continuous-check**  
Continuously check the files, and end the session if the result changes. The default is false.

**[name]**  
Specifies the name of an Endpoint Macintosh Check File agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

list endpoint-mac-check-process [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-mac-check-process
show running-config endpoint-mac-check-process [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all
all-properties
app-service
current-module
non-default-properties
one-line
partition
```

#### DELETE

```
delete endpoint-mac-check-process ([name] | all)
```

### DESCRIPTION

You can use the endpoint-mac-check-process component to create and manage an Endpoint Macintosh Check Process agent that collects information about the Macintosh processes running on the client.

### EXAMPLES

```
create endpoint-mac-check-process MyEndpointWCPagent { (bash OR top)
AND firefox }
```

Creates the Endpoint Macintosh Check Process agent named MyEndpointWCPagent that checks that the client has either bash or top, and firefox launched.

```
list endpoint-mac-check-process
Displays a list of Endpoint Macintosh Check Process agents.
```

```
delete endpoint-mac-check-process MyEndpointWCPagent
Deletes the Endpoint Macintosh Check Process agent named MyEndpointWCPagent.
```

### OPTIONS

#### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### expression

Specifies the expression that you want an Endpoint Macintosh Check Process agent to use to verify the processes that are running on the client in order to allow the access policy to pass. You can use the following operators: AND, OR, NOT, (and). You can use wildcards in the process name, for example, navapvc.\*.

If the check is successful, the system returns 1. If the check fails, the system returns 0. If the expression is incorrect, the system returns -1.

continuous-check  
Continuously check the expression, and end the session if the result changes. The default is false.

[name]  
Specifies the name of an Endpoint Macintosh Check Process agent. This setting is required.

partition  
Displays the partition within which the component resides.

## apm policy agent endpoint-machine-info

NAME  
endpoint-machine-info - Manages an Endpoint Machine Information agent.

MODULE  
apm policy agent

SYNTAX  
Configure the endpoint-machine-info component within the policy agent module using the following syntax.

CREATE/MODIFY  
create endpoint-machine-info [name]  
modify endpoint-machine-info [name]  
options:  
app-service [[string] | none]

edit endpoint-machine-info [ [ [name] | [glob] | [regex] ] ... ]  
options:

DESCRIPTION  
You can use the endpoint-machine-info component to create and manage an agent that collects information about the machine that is attempting to connect.

OPTIONS  
[name]  
Specifies the name of the an Endpoint Check Machine Information agent. This setting is required.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

## apm policy agent endpoint-windows-browser-cache-cleaner

### NAME

endpoint-windows-browser-cache-cleaner - Manages an Endpoint Windows Browser Cache Cleaner agent.

### MODULE

apm policy agent

### SYNTAX

Configure the endpoint-windows-browser-cache-cleaner component within the policy agent module using the following syntax.

#### CREATE/MODIFY

```
create endpoint-windows-browser-cache-cleaner [name]
modify endpoint-windows-browser-cache-cleaner [name]
options
  app-service [[string] | none]
  cache-clean-type [all | all-except-css-js | all-except-img-css-js | none ]
  clean-passwords [false | true ]
  empty-recycle-bin [false | true ]
  idle-timeout [ | immediate | indefinite]
  idle-timeout-screen-lock [ ]
  monitor-webtop [enable | disable]
  partition
  remove-connection-entry [false | true ]
```

```
edit endpoint-windows-browser-cache-cleaner [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list endpoint-windows-browser-cache-cleaner
list endpoint-windows-browser-cache-cleaner [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-windows-browser-cache-cleaner
show running-config endpoint-windows-browser-cache-cleaner [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  app-service
  current-module
  non-default-properties
  one-line
  partition
```

#### DELETE

```
delete endpoint-windows-browser-cache-cleaner ([name] | all)
```

### DESCRIPTION

Endpoint security is a centrally-managed method of monitoring and maintaining client-system security. You can use the endpoint-windows-browser-cache-cleaner component to create and manage an Endpoint Windows Browser Cache Cleaner agent. This agent cleans items from the client browser and computer after logoff, and also enforces session inactivity timeouts.

### EXAMPLES

```
create endpoint-windows-browser-cache-cleaner MyEndpointWBCCagent idle
timeout 0
```

Creates the Endpoint Windows Browser Cache Cleaner agent named MyEndpointWBCCagent that does not enforce a timeout.

```
create endpoint-windows-browser-cache-cleaner MyEndpointWBCCagent {
idle timeout 0 clean passwords enable }
```

Creates the Endpoint Windows Browser Cache Cleaner agent named MyEndpointWBCCagent that does not enforce a timeout, but does clear saved passwords from the client after logoff.

```
list endpoint-windows-browser-cache-cleaner
Displays a list of Endpoint Windows Browser Cache Cleaner agents.
```

```
delete endpoint-windows-browser-cache-cleaner MyEndpointWBCCagent
Deletes the Endpoint Windows Browser Cache Cleaner agent named MyEndpointWBCCagent.
```

### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### cache-clean-type

Specifies which browser cache temporary files are removed. If set to all, the temporary files are removed. If set to all-except-css-js, the browser cache is cleared, but all style sheets and JavaScript are left on the browser cache. If set to all-except-img-css-js, the browser cache is cleared, but all style sheets, JavaScript, and images are left on the browser cache. The default is all.

#### clean-passwords

When true, the Endpoint Windows Browser Cache Cleaner agent ensures that saved passwords are cleared from the client after logoff. The default is false.

#### empty-recycle-bin

When true, the Endpoint Windows Browser Cache Cleaner agent empties the Recycle Bin on the client after logoff. The default is false.

#### idle-timeout

Specifies the number of minutes that the client session can be idle before the Endpoint Windows Browser Cache Cleaner agent disconnects the session. The default is 0, which enforces no timeout. This is a required setting.

#### idle-timeout-screen-lock

Specifies the number of minutes the system can receive no user input before the workstation is locked. The default is 0, which specifies no timeout enforced.

#### monitor-webtop

When true, the Endpoint Windows Browser Cache Cleaner agent forces session termination if the browser or webtop is closed. The default is false.

#### [name]

Specifies the name of the Endpoint Windows Browser Cache Cleaner agent. This is a required setting.

#### partition

Displays the partition within which the component resides.

#### remove-connection-entry

When true, the Endpoint Windows Browser Cache Cleaner agent removes the connection from the Network Connections Dial-up Networking folder on the client. The default is false.

#### SEE ALSO

endpoint-check-software, endpoint-linux-check-file, endpoint-linux-check-process, endpoint-mac-check-file, endpoint-mac-check-process, endpoint-windows-check-file, endpoint-check-machine-cert, endpoint-windows-check-process, endpoint-windows-check-registry, endpoint-windows-info-os, endpoint-machine-info, endpoint-windows-protected-workspace

## apm policy agent endpoint-windows-check-file

#### NAME

endpoint-windows-check-file - Manages an Endpoint Windows Check File agent.

#### MODULE

apm policy agent

#### SYNTAX

Configure the endpoint-windows-check-file component within the policy agent module using the following syntax.

#### CREATE/MODIFY

```
create endpoint-windows-check-file [name]
modify endpoint-windows-check-file [name]
options
  continuous-check [ true | false ]
  app-service [[string] | none]
  files [ filename | md5 | modified | operation | signer | size | version ]
```

```

edit endpoint-windows-check-file [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list endpoint-windows-check-file
list endpoint-windows-check-file [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-windows-check-file
show running-config endpoint-windows-check-file [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  app-service
  current-module
  non-default-properties
  one-line
  partition

DELETE
delete endpoint-windows-check-file ([name] | all)

```

#### DESCRIPTION

Access Policy Manager checks for the presence of one or more files on a client that is attempting to connect. If a file with the described properties exists, the action goes to the successful branch. If the file does not exist, or a file exists but one or more properties are not correct, the action goes to the fallback branch.

You can use the endpoint-windows-check-file component to create or manage an Endpoint Windows Check File agent that verifies the presence of specified Windows files on a client.

#### EXAMPLES

```

create endpoint-windows-check-file Myprofile act_file_check_ag { files
{ filename "C:\\demo\\demofile" md5 "6b61ad518c23650b17e738e1fa2bb04e"
modified 2007-06-01 10:30:10 size 12 } { filename "C:\\demo\\test.file"
md5 "f20d9f2072bbeb6691c0f9c5099b01f3" size 9 } }
Creates the Endpoint Windows Check File agent named
Myprofile_act_file_check_ag that checks that the client contains
two files located in the C:\demo directory: a 12 byte file named
demofile that was modified no later than January 6, 2007 at 10:30
and has an MD5 checksum of 6b61ad518c23650b17e738e1fa2bb04e, and a
9 byte file named test.file that has an MD5 check sum of
f20d9f2072bbeb6691c0f9c5099b01f3.

```

```

list all endpoint-windows-check-file Company8profile act_file_check_ag
Displays information about the Endpoint Windows Check File agent
named Company8profile_act_file_check_ag.

```

```

delete endpoint-windows-check-file Company8profile_act_check_file {
files { filename "C:\\demo\\demofile" }}
Deletes the C:\demo\demofile file from the Endpoint Windows Check
File agent named Company8profile_act_file_check_ag.

```

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### files

Adds files to or deletes files from an Endpoint Windows Check File agent. You can specify the following attributes for the files that you want an Endpoint Windows Check File agent to verify the presence of on the client to allow the access policy to pass.

##### filename

Specifies a file name and includes the full path. The Endpoint windows Check File agent you are creating must be able to verify the file's presence on the client for the access policy to pass. When you add a file to or delete a file from the agent, this setting is required.

**md5** Specifies the value of an MD5 checksum. The Endpoint windows Check File agent that you are creating must match the checksum on the client for the access policy to pass. The default is none.

##### modified

Specifies the last modified date of the specified file. The Endpoint windows Check File agent you are creating must verify this date on the client for the access policy to pass. The default is 1970-01-01 00:00:00.

##### operation

Specifies the operator that you want your Endpoint Windows Check File agent to use when verifying the attributes of the specified file on the client. The default is equal.

##### signer

Specifies that the Endpoint Windows Check File agent must verify that the specified file on the client is signed for the access policy to pass. The default is none.

**size** Specifies the size, in bytes, of the specified file. The Endpoint Windows Check File agent you are creating must verify this file size on the client for the access policy to pass. The default is 0.

##### version

Specifies the version of the specified file that you want your Endpoint Windows Check File agent to verify on the client for the access policy to pass. Specify the version using the following form: x.x.x.x. The maximum value is 65535.65535.65535.65535. The default is none.

**continuous-check**  
Continuously check the files, and end the session if the result changes. The default is false.

**[name]**  
Specifies the name of an Endpoint Windows Check File agent. This option is required.

**partition**  
Displays the partition within which the component resides.

#### SEE ALSO

endpoint-check-software, endpoint-linux-check-file, endpoint-linux-check-process, endpoint-mac-check-file, endpoint-mac-check-process, endpoint-windows-check-file, endpoint-windows-browser-cache-cleaner, endpoint-windows-check-process, endpoint-windows-check-registry, endpoint-windows-group-policy, endpoint-windows-info-os, endpoint-machine-info, endpoint-windows-protected-workspace

## apm policy agent endpoint-windows-check-process

**NAME**  
endpoint-windows-check-process - Manages an Endpoint Windows Check Process agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the endpoint-windows-check-process component within the policy agent module using the following syntax.

```
CREATE/MODIFY
create endpoint-windows-check-process [name]
modify endpoint-windows-check-process [name]
options:
  continuous-check [ true | false ]
  app-service [[string] | none]
  expression ( | none)

edit endpoint-windows-check-process [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list endpoint-windows-check-process
list endpoint-windows-check-process [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-windows-check-process
show running-config endpoint-windows-check-process [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show endpoint-windows-check-process
show endpoint-windows-check-process [name]

DELETE
delete endpoint-windows-check-process [name]
```

**DESCRIPTION**  
You can use the endpoint-windows-check-process component to create and manage an agent that collects information about the Windows processes running on the client.

#### EXAMPLES

```
create endpoint-windows-check-process MyEndpointWCPagent { (NISUM.exe
OR blackd.exe) AND navapvc.* }
Creates the Endpoint Windows Check Process agent named
MyEndpointWCPagent that checks that the client has either
NISUM.exe or blackd.exe, and navapvc.* installed.
```

`list endpoint-windows-check-process`  
Displays a list of Endpoint Windows Check Process agents.

`delete endpoint-windows-check-process MyEndpointWCPagent delete`  
Deletes the Endpoint Windows Check Process agent named MyEndpointWCPagent.

#### OPTIONS

`app-service`  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`expression`  
Specifies the expression that you want an Endpoint Windows Check Process agent to use to verify the processes that are running on the client in order to allow the access policy to pass. You can use the following operators: AND, OR, NOT, (and). You can use wildcards in the process name, for example, `navapvc.*`.

If the check is successful, the system returns 1. If the check fails, the system returns 0. If the expression is incorrect, the system returns -1.

`continuous-check`  
Continuously check the expression, and end the session if the result changes. The default is false.

`[name]`  
Specifies the name of an Endpoint Windows Check Process agent. This setting is required.

`partition`  
Displays the partition within which the component resides.

#### SEE ALSO

`endpoint-check-software`, `endpoint-linux-check-file`, `endpoint-linux-check-process`, `endpoint-mac-check-file`, `endpoint-mac-check-process`, `endpoint-windows-check-file`, `endpoint-check-machine-cert`, `endpoint-windows-browser-cache-cleaner`, `endpoint-windows-check-registry`, `endpoint-windows-group-policy`, `endpoint-windows-info-os`, `endpoint-machine-info`, `endpoint-windows-protected-workspace`

## apm policy agent endpoint-windows-check-registry

#### NAME

`endpoint-windows-check-registry` - Manages an Endpoint Windows Check Registry agent.

#### MODULE

apm policy agent

#### SYNTAX

Configure the `endpoint-windows-check-registry` component within the policy agent module using the following syntax.

##### CREATE/MODIFY

```
create endpoint-windows-check-registry [name]
modify endpoint-windows-check-registry [name]
```

##### options:

```
continuous-check [ true | false ]
app-service [[string] | none]
expression [[string] | none]
```

```
edit endpoint-windows-check-registry [ [ [name] | [glob] | [regex] ] ... ]
options:
```

```
all-properties
non-default-properties
```

##### DISPLAY

```
list endpoint-windows-check-registry
list endpoint-windows-check-registry [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-windows-check-registry
show running-config endpoint-windows-check-registry [ [ [name] | [glob] | [regex] ] ... ]
options:
all-properties
non-default-properties
partition
```

```
show endpoint-windows-check-registry
show endpoint-windows-check-registry [name]
```

```
DELETE
delete endpoint-windows-check-registry [name]
```

#### DESCRIPTION

You can use the endpoint-windows-check-registry component to create and manage an agent that collects information about the Windows registry keys on the client that is attempting to connect.

#### EXAMPLES

```
create endpoint-windows-check-registry MyEndpointWCRagent
{"\HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Internet
Explorer\.\Version\"="5.0.2800.0"}
Creates the Endpoint Windows Check Registry agent named
MyEndpointWCRagent that checks the registry on the client for
version 5.0.2800.0 of Internet Explorer in the
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft directory.
```

```
create endpoint-windows-check-registry MyEndpointWCRagent
{"\HKEY_LOCAL_MACHINE64\SOFTWARE\Microsoft\Internet
Explorer\.\Version\"="5.0.2800.0"}
Creates the Endpoint Windows Check Registry agent named
MyEndpointWCRagent that checks the registry on the client for
version 5.0.2800.0 of Internet Explorer in the
HKEY_LOCAL_MACHINE64\SOFTWARE\Microsoft directory.
```

Note that the registry value HKEY\_LOCAL\_MACHINE64 is one of the 32 and 64-bit registry keys that you can specify on 64-bit Windows versions. On 64-bit Windows systems, you can check for registry keys in either the 64-bit registry or the 32-bit registry. To specify the registry to check, append a number to the registry root key name. The following key names are supported:

```
HKEY_CURRENT_USER
HKEY_CURRENT_USER32
HKEY_CURRENT_USER64
HKEY_LOCAL_MACHINE
HKEY_LOCAL_MACHINE32
HKEY_LOCAL_MACHINE64
HKEY_CLASSES_ROOT
HKEY_CLASSES_ROOT32
HKEY_CLASSES_ROOT64
HKEY_USERS
HKEY_USERS32
```

HKEY\_USERS64 HKEY values specified with a 32 allow you to check values in the 32-bit view of 64-bit registry. This is the perspective used by 32-bit applications running with on a 64-bit operating system.

HKEY values with a 64 appended allow you to check values in the 64-bit view of the registry. This is the perspective used by native 64-bit applications. When checking values on 32-bit Windows, the number of bits specified in the registry key name is ignored.

```
list endpoint-windows-check-registry
Displays a list of Endpoint Windows Check Registry agents.
```

```
delete endpoint-windows-check-registry MyEndpointWCRagent delete
Deletes the Endpoint Windows Check Registry agent named
MyEndpointWCRagent.
```

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### expression

Specifies the expression that you want an Endpoint Windows Check Registry agent to use to verify the registry entries that are present on the client in order to allow the access policy to pass. You can use the following operators: AND, OR, NOT, (and).

If the check is successful, the system returns 1. If the check fails, the system returns 0. If the expression is incorrect, the system returns -1.

Important: You must use quotation marks ( " ") around key and value arguments, and in data when the content contains spaces, commas, slashes, tabs, or other delimiters. If quotation marks exist as part of a registry path or value name, you must use quotation marks around those quotation marks.

Tip: The system treats data in the formats "d.d[.d][.d]" or "d,d[.d][.d]" (where d is a number) as a version number. The system treats data in the format "mm/dd/yyyy" as a date.

##### continuous-check

Continuously check the expression, and end the session if the result changes. The default is false.

##### [name]

Specifies the name of the an Endpoint Windows Check Registry agent. This option is required.

##### partition

Displays the partition within which the component resides.

## apm policy agent endpoint-windows-group-policy

#### NAME

endpoint-windows-group-policy - Manages an Endpoint Windows Group Policy agent.

#### MODULE

apm policy agent

#### SYNTAX

Warning: This page is obsolete. Windows Group Policy is no longer supported.

Configure the external-logon-page component within the policy agent module using the following syntax.

#### CREATE/MODIFY

create endpoint-windows-group-policy [name]

modify endpoint-windows-group-policy [name]

#### options:

app-service [[string] | none]

policy-file { [name] }

edit endpoint-windows-group-policy [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties

non-default-properties

#### DISPLAY

list endpoint-windows-group-policy

list endpoint-windows-group-policy [ [ [name] | [glob] | [regex] ] ... ]

show running-config endpoint-windows-group-policy

show running-config endpoint-windows-group-policy [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties

non-default-properties

partition

show endpoint-windows-group-policy

show endpoint-windows-group-policy [name]

#### DELETE

delete endpoint-windows-group-policy [name]

#### DESCRIPTION

Endpoint Windows Group Policy agents enable you to apply an Endpoint Windows Group Policy to a client machine and create a result session variable.

#### EXAMPLES

create endpoint-windows-group-policy { Firewall\_Settings\_Template }  
Creates a policy for the Access Policy using the Firewall Settings template.

edit endpoint-windows-group-policy Firewall\_Settings\_Template  
Edits the Firewall Settings Template.

#### OPTIONS

[name]

Specifies a name for the Endpoint Windows Group Policy agent.

partition

Displays the partition within which the component resides.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

policy-file

Specifies the group policy template that is applied to the client.

This option is required.

## apm policy agent endpoint-windows-info-os

NAME

endpoint-windows-info-os - Manages an Endpoint Windows Information Operating System agent.

MODULE

apm policy agent

SYNTAX

Configure the endpoint-windows-info-os component within the policy agent module using the following syntax.

CREATE/MODIFY

create endpoint-windows-info-os [name]

modify endpoint-windows-info-os [name]

options:

app-service [[string] | none]

edit endpoint-windows-info-os [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties

non-default-properties

DISPLAY

list endpoint-windows-info-os

list endpoint-windows-info-os [ [ [name] | [glob] | [regex] ] ... ]

show running-config endpoint-windows-info-os

show running-config endpoint-windows-info-os [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties

non-default-properties

partition

show endpoint-windows-info-os

show endpoint-windows-info-os [name]

DELETE

delete endpoint-windows-info-os [name]

DESCRIPTION

You can use the endpoint-windows-info-os component to create and manage an agent that retrieves information about the Microsoft Windows operating system from the client, such as version and hotfix number.

EXAMPLES

create endpoint-windows-info-os MyEndpointWIOSagent { }

Creates the Endpoint Windows Operating System Information agent named MyEndpointWIOSagent.

list endpoint-windows-info-os

Displays a list of Endpoint Windows Operating System Information agents.

delete endpoint-windows-info-os MyEndpointWIOSagent delete

Deletes the Endpoint Windows Operating System Information agent named MyEndpointWCRagent.

OPTIONS

[name]

Specifies the name of an Endpoint Windows Info OS agent. This setting is required.

partition

Displays the partition within which the component resides.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

SEE ALSO

DESCRIPTION

You can use the endpoint-windows-protected-workspace component to create and manage an agent that enables an administrator to impose limitations on applications running on Windows client machines.

OPTIONS

allow-burn-cid

Specifies that the user can burn CDs from within protected workspace. The default is false.

allow-printer-use

Specifies whether a user can print inside a protected workspace. The default is true.

allow-user-switch

Specifies whether a user can temporarily switch from a protected workspace. The default is true.

allowed-network-shares

Specifies a list of Windows network shares to which user has Write

access. The default is none.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**[name]**  
Specifies the name of the Endpoint Windows Protected Workspace agent. This option is required.

**partition**  
Displays the partition within which the component resides.

**usb-flash-access**  
Specifies whether a user has access to a USB port. The default is false.

## apm policy agent external-logon-page

**NAME**  
external-logon-page - Manages an External Logon Page agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the external-logon-page component within the policy agent module using the following syntax.

```
CREATE/MODIFY
create external-logon-page [name]
modify external-logon-page [name]
options:
  app-service [[string] | none]
  split-username [true | false]
  uri [[string]> | none]

edit external-logon-page [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list external-logon-page
list external-logon-page [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

DELETE
delete external-logon-page [name]
```

**DESCRIPTION**  
The External Logon Page agent creates an external Logon page that redirects the client browser.

**EXAMPLES**

```
create external-logon-page MyExternalLogonPageAgent { uri
  "MyExternalLogonPageServerURI" }
Creates the External Logon Page agent named
MyExternalLogonPageAgent that is associated with the URI
MyExternalLogonPageServerURI.

create external-logon-page MyExternalLogonPageAgent { uri
  "%{session.my_server_uri}" }
Creates the External Logon Page agent named
MyExternalLogonPageAgent with a URI of session.my_server_uri.

list external-logon-page
```

Displays a list of External Logon Page agents.

delete external-logon-page MyExternalLogonPageAgent  
Deletes the External Logon Page agent named MyExternalLogonPageAgent.

#### OPTIONS

[name]  
Specifies the name of an External Logon Page agent. This option is required.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

split-username  
Specifies whether user's input is split into username and domain. This option supports UPN style logon ID (userid@domainid) and Windows Domain User account ID (domainid\userid). The default is false. Set this to true when you want to store the username and domain separately.

uri Specifies a predefined configuration that contains several settings that you want the agent to use to configure an External Logon page. This option is required.

#### SEE ALSO

## apm policy agent http-header-modify

#### NAME

http-header-modify - HTTP header and cookie manipulation agent for per-request access policy.

#### MODULE

apm policy agent

#### SYNTAX

Manipulate HTTP headers or cookies within the policy agent module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create http-header-modify [name]
modify http-header-modify [name]
options:
  app-service [[string] | none]
  cookie-entries [add | delete | modify | none | replace-all-with] {
    [name] {
      options:
        app-service [[string] | none]
        cookie-name [string]
        cookie-operation [cookie-delete | cookie-update]
        cookie-value [string]
      }
    }
  header-entries [add | delete | modify | none | replace-all-with] {
    [name] {
      options:
        app-service [[string] | none]
        header-delimiter [string]
        header-name [string]
        header-operation [header-append | header-insert | header-remove | header-replace]
        header-value [string]
      }
    }
}

edit http-header-modify [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list http-header-modify
```

```
list http-header-modify [ [name] | [glob] | [regex] ] ... ]
show running-config http-header-modify
show running-config http-header-modify [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  cookie-entries
  header-entries
  non-default-properties
  partition
```

```
DELETE
delete http-header-modify [name]
```

#### DESCRIPTION

You can use the http-header-modify component to create and manage a http-header-modify agent that manipulates the HTTP and Cookie headers. Operations supported for HTTP header include insert, append, replace and remove while for cookie only update and delete operations are available. Please note that this agent applies only to per-request access policy.

#### EXAMPLES

```
create http-header-modify MyProfile_act_http-header-modify_ag {
  cookie-entries {
    0 {
      cookie-name PHPSESSID
      cookie-value 1234
    }
    1 {
      cookie-name mySession
      cookie-operation cookie-delete
      cookie-value 5678
    }
  }
  header-entries {
    0 {
      header-name Cache-Control
      header-value no-cache
    }
    1 {
      header-delimiter ;
      header-name User-Agent
      header-operation header-append
      header-value "Mozilla/5.0"
    }
    2 {
      header-name Pragma
      header-operation header-replace
      header-value no-store
    }
    3 {
      header-name Pragma
      header-operation header-remove
      header-value no-cache
    }
  }
}
```

In above example, http-header-modify agent named MyProfile\_act\_http-header-modify\_ag in partition Common and adds 2 cookie and 4 HTTP header entries. cookie entry 0 updates cookie value PHPSESSID to '1234' while entry 1 deletes when cookie value 'mySession=5678'. Header entries refer to various header operations. Entry 0 inserts header 'Cache-Control: 5678'. Entry 1 updates value of header User-Agent to include ';Mozilla/5.0'. Entry 2 replaces value of header Pragma by 'no-store'. Finally, 3 entry will remove header-value matching 'Pragma: no-cache' from HTTP headers.

```
list http-header-modify
```

Displays a list of http-header-modify agents.

#### OPTIONS

```
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name
Specifies the name of HTTP header modify agent. This setting is required.

cookie-entries
Specifies a list of entries specifying cookie header manipulations.

cookie-name
Specifies cookie name to match. This setting is required for cookie-entries.

cookie-operation
Specifies operation on the cookie name specified in cookie-name. Possible values include cookie-update and cookie-delete.

cookie-update
Update the cookie value in the cookie-name, cookie-value pair. This is the default cookie-operation.

cookie-delete
Delete the cookie that matches the cookie-name, cookie-value pair.
```

cookie-value  
Specifies cookie value to be operated on. This is required for cookie-entries.

header-entries  
Specifies a list of entries specifying HTTP header manipulations.

header-delimiter  
Specifies delimiter character to use when header-operation is header-append.

header-name  
Specifies HTTP header to match to be operated on. This setting is required for header-entries.

header-operation  
Specifies operation on the HTTP header specified in header-name. Options include the following:

header-append  
Append header-value to the value of HTTP header header-name delimited by header-delimiter.

header-insert  
Insert HTTP header containing header-name, header-value pair. This is the default header-operation.

header-remove  
Remove the HTTP header, value pair that matches the header-name, header-value pair.

header-replace  
Replace value of HTTP header matching header-name by value header-value.

header-value  
Specifies HTTP header value to be operated on. This is required for header-entries.

partition  
Displays the partition within which the component resides.

## apm policy agent irule-event

NAME  
irule-event - Manages an iRule Event agent.

MODULE  
apm policy agent

SYNTAX  
Configure the irule-event component within the policy agent module using the syntax shown in the following sections.

CREATE/MODIFY  
create irule-event [name]  
modify irule-event [name]  
options:  
app-service [[string] | none]  
id [[string] | none]

edit irule-event [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

DISPLAY  
list irule-event  
list irule-event [ [ [name] | [glob] | [regex] ] ... ]  
show running-config irule-event  
show running-config irule-event [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
partition

```
show irule-event
show irule-event [name]
```

```
DELETE
delete irule-event [name]
```

#### DESCRIPTION

You can use the `irule-event` component to add a custom Access iRule event to an access policy. This agent enables you to combine access policy execution with iRule execution.

For example, you can retrieve the current agent ID (using an iRule command `ACCESS::policy agent id`) to determine which of the iRule agents raised the event and then perform some custom logic execution.

#### EXAMPLES

```
when ACCESS_POLICY_AGENT_EVENT { if {[ACCESS::policy agent id] eq
"lastLogon"} { # Our limit in seconds set 2weeks 1209600 # diff in 100
nanosecond increments between MS time attribute (year 1601) and start
of epoch set offset 11644473600000 set adtime "[ACCESS::session data
get session.ad.last.attr.lastLogon]" # convert adtime to milliseconds
set millisecs [expr {$adtime / 10000}] # subtract offset set
lastlogintime [expr {$millisecs - $offset}] # convert to seconds
because milliseconds for 'now' were negative (maybe vmware issue) set
secs [expr {$lastlogintime / 1000}] set now [clock seconds] # finally
calculate the difference set diff [expr {$now - $secs}] log local0.
"lastLogon: $diff seconds from current time" if { $diff $2weeks } {
ACCESS::session data set session.custom.lastLogonWithin2Weeks 0 } else
{ ACCESS::session data set session.custom.lastLogonWithin2Weeks 1 } }
}
```

In this example, `ACCESS_POLICY_AGENT_EVENT` gathers data containing the users whose last logon was within the last two weeks. Note that you can access session variables and create new session variables inside this event.

```
list irule-event all
Displays a list of OAM agents.
```

```
delete irule-event my_irule_agent
Deletes the iRule Event agent named my_irule_agent.
```

#### OPTIONS

`app-service`  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`id` Specifies the ID of the iRule event. The default is none. You can use the ID to determine which agent caused the `ACCESS_POLICY_AGENT_EVENT`. You can also use the ID to perform different processing inside iRule for different agents.

`[name]`  
Specifies the name of the component. This option is required.

`partition`  
Displays the partition within which the component resides.

## apm policy agent kerberos

**NAME**  
kerberos - Manages a Kerberos agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the kerberos component within the policy agent module using the syntax shown in the following sections.

```
CREATE/MODIFY
create kerberos [name]
modify kerberos [name]
options:
  app-service [[string] | none]
```

```

max-logon-attempt [integer]
server [string]

edit kerberos [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list kerberos
list kerberos [ [ [name] | [glob] | [regex] ] ... ]
show running-config kerberos
show running-config kerberos [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show kerberos
show kerberos [name]

DELETE
delete kerberos [name]

DESCRIPTION
  You can use the kerberos component to create and manage a Kerberos
  agent.

EXAMPLES
  create kerberos my_kerberos_agent
  Creates a Kerberos agent named my_kerberos_agent.

  list kerberos all
  Displays a list of Kerberos agents.

  delete kerberos my_kerberos_agent
  Deletes the Kerberos agent named my_kerberos_agent.

OPTIONS
  [name]
  Specifies the name of the component. This option is required.

  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  max-logon-attempt
  Specifies the maximum number of opportunities that users have to
  re-enter credentials after their first attempt to log in fails. If
  you set this value to a number from 2 to 5 inclusive, the system
  allows users the specified number of opportunities to log in after
  the first attempt to log in fails. If you set the value to 1, the
  system does not allow a second log in opportunity after a first
  log in attempt fails. The default value is 3.

  partition
  Displays the partition within which the component resides.

  server
  Specifies the name of the Kerberos server. This option is
  required.

SEE ALSO
COPYRIGHT
  No part of this program may be reproduced or transmitted in any form or
  by any means, electronic or mechanical, including photocopying,
  recording, or information storage and retrieval systems, for any
  purpose other than the purchaser's personal use, without the express
  written permission of F5 Networks, Inc.

  F5 Networks and BIG-IP (c) Copyright 2011-2012. All rights reserved.

BIG-IP      2012-10-19  apm policy agent kerberos(1)

```

---

## apm policy agent logging

```

NAME
  logging - Manages a Logging agent.

MODULE
  apm policy agent

SYNTAX
  Configure the logging component within the policy agent module using
  the syntax shown in the following sections.

CREATE/MODIFY
  create logging [name]

```

```

modify logging [name]
  options:
    app-service [[string] | none]
    log-message [[string] | none]
    variables [[string] | none]

edit logging [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

DISPLAY
list logging
list logging [ [ [name] | [glob] | [regex] ] ... ]
show running-config logging
show running-config logging [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    app-service
    log-message
    non-default-properties
    partition
    variables

DELETE
delete logging [name]

```

#### DESCRIPTION

You can use the logging component to create and manage a logging agent that monitors the value of session variables and identifies the path taken by access policy execution. A logging agent can also be used to create and monitor custom or predefined session variables. Note that a session variable may or may not exist depending on the result of the access policy execution.

#### EXAMPLES

```

create logging MyProfile_act_logging_ag {
  variables
  {
    {session-var "session.logon.*"}
    {session-var "session.windows_check_file.Company8profile_act_file_check_ag.item_x.filename"}
  }
}

```

Creates the logging agent named MyProfile\_act\_logging\_ag in partition Common and adds two session variables that define actions that the agent logs: session.logon.\* indicates to log application logon attempts and session.windows\_check\_file.Company8profile\_act\_file\_check\_ag.item\_x.filename indicates to log the outcome of the file check on the client. The x in item\_x indicates the order of the files in the list configured for the file checker. The list starts with index 0 (zero).

```

create logging MyProfile_act_logging_ag {
  log-message "Logon Name: %{session.logon.last.username}."
}

```

Above example applies only to logging agent tied to per-request access policy. Here logging agent named MyProfile\_act\_logging\_ag in partition Common will print log messages containing logon name. This removes the requirement to configure variables separately for per-request access policy.

```
list logging
```

Displays a list of logging agents.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### log-message

Specifies the log message to display. This option is required. For per-request access policy only, this option can contain session or per-request variables. However, session variables containing wildcard (\*) are not supported.

name Specifies the name of a logging agent. This option is required.

##### partition

Displays the partition within which the component resides.

##### variables

Adds a variable to or deletes a variable from a logging agent. You use the sessionvar option to specify a session variable that indicates which actions the system logs. This option does not apply to per-request access policy agent.

#### SEE ALSO

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## apm policy agent logon-page

**NAME**  
logon-page - Manages a Logon Page agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the logon-page component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create logon-page [name]  
modify logon-page [name]  
options:  
  app-service [[string] | none]  
  basic-auth-realm [[string] | none]  
  customization-group [[string] | none]  
  field-modifiable1 [true | false]  
  field-modifiable2 [true | false]  
  field-modifiable3 [true | false]  
  field-modifiable4 [true | false]  
  field-modifiable5 [true | false]  
  field-type1 [checkbox | none | password | text]  
  field-type2 [checkbox | none | password | text]  
  field-type3 [checkbox | none | password | text]  
  field-type4 [checkbox | none | password | text]  
  field-type5 [checkbox | none | password | text]  
  http-401-auth-level [basic | basic-negotiate | negotiate | none]  
  post-var-name1 [[integer] | none]  
  post-var-name2 [[integer] | none]  
  post-var-name3 [[integer] | none]  
  post-var-name4 [[integer] | none]  
  post-var-name5 [[integer] | none]  
  session-var-name1 [[integer] | none]  
  session-var-name2 [[integer] | none]  
  session-var-name3 [[integer] | none]  
  session-var-name4 [[integer] | none]  
  session-var-name5 [[integer] | none]  
  clean-sess-var1 [true | false]  
  clean-sess-var2 [true | false]  
  clean-sess-var3 [true | false]  
  clean-sess-var4 [true | false]  
  clean-sess-var5 [true | false]  
  split-username [true | false]  
  type [401 | form-based]

edit logon-page [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

**DISPLAY**  
list logon-page  
list logon-page [ [name] | [glob] | [regex] ] ... ]  
show running-config logon-page  
show running-config logon-page [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  partition

show logon-page  
show logon-page [name]

**DELETE**  
delete logon-page [name]

**DESCRIPTION**  
You can use the logon-page component to create and manage a Logon Page agent. This agent creates a logon page that includes the form in which users input the credentials required by an access policy. You can use the customization-group option to customize the logon page.

**EXAMPLES**  
create logon-page MyLogonPageAgent my { type 401 basic-auth-realm myrealm split-username false http-401-auth-level none }  
Creates a basic authentication Logon Page agent named MyLogonPageAgent that results in a 401 response.

list logon-page  
Displays a list of Logon Page agents.

delete logon-page MyLogonPageAgent  
Deletes the Logon Page agent named MyLogonPageAgent.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application

service can modify or delete the object.

**basic-auth-realm**

Specifies the system being accessed for HTTP basic authentication. This value is shown in the 401 response. Use this option only for basic authentication Logon pages.

**clean-sess-var1 - clean-sess-var5**

Specifies whether session variable under corresponding sess-var-name would be cleaned before logon page appearance (i.e. agent execution) or not. Works only with form-based authentication.

**customization-group**

Specifies a predefined configuration that contains several settings that you want the agent to use to configure a logon page. This setting is required, and the customization group that you assign must be of the type logon. Use this option only for basic authentication Logon pages.

**field-modifiable1 - field-modifiable5**

Specifies whether the user can modify the contents of the field on a form-based Logon page. The default is true. You can use this option to display read-only information. A Logon page contains can have a maximum of five fields. Use this option only for form-based Logon pages.

**field-type1 - field-type5**

Specifies the type of fields on a form-based Logon page. The default is text. Use this option only for form-based Logon pages. The options are:

checkbox  
none  
password  
text

**http-401-auth-level**

Use this option only for basic authentication Logon pages. The options are:

basic  
basic-negotiate  
negotiate  
none

**[name]**

Specifies the name of a Logon Page agent. This setting is required.

**partition**

Displays the partition within which the component resides.

**post-var-name1 - post-var-name5**

Specifies the name of the variable that is sent with POST request. Use this option only for form-based Logon pages.

**sess-var-name1 - sess-var-name5**

Specifies the session variable from which the initial value is taken. Use this option only for form-based Logon pages.

**split-username**

Specifies whether the user's input is split into username and domain. This option supports UPN style logon ID (userid@domainid) and Windows Domain User account ID (domainid\userid). The default is false. Set this to true when you want to store the username and domain separately.

Use this option only for basic authentication Logon pages.

**type** Specifies the type of logon page that appears. The options are:

401 Displays a basic HTTP authentication form.

**form-based**

Displays a logon page.

**DISPLAY**  
 list message-box  
 list message-box [ [ [name] | [glob] | [regex] ] ... ]  
 show running-config message-box  
 show running-config message-box [ [ [name] | [glob] | [regex] ] ... ]  
 options:  
 all-properties  
 non-default-properties  
 partition

show message-box  
 show message-box [name]

**DELETE**  
 delete message-box [name]

**DESCRIPTION**  
 You can use the message-box agent to create, display, or delete a Message Box agent. You cannot use the command line interface to create or modify the messages that display in a message box. You can also edit customizable messages using the visual policy editor.

**EXAMPLES**  
 create message-box MyMessageBoxAgent { customization group  
 "MyMessageBoxCG" }  
 Creates the Message Box agent named MyMessageBoxAgent that is associated with the customization group named MyMessageBoxCG.

list message-box  
 Displays a list of Message Box agents.

delete message-box MyMessageBoxAgent  
 Deletes the Message Box agent named MyMessage BoxAgent.

**OPTIONS**  
 [name]  
 Specifies the name of a Message Box agent. This option is required.

app-service  
 Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

customization-group  
 Specifies the name of the customization group that contains the messages you want to apply to an access policy. This option is required.

partition  
 Displays the partition within which the component resides.

## apm policy agent oam

**NAME**

oam - Manages an OAM agent.

#### MODULE

apm policy agent

#### SYNTAX

Warning: This page is obsolete. AAA OAM agent is no longer supported.

Configure the oam component within the policy agent module using the syntax shown in the following sections.

#### CREATE/MODIFY

create oam [name]

modify oam [name]

#### options:

app-service [[string] | none]

max-logon-attempt [integer]

server [[string] | none]

show-extended-error [true | false]

url [[string] | none]

edit oam [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties

non-default-properties

#### DISPLAY

list oam

list oam [ [name] | [glob] | [regex] ] ... ]

show running-config oam

show running-config oam [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties

non-default-properties

partition

show oam

show oam [name]

#### DELETE

delete oam [name]

#### DESCRIPTION

You can use the oam component to create and manage an OAM agent.

#### EXAMPLES

```
create oam oam_agent1 { server oam10g max-logon-attempt 3 show-extended-error false url "http://www.mydomain.com/protected/" }
```

Creates an OAM agent named oam\_agent1 that uses authentication server oam10g and prompts a user for credentials three times before denying access to http://www.mydomain.com/protected/.

```
modify oam oam_agent1 max-logon-attempt 4
```

```
list oam all
```

Displays a list of OAM agents.

```
delete oam my_oam_agent
```

Deletes the OAM agent named my\_tacacsplus\_agent.

#### OPTIONS

[name]

Specifies the name of the component. This option is required.

#### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### max-logon-attempt

Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

#### partition

Displays the partition within which the component resides.

#### server

Specifies the name of the OAM server used for user authentication. This option is required.

url Specifies the URL of the resource that is protected by the OAM server. It is used to authenticate the user using the specified user credentials. This option is required, and you must specify an absolute URL. An absolute URL specifies the exact location of a file or directory on the Internet.

#### show-extended-error

Specifies to display a verbose error message on the retry logon page. The default value is false.

#### SEE ALSO

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## apm policy agent oauth-authz

### NAME

oauth-authz - Manages an OAuth Authorization agent.

### MODULE

apm policy agent

### SYNTAX

Configure the oauth-authz component within the policy agent module using the following syntax.

#### CREATE/MODIFY

```
create oauth-authz [name]
modify oauth-authz [name]
  options
    app-service [[string] | none]
    customization-group [[string] | none]
    entries [ add | delete | modify | none | replace-all-with] {
[entry-name] {
  options:
    app-service [[string] | none]
    expression [[string] | none]
    scope-entries [ add | delete | modify | none | replace-all-with] {
[scope-entry-name] {
  options:
    app-service [[string] | none]
    scope-name [scope-name]
    scope-value [[string] | none]
}
}
}
}
prompt-for-authorization [true | false]

edit oauth-authz [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
```

#### DISPLAY

```
list oauth-authz
list oauth-authz [ [ [name] | [glob] | [regex] ] ... ]
show running-config oauth-authz
show running-config oauth-authz [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all
    all-properties
    app-service
    customization-group
    entries
    non-default-properties
    one-line
    partition
    prompt-for-authorization
    recursive
```

#### DELETE

```
delete oauth-authz [name]
```

### DESCRIPTION

You can use the oauth-authz component to create and manage an OAuth Authorization agent that provides OAuth Authorization server functionality, and also manage scopes to provide different level of access control based on end user's role or any other criteria.

### EXAMPLES

```
create oauth-authz MyOAuthAuthzAgent {
  customization-group "company_authz"
  entries add {
    0 {
      expression "expr {return true}"
      scope-entries add {
        0 {
          scope-name "name"
          scope-value "%{session.logon.last.name}"
        }
        1 {
          scope-name "email"
          scope-value "test@company.com"
        }
        2 {
          scope-name "domain"
          scope-value "%{session.logon.last.domain}"
        }
      }
    }
  }
}
```

```

}
1 {
  expression "expr {[mcget {session.logon.last.name}] == "testuser"}"
  scope-entries add {
    0 {
      scope-name "project"
      scope-value "project-one"
    }
  }
}
}
}
}

```

Creates an OAuth Authorization agent named MyOAuthAuthzAgent that uses customization group company\_authz to customize the OAuth Authorization page.

The agent associates these scopes name, email, and domain and their values to each access token because the first expression always evaluates to true. The agent also associates scope project with value project-one to the token if the user is testuser.

```
list oauth-authz
```

Displays a list of OAuth Authorization agents.

```
delete oauth-authz MyOAuthAuthzAgent
```

Deletes the OAuth Authorization agent named MyOAuthAuthzAgent.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### customization-group

Specifies the customization group that defines the appearance of the OAuth Authorization page.

##### entries

Specifies a list of entries consisting of an expression and a list of scope entries. If the expression evaluates to true, then the OAuth Authorization agent associates the corresponding list of scope entries to an issued token. Scope entries determine the access control that the OAuth Authorization server requests on behalf of the client application.

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### expression

Specifies the expression that you want an OAuth Authorization agent to use to verify in order to associate the corresponding scopes to an issued token. You can use the following operators: AND, OR, NOT, (and).

##### scope-entries

Specifies a list of entries consisting of a scope name and its value.

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### scope-name

Specifies the name of the scope.

##### scope-value

Specifies a value to the corresponding scope. This value can be any string or session variable.

##### [name]

Specifies the name of the OAuth Authorization agent. This setting is required.

##### partition

Displays the partition within which the component resides.

##### prompt-for-authorization

Specifies whether the OAuth Authorization page, for user authorization, is displayed. This is applicable only for "Authorization code" and "Implicit" grants.

#### SEE ALSO

## apm policy agent resource-assign

**NAME**  
resource-assign - Manages a Resource Assign agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the resource-assign component within the policy agent module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create resource-assign [name]  
modify resource-assign [name]  
options:  
  app-service [[string] | none]  
  rules ( | none)  
  type [acls | general | resources | webtop-and-webtop-links]

edit resource-assign [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

**DISPLAY**  
list resource-assign  
list resource-assign [ [ [name] | [glob] | [regex] ] ... ]  
show running-config resource-assign  
show running-config resource-assign [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  partition

show resource-assign  
show resource-assign [name]

**DELETE**  
delete resource-assign [name]

**DESCRIPTION**  
You can use the resource-assign component to create and manage an agent that assigns an ACL, a resource group, or both to an access policy. A resource group is a collection of resources, access control lists, and protection criteria, which includes your company intranet servers, applications, and network shares. An ACL is a set of restrictions associated with a resource or favorite that defines access for users and groups.

**EXAMPLES**  
create resource-assign MyAssignResourceAgent my rules { { expression "expr { [mcget {session.ad.last.authresult}] == 1 }" webtop-links add { google } } }  
Creates the Resource Assign agent named MyAssignResourceAgent and assigns webtop-link google when authentication is passed.

list resource-assign all  
Displays a list of Resource Assign agents.

delete resource-assign MyAssignResourceAgent  
Deletes the Resource Assign agent named MyAssignResourceAgent.

**OPTIONS**  
[name]  
Specifies the name of the Resource Assign agent. This option is required.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

rules  
Adds a rule to or deletes a rule from the Resource Assign agent. You can use the following attributes to define a rule:

acl Specifies an access control list that this rule assigns to users.

connectivity-resource-group  
Specifies the name of the connectivity resource group to

which this rule applies.

**expression**  
Specifies the expression that indicates which resource groups this rule assigns to users.

**type** Specifies the type of Resource Assign agent. The default is general.

## apm policy agent route-domain-selection

**NAME**  
route-domain-selection - Manages a Route Domain Selection agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the route-domain-selection component within the policy agent module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create route-domain-selection [name]
modify route-domain-selection [name]
```

#### options:

```
app-service [[string] | none]
location-specific [true | false]
route-domain [[integer] | none]
snat [automap | none]
snatpool [[string] | none]
```

```
edit route-domain-selection [ [ [name] | [glob] | [regex] ] ... ]
options:
```

```
all-properties
non-default-properties
```

### DISPLAY

```
list route-domain-selection
list route-domain-selection [ [ [name] | [glob] | [regex] ] ... ]
show running-config route-domain-selection
show running-config route-domain-selection [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
partition
```

```
show route-domain-selection
show route-domain-selection [name]
```

### DELETE

```
delete route-domain-selection [name]
```

### DESCRIPTION

You can use the route-domain-selection component to create a Route Domain Selection agent.

### EXAMPLES

```
create route-domain-selection my_rds_ag route-domain 0 snat automap
Creates the my_rds_ag Route Domain Selection agent.
```

```
show route-domain-selection
Displays a list of Route Domain Selection agents.
```

```
delete route-domain-selection my_rd_selection_agent
Deletes the Route Domain Selection agent named
my_rd_selection_agent.
```

### OPTIONS

[name]  
Specifies the name of a Variable Assignment agent. This option is required.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object,

you cannot modify or delete the object. Only the application service can modify or delete the object.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**route-domain**  
Specifies the route domain. The default is 0 (zero).

**snat**  
**automap**  
none Snat is not used.

**snatpool**

## apm policy agent tacacsplus

**NAME**  
tacacsplus - Manages a TACACS+ agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the tacacsplus component within the policy agent module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create tacacsplus  
modify tacacsplus

**options:**  
app-service [[string] | none]  
max-logon-attempt [integer]  
server [[string] | none]

edit tacacsplus [ [ [name] | [glob] | [regex] ] ... ]  
**options:**  
all-properties  
non-default-properties

**DISPLAY**  
list tacacsplus  
list tacacsplus [ [ [name] | [glob] | [regex] ] ... ]  
show running-config tacacsplus  
show running-config tacacsplus [ [ [name] | [glob] | [regex] ] ... ]  
**options:**  
all-properties  
non-default-properties  
partition

show tacacsplus  
show tacacsplus [name]

**DELETE**  
delete tacacsplus [name]

**DESCRIPTION**  
You can use the tacacsplus component to create and manage a TACACS+ agent.

**EXAMPLES**  
list tacacsplus all  
Displays a list of TACACS+ agents.

delete tacacsplus my\_tacacsplus\_agent  
Deletes the TACACS+ agent named my\_tacacsplus\_agent.

**OPTIONS**  
[name]  
Specifies the name of the component. This option is required.  
  
app-service  
Specifies the name of the application service to which the object

belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**max-logon-attempt**  
Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

**partition**  
Displays the partition within which the component resides.

**server**  
Specifies the name of the TACACS+ server. This option is required.

## apm policy agent variable-assign

**NAME**  
variable-assign - Manages a Variable Assignment agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the variable-assign component within the policy agent module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create variable-assign [name]  
modify variable-assign [name]  
options:  
app-service [[string] | none]  
type [citrix-smart-access | general | intranet-webtop | sso-cred-mapping | virtual-keyboard]  
variables { [varname [name] expression [{string} ] }  
edit variable-assign [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
**DISPLAY**  
list variable-assign  
list variable-assign [ [ [name] | [glob] | [regex] ] ... ]  
show running-config variable-assign  
show running-config variable-assign [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
partition  
show variable-assign  
show variable-assign [name]  
**DELETE**  
delete variable-assign [name]

**DESCRIPTION**  
You can use the variable-assign component to create and manage an agent that assigns one or more variables to an access policy. F5 Networks recommends that you use the visual policy editor to create complex variable assignments.

**EXAMPLES**  
create variable-assign username\_variable\_assign\_ag { variables {  
varname "session.logon.last.username" expression "{{mcget  
{session.ssl.cert.cn}}}" } }  
Creates the username\_variable\_assign\_ag Variable Assignment agent that automatically assigns the value of the common name field in the client certificate to the username field of the logon page. This is useful when an access policy contains the Variable Assignment agent between the client certification and the AAA Active Directory server query actions.

create variable-assign acl\_variable\_assign\_ag { variables { varname

```
"config.connectivity_resource_network_access.MyprofileNR2.acl_name"
expression "expr {"MY_ACL1"}" }
```

Creates a Variable Assignment agent that carries out a configured ACL when a particular branch in the access policy is followed, using the Variable Assignment agent to populate the appropriate variables with the ACL name.

```
show variable-assign
Displays a list of Variable Assignment agents.
```

```
delete variable-assign MyAssignVariableAgent delete
Deletes the Variable Assignment agent named MyAssignVariableAgent.
```

#### OPTIONS

```
[name]
Specifies the name of a Variable Assignment agent. This setting is required.
```

```
partition
Displays the partition within which the component resides.
```

```
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.
```

```
type Specifies the type of agent. The default is general.
```

```
variables
Adds a variable to or deletes a variable from the Variable Assignment agent. You must specify the following attributes for each variable:
```

```
expression
A Tcl expression that the system evaluates, and then assigns the value of the expression to a specific property of the assigned Network Access resource or to a newly created session variable.
```

```
varname
A variable that forms the left-hand side of the expression. You can use the name of an existing variable or a new session variable.
```

show running-config access [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    partition

```

```

show access
show access [name]

```

#### DELETE

```

delete access [name]

```

#### DESCRIPTION

You can use the access component to configure an access profile. An access profile is a pre-configured group of settings that you can use to configure secure Network Access for an application.

#### EXAMPLES

```

create access MyAccessProfile { defaults-from access access-policy
    "my_access_policy" accepted-languages "my_accepted_languages" default-
    language "en" customization-group "company_logout" eps-group
    'myepsgroup' framework-installation-group "company_header"
    "company_footer" error-map-group "company_errormap" }

```

Creates an access profile named MyAccessProfile that is based on the default access profile named access, uses the access policy named my\_access-policy, accepts the languages in the my\_accepted\_languages class, uses English as the default language, and uses these groups to customize the application pages and messages: company\_logout, company\_header, company\_footer, and company\_errormap.

```

list access all all-properties

```

Displays a list of access profiles, including parameter values.

```

delete access MyAccessProfile

```

Deletes the access profile named MyAccessProfile.

#### OPTIONS

**accept-languages**  
Specifies the name of a class that defines the languages supported by the access profile. The default languages are en (English), ja (Japanese), zh-cn (simplified Chinese (PRC)), and zh-tw (traditional Chinese (Taiwan)). This option is required.

**access-policy**  
Specifies the access policy that you want to enforce using this access profile. An access policy contains various security checks that a client must pass before the BIG-IP Access Policy Manager grants access to a protected application. This option is required.

**access-policy-timeout**  
Specifies, for this access profile, the number of seconds within which a user must complete the steps to gain access to an application. The default is 300 seconds. This option is designed to quickly release session resources when a user does not complete the access process, for example, when the user closes the browser before completing the access process.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**customization-group**  
Specifies the customization group that defines the appearance of the logout and error pages. This option is required.

**default-language**  
Specifies the default language for the BIG-IP Access Policy Manager that you want to implement with this access profile. The default is en (English). If the client requests a language that is not supported, the BIG-IP Access Policy Manager uses the default value. This option is required.

**defaults-from**  
Specifies the default access policy from which this profile is created. This option is required.

**domain-cookie**  
Specifies a domain cookie to use with an application access control connection. If you specify a domain cookie, then the line `domain=specified_domain` is added to the MRHsession cookie. The default is none.

**domain-groups**  
Specifies a group of multiple domains or multiple hosts in multiple domains to which a single user session has access. For example, you can use this option to configure a single user session to have access to three domains: `www.a.com`, `www.b.com`, and `www.c.com`. When a user logs in to any of these domains, that user can access the other domains without logging in again. This option is required when you set the `domain-mode` option to `multi-domain`. This option is ignored when you set the `access domain-mode` option to `single-domain`.

For each domain in the domain group, you can specify the following settings:

**cookie-host**  
Specifies the host name for which to create the user's session cookie.

**cookie-domain**  
Specifies the domain for which to create the user's session cookie.

**secure-cookie**  
Adds a security attribute to the user's session cookie.

**persistent-cookie**  
Adds a persistence attribute to the user's session.

**sso-name**  
Specifies the SSO method to use when accessing a backend application.

**domain-mode**  
Specifies how the SSO configuration is applied. The options are:

**single-domain**  
Applies the SSO configuration to a single domain. This is the default.

When you set `domain-mode` to `single-domain`, you must also set the `sso-name` option.

**multi-domain**  
Applies the SSO configuration across multiple domains. This option allows users a single APM login/session and applies the credentials across multiple Local Traffic Manager or Access Policy Manager virtual servers in front of different domains. Note that to apply SSO configurations across multiple domains, all virtual servers must be on one BIG-IP system.

When you set `domain-mode` to `multi-domain`, you must also configure the `domain-group` option, and provide a URI for the `primary-auth-service` option.

**user-identity-method**  
Specifies how access will bind a session to a request.

**http** Use http information such as cookies and URI query string to identify user.

**ip-address**  
Use IP address to identify a user. Do not use this setting if clients may be behind a NAT.

**eps-group**  
This option is required.

**errormap-group**  
Specifies the customization settings for the error map that you want to implement with this access profile. This setting is required.

**framework-installation-group**  
Specifies the customization settings for the header and footer that you want to implement with this access profile. This setting is required.

**generation-ui-group**  
Specifies the generation of the user interface group for the new generation access configuration. This option is required.

**generation-timeout**

Specifies the timeout, in seconds, for the new generation access configuration.

generation-action  
increment

Activates the current access policy configuration for an access profile. For example, the following command activates current access policy configuration for profile myAccessProfile: tmsm modify apm profile access myAccessProfile generation-action increment

noop Specifies "no operation to be performed". This is the default.

sync Specifies that the policy is being modified due to APM policy sync operation. This is an internal action; you should not set it.

httponly-cookie  
Specifies whether HttpOnly directive should be inserted in HTTP response from BIG-IP. The client browser should prevent script from accessing cookie, if this flag is set in the response. The default is false.

inactivity-timeout  
Specifies, for this access profile, the number of seconds that the session on the client can be idle before the server disconnects the VPN tunnel. The default is 900 seconds.

logout-uri-include  
Specifies a list of URIs to include in the access profile for initiating session logout.

logout-uri-timeout  
Specifies the timeout used to delay logout for the customized logout URIs defined in the logout uri include list

log-settings  
Specifies one or more log-setting containers to associate with this profile

max-concurrent-sessions  
Specifies, for this access profile, the number of concurrent sessions allowed. The default is 0 (zero), which represents unlimited sessions. Users assigned an administrative role of Application Editor can view the value of this option. Users assigned any other administrative role can modify this option.

max-concurrent-users  
Specifies, for this access profile, the number of concurrent sessions allowed. The default is 0 (zero), which represents unlimited sessions. This field is Read-only for Application Editors. Users assigned any other administrative role can modify this field.

max-failure-delay  
Specifies the maximum random delay after authentication failure during the access policy. It is the maximum number of seconds before the user is shown an error message on the logon page and prompted to re-enter credentials. The default is 5 seconds. 0 (zero) represents no delay. Note: Set max-failure-delay to no more than one-half the access-policy-timeout value and no more than 65 seconds greater than min-failure-delay.

max-in-progress-sessions  
Specifies the maximum number of in-progress concurrent sessions a user can have. The in-progress sessions are the sessions for which an access policy has not completed. The default is 0, which represents an unlimited number of such sessions.

max-session-timeout  
Specifies the maximum lifetime of one session. The maximum lifetime is the number of seconds between session creation and session termination.

min-failure-delay  
Specifies the minimum random delay after authentication failure during the access policy. It is the minimum number of seconds before the user is prompted for credentials again or shown an error message on the logon page. The default is 2 seconds.

[name]  
Specifies the name of the access profile. This option is required.

oauth-profile  
Specifies an oauth profile for use with an OAuth Authorization Server.

persistent-cookie  
Specifies to retain the cookie for a user session, even when the user session is terminated, when set to true. Although this is an insecure method, this setting is useful and required in cases where you have a third-party application, such as Sharepoint, and need to store the cookie in a local database so that any attempt to access backend server applications through Access Policy Manager succeeds. The default is false.

primary-auth-service  
Specifies the address of your primary authentication URI. This setting is required when you set the domain-mode option to multi-domain.

For example, when you set this option to https://logon.yourcompany.com, the user session is stored on this

primary domain, and the user can access multiple backend applications from multiple domains and hosts without re-entering credentials.

#### restrict-to-single-client-ip

Specifies whether a user session is tied to a single client IP. If during session's lifetime, the user's client IP address changes, the current session is terminated. The user needs to re-login to create a new session from the new client IP address. The default is false.

#### sandboxes

Specifies the association between the access profile and the sandbox. If retain-public-access is set to true, this association is retained even if there is no resource that uses sandbox files in the access policy that corresponds to this access profile.

#### scope

Specifies the confining scope for sessions created by the profile. Set this option to profile (which is also the default-value) to confine the validity of a session to the profile from which it was created. Set this option to virtual-server to further confine the validity of a session to the virtual server from which it was created. Setting this option to global allows the session to be valid on any virtual server with any access profile that also specifies global scope.

#### secure-cookie

Set this option to true, if you want to add a secure keyword to the session cookie. Set this option to false, if you want to configure an application access control scenario that uses an HTTPS virtual server to authenticate the user, and then sends the user to an existing HTTP virtual server to use applications. The default is true.

#### sso-name

Specifies the SSO configuration that you want BIG-IP Access Policy Manager to use to submit the user's credentials to the backend application. This allows the user to log in once to the Access Policy Manager and then gain access to backend applications without logging in again.

type Specifies the type of access profile. You can specify the following types for an access profile.

all Supports ltm-apm and ssl-vpn access types.

#### identity-service

Used internally to provide identity service for a supported integration. Only APM creates this type of profile.

#### ltm-apm

For web access management configuration.

#### oauth-resource-server

Supports apps and devices that use OAuth tokens but do not support cookies.

#### rdg-rap

For validating connections to hosts behind APM when APM acts as a gateway for RDP clients.

#### ssl-vpn

For network access, portal access, or application access.

sso For configuring matching virtual servers for Single Sign-On (SSO).

#### swg-explicit

For Secure Web Gateway explicit forward proxy.

#### swg-transparent

For Secure Web Gateway transparent forward proxy.

#### system-authentication

For configuring administrator access to the BIG-IP system (when using APM as a pluggable authentication module).

#### use-http-503-on-error

Set this option to true to use HTTP response code 503 for error pages sent by BIG-IP Access Policy Manager to clients. Set this option to false to use HTTP response code 200. The default is false.

DESCRIPTION
  You can use the connectivity component to configure a connectivity
  profile. By using the connectivity profile, you can configure L2 and L4
  tunnels, compression, Windows and mobile client settings, and client
  component downloads from F5 Networks and Citrix.

EXAMPLES
  create connectivity myconnectivityprofile { }

  Creates a connectivity profile named myconnectivityprofile that
  inherits its settings from the system default connectivity
  profile.

OPTIONS
  adaptive-compression
  Enables or disables adaptive compression. Use this option to
  configure compression settings for application tunnels and to
  optimize applications and RDP traffic. The default is enabled.

  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  citrix-client-bundle
  Specifies the Citrix client bundle used by this connectivity
  profile. The default is default-citrix-client-bundle.

  client-policy
  Adds, deletes, or modifies the client policy for any of the
  following clients:

  android-ec Android Edge Client

  android-ep Android Edge Portal

  chromeos-ec Chrome OS Edge Client

  ec Windows/OSX Edge Client

  ios-ec iOS Edge Client

  ios-ep iOS Edge Portal

  Options (please refer to the SYNTAX section to see if a certain
  option is supported for a particular client):

  component-update
  Specifies how the client handles automatic updates. The
  options are:

  yes Automatically installs a client update when one is
  available.

  prompt
  Prompts the user about installing a client update.

  No Disables the client from receiving automatic updates.

  device-lock-method
  Specifies the device lock quality that the client should
  enforce on the device. The options are:

  alphabetic
  Device passcode must contain at least alphabetic (or
  other symbol) characters.

```

alphanumeric

Device passcode must contain at least both numeric and alphabetic (or other symbol) characters.

any A device passcode must be set but does not matter what it is.

numeric

Device passcode must contain at least numeric characters.

enable-mobilesafe

Enables or disable MobileSafe checks. Use this option to configure whether client should execute the MobileSafe security checks as part of the logon. The default is false.

enforce-device-lock

Specifies whether client should enforce a device passcode policy on the device. The default is true.

enforce-logon-mode

Specifies whether client should enforce a logon mode on the device. The default is false. Set to true if external logon page is used.

logon-mode

Specifies logon mode to be enforced on the device. The default is native. Set to web if external logon page is used.

enforce-pin-lock

Specifies whether client should enforce an app-level PIN before allowing access to the app. The default is true.

location-dns

Specifies a list of DNS suffixes used by the Network Location Awareness feature of the client. This list represents the internal network where local resources are available without the need of a Network Access connection. The default is none.

max-grace-period

Specifies the length of time (in minutes) the app was taken to the background before the user will be asked for a PIN. With the option set to 0, user will be asked for the PIN every time the app is taken from the background. The default is 2.

max-inactivity-time

Sets the length of time (in minutes) since the user last touched the screen or pressed a button before the device locks the screen. The default is 5.

min-passcode-length

Specifies the minimum required number of characters for the device passcode. The default is 4.

require-device-auth

Specifies whether device authentication is needed before accessing cached credentials. The default is false.

reuse-winlogon-creds

Specifies whether client can reuse logon credentials entered by a user for a subsequent log in. The default is false.

reuse-winlogon-session

Specifies whether client should attempt to use the same Windows logon session. The default is false.

save-password

Specifies whether client allows user password caching. The default is false.

save-password-method

Specifies whether client saves encrypted passwords on disk or caches passwords in memory only. The default is disk.

save-password-timeout

Specifies the number of minutes that a cached password remains valid (applies only to in-memory password caching). The default is 240.

save-servers-on-exit

Specifies whether client maintains a list of Access Policy Manager systems that the client accessed. The default is true.

servers

Specifies a list of server and alias pairs in the client's server list.

compress-buffer-size

Specifies the size of compressed data for Network Access tunnels. The default is 4096.

compress-cpu-saver

Specifies whether the system monitors the percentage of CPU usage and adjusts compression rates automatically when CPU usage reaches either the CPU saver high threshold or the CPU saver low threshold. The default is true.

compress-cpu-saver-high

Specifies the percentage of CPU usage at which the system starts automatically decreasing the amount of content being compressed, as well as the amount of compression which the system is applying. The default is 90 percent.

`compress-cpu-saver-low`  
Specifies the percentage of CPU usage at which the system resumes content compression at the user-defined rates. The default is 75 percent.

`compress-gzip-level`  
Specifies the degree to which the system compresses the content. Higher compression levels slow down the compression process. The default is 6, which provides a higher amount of compression at the expense of more CPU processing time. 1 is the lowest level and 9 is the highest level. 0 disables compression.

`compress-gzip-memlevel`  
Specifies the number of kilobytes of memory that the system uses for internal compression buffers when compressing data. You can select a value between 1 and 256. The default is 8192.

`compress-gzip-window-size`  
Specifies the number of kilobytes in the window size that the system uses when compressing data. You can select a value between 1 and 128. The default is 16384.

`compress-ingress`  
Specifies whether incoming data is compressed. The default is false.

`compress-preferred-method`  
Specifies the preferred method of data compression. The default is zlib.

`compression`  
Enables or disables compression between the client and the server. The default is enabled.

`compression-codecs`  
Specifies the available compression codecs for server-to-client connections. The server compares the available compression types you configure with the available compression types on the client, and then chooses the most effective mutual compression setting. Compression for the client is configured separately. The default includes all three available codecs:

`lzo` Offers a balance between CPU resources and compression ratio, compressing more than deflate, but with less CPU resources than bzip2.

`deflate`  
Uses the least CPU resources, but compresses the least effectively.

`bzip2`  
Uses the most CPU resources, but compresses the most effectively.

`customization-group`  
Specifies which customization groups are applied. This option is required.

`defaults-from`  
Specifies the profile from which this profile inherits properties that are not specified explicitly. The default is connectivity.

`deflate-compression-level`  
Specifies the level of compression performed by the deflate codec. The default is 1.

`description`  
Specifies a user-defined description for the connectivity profile.

`location-specific`  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

`[name]`  
Specifies the profile that you want to use as the parent profile. The new profile inherits all settings and values from the parent profile.

`tunnel-name`  
Specifies the name of the tunnel through which data passes. The default is none.

**DESCRIPTION**  
You can use the exchange component to configure an exchange profile. An exchange profile is a preconfigured group of settings that you can use to configure authentication for exchange services such as Outlook Anywhere, ActiveSync, Autodiscover and Offline Address Book, so that those work with BIG-IP.

**EXAMPLES**  
create exchange MyExchangeProfile {  
ntlm-auth-name "MyNTLMAuth"  
rpc-over-http-url "/rpc/rpcproxy.dll"  
rpc-over-http-auth-type ntlm  
rpc-over-http-sso-config "MyKerberosSSOConfig"  
}>

Creates an exchange profile named MyExchangeProfile that is based on the general settings such as NTLM Authentication configuration MyNTLMAuth. The profile is configured for Outlook Anywhere (RPC over HTTP) service with url "/rpc/rpcproxy.dll\*", client authentication type ntlm and SSO configuration type MyKerberosSSOConfig

list exchange all all-properties  
Displays a list of exchange profiles, including parameter values.

delete access MyExchangeProfile  
Deletes the exchange profile named MyExchangeProfile.

**OPTIONS**  
ntlm-auth-name  
Specifies the NTLM configuration object that clients can use to authenticate on the front-end. Backend SSO type must be Kerberos for ntlm or basic-ntlm front end.

active-sync-auth-type  
Specifies the client-side authentication type for ActiveSync exchange service. The valid value is basic.

**active-sync-sso-config**  
Specifies the back end SSO config for ActiveSync exchange service. This is optional.

**active-sync-url**  
Specifies the URL for ActiveSync exchange service. URL is required for ActiveSync service to be enabled through BIG-IP.

**auto-discover-auth-type**  
Specifies the client-side authentication type for Autodiscover exchange service. The valid values are basic, ntlm and basic-ntlm.

**auto-discover-sso-config**  
Specifies the back end SSO config for Autodiscover exchange service. This is optional.

**description**  
Specifies a user-defined description for the exchange profile.

**auto-discover-url**  
Specifies the URL for Autodiscover exchange service. URL is required for Autodiscover service to be enabled through BIG-IP.

**offline-address-book-auth-type**  
Specifies the client-side authentication type for Offline Address Book exchange service. The valid values are basic, ntlm and basic-ntlm.

**offline-address-book-sso-config**  
Specifies the back end SSO config for Offline Address Book exchange service. This is optional.

**offline-address-book-url**  
Specifies the URL for Offline Address Book exchange service. URL is required for Offline Address Book service to be enabled through BIG-IP.

**rpc-over-http-auth-type**  
Specifies the client-side authentication type for Outlook Anywhere (RPC over HTTP) exchange service. The valid values are basic, ntlm and basic-ntlm.

**rpc-over-http-sso-config**  
Specifies the back end SSO config for Outlook Anywhere (RPC over HTTP) exchange service. This is optional.

**rpc-over-http-url**  
Specifies the URL for Outlook Anywhere (RPC over HTTP) exchange service. URL is required for Outlook Anywhere (RPC over HTTP) service to be enabled through BIG-IP.

**user-agent-pattern-for-utf8**  
Specifies the user agent pattern for UTF8.

**web-service-auth-type**  
Specifies the client-side authentication type for Web Exchange service. The valid values are basic, ntlm and basic-ntlm.

**web-service-sso-config**  
Specifies the back end SSO config for Web Exchange service. This is optional.

**web-service-sync-url**  
Specifies the URL for Web Exchange service. URL is required for Web Service to be enabled through BIG-IP.

## apm profile oauth

**NAME**  
oauth - Configures an oauth profile.

**MODULE**  
apm profile

**SYNTAX**  
Configure the oauth component within the profile module using the

syntax shown in the following sections.

```
CREATE/MODIFY
create oauth [name]
modify oauth [name]
options:
  access-token-lifetime [integer]
  app-service [[string] | none]
  auth-code-lifetime [integer]
  auth-url [string]
  client-apps [add | delete | replace-all-with] {
    [client-app-name]
  }
  db-instance [db-instance-name]
  defaults-from [[string] | none]
  generate-refresh-token [true | false]
  per-user-token-limit [integer]
  refresh-token-lifetime [integer]
  refresh-token-usage-limit [integer]
  resource-servers [add | delete | replace-all-with] {
    [resource-server-name]
  }
  reuse-access-token [true | false]
  reuse-refresh-token [true | false]
  token-issuance-url [string]
  token-revocation-url [string]
  token-introspection-url [string]
edit oauth [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list oauth
list oauth [ [name] | [glob] | [regex] ] ... ]
show running-config oauth
show running-config oauth [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show oauth
show oauth [name]

DELETE
delete oauth [name]
```

#### DESCRIPTION

You can use the oauth component to configure an oauth profile. An oauth profile is a pre-configured group of settings that you can use to configure OAuth Authorization Server.

**NOTE:** For the oauth profile to take effect, this profile must be associated with an access profile. (See man page for apm access profile.)

#### EXAMPLES

```
create oauth myOAuthProfile {
  defaults-from oauth
  client-apps add { client_1 client_2}
  resource-servers add { rs_1 rs_2}
  db-instance db_test
  auth-url /f5-oauth2/v1/authorize
  token-issuance-url /f5-oauth2/v1/token
  token-revocation-url /f5-oauth2/v1/revoke
  token-introspection-url /f5-oauth2/v1/introspect
}
```

Creates an oauth profile named myOAuthProfile that is based on the default oauth profile named oauth. The profile serves OAuth requests from client applications named client\_1 and client\_2 and resource servers named rs\_1 and rs\_2.

The profile uses db instance named db\_test, /f5-oauth2/v1/authorize as the authorization endpoint, /f5-oauth2/v1/token as token issuance endpoint, /f5-oauth2/v1/revoke as revocation endpoint, and /f5-oauth2/v1/introspect as token introspection endpoint.

```
list oauth all all-properties
```

Displays a list of oauth profiles, including parameter values.

```
delete oauth myOAuthProfile
```

Deletes the oauth profile named myOAuthProfile.

#### OPTIONS

**access-token-lifetime**  
Specifies the number of minutes for which the access token should be valid. The default is 5 minutes.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**auth-code-lifetime**  
Specifies the number of minutes for which the authorization code should be valid. The default is 5 minutes.

**auth-url**  
Specifies the path of the authorization endpoint that is used to authenticate the resource owner and provide the authorization code. The default is /f5-oauth2/v1/authorize.

**client-apps**  
Specifies the list of client applications that is served by the OAuth Authorization Server associated with this profile.

**db-instance**  
Specifies the db instance that is used to store tokens generated by the OAuth Authorization Server that is associated with this profile.

**defaults-from**  
Specifies the default oauth profile from which this profile is created. The default is oauth.

**generate-refresh-token**  
Specifies whether a refresh token should be generated along with the access token. This is applicable only for "Authorization Code" and "Resource Owner Password Credentials" grant types.

**per-user-token-limit**  
Specifies the maximum number of active access tokens that can be generated for a user. The default is 255. The range is 0 to 5000.

**refresh-token-lifetime**  
Specifies the number of minutes for which the refresh token should be valid. The default is 480 minutes.

**refresh-token-usage-limit**  
Specifies the maximum number of times the access token can be obtained using the refresh token request. The default value is 0, which represents unlimited number of times.

**resource-servers**  
Specifies the list of resource servers that is served by the OAuth Authorization Server that is associated with this profile.

**reuse-access-token**  
Specifies whether an access token is reused or a new access token is generated when it is obtained using refresh token request. When the access token is reused, its expiry time is extended.

**reuse-refresh-token**  
Specifies whether a refresh token is reused or a new refresh token is generated when it is obtained using refresh token request.

**token-issuance-url**  
Specifies the path of token issuance endpoint that is used to issue an access token and possibly a refresh token. The default is /f5-oauth2/v1/token.

**token-revocation-url**  
Specifies the path of token revocation endpoint that is used to revoke an access token or a refresh token. The default is /f5-oauth2/v1/revoke.

**token-introspection-url**  
Specifies the path of token introspection endpoint that is used to introspect an access token. The default is /f5-oauth2/v1/introspect.

## apm profile remote-desktop

#### NAME

remote-desktop - Displays information about a default profile that supports a Citrix remote desktop resource.

MODULE  
apm profile

SYNTAX  
Displays the properties of the remote-desktop component within the profile module.

DISPLAY  
list remote-desktop  
list remote-desktop [ [ [name] | [glob] | [regex] ] ... ]  
show running-config remote-desktop  
show running-config remote-desktop [ [glob] | [regex] ] ... ]  
options:  
all-properties  
location-specific [true | false]  
non-default-properties  
one-line

DESCRIPTION  
You can use the remote-desktop component to display the properties of the default remote desktop profile.

A remote desktop profile is for internal use only. You should not create or modify a remote desktop profile.

EXAMPLES  
list remotedesktop all-properties

Displays all of the properties of the default remote desktop profile.

OPTIONS  
location-specific  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

## apm profile vdi

NAME  
vdi - Configures a VDI profile.

MODULE  
apm profile

SYNTAX  
Configure the vdi component within the profile module using the syntax shown in the following sections.

CREATE/MODIFY  
create vdi [name]  
modify vdi [name]  
options:  
msrdp-ntlm-auth-name [[string] | none]

edit vdi [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

DISPLAY  
list vdi  
list vdi [ [ [name] | [glob] | [regex] ] ... ]  
show running-config vdi  
show running-config vdi [ [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line

DELETE  
delete vdi [name]

## DESCRIPTION

You can use the vdi component to configure a VDI profile. A VDI profile is a group of settings that you can use to enable and configure VDI services such as Citrix, VMware View and MSRDP, so that those work with the BIG-IP system.

## EXAMPLES

```
create vdi MyVdiProfile {
  msrdp-ntlm-auth-name "MyNTLMAuth"
}
```

Creates a VDI profile named MyVdiProfile with NTLM Authentication configuration MyNTLMAuth to be used for MSRDP clients authentication.

```
list vdi all-properties
Displays a list of VDI profiles, including parameter values.
```

```
delete vdi MyVdiProfile
Deletes the VDI profile named MyVdiProfile.
```

## OPTIONS

**msrdp-ntlm-auth-name**  
Specifies the NTLM auth configuration object to be used by this VDI profile for MSRDP client authentication.

## SEE ALSO

## apm report custom-report-field

### NAME

custom-report-field - Configures a custom report field.

### MODULE

apm report

### SYNTAX

Configure the custom-report-field component within the custom-report module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create custom-report-field name [string] field-id [integer] field-position [integer] report-name [string]
options
```

```
  alias [string]
  app-service [string]
  sort-direction [asc|desc|unsorted]
  sort-order [integer]
```

```
modify custom-report-field [alias | app-service | field-id | field-position | name | report-name | sort-direction | so
options
```

```
  alias [string]
  app-service [string]
  field-position [integer]
  report-name [string]
  sort-direction [asc|desc|unsorted]
  sort-order [integer]
```

#### DISPLAY

```
list custom-report-field
list custom-report-field [alias | app-service | field-id | field-position | name | report-name | sort-direction | sort
```

### DESCRIPTION

Configures a custom report field with options.

It is highly recommended that you use the web GUI to configure this custom object.

### EXAMPLES

```
create alias UserName field-id 12 field-position 1 name
APDNOTICE_USERNAME.User_Name report-name cust1 sort-direction asc
sort-order 100000
```

Creates a custom-report-field named UserName under custom report named cust1, field-position is 1, sort direction is ascending and sort-order is 100000.

Note: Some field-id's and names are predefined and fixed values and not customizable, see below for details:

```
apm report custom-report-field {
```

```

field-id 21
name APDNOTICE_CLIENT_INFO.Client_Version
}
  apm report custom-report-field {
field-id 19
name APDNOTICE_CLIENT_INFO.Client_UI_Mode
}
  apm report custom-report-field {
field-id 16
name APDNOTICE_ASSIGN_WEBTOP_LINKS.Webtop_Links
}
  apm report custom-report-field {
field-id 18
name APDNOTICE_ACCESS_POLICY_RESULT.Access_Policy_Result
}
  apm report custom-report-field {
field-id 20
name APDNOTICE_CLIENT_INFO.Client_Type
}
  apm report custom-report-field {
field-id 15
name APDNOTICE_ASSIGN_WEBTOP.Webtop_Name
}
  apm report custom-report-field {
field-id 13
name APDNOTICE_ASSIGN_ACL.ACL_variable
}
  apm report custom-report-field {
field-id 12
name APDNOTICE_USERNAME.User_Name
}
  apm report custom-report-field {
field-id 14
name APDNOTICE_ASSIGN_RESOURCE.resource_var
}
  apm report custom-report-field {
field-id 17
name APDNOTICE_CLIENT_INFO.Client_Platform
}

```

#### OPTIONS

**alias**  
Specifies the alias of the custom report field.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**field-id**  
Specifies a unique id of the custom report field. This item is fixed and not customizable.

**field-position**  
Specifies field's position among all available fields.

**name** Specifies a unique name for the custom report field. This item is fixed and not customizable.

**report-name**  
Specifies the custom report that the custom-report-field belongs to.

**sort-direction**  
Specifies the sort direction of the custom-report-field. It can be asc, desc, or unsorted. Default is asc.

**sort-order**  
Specifies the sort order of the custom-report-field. Default is 100000.

#### SEE ALSO

## apm resource app-tunnel

NAME

app-tunnel - Configures an application tunnel.

#### MODULE

apm resource

#### SYNTAX

Configure the app-tunnel component within the resource module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create app-tunnel [name]
modify app-tunnel [name]
options:
  acl-order [integer]
  app-service [[string] | none]
  application-launch-warning [true | false]
  apps [add | delete | modify | replace-all-with] {
    [name]
  }
  customization-group [add | delete | modify | replace-all-with] {
    [name]
  }
  description [[string] | none]
  location-specific [true | false]
  type [app-tunnel | last | network-access | remote-desktop | web-application]
```

```
edit app-tunnel [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list app-tunnel
list app-tunnel [ [ [name] | [glob] | [regex] ] ... ]
show running-config app-tunnel
show running-config app-tunnel [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
  one-line
```

```
show app-tunnel
show app-tunnel [name]
```

##### DELETE

```
delete app-tunnel [name]
```

#### DESCRIPTION

You can use the app-tunnel component to configure an application tunnel to provide secure access to a network, remote desktop, or specific applications.

#### EXAMPLES

```
item create app-tunnel myapptunnel customization-group
myapptunnelcg
```

Creates an application tunnel named myapptunnel that uses the policies in the customization group myapptunnelcg.

```
item delete app-tunnel myapptunnel
```

Deletes the application tunnel named myapptunnel.

#### OPTIONS

##### acl-order

Specifies the location of this app tunnel in the ACL hierarchy in Access Policy Manager ACL lists. The default is 0 (zero).

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### application-launch-warning

Specifies whether to display a warning before launching an application. The options are:

true The system displays security warnings before launching an application, regardless of whether the site is considered a Trusted site. This is the default value.

##### false

The system displays security warnings before launching an application, only if the site is not in the Trusted Sites list.

apps Specifies the applications that a user can access using this application tunnel. The default is none.

##### customization-group

Specifies whether customizations are applied to the application tunnel. You can add, modify, delete, or replace all customization groups. This option is required.

##### description

Specifies a description for the application tunnel. The default is none.

##### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either

true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]  
Specifies a name for the component.

partition  
Displays the partition within which the app-tunnel component resides. The default is common.

type Specifies the type of application tunnel. The options are:

app-tunnel  
This is the default.

network-access  
Provides access to a network.

remote-desktop  
Provides access to a remote desktop.

web-application  
Provides access to a Web application.

## apm resource client-rate-class

NAME  
client-rate-class - Configures a client rate class resource.

MODULE  
apm resource

SYNTAX  
Configure the client-rate-class component within the resource module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create client-rate-class [name]
modify client-rate-class [name]
```

#### options:

```
app-service [[string] | none]
burst [integer]
ceiling [integer]
description [[string] | none]
dscp [integer]
location-specific [true | false]
mode [borrow | discard | shape]
rate [integer]
type [best-effort | controlled-load | guaranteed]
```

```
edit client-rate-class [ [ [name] | [glob] | [regex] ] ... ]
options:
```

```
all-properties
non-default-properties
```

#### DISPLAY

```
list client-rate-class
list client-rate-class [ [ [name] | [glob] | [regex] ] ... ]
show running-config client-rate-class
show running-config client-rate-class [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
```

```
show client-rate-class
show client-rate-class [name]
```

#### DELETE

```
delete client-rate-class [name]
```

#### DESCRIPTION

You can use the client-rate-class component to configure a client rate class resource, which is used in traffic control.

#### EXAMPLES

```
create client-rate-class sf1{ dscp 40 rate 60000 ceiling 80000 mode
shape }
```

Creates a client rate class resource named sfl used in traffic control. Sets the dscp to 40 and the rate to 60000, sets the ceiling to 80000, and sets the mode to shape.

list client-rate-class all  
Displays a list of all client rate class on the system.

delete client-rate-class sfl  
Deletes the client rate class named sfl from the system.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### burst

Specifies in bytes the maximum amount of data that can reach the ceiling rate at one time. The default is 0 (zero).

##### ceiling

Specifies how far, beyond the value specified for the rate option, that traffic can flow when bursting. This number sets an absolute limit. No traffic can exceed this rate. The rate class might limit traffic throughput to the value of the rate option when there is high contention among siblings of a parent-child class hierarchy. The default value is the value of the rate option. The minimum value is 296 bp.

##### description

Specifies a description for the client rate class. The default is none.

dscp Specifies six bits of DS field used as a codepoint to select the PHB (Per Hop Behavior) for a packet in each network node. The default is -1.

##### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

##### [name]

Specifies a unique name to identify the client rate class.

mode Specifies the mode to use for this client rate class. The options are:

##### borrow

Allows traffic on the client rate class to borrow resources from other flows that are temporarily idle. Traffic that borrows resources is marked as nonconforming and receives a lower priority. This is the default.

##### discard

Discards packets that do not conform to the specified traffic control descriptor.

##### shape

Delays packets submitted for transmission until the packets conform to the specified flow parameters

##### partition

Displays the partition within which this component resides. The default is common.

rate Specifies the guaranteed throughput rate of the traffic handled by this rate class. You can configure the rate in bits per second (bps), kilobits per second (Kbps), megabits per second (Mbps), or gigabits per second (Gbps).

type Specifies the service type in use for the client rate class. The options are:

##### best-effort

Windows traffic control creates a flow for this client traffic class, and traffic on the flow is handled with the same priority as other Best Effort traffic. This is the default.

##### controlled-load

Traffic control transmits a very high percentage of packets to the intended receivers. Packet loss for this type closely approximates the basic packet error rate of the transmission medium. Transmission delay for a very high percentage of the delivered packets does not greatly exceed the minimum transit delay experienced by any successfully delivered packet.

##### guaranteed

Guarantees that datagrams arrive within a specified delivery time and will not be discarded due to queue overflows, provided that the flow of traffic stays within specified traffic parameters. This type is intended for applications that require guaranteed packet delivery.

## apm resource client-traffic-classifier

### NAME

client-traffic-classifier - Configures client traffic classifier entries.

### MODULE

apm resource

### SYNTAX

Configure the client-traffic-classifier component within the resource module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create client-traffic-classifier [name]
modify client-traffic-classifier [name]
options:
  app-service [[string] | none]
  entries [add | delete | modify | replace-all-with] {
    [name] {
      app-service [[string] | none]
      client-rate-class [[string] | none]
      dst-ip [[ipv4 address] | none]
      dst-mask [[integer] | none]
      dst-port [[integer] | none]
      protocol [[integer] | none]
      src-ip [[ipv4 address] | none]
      src-mask [[integer] | none]
      src-port [[integer] | none]
    }
  }
  location-specific [true | false]
}

edit client-traffic-classifier [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list client-traffic-classifier
list client-traffic-classifier [ [ [name] | [glob] | [regex] ] ... ]
show running-config client-traffic-classifier
show running-config client-traffic-classifier [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

show client-traffic-classifier
show client-traffic-classifier [name]

DELETE
delete client-traffic-classifier [name]
```

### DESCRIPTION

You can use the client-traffic-classifier component to configure a client traffic classifier, which is used by traffic control agent.

### EXAMPLES

```
create client-traffic-classifier tf1{ entries entry1 { protocol "6"
  dst-ip "192.168.0.0" dst-mask "255.255.0.0" dst-port "0" client-rate-
  class "sf1" }
  entry2{protocol "6"
  src-ip "10.10.0.0"
  src-mask "255.255.255.0"
  client-rate-class "sf2"}}}
```

Creates a client traffic classifier named tf1, sets the entry to entry1, the protocol to 6, the DST IP to 192.168.0.0, the DST mask to 255.255.0.0, the DST port to 0 (zero), and the client rate class to sf1.

```
list client-traffic-classifier all
Displays a list of all client traffic classifiers on the system.
```

```
modify client-traffic-classifier tf1 entries entry1 protocol 17
Modifies the client traffic classifier named tf1.
```

```
delete client-traffic-classifier tfl
Deletes the client traffic classifier named tfl from the system.
```

#### OPTIONS

```
app-service
Specifies the name of the application service to which the object
belongs. The default value is none. Note: If the strict-updates
option is enabled on the application service that owns the object,
you cannot modify or delete the object. Only the application
service can modify or delete the object.
```

```
dst-ip
Specifies the IP address of the receiver of the packet.
```

```
dst-mask
Specifies the subnet mask for the destination address.
```

```
dst-port
Specifies the 16-bit number to identify the sending port for
either UDP or TCP network application.
```

```
location-specific
Specifies whether or not this object contains one or more
attributes with values that are specific to the location where the
BIG-IP device resides. The location-specific attribute is either
true or false. When using policy sync, mark an object as location-
specific to prevent errors that can occur when policies reference
objects, such as authentication servers, that are specific to a
certain location.
```

```
[name]
Specifies the name of the component.
```

```
partition
Displays the partition within which the component resides. The
default is Common.
```

```
protocol
Specifies which traffic protocol to use in the filtering rule.
```

```
src-ip
Specifies the address from which the packet is being sent.
```

```
src-mask
Specifies the subnet mask for the source address.
```

```
src port
Specifies a 16-bit number to identify the sending port for either
UDP or TCP network application.
```

## apm resource ipv6-leasepool

NAME  
ipv6-leasepool - Configures a lease pool.

MODULE  
apm resource

SYNTAX  
Configure the ipv6-leasepool component within the resource module using the syntax shown in the following sections.

```
CREATE/MODIFY
create ipv6-leasepool [name]
modify ipv6-leasepool [name]
options
  app-service [[string] | none]
  description [[string] | none]
  location-specific [true | false]
  members [add | delete | modify | replace-all-with] {
    [[first ip address in range] - [last ip address in range]]
  }
}
```

```
DISPLAY
list ipv6-leasepool
```

```
list ipv6-leasepool [ [ [name] | [glob] | [regex] ] ... ]
show running-config ipv6-leasepool
show running-config ipv6-leasepool [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show ipv6-leasepool
show ipv6-leasepool [name]

DELETE
delete ipv6-leasepool [name]
```

#### DESCRIPTION

Configures an IPv6 lease pool to create a collection of IPv6 addresses grouped as a single object. You can use a lease pool to associate that collection of IP addresses with a network access resource.

#### EXAMPLES

```
create ipv6-leasepool myipv6-leasepool {fd1f::1-fd1f::64}
```

Creates a ipv6-leasepool named myipv6-leasepool that contains the IPv6 addresses in the range fd1f::1 - fd1f::64.

Note: No spaces are allowed between the first IPv6 address, hyphen, and second IPv6 address.

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
Specifies a unique description of the lease pool.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies a unique name for the lease pool.

**members**  
Specifies a range of IPv6 addresses separated by a hyphen.

**partition**  
Displays the partition within which the component resides. The default is Common.

#### SEE ALSO

apm profile, ltm virtual

## apm resource leasepool

**NAME**  
leasepool - Configures a lease pool.

**MODULE**  
apm resource

**SYNTAX**  
Configure the leasepool component within the resource module using the syntax shown in the following sections.

```
CREATE/MODIFY
create leasepool [name]
modify leasepool [name]
options
  app-service [[string] | none]
  description [[string] | none]
```

```
location-specific [true | false]
members [add | delete | modify | replace-all-with] {
  [[first ip address in range] - [last ip address in range]]
}
```

#### DISPLAY

```
list leasepool
list leasepool [ [ [name] | [glob] | [regex] ] ... ]
show running-config leasepool
show running-config leasepool [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show leasepool
show leasepool [name]
```

#### DELETE

```
delete leasepool [name]
```

#### DESCRIPTION

Configures a lease pool to create a collection of IPv4 addresses grouped as a single object. You can use a lease pool to associate that collection of IPv4 addresses with a network access resource.

#### EXAMPLES

```
create leasepool myleasepool {10.10.10.1-10.10.10.10}
```

Creates a leasepool named myleasepool that contains the IPv4 addresses in the range 10.10.10.1 - 10.10.10.10.

Note: No spaces are allowed between the first IPv4 address, hyphen, and second IPv4 address.

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
Specifies a unique description of the lease pool.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies a unique name for the lease pool.

**members**  
Specifies a range of IP addresses separated by a hyphen.

**partition**  
Displays the partition within which the component resides. The default is Common.

#### SEE ALSO

  optimized-app [add | delete | modify | none | replace-all-with ]
  provide-client-cert [true | false]
  proxy-arp [true | false]
  split-tunneling [true | false]
  static-host [[string] | none]
  supported-ip-version [ipv4 | ipv4-ipv6]
  sync-with-active-directory [true | false]
  type [app-tunnel | last | network-access | remote-desktop | web-application]
  wins-primary [ip addr]
  wins-secondary [ip addr]
```

```
edit network-access [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list network-access
list network-access [ [ [name] | [glob] | [regex] ] ... ]
show running-config network-access
show running-config network-access [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show network-access
show network-access [name]
```

#### DELETE

```
delete network-access [name]
```

#### DESCRIPTION

You can use the network-access component to configure the general settings for a network access connection.

#### EXAMPLES

```
create network-access mynetwork-access customization-group mynetaccess
Creates a network access connection configuration object named mynetwork-access that uses the policies in the customization group named mynetaccess.
```

```
delete network-access mynetwork-access
Deletes the network access connection configuration object named mynetwork-access.
```

#### OPTIONS

```
app-service
Specifies the name of the application service to which the object
```

belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**address-space-dhcp-requests-excluded**  
Specifies whether requests from IP addresses using DHCP are excluded from accessing the network. The default is true.

**address-space-exclude-subnet**  
Specifies the IPv4 address spaces whose traffic you want to exclude from access to a subnet on the network. The default is none.

**ipv6-address-space-exclude-subnet**  
Specifies the IPv6 address spaces whose traffic you want to exclude from access to a subnet on the network. The default is none.

**address-space-include-dns-name**  
Specifies a list of domain names describing the target LAN DNS addresses for split tunneling only. You can add multiple address spaces to the list. For each address space, type the domain name, in the form site.siterequest.com or \*.siterequest.com. The default is none.

**address-space-exclude-dns-name**  
Specifies the DNS address spaces whose traffic you want to exclude from access to a subnet on the network. You can add multiple address spaces to the list. For each address space, type the domain name, in the form site.siterequest.com or \*.siterequest.com. The default is none.

**address-space-include-subnet**  
Specifies a list of IPv4 addresses or address/mask pairs describing the target LAN. When using split tunneling, only the traffic to these addresses and network segments goes through the tunnel configured for Network Access. You can add multiple address spaces to the list. For each address space, type the IPv4 address and network mask. The default is none.

**ipv6-address-space-include-subnet**  
Specifies a list of IPv6 addresses or address/mask pairs describing the target LAN. When using split tunneling, only the traffic to these addresses and network segments goes through the tunnel configured for Network Access. You can add multiple address spaces to the list. For each address space, type the IPv6 address and network mask. The default is none.

**address-space-local-subnets-excluded**  
Specifies whether to exclude local access to any host or subnet in routes that you have specified in the client routing table. The default is false. When you set this option to true, the system does not support integrated IP filtering.

**address-space-loc-dns-servers-excluded**  
Specifies whether to exclude local access to DNS servers configured on client prior to establishing network access connection. The default is false.

**address-space-protect**  
Specifies whether the IP address spaces whose traffic is forced through the tunnel are protected. The default is false.

**app-service**  
The default is none.

**application-launch**  
Specifies the applications to launch when the client accesses the network. The default is none.

**application-launch-warning**  
Specifies whether the user is warned that an application is being launched. The default is true.

**auto-launch**  
Specifies whether NA resource is to be launched automatically from full webtop. The default is false.

**client-interface-speed**  
Specifies the baud rate of the client interface with the network. The default is 100000000.

**client-ip-filter-engine**  
Specifies whether the client IP address is filtered. The default is .

**client-power-management**  
Specifies how to interact with Windows power management features.

**prevent**  
Prevents Windows from entering standby/hibernate during connection.

**terminate**  
Terminate network access connection if Windows is entering standby/hibernate

**ignore**  
Do nothing. Ignore power management events. This is the default value.

**client-proxy**  
Specifies whether this resource handles a client proxy. The

default is false.

**client-proxy-address**  
Specifies the IP address of the proxy client. The default is any6.

**client-proxy-enforce-subnets**  
Specifies whether address space subnets must be enforced in proxy auto-configuration. The default is true.

**client-proxy-exclusion-list**  
Specifies the Web addresses that do not need to be accessed through your proxy server. You can use wild cards to match domain and host names or addresses, for example, www.\*.com, 128.\*, 240.8, 8., mygroup.\*, and \*.\*. The default is none.

**client-proxy-ignore-auto-config-error**  
Allow client to connect even after an error in merging or downloading a proxy auto-configuration file. The default is false.

**client-proxy-local-bypass**  
Specifies whether you want to allow local (intranet) addresses to bypass the proxy server. The default is false.

**client-proxy-port**  
Specifies the port number of the proxy server you want Network Access clients to use to connect to the Internet. The default is 0 (zero).

**client-proxy-script**  
Specifies the URL for a proxy auto-configuration script, if one is used with this connection. The default is none.

**client-proxy-use-http-pac**  
Specifies whether the browser uses http:// to locate the proxy the autoconfig file, instead of file://. Set this to true for applications, like Citrix MetaFrame, that cannot use the client proxy autoconfig script when the browser attempts to use the prefix file:// to locate the script. The default is false.

**client-proxy-use-local-proxy**  
Specifies whether the browser uses the proxy configured on client prior to establishing network access connection. The default is false.

**client-traffic-classifier**  
Specifies a client traffic classifier to use with this network access connection. The default is none.

**compression**  
Specifies whether you want to compress all traffic between the Network Access client and the controller. The default is none.

**customization-group**  
Specifies the customization group that defines the policies that apply to network access. This option is required.

**description**  
Specifies a unique description of the network access configuration object. The default is none.

**dns-primary**  
For split tunneling, specifies the IPv4 address of the primary name server that is conveyed to the remote access point for IPv4 traffic. The default is any6.

**ipv6-dns-primary**  
For split tunneling, specifies the IPv6 address of the primary name server that is conveyed to the remote access point for IPv6 traffic. The default is any6.

**dns-secondary**  
For split tunneling, specifies the IPv4 address of the secondary name server that is conveyed to the remote access point for IPv4 traffic. The default is any6.

**ipv6-dns-secondary**  
For split tunneling, specifies the IPv6 address of the secondary name server that is conveyed to the remote access point for IPv6 traffic. The default is any6.

**dns-suffix**  
Type in a DNS suffix to send to the client. If this field is left blank, the controller sends its own DNS suffix. You can specify multiple default domain suffixes separated with commas. The default is none.

**drive-mapping**  
For split tunneling, specifies the drive to which this resource provides a network access connection. The default is none.

**dtls** Specifies whether the network access connection uses Datagram Transport Level Security (DTLS). DTLS uses UDP instead of TCP, to provides better throughput for high demand applications like VoIP or streaming video, especially with lossy connections. The default is false.

**dtls-port**  
Specifies the port number that the network access resource uses for secure UDP traffic with DTLS. The default is 4433.

**execute-logoff-scripts**  
Specifies whether the system to executes logoff scripts (configured on the Active Directory domain) when the connection is terminated. The default is false.

#### idle-timeout-threshold

Defines the average byte rate that either ingress or egress tunnel traffic must exceed for the tunnel to update a session. If the average byte rate falls below the specified threshold, the system applies the inactivity timeout, which is defined in the session's Access Profile. The default is 0 (zero).

#### idle-timeout-window

Defines the value that the system uses to calculate the Exponential Moving Average (EMA) byte rate of ingress and egress tunnel traffic. The default is 0 (zero).

#### leasepool-name

Specifies the IPv4 lease pools that the user can access with this network access connection. The default is none.

#### ipv6-leasepool-name

Specifies the IPv6 lease pools that the user can access with this network access connection. The default is none.

#### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

#### microsoft-network-client

Specifies whether the client PC can access remote resources over a VPN connection. The default is true.

#### microsoft-network-server

Specifies whether the server can access remote resources over a VPN connection. The default is false.

#### network-tunnel

Enables or disables the network tunnel. The default is enabled.

#### optimized-app

Specifies the optimized applications that you want to users to access using this network access connection resource. You can add, delete, modify, or replace the current optimized applications. The default is none.

#### partition

Displays the partition within which this network access connection component resides. The default is Common.

#### provide-client-cert

Specifies whether client certificates are required to establish an SSL connection. You can set this option to false if the client certificates are only requested in an SSL connection. In this case, the client is configured to not send client certificates. The default is true.

#### proxy-arp

Select Enable to enable Proxy ARP for this network access resource. When you implement Proxy ARP for a network access resource, remote VPN tunnel clients can use IP addresses from the LAN IP subnet without additional network infrastructure changes. Ranges of IP addresses from the LAN subnet can be configured in the lease pools and assigned to tunnel clients. When a host on the LAN sends traffic to a tunnel client, an ARP query is sent to request the client address. Access Policy Manager then responds with its own MAC address. Traffic is then sent to network access and forwarded to the client over the network access tunnel. No configuration changes are required on devices other than the Access Policy Manager.

See your Network Access documentation for more information about Proxy ARP configuration. The default is false.

#### split-tunneling

Specifies whether only traffic targeted to a specified address space is sent over the network access tunnel. With split tunneling, all other traffic bypasses the tunnel. The default is false. When you set this option to true, all traffic passing over the network access connection uses this setting.

#### static-host

Specifies the static hosts to which this resource provides a network access connection. The default is none.

#### supported-ip-version

Specifies the supported IP protocol version. The default is ipv4.

#### sync-with-active-directory

Specifies whether you want the network access connection to emulate the Windows logon process for a client on an Active Directory domain. The default is false.

When this option is set to true, network policies are synchronized when the connection is established, or at logoff. The following items are synchronized:

- o Logon scripts are started as specified in the user profile.
- o Drives are mapped as specified in the user profile.
- o Group policies are synchronized as specified in the user profile. Group Policy logon scripts are started when the

connection is established, and Group Policy logoff scripts are run when the network access connection is stopped.

`type` Specifies the type of network access connection this component provides. The default is `network-access`.

`wins-primary`  
Specifies the primary IP address to which this resource provides a network access connection. The default is `any6`.

`wins-secondary`  
Specifies the secondary IP address to which this resource provides a network access connection. The default is `any6`.

## apm resource portal-access

NAME  
`portal-access` - Configures a portal access resource.

MODULE  
`apm resource`

SYNTAX  
Configure the `portal-access` component within the resource module using the syntax shown in the following sections.

```
CREATE/MODIFY
create portal-access [name]
modify portal-access [name]
options:
  acl-order [integer]
  application-uri [string] | none]
  app-service [[string] | none]
  css-patching [true | false]
  customization-group [string] | none]
  description [string] | none]
  flash-patching [true | false]
  host-replace-string [string] | none]
  host-search-strings [string] | none]
  html-patching [true | false]
  items [add | delete | modify | replace-all-with] {
    [string]
  }
  javascript-patching [true | false]
  location-specific [true | false]
  patching-type [full-patch | min-patch]
  path-match-case [true | false]
  proxy-host [string] | none]
  proxy-port [string] | none]
  publish-on-webtop [true | false]
  scheme-patching [true | false]

edit portal-access [ all-properties | non-default-properties ]
options:
  all-properties
  non-default-properties

DISPLAY
list portal-access
list portal-access [ [ [name] | [glob] | [regex] ] ... ]
show running-config portal-access
show running-config portal-access [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show portal-access
show portal-access [name]

DELETE
delete portal-access [name]
```

DESCRIPTION  
You can use the `portal-access` component to specify a portal access

resource.

#### EXAMPLES

```
item create portal-access myportalaccess acl-order 14 patching-  
type full-patch items add { item1 { host www.mywebsite.com paths  
/* }}
```

Creates a portal access resource named myportalaccess.

```
item delete portal-access myportalaccess
```

Deletes the portal access resource named myportalaccess.

#### OPTIONS

acl-order

Specifies the order of this portal access in Access Policy Manager ACL lists. This option is required.

application-uri

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

css-patching

Specifies whether the response content type CSS is patched. The default is true.

customization-group

The customization group is created automatically if not specified.

description

Specifies a description of the resource. The default is none.

flash-patching

Specifies whether the system patches Flash content. The default is true.

host-replace-string

Specifies the replacement host string, when you specify minimal for the patching-type option.

host-search-strings

Specifies the host string to replace, when you specify minimal for the patching-type option.

html-patching

Specifies whether the system patches HTML content. The default is true.

items

Configures the host name or IP address, the network mask (if the resource is a network), the port, and any paths specified for a portal access resource. The default is none.

javascript-patching

Specifies whether the system patches JavaScript content. The default is true.

location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]

Specifies a unique name for the component.

patching-type

Specifies whether this resource provides minimal or full path patching.

path-match-case

Specifies whether the application URI is case-sensitive. The default is true.

proxy-host

Specifies the proxy host that the portal access uses. The default is none. If you configure this option, you must also configure the option proxy-port.

proxy-port

Specifies the port that the portal access proxy uses. The default is none. Configure this option, only when you configure the option proxy-host.

publish-on-webtop

Specifies whether to publish this resource on the webtop. The default is false. If you set this option to true, you must also specify the Application URI using the application-uri option.

scheme-patching

Specifies whether this resource replaces all HTTP scheme addresses with HTTPS scheme addresses. This option is effective only when minimal patching is selected for patching-type. The default is false.

## apm resource remote-desktop citrix-client-bundle

### NAME

citrix-client-bundle - Configures a Citrix Client Bundle remote desktop resource configuration object.

### MODULE

apm resource remote-desktop

### SYNTAX

Configure the citrix-client-bundle component within the resource remote desktop module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create citrix-client-bundle [name]
```

```
modify citrix-client-bundle [name]
```

#### options:

```
app-service [[string] | none]
```

```
download-url [[url] | none]
```

```
packages [[string] | none]
```

```
windows-download-url [[url] | none]
```

```
windows-min-version [[string] | none]
```

```
windows-package [[string] | none]
```

```
edit citrix-client-bundle [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
```

```
non-default-properties
```

#### DISPLAY

```
list citrix-client-bundle
```

```
list citrix-client-bundle [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config citrix-client-bundle
```

```
show running-config citrix-client-bundle [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
```

```
non-default-properties
```

```
one-line
```

```
partition
```

```
show citrix-client-bundle
```

```
show citrix-client-bundle [name]
```

#### DELETE

```
delete citrix-client-bundle [name]
```

### DESCRIPTION

You can use the citrix-client-bundle component to configure a Citrix Client Bundle remote desktop resource.

### EXAMPLES

```
create citrix-client_bundle myccb { windows-min-version xp }
```

Creates a Citrix Client Bundle remote desktop resource named myccb that can be downloaded from receiver.citrix.com (the default value), where the client must have at least Windows XP installed.

### OPTIONS

#### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### download-url

Specifies the default location receiver.citrix.com from which to download the Citrix installation package.

#### packages

Specifies the location from which to download client installer package. The default is none.

#### [name]

Specifies an object name. This option is required; however, the parameter name is implicit and must not be typed in the syntax.

#### windows-download-url

Specifies the location from which to download the Windows version.

You can provide a value for either the windows-download-url or windows-package option, but not both. The default is none.

**windows-min-version**  
Specifies the oldest version of the Citrix client that can be used with this remote desktop resource. The default is none.

**windows-package**  
Specifies the location from which to download the Windows package. You can provide a value for either the windows-package or windows-download-url option, but not for both. The default is none.

SEE ALSO

## apm resource remote-desktop citrix-client-package-file

NAME

citrix-client-package-file - Configures a Citrix client package file configuration object.

MODULE

apm resource remote-desktop

SYNTAX

Configure the citrix-client-package-file component within the resource remote desktop module using the syntax shown in the following sections.

CREATE/MODIFY

```
create citrix-client-package-file [name]
modify citrix-client-package-file [name]
options:
  app-service [[string] | none]
  location-specific [true | false]
  original-file-name [[string] | none]
  source-path [[string] | none]
```

```
edit citrix-client-package-file [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list citrix-client-package-file
list citrix-client-package-file [ [name] | [glob] | [regex] ] ... ]
show running-config citrix-client-package-file
show running-config citrix-client-package-file [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete citrix-client-package-file [name]
```

DESCRIPTION

You can use the citrix-client-package-file component to configure access to a Citrix client package file.

EXAMPLES

```
create citrix-client-package myccpackage { source-path
www.siterequest.citrix_download.com }
Creates a Citrix client package remote desktop resource named
myccpackage that is available from
www.siterequest.citrix_download.com.
```

OPTIONS

[name]  
Specifies an object name. This option is required; however, the parameter name is implicit and must not be typed in the syntax.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**location-specific**

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

`original-file-name`

Specifies the original file name of the Citrix Installation package file name to download. The default is none.

`source-path`

Specifies the location from which to download the Citrix client package file. This option is required.

SEE ALSO

`citrix`, `citrix-client-bundle`, `rdp`

## apm resource remote-desktop citrix

NAME

`citrix` - Configures a Citrix remote desktop resource configuration object.

MODULE

`apm resource remote-desktop`

SYNTAX

Configure the `citrix` component within the resource remote desktop module using the syntax shown in the following sections.

CREATE/MODIFY

```
create citrix [name]
modify citrix [name]
options:
  app-service [[string] | none]
  auto-logon [enabled | disabled]
  customization-group [add | delete | modify | replace-all-with] {
    [name] {
      options:
        caption [[string] | none]
        detailed-description [[string] | none]
      }
    }
  description [[string] | none]
  domain-source [session.logon.last.domain | none]
  enable-serverside-ssl [enabled | disabled]
  pool [pool name]
  host [fqdn]
  ip [ip address]
  location-specific [true | false]
  password-source [session.logon.last.password | none]
  port [[string] | none]
  username-source [session.logon.last.username | none]
```

```
edit citrix [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list citrix
list citrix [ [ [name] | [glob] | [regex] ] ... ]
show running-config citrix
show running-config citrix [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
show citrix
show citrix [name]
```

DELETE

```
delete citrix [name]
```

DESCRIPTION

You can use the B component to configure a Citrix remote desktop resource.

EXAMPLES

```
create citrix mycitrix { ip 172.29.67.130 }
Creates a Citrix remote desktop resource named mycitrix with
Citrix XML Broker server specified as IP address 172.29.67.130.
```

```
create citrix mycitrix { host mycitrix.mycompany.com auto-logon enabled
}
Creates a Citrix resource with Citrix XML Broker server specified
as hostname mycitrix.mycompany.com and auto-logon enabled with APM
credentials (that user types on Logon Page).
```

```
create citrix mycitrix { pool /Common/mycitrix-pool enable-serverside-
ssl enabled }
Creates a Citrix resource with Citrix XML Broker server(s)
specified in pool named /Common/mycitrix-pool and SSL
communication enabled to the server(s) (SSL should also be enabled
on the servers and APM virtual should have serverssl profile).
```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**auto-logon**  
Enables or disables automatic log on to the Citrix server. If you enable this option, you must also provide values for the username-source, password-source, and domain-source options. The default is disabled.

**customization-group**  
Specifies whether customization groups are applied to the Citrix remote desktop. You can add, modify, or delete customization groups. You can also replace all current customization groups with new customization groups. The default is none.

**description**  
Specifies a description for your Citrix remote desktop. The default is none.

**domain-source**  
Specifies the Session variable used as a source for the auto-logon user password. The default is session.logon.last.domain.

**enable-serverside-ssl**  
Enables or disables SSL capabilities between the BIG-IP system and the Citrix server. When enabled, the port number automatically changes to 443. The default is disabled.

**pool** Specifies the pool name that contains your Citrix XML Broker server(s). You must use one of these options to specify the server address: pool, host, or ip.

**host** Specifies the hostname of your Citrix XML Broker server. You must use one of these options to specify the server address: pool, host, or ip.

**ip** Specifies the IP address of your Citrix XML Broker server. You must use one of these options to specify the server address: pool, host, or ip.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies an object name. This option is required; however, the parameter name is implicit and must not be typed in the syntax.

**password-source**  
Specifies the session variable that is used as a source for the auto-logon password. The default is session.logon.last.password.

**port** Specifies the port for your Citrix server. The default is 80.

**username-source**  
Specifies the session variable that is used as a source for the auto-logon user name. The default is session.logon.last.username.

## apm resource remote-desktop quest

### NAME

quest - Configures a Quest vWorkspace remote desktop resource configuration object.

### MODULE

apm resource remote-desktop

### SYNTAX

Configure the quest component within the resource remote desktop module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create quest [name]
modify quest [name]
options:
  app-service [[string] | none]
  auto-logon [enabled | disabled]
  customization-group [add | delete | modify | replace-all-with] {
    [name] {
      options:
        caption [[string] | none]
        detailed-description [[string] | none]
      }
    }
  description [[string] | none]
  domain-source [session.logon.last.domain | none]
  enable-serverside-ssl [enabled | disabled]
  pool [pool name]
  host [fqdn]
  ip [ip address]
  location-specific [true | false]
  password-source [session.logon.last.password | none]
  port [[string] | none]
  username-source [session.logon.last.username | none]
```

```
edit quest [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list quest
list quest [ [name] | [glob] | [regex] ] ... ]
show running-config quest
show running-config quest [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

show quest
show quest [name]
```

#### DELETE

```
delete quest [name]
```

### DESCRIPTION

You can use the B component to configure a Quest vWorkspace remote desktop resource.

### EXAMPLES

```
create quest myquest { ip 172.29.67.130 }
Creates a Quest vWorkspace remote desktop resource named myquest
with the Quest vWorkspace connection broker server specified as IP
address 172.29.67.130.
```

```
create quest myquest { host myquest.mycompany.com auto-logon enabled }
Creates a Quest vWorkspace resource with the Quest vWorkspace
connection broker server specified as hostname
myquest.mycompany.com and with auto-logon enabled using the
credentials that the user types into the access policy Logon Page.
```

```
create quest myquest { pool /Common/myquest-pool enable-serverside-ssl
enabled }
Creates a Quest vWorkspace resource with the Quest vWorkspace
connection broker servers specified in a pool named
/Common/myquest-pool and with SSL communication enabled to the
servers. Note: SSL should also be enabled on the servers
themselves and the APM virtual server should specify a server SSL
profile.
```

### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**auto-logon**  
Enables or disables automatic log on to the Quest vWorkspace connection broker server. If you enable this option, you must also provide values for the username-source, password-source, and domain-source options. The default is disabled.

**customization-group**

Specifies whether customization groups are applied to the Quest vWorkspace resource. You can add, modify, or delete customization groups. You can also replace all current customization groups with new customization groups. The default is none.

**description**

Specifies a description for your Quest vWorkspace remote desktop. The default is none.

**domain-source**

Specifies the session variable to use as a source for the auto-logon user password. The default is session.logon.last.domain.

**enable-serverside-ssl**

Enables or disables SSL capabilities between the BIG-IP system and the Quest vWorkspace connection broker server. When enabled, the port number automatically changes to 443. The default is disabled.

**pool** Specifies the pool name that contains your Quest vWorkspace connection broker servers. (You must specify the server address using one of these options: pool, host, or ip.)

**host** Specifies the hostname of your Quest vWorkspace connection broker server. (You must specify the server address using one of these options: pool, host, or ip.)

**ip** Specifies the IP address of your Quest vWorkspace connection broker server. (You must specify the server address using one of these options: pool, host, or ip.)

**location-specific**

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**

Specifies an object name. This option is required. Note: The parameter name is implicit. Do not type name in the syntax.

**password-source**

Specifies the session variable to use as a source for the auto-logon password. The default is session.logon.last.password.

**port** Specifies the port for your Quest vWorkspace connection broker server. The default is 8080.

**username-source**

Specifies the session variable to use as a source for the auto-logon user name. The default is session.logon.last.username.

**SEE ALSO**

show rdp [name]

  DELETE
delete rdp [name]

DESCRIPTION
  You can use the rdp component to configure an MSRDP resource.

EXAMPLES
  create rdp myrdp { host 172.29.67.130 }
  Creates a MSRDP remote desktop resource named myrdp with an MSRDP
  server with an IP address of 172.29.67.130.

  create rdp myrdp { host 172.29.67.130 rdp-cache-bitmaps true }
  Creates a MSRDP remote desktop resource named myrdp with an MSRDP
  server with an IP address of 172.29.67.130 where bitmaps are
  cached on the client PC.

OPTIONS
  acl-order
  Specifies the order in which you want the RDP server to appear in
  the ACL Order list. The default is 0 (zero).

  application
  Specifies the executable name of the application, for example
  notepad.exe. You can include the full path to the application, for
  example "C:\my\mybinary.exe".

  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  auto-logon
  Specifies if automatic log on to the Microsoft RDP server is used.
  If you enable this option, you must also provide values for the
  username-source, password-source, and domain-source options. The
  default is disabled.

  color-depth
  Specifies the requested remote session color depth. The default is
  32. The options are:

  24-bit
  16-bit
  8-bit
  4-bit
  customization-group
  Specifies whether customization-groups are applied to the remote
  desktop. You can add, modify, delete, or replace all
  customization-groups. The default is none.

  description

```

Specifies a description of an MSRDp resource. The default is none.

`domain-source`

Specifies the session variable used as a source for the auto-logon user password. The default is `session.logon.last.domain`.

`host` Specifies the hostname of your Microsoft RDP server. Either the host or ip option is required; however, you cannot specify both options.

`ip` Specifies the IP address of your Microsoft RDP server. Either the host or ip option is required; however, you cannot specify both options.

`java-client`

Specifies whether to use Java RDP client to launch this resource. The default is disabled.

`native-client`

Specifies whether to use native RDP client to launch this resource. The default is disabled. `java-client` and `native-client` can't be enabled at the same time. When both `java-client` and `native-client` are disabled, RDP resource is launched using ActiveX control.

`location-specific`

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

`log` Specifies the log format. The default is none. The options are:

`config`

`none` The system does not log packets sent to and from the Microsoft RDP server.

`packet`

The system logs packets sent to and from the Microsoft DP server.

`summary`

The system provides a short summary of the communications between the BIG-IP system and the Microsoft RDP server.

`verbose`

The system provides an extensive summary of the communications between the BIG-IP system and the Microsoft RDP server.

`[name]`

Specifies an object name. This option is required; however, the parameter name is implicit and must not be typed in the syntax.

`password-source`

Specifies the session variable used as a source for the auto-logon password. The default is `session.logon.last.password`.

`port` Specify port 3389 for your Microsoft RDP server. The default is 0 (zero).

`rdp-cache-bitmaps`

Specifies whether to cache bitmap files on the client. The default is true.

`rdp-show-contents-while-dragging`

Specifies whether to show the contents of a window when the user is dragging the window. The default is false.

`rdp-show-desktop-wallpaper`

Specifies whether to display the desktop background. The default is false.

`rdp-show-themes`

Specifies whether to display the desktop theme. The default is false.

`rdp-window-animations`

Specifies whether to display Window animations. The default is false.

`redirect-com-ports`

Specifies whether to connect to your communication ports. The default is false.

`redirect-drives`

Specifies whether to connect to your local drives. The default is false.

`redirect-keyboard-commands`

Specifies when to redirect keyboard commands to a remote session. When enabled, commands such as Alt-tab and Ctrl-Alt-Del are available in remote sessions. The default is `in-full-screen`. The options are:

`enable`

The keyboard commands for the remote desktop are available to the user.

`disable`

The keyboard commands for the remote desktop are not

available to the user.

#### in-full-screen

The keyboard commands for the remote desktop are available to the user only when the value of the window-size option is full-screen.

#### redirect-printers

Enables or disables connection to a local printer. The default is disabled.

#### redirect-sound

Enables or disables sounds playing in a remote session. The default is disabled.

#### username-source

Specifies the session variable used as a source for the auto-logon user name. The default is session.logon.last.username.

#### window-height

Specifies the height, in pixels, of the remote desktop window. Set this option only when you set the value of the window-size option to custom. The default is 600 pixels.

#### window-percent-of-desktop

Specifies the width and height of the remote session window as a percentage of the user's desktop.

#### window-size

Specifies the type of window sizing to use on the client desktop. The default is custom-size.

The options are:

#### full-screen

The remote desktop window fills the entire screen.

#### percent-of-desktop

The value you configure represents a percentage of the screen that the remote desktop fills.

#### custom

When you use this option, you must also set the window-height and window-width options.

#### seamless

##### window-width

Specifies the width, in pixels, of the remote desktop window. The default is 800 pixels.

#### workdir

Specifies the directory you want the user to access on the target server. The default is none.

DELETE
delete vmware-view [name]

DESCRIPTION
You can use the B component to configure a VMware View remote desktop resource.

EXAMPLES
  create vmware-view myview { ip 172.29.67.130 }
  Creates a VMware View remote desktop resource named myview with
  the VMware View Connection server specified as IP address
  172.29.67.130.

  create vmware-view myview { host myview.mycompany.com auto-logon
  enabled }
  Creates a VMware View resource with the VMware View Connection
  server specified as hostname myview.mycompany.com and auto-logon
  enabled with APM credentials (that user types on Logon Page).

  create vmware-view mview { pool /Common/myview-pool enable-serverside-
  ssl enabled }
  Creates a VMware View resource with the VMware View Connection
  server(s) specified in pool named /Common/myview-pool and SSL
  communication enabled to the server(s) (SSL should also be enabled
  on the servers and APM virtual should have serverssl profile).

OPTIONS
  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  auto-logon
  Enables or disables automatic log on to the VMware View Connection
  Server server. If you enable this option, you must also provide
  values for the username-source, password-source, and domain-source
  options. The default is disabled.

  customization-group
  Specifies whether customization groups are applied to the VMware
  View resource. You can add, modify, or delete customization
  groups. You can also replace all current customization groups with
  new customization groups. The default is none.

  description
  Specifies a description for your VMware View remote desktop. The
  default is none.

  domain-source
  Specifies the Session variable used as a source for the auto-logon
  user password. The default is session.logon.last.domain.

  enable-serverside-ssl
  Enables or disables SSL capabilities between the BIG-IP system and
  the VMware View Connection server. When enabled, the port number
  automatically changes to 443. The default is disabled.

  pool Specifies the pool name that contains your VMware View Connection
  server(s). You must use one of these options to specify the server
  address: pool, host, or ip.

  host Specifies the hostname of your VMware View Connection server. You
  must use one of these options to specify the server address: pool,
  host, or ip.

  ip Specifies the IP address of your VMware View Connection server.
  You must use one of these options to specify the server address:
  pool, host, or ip.

  location-specific
  Specifies whether or not this object contains one or more

```

attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]

Specifies an object name. This option is required; however, the parameter name is implicit and must not be typed in the syntax.

password-source

Specifies the session variable that is used as a source for the auto-logon password. The default is session.logon.last.password.

port Specifies the port for your VMware View Connection server. The default is 80.

username-source

Specifies the session variable that is used as a source for the auto-logon user name. The default is session.logon.last.username.

## apm resource sandbox

NAME

sandbox - Configures a sandbox.

MODULE

apm resource

SYNTAX

Configure the sandbox component within the resource module using the syntax shown in the following sections.

CREATE

The CREATE command is currently not available. However, a number of sandboxes have already been created. Use these to upload files.

MODIFY

```
modify sandbox [name]
options
  base-uri [string]
  description [[string] | none]
  files [add | delete | modify | replace-all-with] {
    [item name] {
      content-type [string]
      filename [string]
      file-type [citrix-bundle | customization | unknown]
      folder [string]
      local-path [string]
      name [string]
    }
  }
}
```

DISPLAY

```
list sandbox
list sandbox [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DESCRIPTION

Configures a sandbox and its files. A sandbox is a container for files stored on the BIG-IP, to which you want to provide client access.

EXAMPLES

```
modify sandbox hosted-content files add { BIGIPEdgeClient.exe { folder
/client local-path /tmp/BIGIPEdgeClient.exe } }
```

Adds a file called BIGIPEdgeClient.exe to sandbox named hosted-content. The virtual path to this file consists of the sandbox's base-uri, the file's folder, and the name of the file. Putting these components together, the virtual path for the uploaded file is /public/share/client/BIGIPEdgeClient.exe, where /public/share is the base-uri, /client is the folder, and BIGIPEdgeClient.exe is the

filename. The local-path indicates the location of the file on the disk drive to be added into the sandbox.

Note: The file you add must already be on the BIG-IP system.

#### OPTIONS

##### base-uri

Specifies the first component of the virtual path to the sandbox file. The base-uri for sandbox "hosted-content" is /public/share. The virtual path to a sandbox box file is made up of three components: base-uri/folder/filename

All files in a sandbox share the same base-uri, but the folder can be different for each file.

##### description

Specifies a unique description about the sandbox.

##### files

Specifies the list of files in the sandbox.

##### item name

Specifies the name of an item in the list of files. You can use the original filename as the item name. Each item name in a sandbox must be unique.

##### content-type

Specifies the content-type field in a HTTP header such as "image/gif" or "text/plain". If none is provided, tmsh will try its best to provide this value.

##### filename

Specifies the last component of the virtual path to the sandbox file. We recommend that you use the filename of the original file for this name.

##### file-type

Specifies the F5 file type. Currently there are only three types: unknown, citrix-bundle, and customization. No value is required if a file is uploaded to sandbox for "citrix-client-bundle", since this sandbox is the repositories for F5 specific type of file. However, for files uploaded to sandbox "hosted-content" if no value is provided, the file type defaults to "unknown".

##### folder

Specifies the second component of the virtual path to the sandbox file.

##### local-path

Specifies the location of the file to be inserted into the sandbox. This file must be on the BIG-IP already.

name Specifies a value for the underlying file object. Use this only if you are trying to add more than one sandbox file in a modify command. Otherwise, don't specify a value for this attribute. The value must be specified as follows: full path of sandbox name:item name. For example, if the sandbox name is '/Common/hosted-content' and the item name is 'index.html', the value should be '/Common/hosted-content:index.html'.

## apm resource webtop-link

#### NAME

webtop-link - Configures a webtop link resource.

#### MODULE

apm resource

#### SYNTAX

Configure the webtop-link component within the resource module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create webtop-link [name]
modify webtop-link [name]
options:
```

```

    application-uri [string]
    app-service [[string] | none]
    customization-group [string]
    description [[string] | none]
    location-specific [true | false]

edit webtop-link [ [ [name] | [glob] | [regex] ] ... ]
options:
    all

DISPLAY
list webtop-link
list webtop-link [ [ [name] | [glob] | [regex] ] ... ]
show running-config webtop-link
show running-config webtop-link [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line

show webtop-link
show webtop-link [name]

DELETE
delete webtop-link [name]

DESCRIPTION
    Configures the settings necessary to define a link to a webtop that is
    displayed to the end-user as part of the access policy execution.

EXAMPLES
    create webtop-link mywebtoplinkcgl application-uri
    "http://www.externalsite.com/"
    Creates a webtop named mywebtoplinkcgl with the application-uri of
    http://www.externalsite.com/.

OPTIONS
    application-uri
    Specifies the application URI of the external portal to which this
    resource provides access for this webtop link. This is a required
    setting.

    app-service
    Specifies the name of the application service to which the object
    belongs. The default value is none. Note: If the strict-updates
    option is enabled on the application service that owns the object,
    you cannot modify or delete the object. Only the application
    service can modify or delete the object.

    customization-group
    Specifies the customization settings for the webtop.

    Note: You must create a customization group of type webtop before
    you can create a webtop resource. If you do not specify a
    customization group, a group will be created automatically.

    description
    Specifies a description of the resource. The default is none.

    location-specific
    Specifies whether or not this object contains one or more
    attributes with values that are specific to the location where the
    BIG-IP device resides. The location-specific attribute is either
    true or false. When using policy sync, mark an object as location-
    specific to prevent errors that can occur when policies reference
    objects, such as authentication servers, that are specific to a
    certain location.

  non-default-properties

DISPLAY
list webtop
list webtop [ [ [name] | [glob] | [regex] ] ... ]
show running-config webtop
show running-config webtop [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

show webtop
show webtop [name]

DELETE
delete webtop [name]

DESCRIPTION
  Configures the settings necessary to define the webtop assigned to the
  end-user as part of the access policy execution.

EXAMPLES
  create webtop mynawebtop { customization-group mywebtopcgl minimize-to-
  tray false }
  Creates a webtop named mynawebtop with the customization group
  mywebtopcgl and the network access minimize-to-tray option set to
  false.

  create webtop mywawebtop { customization-group mywebtopcgl portal-
  access-start-uri "http://www.siterequest.com" }
  Creates a webtop named mywawebtop with the customization group
  mywebtopcgl and the starting URI for the portal access of
  http://www.siterequest.com.

OPTIONS
  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  customization-group
  Specifies the customization settings for the webtop.

  Note: You must create a customization group of type webtop before
  you can create a webtop resource. This option is required.

  description
  Specifies a description of the resource. The default is none.

  portal-access-start-uri
  Specifies the URI that the webtop starts. You can only configure
  this option if you have configured the webtop-type option for
  portal-access.

  location-specific
  Specifies whether or not this object contains one or more
  attributes with values that are specific to the location where the
  BIG-IP device resides. The location-specific attribute is either
  true or false. When using policy sync, mark an object as location-
  specific to prevent errors that can occur when policies reference
  objects, such as authentication servers, that are specific to a
  certain location.

  minimize-to-tray
  Specifies whether the network access window (launched from the
  full webtop) is minimized to the system tray automatically after
  the network access connection starts. The default is true.

  You can configure this option only if you configured the webtop-
  type option as network-access or full. With a network access
  webtop, the webtop automatically minimizes to the tray. With a
  full webtop, the webtop minimizes to the system tray only after
  the network access connection is started.

  warn-when-closed
  Specifies whether the network access window (launched from the
  full webtop) should display a warning message when the webtop
  closes.

  You can configure this option only if you configured the webtop-
  type option as full.
```

webtop-type  
Specifies the type of webtop this resource creates. The options are:

full A webtop to which you assign a single network access resource, multiple portal access resources, and multiple application access app tunnel resources, or any combination of the three types. This is the default.

last  
network-access  
A webtop to which you assign only a single network access resource.

portal-access  
A webtop to which you assign only portal access resources.

## apm saml artifact-resolution-service

NAME  
artifact-resolution-service - Specify service used to resolve SAML artifacts

MODULE  
apm saml

SYNTAX  
Configure the artifact-resolution-service component within the saml module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create artifact-resolution-service [name]
modify artifact-resolution-service [name]
options:
  app-service [[string] | none]
  artifact-resolution-service-host [[string] | none]
  artifact-resolution-service-port [integer]
  artifact-send-method [http-post | http-redirect]
  artifact-validity [integer]
  basic-auth-password [[string] | none]
  basic-auth-username [[string] | none]
  description [[string] | none]
  location-specific [ true | false ]
  virtual-server-name [name]
  want-artifact-resolution-rq-signed [true | false]
```

```
edit artifact-resolution-service [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

### DISPLAY

```
list artifact-resolution-service
list artifact-resolution-service [ [ [name] | [glob] | [regex] ] ... ]
show running-config artifact-resolution-service
show running-config artifact-resolution-service [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete artifact-resolution-service [name]
```

### DESCRIPTION

You can use the artifact-resolution-service to create and manage artifact resolution services.

### EXAMPLES

```
create artifact-resolution-service my_ars {virtual-server-name my_virt}
Creates a SAML artifact resolution service named my_ars. In this example, the virtual server my_virt will be used to receive artifact resolve requests and send artifact responses.
```

```
create artifact-resolution-service my_ars1 {virtual-server-name
```

```
my_virt1 artifact-resolution-service-host bigip.mycompany.com basic-  
auth-username user basic-auth-password password artifact-send-method  
http-redirect }
```

Creates a SAML artifact resolution service named `my_ars1`. The service requires that artifact resolve requests be sent using the `http-redirect` method with an authorization header that contains the specified credentials.

```
list artifact-resolution-service  
Displays a list of artifact resolution services.
```

```
delete artifact-resolution-service my_ars  
Deletes the my_ars artifact resolution service.
```

#### OPTIONS

```
app-service  
Specifies the name of the application service to which the object  
belongs. The default value is none. Note: If the strict-updates  
option is enabled on the application service that owns the object,  
you cannot modify or delete the object. Only the application  
service can modify or delete the object.
```

```
artifact-resolution-service-host  
Specifies the hostname of the artifact resolution service.
```

```
artifact-resolution-service-port  
Specifies the port that artifact resolution service will be  
listening on.
```

```
artifact-send-method  
Specifies method resolver will use when sending artifact resolve  
requests. Default value is http-redirect.
```

```
artifact-validity  
Specifies in seconds how long an artifact remains valid. Default  
value is 60 seconds.
```

```
basic-auth-password  
Specifies the basic authentication password to send with an  
artifact resolve request to this BIG-IP.
```

```
basic-auth-username  
Specifies the basic authentication username to send with an  
artifact resolve request to this BIG-IP.
```

```
description  
Specifies a unique description for the artifact resolution  
service. Default is none.
```

```
location-specific  
Objects of this class might have location-specific attributes. If  
the object is location-specific, set to true.
```

```
virtual-server-name  
Specifies the virtual server to be used by the artifact resolution  
service.
```

```
want-artifact-resolution-rq-signed  
Specifies whether this BIG-IP requires artifact resolution  
requests to be signed. Default value is true.
```

## apm saml auth-context-class-list

**NAME**  
auth-context-class-list - Configure a list of SAML authentication context classes.

**MODULE**  
apm saml

**SYNTAX**  
Configure the `auth-context-class-list` component within the `saml` module using the syntax shown in the following sections.

```
MODIFY  
create auth-context-class-list [name]  
modify auth-context-class-list [name]  
options:  
  app-service [[string] | none]
```

```

classes [add | delete | modify | none | replace-all-with] {
    name [string] {
    order [integer]
    value [string]j
    }
}
description [[string] | none]

edit auth-context-class-list [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list auth-context-class-list
list auth-context-class-list [ [ [name] | [glob] | [regex] ] ... ]
show running-config auth-context-class-list
show running-config auth-context-class-list [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    app-service
    non-default-properties
    one-line
    partition

DELETE
delete auth-context-class-list [name]

```

#### DESCRIPTION

You can use the `auth-context-class-list` to create and manage lists of SAML authentication context classes. Each class in the list must contain a unique order and a unique value. Order indicates the relative level of security ranging from 1 (least secure) to 255 (most secure).

#### EXAMPLES

```

create sp_authn_ctx_classes_list classes add { password { order 1 value
urn:oasis:names:tc:SAML:2.0:ac:classes:Password} kerberos { order 2
value urn:oasis:names:tc:SAML:2.0:ac:classes:Kerberos } }
Creates a new list named 'sp_authn_ctx_classes_list' with two
authentication context classes: password and kerberos. Higher
order number implies higher security associated with class. In
this example, the fact that the kerberos class order is 2 implies
that it has higher security than the password class with order 1.

```

```

modify authentication_contexts_list classes add { SmartcardPKI { order
8 value urn:oasis:names:tc:SAML:2.0:ac:classes:SmartcardPKI } }
Modifies default list of authentication context classes to include
a class 'SmartcardPKI' with priority order '8' and value
'urn:oasis:names:tc:SAML:2.0:ac:classes:SmartcardPKI'.

```

```

modify authentication_contexts_list classes delete { smartcard }
Removes authentication context class 'smartcard' from the default
list of authentication context classes
'authentication_contexts_list'.

```

```

list auth-context-class-list
Displays default list of authentication context classes.

```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**classes**  
Specifies a list of authentication context classes. Properties 'order' and 'value' must be unique within the `auth-context-class-list` object. Property 'order' specifies the security of the class in the context of the BIG-IP system; order ranges from the least secure '1' to the most secure '255'. Property 'value' specifies a URL of authentication context class, for example, 'urn:oasis:names:tc:SAML:2.0:ac:classes:Kerberos'.

**description**  
Specifies a unique description for the list of authentication context classes.

## apm sso basic

**NAME**  
 basic - Configures a single sign-on HTTP basic authentication configuration object.

**MODULE**  
 apm sso

**SYNTAX**  
 Configure the basic component within the sso module using the syntax shown in the following sections.

**CREATE/MODIFY**  
 create basic [name]  
 modify basic [name]  
 options:  
 apm-log-config [[string] | none]  
 app-service [[string] | none]  
 headers [add | delete | modify | | replace-all-with] {  
 location-specific [true | false]  
 [name] {  
 options:  
 app-service [[string] | none]  
 hname [[URL] | none]  
 hvalue [[integer] | none]  
 }  
 }  
 password-source [session.sso.token.last.password | none]  
 username-conversion [enabled | disabled]  
 username-source [session.sso.token.last.username | none]

edit basic [ [ [name] | [glob] | [regex] ] ... ]  
 options:  
 all-properties  
 non-default-properties

**DISPLAY**  
 list basic  
 list basic [ [ [name] | [glob] | [regex] ] ... ]

```
show running-config basic
show running-config basic [ [ [name] | [glob] |
    [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show basic
show basic [name]
```

```
DELETE
delete basic [name]
```

#### DESCRIPTION

You can use the basic component to create, modify, display, or delete an SSO HTTP basic authentication configuration object.

#### EXAMPLES

```
create basic mybasic
```

Creates an SSO basic configuration object named mybasic.

#### OPTIONS

apm-log-config

Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

headers

Specifies the name and value of the HTTP header content to be inserted in an HTTP Request that passes through the APM SSO module. The default is none. The options are:

app-service

Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

hname

The name of the HTTP header.

hvalue

The value of the HTTP header.

location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]

Specifies a name for the SSO configuration. This option is required.

partition

Displays the partition in which the object resides.

oam-server

Specifies the name of your Oracle Access Manager server. The default value is none.

password source

Specifies the source from which you want SSO to retrieve the password to use to authenticate applications.

username-conversion

Enables or disables conversion of PREWIN2k/UPN username input format to the format for SSO to use. The default value is disabled.

username-source

Specifies the source from which you want SSO to retrieve the username to use to authenticate applications.

options:  
  all-properties  
  non-default-properties

**DISPLAY**  
list form-based  
list form-based [ [ [name] | [glob] | [regex] ] ... ]  
show running-config form-based  
show running-config form-based [ [ [name] | [glob] |  
  [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  one-line  
  partition

show form-based  
show form-based [name]

**DELETE**  
delete form-based [name]

**DESCRIPTION**  
You can use the form-based component to configure an SSO form-based configuration object.

**EXAMPLES**  
create form-based fb\_2011\_sso { start-uri  
  "/fb/auth/logon.aspxurl=https://exch2011.mvl.fp.com/fp/&reason=0"  
  form-action "/fp/auth/fpauth.dll" form-username "username" form-  
  password "password" form-field "destination  
  https://exch2011.mvl.fp.com/fp/" }

Creates an SSO form-based configuration object named fb\_2011\_sso.

**OPTIONS**

**apm-log-config**  
Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**external-access-management**  
**form-action**  
Specifies the form action URL that is used for HTTP form-based authentication. This is optional. If you do not specify a form action, then Access Policy Manager uses the URI from the request to perform HTTP form-based authentication. The default is none.

**form-field**

Specifies the hidden form parameters that are required by the authentication server logon form at your location. The default is none. Specify a parameter name, a space, and the parameter value, if any. Multiple parameters can be configured with each "name value" pair in one line. Use edit to add multiple parameters. Please note that create and modify do not allow using new line on the terminal.

**form-method**

Specifies the form method to use for form-based HTTP authentication. The value is either get or post. The default is post.

If you specify get, Access Policy Manager forces the authentication using HTTP GET rather than authenticating using form-based POST.

**form-password**

Specifies the parameter names used by the form that is sent the POST request.

**form-username**

Specifies the parameter names used by the form that is sent the POST request.

**headers**

Specifies the name and value of the HTTP header content to be inserted in an HTTP Request that passes through the APM SSO module. The default is none.

The options are:

**app-service**

Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

**hname**

Specifies the name of the HTTP header.

**hvalue**

Specifies the value of the HTTP header.

**[name]**

Specifies a name for the component.

**password-source**

Specifies the password you want cached for single sign-on.

The default is session.sso.token.last.password.

**start-uri**

Specifies a URL resource. For example, for FB, it would be /fb/auth/logon.aspx\*. For Citrix, /Citrix/XenApp/auth/logon.aspx. This resource must respond with a challenge to a non-authenticated request.

The default is none.

**success-match-type**

Specifies the method your authentication server uses. If you specify a value for this option, you must also specify a value for success-match-value. The default is none. The options are:

**url** One or more URLs. The system supports only the wildcard character (\*).

**cookie**

A cookie name.

**success-match-value**

Specifies the value used to specify either the URL(s) or cookie for the success-match-type option. The default is none.

**username-source**

Specify the username you want cached for single sign-on. The default is session.sso.token.last.username.

**SEE ALSO**

basic, kerberos, ntlmv1, ntlmv2

**COPYRIGHT**

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

DELETE  
delete form-basedv2 [name]

#### DESCRIPTION

You can use the form-basedv2 component to configure an SSO form-basedv2 configuration object. When creating a new SSO form-based v2 configuration object, you must add at least one forms item and within it at least one controls item. You must also provide a value for the request-value option in the forms item.

The SSOv2 module identifies and processes two types of application HTTP requests - logon page requests and credentials submit requests. Logon page requests are identified using the request- set of options. Credentials submit requests, in most cases, are identified automatically. When this fails, you can set the submit-autodetect option to false and use the submit- set of options to identify these requests.

When the SSOv2 module identifies a logon page request, it scans the response trying to find the logon form. If the logon form is found, SSOv2 inserts a JavaScript code that will cause the logon form to be submitted automatically by the browser. The client must support JavaScript.

When the SSOv2 module identifies a credentials submit request, it compares POST data parameter names with form controls defined in the configuration. For a POST data parameter name that has a corresponding form control, the SSOv2 module replaces its value with the control value from the configuration. Control values are usually supplied through session variables, such as session.sso.token.last.username and session.sso.token.last.password. POST data parameters that have no corresponding controls in the configuration are not changed.

The majority of web applications have a single logon page with one logon form. You will need to define a single forms item for these applications. In rare cases when an application has multiple logon pages with different logon forms, you will need to create multiple forms items, one for each logon page/form. If multiple logon pages use the same form, you will need only one forms item with a list of URIs for all logon pages.

Every forms item must include at least one controls item, and can include up to 32 controls items. Each controls item represents an input element of an HTML logon form, such as form fields for entering username and password, and, optionally, any hidden form parameters. The name of the controls item must match the name attribute of the corresponding input tag of the form. For example, if the form has the following HTML tag for entering the username:

the forms item must include a controls item with the name Bugzilla login. The controls item used for entering the user's password must have the secure option set to true. The value of a control item should usually be the name of a session variable, starting with the percent (%) sign and enclosed in curly braces ({}); for example, the value for the username control item: `{session.sso.token.last.username}`. The value can also be a string, or a combination of strings and session variable names.

#### EXAMPLES

```
create form-basedv2 fbssov2-owa2010 { forms add { owa2010 { controls
add { password { secure true value %{session.sso.token.last.password}
} username { value %{session.sso.token.last.username} } } request-
value /owa/auth/logon.aspx?replaceCurrent=1 submit-javascript clkLgn()
submit-javascript-type extra success-match-type cookie success-match-
value sessionid } } }
```

Creates an SSO form-basedv2 configuration object named fbssov2-owa2010.

```
delete fbssov2-owa2010
```

Deletes an SSO form-basedv2 configuration object named fbssov2-owa2010.

#### OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

forms

Specifies one or more items, each defining SSO processing of a separate application logon form.

[name]

Specifies the name of the form item. It does not have to match the actual name of the HTML form and can be arbitrary.

The options are:

app-service

Specifies the name of the application service to which the form item belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the form item. Only the application service can modify or delete the form item.

attribute-value

Specifies the value of the HTML tag attribute used to identify the logon form. The attribute could be id, name, or

action, and is specified by the id-type option. For other values of the id-type option, this is not used and should be set to none.

#### controls

Specifies one or more form control items (up to 32) that you want to be processed by SSOv2.

#### [name]

Specifies the name of the HTML form control item. It must match the name attribute value of the HTML form's input tag.

The options are:

#### app-service

Specifies the name of the application service to which the control item belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the control item. Only the application service can modify or delete the control item.

#### secure

Specifies whether the control item represents the HTML input tag of type "password". The default is false.

#### value

Specifies the value of the control item. This is usually the name of a session variable. If the session variable is not found when the SSO request is processed, the value of the corresponding POST parameter will be empty. The value could also be a literal string or a combination of strings and session variable names.

#### description

User-defined description.

#### form-order

Specifies the order of the HTML logon form on the logon page when the id-type option is set to order. Starts with 1.

#### id-type

Specifies how the HTML logon form is found in the HTML body of the logon page. If there is more than one form on the logon page matching the criteria, the first match is used. The default is inputs.

The options are:

#### action

The logon form is identified by the value of the tag in the action attribute. The value is specified in the attribute-value option.

id The logon form is identified by the id attribute's value of the tag. The value is specified in the attribute-value option.

name The logon form is identified by the name attribute's value of the tag. The value is specified in the attribute-value option.

#### order

The logon form is identified by its relative order on the logon page (starting from 1). The order is specified in the form-order option.

#### inputs

The logon form is identified by a combination of controls items. The controls in the configuration must have corresponding  elements in the form.

#### request-method

Specifies the HTTP method of the application's request returning logon page. Default is get.

#### request-name

Specifies the name of the HTTP cookie or the name of the HTTP header used to identify application's request for logon page. The cookie or header is selected by the request-type option. The value of the cookie or header is specified by the request-value option. When the request-type option is set to uri, this option is not used and should be set to none.

#### request-negative

When set to true, the application's request for logon page will be identified by the absence of the specified cookie or header, or by a failed match against the list of specified URIs. The default is false.

#### request-prefix

Specifies how the value of the request-value option will be used to match one of the HTTP request cookie, header, or URI. The default is true and specifies a partial match; false specifies an exact match.

#### request-type

Specifies which element of the HTTP request headers is used to identify the application's request for logon page. The default is uri.

The options are:

cookie

The request is identified by the presence (or absence) of a cookie. The name and value of the cookie are specified by the request-name and request-value options.

#### header

The request is identified by the presence (or absence) of the HTTP header. The name and value of the header are specified by the request-name and request-value options.

uri The request is identified by a successful (or failed) match against a list of URIs specified by the request-value option, and the request-name option is not used.

#### request-value

Specifies the value of the HTTP request element that must be matched to identify the request as the application's request for the logon page. This is one of: the cookie value, the header value, or a list of URIs (one per line) as specified by the request-type option. Cookie or header value could be set to none, in which case only the presence of the named cookie or header is checked and the value is not checked. When checking for URI, the value must be specified.

#### submit-autodetect

When set to true, the application's HTTP request that submits the user's credentials will be identified automatically and other submit- options should not be used. When false, the form submit will be identified using a combination of other submit- options. The default is true.

#### submit-javascript

Specifies user-provided JavaScript code to be inserted into the logon page to perform automatic form submission when the submit-javascript-type option is set to custom. The custom JavaScript code replaces the code automatically generated by the SSOv2 module. When the submit-javascript-type option is set to extra, it specifies the application's JavaScript functions to call from the automatically generated JavaScript code prior to submitting a logon form. When the submit-javascript-type option is set to auto, this option should be set to none.

#### submit-javascript-type

Specifies the type of JavaScript code to be inserted into the logon page by the SSOv2 module to perform automatic logon form submission.

The options are:

auto JavaScript code is automatically generated by the SSOv2 module.

custom JavaScript code is provided by the user in the submit-javascript option.

#### extra

JavaScript code is automatically generated by the SSOv2 module, and additional JavaScript code provided by the user in the submit-javascript option is inserted before the form submit statement.

#### submit-method

Specifies the HTTP method of credentials submit request for the application. This must be set to post. This option is not used when submit-autodetect is true.

#### submit-name

Specifies the name of the HTTP cookie or the name of HTTP header used to identify credentials submit request for the application. The cookie or header is selected by the submit-type option. The value of the cookie or header is specified by the submit-value option. When the submit-type option is set to uri, this option is not used and should be set to none. This option is not used when submit-autodetect is true.

#### submit-negative

When set to true, the credentials submit request for the application is identified by the absence of a specified cookie or header, or by a failed match against the list of specified URIs. The default is false. This option is not used when submit-autodetect is true.

#### submit-prefix

Specifies how the value of the submit-value option will be used to match the HTTP request cookie, header, or URI. The default is true and specifies partial match; false specifies exact match. This option is not used when submit-autodetect is true.

#### submit-type

Specifies which element of HTTP request headers is used to identify the credentials submit request for the application. The default is uri. This option is not used when submit-autodetect is true.

The options are:

#### cookie

The request is identified by the presence (or absence) of a cookie. The name and value of the cookie are specified by the submit-name and submit-value options.

#### header

The request is identified by the presence (or absence) of the HTTP header. The name and value of the header are specified

by the submit-name and submit-value options.

**uri** The request is identified by a successful (or failed) match against a list of URIs specified by the submit-value option and the submit-name option is not used.

**submit-value**

Specifies the value of the HTTP request element that must be matched to identify the request as a credentials submit request for the application. This is one of: the cookie value, the header value, or a list of URIs (one per line) as specified by the submit-type option. Cookie or header value could be set to none, in which case only the presence of the named cookie or header is checked and the value is not checked. When checking for URI, the value must be specified. This option is not used when submit-autodetect is true.

**success-match-type**

Specifies how the SSOv2 module detects whether the credentials submit request was successful. When the SSOv2 module detects that the credentials submission failed, the SSOv2 configuration used for this HTTP transaction is disabled for the user session. If you specify a value for this option, you must also specify a value for success-match-value. The default is none. The options are:

**url** Credentials submission was successful if the response contains the HTTP Location header with a value matching one of the URLs specified by the success-match-value option.

**cookie**

Credentials submission was successful if the response contains the HTTP cookie with the name specified by the success-match-value option.

**none** No check is performed. If SSO logon fails and the application server redirects back to the logon page that matches the criteria of the logon page request, SSO will be retried, possibly causing authentication loop.

**success-match-value**

Specifies the value used to detect the success or failure of the SSO logon. When the success-match-type option is set to url, this is a list of URLs. Each URL in the list can contain a single wildcard character (\*). When the success-match-type option is set to cookie, this option specifies the name of the cookie. The default is none.

**headers**

Specifies the name and value of the HTTP header to be inserted in an HTTP Request that passes through the APM SSOv2 module.

**[name]**

Specifies the name of the headers item.

The options are:

**app-service**

Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

**name** Specifies the name of the HTTP header.

**value**

Specifies the value of the HTTP header.

**apm-log-config**

Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

**log-level**

log-level is deprecated. Instead use apm-log-config to customize log-setting.

show kerberos  
show kerberos [name]

**DELETE**  
delete kerberos [name]

**DESCRIPTION**  
You can use the kerberos component to configure an SSO Kerberos configuration object. Kerberos is an authentication protocol, where both the user and the server verify the other's identity.

**EXAMPLES**  
create mykerberos { realm MYREALM.COM account-name apmaccount account-password \*\*\*\* }  
Creates an SSO kerberos configuration object named mykerberos for the realm myrealm.com, where the account name is apmaccount and the password is \*\*\*\*.

**OPTIONS**

**account-name**  
Specifies the name of the Active Directory account configured for delegation. This account must be configured in the server's Kerberos realm (AD Domain). If servers are from multiple realms, each realm (AD Domain) must have its own delegation account. This option is required.

**account-password**  
Specifies the password for the delegation account specified in account-name. This option is required.

**apm-log-config**  
Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**headers**  
Specifies custom HTTP headers to insert into a request. The default value is none. The options are:

**app-service**  
Specifies the name of the application service to which the header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service

that owns the object, you cannot modify or delete the header. Only the application service can modify or delete the header.

hname

Specifies the name of a header to add to a request.

hvalue

Specifies the value of a header to add to a request.

kdc Specifies the IP Address or host name of the Kerberos Key Distribution Center (KDC) for the server's realm. This is normally an Active Directory domain controller. If you leave this empty, the KDC must be discoverable through DNS, for example, BIG-IP system must be able to fetch SRV records for the server realm's domain. If the server realm's domain name is different from the server's realm name, you must specify the server realm's domain name in the /etc/krb5.conf file. Kerberos SSO processing is fastest when KDC is specified by its IP address, slower when specified by host name, and even slower (due to additional DNS queries) when left empty. When a user's realm is different from server's realm, the KDC value must be empty. This is true in cases of cross-realm SSO. The default is none.

location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]

Specifies the name for the SSO Kerberos configuration object. This option is required.

realm

Specifies the realm of application server(s), for example, pool members or portal access resource hosts. If the servers are located in multiple realms, each realm requires a separate SSO configuration. You must specify the realm in uppercase letters. The user's realm can be specified through the session.logon.last.domain session variable, and if this variable is not set, then the user's realm is assumed to be the same as the server's realm. This option is required.

send-authorization

Specifies when to submit a Kerberos ticket to the application server(s). The ticket is submitted in an HTTP Authorization header. The header value starts with the word Negotiate, followed by one space and a base64-encoded GSSAPI token containing the Kerberos ticket. If a request contains an Authorization header from the user's browser, it is deleted. The default is always. The options are:

401 The BIG-IP system first forwards the user's HTTP request to the web server without inserting a new Authorization header; however, the browser's Authorization header is deleted. If the server requests authentication by responding with a 401 status code, BIG-IP retries the request with the Authorization header. The Kerberos ticket GSSAPI representation uses the SPNEGO mechanism type (OID 1.3.6.1.5.5.2).

Specifying 401 results in additional BIG-IP/server request round trips in case authentication is required for the request.

always

The BIG-IP system inserts an Authorization header, including the Kerberos ticket, into every HTTP request, whether the request requires authentication or not. The Kerberos ticket GSSAPI representation uses the KRB5 Kerberos 5 mechanism type (OID 1.2.840.113554.1.2.2).

Specifying Always results in the additional overhead of generating a Kerberos token for every request. This is the default value.

spn-pattern

Specifies how the Service Principal Name (SPN) for the server is constructed. For example, HTTP/%s@[server realm name configured in the realm option], where %s will be substituted with the hostname of your server discovered through reverse DNS lookup using the server IP address. Only specify this option when you need non-standard SPN format. The default is none.

ticket-lifetime

Specifies the lifetime of Kerberos tickets obtained for the user. The value represents the maximum ticket lifetime. The actual ticket lifetime may be less by up to 1 hour, because a user's ticket lifetime is the same as the Kerberos Ticket Granting Ticket (TGT) lifetime. A TGT is obtained for the delegation account specified in this configuration. A new TGT is fetched every time the current TGT is older than one hour. The new TGT can only be fetched when an SSO request is processed.

The minimum ticket lifetime is 10 minutes. There is no maximum, however, the ticket lifetime of most AD domains is 10 hours (600 minutes). F5 Networks recommends that you set the ticket lifetime in an SSO configuration above what is specified in an AD domain. The default is 600 minutes.

## apm sso ntlmv1

#### NAME

ntlmv1 - Configures a single sign-on (SSO) NT LAN Manager, version 1 (ntlmv1) configuration object.

#### MODULE

apm sso

#### SYNTAX

Configure the ntlmv1 component within the sso module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create ntlmv1 [name]
modify ntlmv1 [name]
options:
  apm-log-config [[string] | none]
  app-service [[string] | none]
  domain-source [session.logon.last.domain | none]
  headers [add | delete | modify | replace-all-with] {
    [name] {
      options:
        app-service [[string] | none]
        hname [[string] | none]
        hvalue [[integer] | none]
      }
    }
  location-specific [true | false]
  ntlm-domain [[string] | none]
  password-source [session.sso.token.last.password | none]
  username-conversion [enabled | disabled]
  username-source [session.sso.token.last.username | none]
```

```
edit ntlmv1 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list ntlmv1
list ntlmv1 [ [ [name] | [glob] | [regex] ] ... ]
show running-config ntlmv1
show running-config ntlmv1 [ [ [name] | [glob] |
  [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show ntlmv1
show ntlmv1 [name]
```

##### DELETE

```
delete ntlmv1 [name]
```

#### DESCRIPTION

You can use this ntlmv1 component to configure a single sign-on NT LAN Manager, version 1 configuration object.

#### EXAMPLES

```
create ntlmv1 myntlmv1
Creates an SSO ntlmv1 configuration object named myntlmv1.
```

#### OPTIONS

**apm-log-config**  
Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**domain-source**  
Specifies the Session variable used as a source for the single sign-on user domain. The default is session.logon.last.domain.

**headers**  
Specifies the name and value of the HTTP header content to be inserted in an HTTP Request that passes through the APM SSO module. The default is none.

The options are:

**app-service**  
Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

**hname**  
Specifies the name of the HTTP header.

**hvalue**  
Specifies the value of the HTTP header.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies the name for the SSO ntlmv1 configuration object. This option is required.

**ntlm-domain**  
Specifies the static domain setting. If the domain is not retrieved successfully from the source specified in the domain-source option, the system uses this value for the source.

**password source**  
Specifies the source from which you want SSO to retrieve the password to use to authenticate applications. The default is session.sso.token.last.password.

**username-conversion**  
Enables or disables conversion of PREWIN2k/UPN username input format to the format you want to use for SSO. The default is disabled.

**username-source**  
Specifies the source from which you want SSO to retrieve the username used to authenticate applications.

    [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
    partition

show ntlmv2
show ntlmv2 [name]

DELETE
delete ntlmv2 [name]

DESCRIPTION
    You can use the ntlmv2 component to configure a single sign-on NT LAN
    Manager, version 2 configuration object.

EXAMPLES
    create ntlmv2 myntlmv2
    Creates an SSO ntlmv2 configuration object named myntlmv2.

OPTIONS
    apm-log-config
    Specifies log-setting object to associate with this sso. If this
    value is empty, logging framework uses log-setting configuration
    associated with the access profile where sso is used.

    app-service
    Specifies the name of the application service to which the object
    belongs. The default value is none. Note: If the strict-updates
    option is enabled on the application service that owns the object,
    you cannot modify or delete the object. Only the application
    service can modify or delete the object.

    domain-source
    Specifies the Session variable used as a source for the single
    sign-on user domain. The default is session.logon.last.domain.

    headers
    Specifies the name and value of the HTTP header content to be
    inserted in an HTTP Request that passes through the APM SSO
    module. The default is none.

    The options are:

    app-service
    Specifies the name of the application service to which the
    HTTP header belongs. The default value is none. Note: If the
    strict-updates option is enabled on the application service
    that owns the object, you cannot modify or delete the HTTP
    header. Only the application service can modify or delete the
    HTTP header.

    hname
    Specifies the name of the HTTP header.

    hvalue
    Specifies the value of the HTTP header.

    location-specific
    Specifies whether or not this object contains one or more
    attributes with values that are specific to the location where the
    BIG-IP device resides. The location-specific attribute is either
    true or false. When using policy sync, mark an object as location-
    specific to prevent errors that can occur when policies reference
    objects, such as authentication servers, that are specific to a
    certain location.

    [name]
    Specifies a name for the sso ntlmv2 configuration object. This
    option is required.

    ntlm-domain
    Specifies the static domain setting. If the domain is not
    retrieved successfully from the source specified in the domain-
    source option, the system uses this value for the source.

    password source
    Specifies the source from which you want SSO to retrieve the
    password to use to authenticate applications. The default is

```

session.sso.token.last.password.

username-conversion

Enables or disables conversion of PREWIN2k/UPN username input format to the format you want to use for SSO. The default is disabled.

username-source

Specifies the source from which you want SSO to retrieve the username used to authenticate applications.

## apm sso oauth-bearer

NAME

oauth-bearer - Configures a single sign-on (SSO) oauth-bearer configuration object.

MODULE

apm sso

SYNTAX

Configure the oauth-bearer component within the sso module using the syntax shown in the following sections.

CREATE/MODIFY

```
create oauth-bearer [name]
modify oauth-bearer [name]
options:
  app-service [[string] | none]
  headers [add | delete | modify | | replace-all-with] {
  location-specific [true | false]
  [name] {
    options:
      app-service [[string] | none]
      hname [[URL] | none]
      hvalue [[integer] | none]
    }
  }
  location-specific [true | false]
  oauth-server [string]
```

```
edit oauth-bearer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list oauth-bearer
list oauth-bearer [ [ [name] | [glob] | [regex] ] ... ]
show running-config oauth-bearer
show running-config oauth-bearer [ [ [name] | [glob] |
[regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show oauth-bearer
show oauth-bearer [name]
```

DELETE

```
delete oauth-bearer [name]
```

DESCRIPTION

You can use the oauth-bearer component to create, modify, display, or delete an SSO oauth-bearer configuration object.

EXAMPLES

```
create oauth-bearer myoauth-bearer
```

Creates an SSO oauth-bearer configuration object named myoauth-bearer.

OPTIONS

app-service  
Specifies the name of the application service to which the object

belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### headers

Specifies the name and value of the HTTP header content to be inserted into an HTTP Request that passes through the APM SSO module. The default is none. The options are:

#### app-service

Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

#### hname

The name of the HTTP header.

#### hvalue

The value of the HTTP header.

#### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

#### [name]

Specifies a name for the SSO oauth-bearer configuration object. This option is required.

#### partition

Displays the partition in which the object resides.

#### oauth-server

Specifies the name of your OAuth Server. This option is required.

#### SEE ALSO

## apm sso saml-resource

#### NAME

saml-resource - Configures saml resource.

#### MODULE

apm sso

#### SYNTAX

Configure a saml-resource using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create saml-resource [name]
```

```
modify saml-resource [name]
```

#### options:

```
app-service [[string] | none]
customization-group [[string] | none]
description [[string] | none]
location-specific [true | false]
publish-on-webtop [true | false]
sso-config-saml [[string] | none]
```

```
edit saml-resource [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
```

#### DISPLAY

```
list saml-resource
```

```
list saml-resource [ [ [name] | [glob] | [regex] ] ... ]
```

```

```

```
show running-config saml-resource [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

all-properties  
non-default-properties  
one-line

DELETE  
delete saml-resource [name]

DESCRIPTION  
You can use saml-resource component to configure saml resource.

EXAMPLES  
create saml-resource my\_saml\_resource { sso-config-saml my\_saml\_sso\_obj  
publish-on-webtop true }  
Creates a saml resource named my\_saml\_resource with saml sso  
object 'my\_saml\_sso\_obj' and with option to display this resource  
on full webtop.  
  
delete saml-resource my\_saml\_resource  
Deletes the saml resource named my\_saml\_resource.

OPTIONS  
app-service  
Specifies the name of the application service to which the object  
belongs. The default value is none. Note: If the strict-updates  
option is enabled on the application service that owns the object,  
you cannot modify or delete the object. Only the application  
service can modify or delete the object.  
  
customization-group  
Specifies the customization group associated with saml resource.  
  
description  
Specifies a description for the saml resource. The default is  
none.  
  
location-specific  
Specifies whether or not this object contains one or more  
attributes with values that are specific to the location where the  
BIG-IP device resides. The location-specific attribute is either  
true or false. When using policy sync, mark an object as location-  
specific to prevent errors that can occur when policies reference  
objects, such as authentication servers, that are specific to a  
certain location.  
  
publish-on-webtop  
Specifies whether to display the SAML resource on the full webtop  
or not. Default value is true.  
  
sso-config-saml  
Specifies saml sso config object associated with this saml  
resource. This saml sso object should only have one saml sp  
connector associated with it.

## apm sso saml-sp-connector

NAME  
saml-sp-connector - Specify saml sp connector configuration.

MODULE  
apm sso

SYNTAX  
Configure a saml-sp-connector within the sso module using the syntax  
shown in the following sections.

CREATE/MODIFY  
create saml-sp-connector [name]  
modify saml-sp-connector [name]  
options:  
app-service [[string] | none]  
assertion-consumer-services [ {  
binding [http-artifact | http-post | paos]  
index [0 - 65535]  
is-default [true | false]  
uri [string]  
} ]  
description [[string] | none]  
encryption-type [aes128 | aes192 | aes256]

```
entity-id [string]
import-metadata [ string | none ]
is-authn-request-signed [ true | false ]
location-specific [ true | false ]
metadata-cert [[string] | none]
relay-state [[string] | none]
signature-type [rsa-shal | rsa-sha256 | rsa-sha384 | rsa-sha512]
single-logout-binding
single-logout-response-uri [string]
single-logout-uri [string]
sp-certificate [[string] | none]
want-assertion-encrypted [ true | false ]
want-assertion-signed [ true | false ]
want-response-signed [ true | false ]
```

```
edit saml-sp-connector [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
```

```
all-properties
non-default-properties
```

```
DISPLAY
```

```
list saml-sp-connector
```

```
list saml-sp-connector [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config saml-sp-connector
```

```
show running-config saml-sp-connector [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
```

```
all-properties
app-service
non-default-properties
one-line
partition
```

```
DELETE
```

```
delete saml-sp-connector [name]
```

```
DESCRIPTION
```

You can use the saml-sp-connector component to create and manage saml sp connectors

```
EXAMPLES
```

```
create saml-sp-connector my_saml_sp_connector { entity-id
"https://companyx.sp.com/sp" assertion-consumer-services { { uri
"https://companyx.sp.com/acs/" is-default true } } want-assertion-
signed true want-response-signed true want-assertion-encrypted true
encryption-type aes256 is-authn-request-signed false sp-certificate
default.crt }
```

Creates a SAML sp-connector named my\_saml\_sp\_connector with security options to encrypt and sign the assertion as well as SAML response.

```
create saml-sp-connector my_saml_sp_connector1 { import-metadata
/shared/tmp/sp_metadata.xml }
```

Creates a SAML sp-connector named my\_saml\_sp\_connector1 from metadata file "/shared/tmp/sp\_metadata.xml"

```
list saml-sp-connector
```

Displays a list of SAML sp connectors.

```
delete saml-sp-connector my_saml_sp_connector
```

Deletes the my\_saml\_sp\_connector SAML sp connector.

```
OPTIONS
```

```
app-service
```

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

```
assertion-consumer-services
```

List of assertion consumer services (ACS) used by external SP. Each ACS entry contains attributes 'binding', 'index', 'is-default', and 'url'. Each ACS must contain a valid URL, and a unique 'index'. One ACS entry must be set as default.

```
assertion-consumer-binding
```

This attribute is DEPRECATED. Use assertion-consumer-services instead.

```
assertion-consumer-uri
```

This attribute is DEPRECATED. Use assertion-consumer-services instead.

```
description
```

Specifies a unique description for saml sp connector. The default is none.

```
encryption-type
```

Specifies the type of encryption BIG-IP as IdP should use to encrypt the assertion. Default is aes128.

```
entity-id
```

Specifies a unique ID to identify SP pointed by sp connector.

```
import-metadata
```

Specifies the metadata file to be used to create sp connector object. For example: create saml-sp-connector my\_saml\_sp\_connector1 { import-metadata /shared/tmp/sp\_metadata.xml }

```
is-authn-request-signed
```

Specifies whether SP signs authentication requests while sending them to BIG-IP as IdP. The default value for this is false.

location-specific  
Objects of this class might have location specific attribute(s).  
Admin can indicate if object is location specific by setting it to true.

metadata-cert  
Specifies the certificate to be used to verify the signature of metadata imported from a file.

relay-state  
Specifies the value sent to the SP by BIG-IP as IdP as part of the response. This value is only used if the SP did not send RelayState as part of the authentication request.

signature-type  
Signature algorithms to be used for digital signing of SAML messages. Default value is rsa-shal.

single-logout-binding  
This attribute is reserved for future functionality.

single-logout-response-uri  
A URI where this BIG-IP as IdP will send single logout (SLO) responses.

single-logout-uri  
A URI where this BIG-IP as IdP will send single logout (SLO) requests.

sp-certificate  
Specifies SP certificate used by BIG-IP as IdP to verify the signature of authentication request.

want-assertion-encrypted  
Specifies whether SP requires encrypted assertions. The default value for this attribute is false

want-assertion-signed  
Specifies whether SP requires signed assertions. The default value for this attribute is true

want-response-signed  
Specifies whether SP requires signed SAML responses. The default value for this attribute is false

## apm sso saml

NAME  
saml - Specify SAML SSO configuration.

MODULE  
apm sso

SYNTAX  
Configure the saml within the sso module using the syntax shown in the following sections.

```
CREATE/MODIFY
create saml [name]
modify saml [name]
options:
  apm-log-config [[string] | none]
  app-service [[string] | none]

  non-default-properties
  one-line
  partition

```

```

DELETE
delete saml [name]

```

**DESCRIPTION**  
You can use the saml component to create and manage SAML SSO objects.

**EXAMPLES**

```

create saml my_saml_sso_obj { entity-id
  "https://myidpvs.big-ip.com/idp" subject-type email-address subject-
  value test@mycompany.com idp-certificate default.crt idp-signkey
  default.key sp-connectors add { google_apps salesforce }
Creates a SAML SSO object named my_saml_sso_obj with SP connectors
"google_apps" and "salesforce"

create saml my_saml_sso_obj1 { entity-id
  "https://myidpvs.big-ip.com/idp" subject-type email-address subject-
  value test@mycompany.com idp-certificate default.crt idp-signkey
  default.key sp-connectors add { google_apps sp_salesforce } attributes
  {{name "group" multi-values { "PD" "Admin" }} {name "title" multi-
  values { "engineer1" }}} }
Creates a SAML SSO object named my_saml_sso_obj1 with attributes
"group" and "title".

list saml
Displays list of SAML SSO objects.

delete saml my_saml_sso_obj
Deletes the my_saml_sso_obj SAML SSO object.

```

**OPTIONS**

```

apm-log-config
Specifies log-setting object to associate with this saml. If this
value is empty, logging framework uses log-setting configuration
associated with the access profile where sso is used.

app-service
Specifies the name of the application service to which the object
belongs. The default value is none. Note: If the strict-updates
option is enabled on the application service that owns the object,
you cannot modify or delete the object. Only the application
service can modify or delete the object.

assertion-validity
Specifies assertion validity period in seconds.

artifact-resolution-service-name
Specifies the artifact resolution service to be used by this BIG-
IP as IdP to receive artifacts and resolve them for assertions.

attributes
Specifies list of attributes as part of assertion. Both attribute
name and values can be session variables. Property 'value' is
DEPRECATED; "multi-values" must be used instead.

create saml my_saml_sso_obj1 { entity-id
  "https://myidpvs.big-ip.com/idp" subject-type email-address
  subject-value test@mycompany.com idp-certificate default.crt idp-
  signkey default.key sp-connectors add { google_apps sp_salesforce
  } attributes {{name "group" multi-values {
  "%{session.ldap.last.attr.primarygroup}" }} {name "name" multi-
  values { "firstName" "lastName" }}} }
Creates a SAML SSO object named my_saml_sso_obj1 with attributes
"group" and "name".

```

#### auth-context-method

Specifies an authentication context method used by this BIG-IP as IdP when creating assertions. This attribute can be a session variable.

#### description

Specifies a unique description for SAML SSO object. The default is none.

#### encrypt-subject

Set to true if assertion 'Subject' must be encrypted. Default value is false.

#### encryption-type-subject

Encryption algorithm used to encrypt 'Subject' element in assertion. Default value is aes128.

#### entity-id

Specifies unique identifier for BIG-IP as IdP. Typically, 'entity-id' is a URI that points to the BIG-IP virtual server that is going to act as a SAML IdP. In case 'entity-id' is not a valid URL, the idp-host attribute is required. Examples of valid configuration include "https://mycompany-idp", "idp:my:company", and "idp.my.company.com"

#### export-metadata

You can simplify SAML configuration using metadata files. When you use APM as an IdP, you can export metadata for IdP. You can save metadata to a file and give it to the SP to enable SP to import SP's SAML configuration or enable SP to use information from the metadata file to configure the IdP. You can choose to sign metadata while exporting it for better security.

For example:

1. Exporting metadata with signing. This requires metadata-signkey and metadata-cert files.

```
modify saml my_saml_sso_obj {export-metadata with-signing metadata-file /shared/idp_signed_metadata.xml metadata-
```

2. Exporting metadata with no signing.

```
modify saml my_saml_sso_obj {export-metadata no-signing metadata-file /shared/idp_metadata.xml}
```

#### idp-certificate

BIG-IP includes this certificate in the SAML IdP metadata that you export. After the SAML IdP metadata is imported on the SP, the SP can use this certificate to verify the signature of assertion sent by this BIG-IP as IdP.

#### idp-host

Hostname of this BIG-IP as IdP. This attribute is required when "entity-id" is not a valid URL.

#### idp-scheme

Scheme used by this BIG-IP as IdP. This attribute is only used when idp-host is not empty. Default value is https.

#### idp-signkey

Specifies the private key used for signing assertion by BIG-IP as IdP.

#### key-transport-algorithm

Specifies the key transport algorithm to be used for encrypted attributes, subject-value, or assertion. Default and recommended value is rsa-oaep. rsa-v1.5 is NOT RECOMMENDED due to security risks associated with the algorithm, and should NOT be used except for compatibility with older applications.

#### location-specific

Objects of this class might have location specific attribute(s). Admin can indicate if object is location specific by setting it to true.

#### log-level

log-level is deprecated. Instead use apm-log-config to customize log-setting.

#### metadata-cert

Specifies the certificate with public key of the key pair used in signing the metadata. See export-metadata for more information on metadata export functionality. This is the certificate to include in signed metadata when we export metadata. This might or might not be IdP certificate.

#### metadata-file

Specifies the file to which metadata is saved. See export-metadata for more information on metadata export functionality.

#### metadata-signkey

This specifies the key that is used to sign IdP's metadata. See export-metadata for more information on metadata export functionality.

#### saml-profiles

List of SAML profiles enabled on this BIG-IP as IdP. Default value is web-browser-ssso.

#### sp-connectors

Specifies list of SP connectors associated with this SAML SSO object. When this SSO object is assigned to SAML resource then only one entry is allowed for SP connectors. If SAML SSO object is assigned to access profile then you can add multiple SAML SP connectors.

**subject-type**  
Specifies type of the subject to be used while creating SAML assertion.

**subject-value**  
Specifies the value of the subject to be included inside SAML assertion. This can be a session variable. For example:  
`{session.last.logonname}`, `{session.ad.last.attr.userEmail}`

## apm swg-scheme

**NAME**  
swg-scheme - Configures SWG Scheme

**MODULE**  
apm

**SYNTAX**  
Configure a swg-scheme component within the apm module using the syntax shown in the following sections.

**CREATE/MODIFY**  
Each swg-scheme consists of the following.

```
create swg-scheme [name]
options:
  app-service [[string] | none]
  description [[string] | none]
```

```
modify swg-scheme [name]
options:
  app-service [[string] | none]
  description [[string] | none]
```

**DISPLAY**  
list swg-scheme  
list swg-scheme [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DESCRIPTION**  
Configures an swg-scheme object

**EXAMPLES**  
create apm swg-scheme scheme1 { app-service none description "My SWG Scheme" }

Creates a new swg-scheme.

```
modify swg-scheme scheme1 { description "My SWG Scheme" }
```

Modify a swg-scheme by modifying its description string.

**OPTIONS**  
**app-service**  
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

**description**  
Specifies a user-defined description for the swg scheme.

SEE ALSO  
apm url-filter

## apm url-filter

**NAME**  
url-filter - Configures URL filters for URL classification and filtering

**MODULE**  
apm

**SYNTAX**  
Configure a url-filter component within the apm module using the syntax shown in the following sections.

**CREATE/MODIFY**  
Each url-filter consists of two url-category lists: a list of allowed URL categories and a list of blocked URL categories. The requests for URLs contained in the allowed list are allowed to pass unfettered, whereas requests for URLs in the blocked list will not go out into the Internet.

```
create url-filter [name]
  options:
    allowed-categories [add | delete | modify | replace-all-with] {
      [string]
    }
    blocked-categories [add | delete | modify | replace-all-with] {
      [string]
    }
}

modify url-filter [name]
  allowed-categories [add | delete | modify | replace-all-with] {
    [string]
  }
  blocked-categories [add | delete | modify | replace-all-with] {
    [string]
  }
}
```

**DISPLAY**  
list url-filter  
list url-filter [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**CP**  
cp url-filter [source-name] [target-name]

**DESCRIPTION**  
Configures a url-filter

**NOTE:** A url-filter can have a large number of URL categories in each list. To facilitate the creation of url-filter, you can create a new url-filter by copying from an existing url-filter. Then modify each list by adding or removing url-categories to suit your needs.

**EXAMPLES**  
create url-filter my-url-filter allowed-categories add {  
Business\_and\_Economy Education } blocked-categories add { Adult\_Content  
Shopping }

Creates a new url-filter.

```
modify url-filter my-own-filter allowed-categories delete { Education }
```

Modify a url-filter by deleting a URL category from the allowed list.

```
cp url-filter existing-filter another-filter
```

Create a new url-filter by copying from an existing filter.

**OPTIONS**  
allowed-categories  
Specifies the URL categories that should be allowed to pass.

description  
Specifies a unique description for the URL filter.

blocked-categories  
Specifies the URL categories that should be blocked.

**SEE ALSO**  
sys url-db download-result sys url-db download-schedule and sys url-db url-category

**COPYRIGHT**

## asm

### asm device-sync

**NAME**  
device-sync - Contains the ASM timestamp for each device in the group.

**MODULE**  
asm

**SYNTAX**  
Retrieve the list of the device-sync values using the syntax shown in the following section.

**DISPLAY**  
list device-sync  
list device-sync [ [ [name] | [glob] | [regex] ] ... ]

**DESCRIPTION**  
Use this command to display the current values of the device-sync object, i.e. ASM change times for all devices in the group. This object is designed for internal purposes only (incremented on every ASM change), so do not try to create, modify, or delete it manually.

**EXAMPLES**  
list device-sync  
  
Displays all last ASM change times of the device group.

**SEE ALSO**  
tmsh, list, glob, regex

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

### asm http-method

**NAME**  
http-method - Lists the available HTTP request methods that can be used in the context of the Application Security Manager(TM).

**MODULE**  
asm

**SYNTAX**  
Retrieve the list of the http-method values using the syntax shown in the following sections.

**DISPLAY**  
list http-method  
list http-method [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
app-service  
default-act-as  
one-line  
partition

recursive

#### DESCRIPTION

Use this command to display the possible values of the http-method object to be used in the context of the Application Security Manager. These possible values include predefined and user-defined allowed methods for all security policies, and also are intended to be used in filters of Application Security Logging and in HTTP security profiles.

#### EXAMPLES

```
list http-method
```

Displays all the HTTP methods supported by the ASM.

#### OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

default-act-as

Displays the HTTP request method, either GET or POST, based on how you have instructed the system to treat the listed method name; a predefined method has its system default and a user-defined allowed method is configured in the security policy.

partition

Displays the administrative partition within which the component resides.

#### SEE ALSO

glob, list, regex, security http profile, security log profile, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## asm httpclass-asm

#### NAME

httpclass-asm - configure initial ASM settings for applications. This component has been deprecated as of BIG-IP v11.3.0, please use the policy component in the asm module instead.

#### MODULE

asm

#### SYNTAX

Configure the httpclass-asm component within the asm module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create httpclass-asm [name]
modify httpclass-asm [name]
options:
  active-policy-name [string]
  app-service [[string] | none]
  language [language]
  predefined-policy [predefined-policy]
```

##### DISPLAY

```
list httpclass-asm
list httpclass-asm [ [name] | [glob] | [regex] ] ... ]
show running-config httpclass-asm
show running-config httpclass-asm [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition
```

##### DELETE

```
delete httpclass-asm [name]
```

#### DESCRIPTION

Use this command to create, modify, display, or delete an httpclass-asm profile that configures ASM security policies. Changing/setting attributes for an httpclass-asm profile affects the ASM security policy with the same name. Note that modifying the language of an existing profile reconfigures the ASM security policy and deletes the configurations, log entries and statistics of the security policy. This is for advanced usage - this command is intended to be used by the application templates system (iApps(tm)).

## EXAMPLES

```
create asm httpclass-asm my_class active-policy-name my_class_policy
language utf-8 predefined-policy POLICY_TEMPLATE_RAPID_DEPLOYMENT_HTTP
```

Creates a custom httpclass-asm profile named `my_class` that causes ASM to configure a security policy that uses the utf-8 application language and the Rapid Deployment security policy.

```
list httpclass-asm
```

Displays the properties of all httpclass-asm profiles.

## OPTIONS

`active-policy-name`

Specifies the name of the active security policy. This property has been deprecated. As of BIG-IP v11.1.0, the active security policy name is identical to the HTTP class profile's name.

`app-service`

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`language`

Specifies the language of the web application that the ASM security policy is protecting. Use autocomplete or list /asm webapp-language to get the list of supported languages.

`name` Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

`predefined-policy`

Specifies a predefined security policy for a web application. This security policy was prebuilt to provide out of the box security for a known application. Use autocomplete to get a list of applications for which ASM has predefined policies.

## SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, tmsk

## COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2013. All rights reserved.

BIG-IP 2013-04-12 asm httpclass-asm(1)

---

## asm policy

### NAME

policy - Configures an application security policy.

### MODULE

asm

### SYNTAX

Configure the policy component within the asm module using the syntax shown in the following sections.

#### CREATE

```
create policy [name]
```

options:

```
[active | inactive]
app-service [[string] | none]
blocking-mode [enabled | disabled]
description [[string] | none]
encoding [[name] | none]
policy-builder [enabled | disabled]
policy-template [name]
policy-type [security | parent]
parent-policy [name]
```

#### MODIFY

```
modify policy [name]
```

options:

```
[active | inactive]
app-service [[string] | none]
blocking-mode [enabled | disabled]
description [[string] | none]
encoding [[name] | none]
policy-builder [enabled | disabled]
policy-template [name]
```

DISPLAY  
list policy [ [ [name] | [glob] | [regex] ] ... ]  
show running-config policy [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
one-line  
partition  
virtual-servers

DELETE  
delete policy [name]

SAVE  
save policy [name]  
options:  
overwrite  
bin-file [filename]  
min-xml-file [filename]  
xml-file [filename]

LOAD  
load policy [name]  
options:  
overwrite  
file [filename]  
xml-string [string]

PUBLISH  
publish policy [name]

#### DESCRIPTION

You can use the policy component to create, modify, display, delete, save, load, or publish an application security policy for use with Application Security Manager functionality.

Note: To display all policy properties available in tmsh, including initial settings used by iApp and advanced configuration accessible in ASM GUI, specify the all-properties option or the detailed properties. By default, only initial properties are displayed: encoding, policy-template and [active | inactive].

Note: The modify command with the properties encoding and/or policy-template causes ASM to reconfigure the security policy and clear all its former data.

Note: The policy-type cannot be modified after the creation of the policy.

Note: The parent-policy can only, optionally, be set while creating a policy with policy-type set to security.

#### EXAMPLES

```
create policy my_asm_policy encoding utf-8
```

Creates a new policy named my\_asm\_policy with the default language encoding, policy-type set to security and no parent-policy.

```
modify policy my_asm_policy active
```

Activates the inactive policy named my\_asm\_policy.

```
create policy my_parent_asm_policy encoding utf-8 policy-type parent
```

Creates a new policy named my\_parent\_asm\_policy with the default language encoding.

```
create policy my_security_asm_policy policy-type security parent-policy my_parent_asm_policy
```

Creates a new policy named my\_security\_asm\_policy, policy-type set to security and my\_parent\_asm\_policy set as the parent policy.

```
list policy
```

Displays the properties of all application security policies.

```
save policy my_asm_policy xml-file my_asm_policy.xml
```

Exports the policy named my\_asm\_policy to the XML file /var/tmp/my\_asm\_policy.xml.

```
load policy my_asm_policy overwrite file /tmp/my_asm_policy.plc
```

Imports the policy named my\_asm\_policy from the file /tmp/my\_asm\_policy.plc and overwrites the policy if it already exists.

```
publish policy my_asm_policy
```

Applies the active policy named my\_asm\_policy.

#### OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

[active | inactive]

Activates or deactivates the policy for later association with L7 policies and virtual servers. The default value is inactive.

bin-file

Specifies the exported file name to be saved in binary format when

using the save command. The file name should be simple (not a full path); it is saved to the /var/tmp directory on the system.

**blocking-mode**

Specifies whether the system blocks a request that triggers a security policy violation or only logs the violation event (transparent mode).

**description**

Specifies an optional description of the security policy.

**encoding**

Specifies the language encoding, which determines how the security policy processes the character sets. This property corresponds to the language property of the httpclass-asm component.

**file** Specifies the file name from which the policy is going to be imported when using the load command. A full path should be specified.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**min-xml-file**

Specifies the exported file name to be saved in compact XML format when using the save command. The file name should be simple (not a full path); it is saved to the /var/tmp directory on the system. To display the XML output immediately, omit this property, the properties xml-file and bin-file.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, modify, save, and publish. If it is not specified for the load command, the policy name will be taken from the imported settings.

**overwrite**

Specifies that the policy file for the save command or the policy component for the load command can be overwritten if it exists.

**partition**

Displays the administrative partition within which the component resides.

**policy-builder**

Enables or disables automatic policy building.

**policy-template**

Specifies whether the security policy is based on a predefined security policy template, and if so, which one. If you create or modify a security policy based on a template, the system automatically configures the new security policy according to the conditions of the template. This property corresponds to the predefined-policy property of the httpclass-asm component.

**policy-type**

Specifies the security policy type, which cannot be changed after you create the policy. The parent policy type cannot be active and cannot have a parent. The security policy type may or may not have a single parent policy defined.

**parent-policy**

Optionally, specifies the name of an existing policy, of policy-type parent, to be set as the parent policy, while creating a policy-type security.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**Note:** This component supports matching by the regex expression only when displaying the initial policy properties.

**virtual-servers**

Displays the name of the protected virtual server, or virtual servers, which have attached to them the security policy via L7 policies.

**xml-file**

Specifies the exported file name to be saved in XML format when using the save command. The file name should be simple (not a full path); it is saved to the /var/tmp directory on the system. To display the XML output immediately, omit this property, the properties min-xml-file and bin-file.

**xml-string**

Specifies the XML document from which the policy is going to be imported when using the load command.

**SEE ALSO**

asm predefined-policy, asm webapp-language, create, delete, glob, list, load, ltm policy, ltm virtual, modify, publish, regex, save, tmsh

**COPYRIGHT**

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2010-2012. All rights reserved.

## asm predefined-policy

**NAME**  
predefined-policy - Lists the available predefined policies that can be used in the context of the httpclass-asm profile.

**MODULE**  
asm

**SYNTAX**  
Retrieve the list of the predefined-policy values using the syntax shown in the following sections.

**DISPLAY**  
list predefined-policy  
list predefined-policy [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
one-line

**DESCRIPTION**  
Use this command to display the possible values of the predefined-policy object to be used in the context of the httpclass-asm profile. This is for advanced usage; this command is intended for use by the application templates system (iApps).

**EXAMPLES**  
list predefined-policy  
  
Displays all the predefined policies supported by the ASM.

**SEE ALSO**  
asm httpclass-asm, glob, list, regex, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## asm response-code

**NAME**  
response-code - Lists the available HTTP response status codes that can be used in the context of the Application Security Manager.

**MODULE**  
asm

**SYNTAX**  
Retrieve the list of the response-code values using the syntax shown in the following sections.

**DISPLAY**  
list response-code  
list response-code [ [ [number] | [glob] | [regex] ] ... ]  
options:  
all  
app-service  
name  
one-line

**DESCRIPTION**  
Use this command to display the possible values of the response-code object to be used in the context of the Application Security Manager. These possible values are predefined and intended to be used in filters of Application Security Logging.

**EXAMPLES**  
list response-code

Displays all the response codes supported by the ASM.

#### OPTIONS

##### app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

name Displays a well-known textual meaning of the HTTP response code.

#### SEE ALSO

glob, list, regex, security log profile, tmsh

## asm webapp-language

#### NAME

webapp-language - Lists the available languages that can be used in the context of the httpclass-asm profile.

#### MODULE

asm

#### SYNTAX

Retrieve the list of the webapp-language values using the syntax shown in the following sections.

##### DISPLAY

```
list webapp-language
list webapp-language [ [ [name] | [glob] ... ]
options:
all
one-line
```

#### DESCRIPTION

Use this command to display the possible values of the webapp-language object to be used in the context of the httpclass-asm profile. This is for advanced usage - this command is intended to be used by the application templates system.

#### EXAMPLES

```
list webapp-language
```

Displays all the languages supported by the ASM.

#### SEE ALSO

asm httpclass-asm, glob, list, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## auth

### auth apm-auth

#### NAME

apm-auth - Configures an APM-based authentication object for implementing access policy execution-based authentication of BIG-IP(r) system users.

#### MODULE

auth

#### SYNTAX

Configure the apm-auth component within the auth module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create apm-auth [name]
modify apm-auth [name]
  options:
    profile-access [string]
```

```
edit apm-auth [ [ [name] | [glob] | [regex] ] ...]
  options:
    all-properties
    non-default-properties
```

##### DISPLAY

```
list apm-auth
list apm-auth [ [ [name] | [glob] | [regex] ] ...]
show running-config apm-auth
show running-config apm-auth [ [ [name] | [glob] | [regex] ] ...]
  options:
    all-properties
    non-default-properties
    one-line
    partition
```

##### DELETE

```
delete apm-auth [name]
```

#### DESCRIPTION

You can configure APM-based authentication to execute an access policy for BIG-IP system users to authenticate and authorize them.

APM authentication methods like HTTP, AD/LDAP, TACACS+ authentication can be used in box authentication To authenticate BIG-IP system users. To do this, create an access profile, create APM configuration object with the above access profile, and then activate the object.

The following steps describe how to configure APM-based authentication for BIG-IP system users:

1. Use the profile-access component in the apm module to create a access profile.
2. Use the apm-auth component in the auth module to map an access profile to an APM-based authentication object.
3. To activate APM-based authentication for BIG-IP system users, run the command sequence modify / auth source type apm-auth

#### EXAMPLES

```
create apm-auth system-auth {profile-access apm-profile}

Creates an APM-based authentication object named system-auth

delete apm-auth system-auth

Deletes the APM-based authentication object named system-auth.
```

#### OPTIONS

**description**  
User-defined description.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**partition**  
Displays the administrative partition within which the component resides.

**profile-access**  
Specifies the access profile that the system must use for APM-based authentication. You must specify an access profile when you create an APM-based configuration object.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### SEE ALSO

auth user, create, delete, glob, list, modify, regex, run, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2013. All rights reserved.

## auth cert-ldap

### NAME

cert-ldap - Configures an LDAP configuration object for implementing Single Sign On based on a valid client certificate for BIG-IP(r) system users. The user is required to properly configure the Certificate Authority so that unique identifying attributes appear in the subjectName or subjectAltName fields of signed client certificates; the OSCP responder so that it is available to the BIG-IP at the time a client certificate is presented; and the LDAP server so that it includes the required attributes from the client certificate and the corresponding user name.

### MODULE

auth

### SYNTAX

Configure the cert-ldap component within the auth module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create cert-ldap [name]
```

```
modify cert-ldap [name]
```

#### options:

```
bind-dn [ [account dn] | none]
bind-pw [none | [password] ]
bind-timeout [integer]
check-host-attr [disabled | enabled]
check-roles-group [disabled | enabled]
debug [disabled | enabled]
description [string]
filter [ [filter name] | none]
idle-timeout [integer]
ignore-auth-info-unavail [no | yes]
ignore-unknown-user [disabled | enabled]
login-attribute [ [account name] | none]
login-filter [ [string] | none]
login-name [ [ldap attribute] | none]
port [ [name] | [integer]]
scope [base | one | sub]
search-base-dn [[search base dn] | none]
search-timeout [integer]
servers [add | delete | replace-all-with] {
  [ [ip address] | [server name] ...] }
servers none
ssl [disabled | enabled]
ssl-ca-cert-file [ [file name] | none]
ssl-check-peer [disabled | enabled]
ssl-ciphers [ [string] | none]
ssl-client-cert [ [string] | none]
ssl-client-key [ [string] | none]
ssl-cname-field [ subjectname-cn | san-other | san-email
  san-dns | san-x400 | san-dirname | san-ediparty
  san-uri | san-ipadd | san-rid ]
ssl-cname-otheroid [ [OID in dotted-decimal] | none]
sso [on | off]
version [integer]
warnings [disabled | enabled]
```

```
edit cert-ldap [ [ [name] | [glob] | [regex] ] ...]
```

#### options:

```
all-properties
non-default-properties
```

#### DISPLAY

```
list cert-ldap
```

```
list cert-ldap [ [ [name] | [glob] | [regex] ] ...]
```

```
show running-config cert-ldap
```

```
show running-config cert-ldap [ [ [name] | [glob] | [regex] ] ...]
```

#### options:

```
all-properties
non-default-properties
one-line
partition
```

#### DELETE

```
delete cert-ldap [name]
```

### DESCRIPTION

The CERT-LDAP authentication mode is required to provide Single Sign On capability to the control plane based on a valid client certificate. This mode involves configuring an Apache server to initiate a client certificate request, perform certificate validation against an OSCP server, and then authenticate/authorize certificate credentials against a configured remote LDAP server or a Microsoft(r) Windows(r) Active Directory(r). The mode is not based on basic HTTP authentication (that is, user name and password). CERT-LDAP mode is equivalent to LDAP mode with custom attributes.

To authenticate BIG-IP system users when their authentication data is

stored on a remote LDAP server, you create an LDAP configuration object, and then activate the object. Make sure that Apache is configured to support the client certificate validation.

To configure CERT-LDAP authentication for BIG-IP system users:

1. Use the cert-ldap component in the auth module to configure an LDAP configuration object.
2. To activate LDAP authentication for BIG-IP system users, run the command sequence `modify / auth source type cert-ldap`

#### EXAMPLES

```
create cert-ldap bigip_cert_ldap_auth servers add {my_ldap_server}
```

Creates a configuration object named `bigip_cert_ldap_auth`.

```
delete cert-ldap bigip_cert_ldap_auth
```

Deletes the configuration object named `bigip_cert_ldap_auth`.

#### OPTIONS

`bind-dn`

Specifies the distinguished name of an account to which to bind to perform searches. This search account is a Read-only account. You can also use the admin account as the search account. If an administrative distinguished name is not specified, then a bind is not attempted. The default value is none.

Note: If the remote server is a Microsoft Windows Active Directory server, the distinguished name must be in the form of an email address.

`bind-pw`

Specifies the password for the search account created on the LDAP server. This option is required if you enter a value for the `bind-dn` option. The default value is none.

`bind-timeout`

Specifies a bind timeout limit, in seconds. The default value is 30.

`check-host-attr`

Confirms the password for the bind distinguished name. This option is optional. The default value is disabled.

`check-roles-group`

Specifies whether to verify a user's group membership given in the remote-role definitions, formatted as `*member*of="group-dn"`. The default value is disabled.

`debug`

Enables or disables `syslog-ng` debugging information at the LOG DEBUG level. The default value is disabled. F5 Networks does not recommend using this option for normal configuration.

`description`

User defined description.

`filter`

Specifies a filter. Use this option for authorizing client traffic. The default value is none.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

`group-dn`

Specifies the group distinguished name. The system uses this option for authorizing client traffic. The default value is none.

`group-member-attribute`

Specifies a group member attribute. The system uses this option for authorizing client traffic. The default value is none.

`idle-timeout`

Specifies the idle timeout, in seconds, for connections. The default value is 3600 seconds.

`ignore-auth-info-unavail`

Specifies whether the system ignores authentication information if it is not available. The default value is no.

`ignore-unknown-user`

Specifies whether the system ignores a user that is unknown. The default value is disabled.

`login-attribute`

Specifies a logon attribute. Normally, the value for this option is `uid`; however, if the server is a Microsoft Windows Active Directory server, the value must be the account name `samaccountname` (not case-insensitive). The default value is none.

`login-filter`

Specifies the filter to be applied on the CN of the client certificate. This filter is a regular expression to extract required information from CN of client certificate which will be used to match against LDAP search results. The default is disabled.

`login-name`

Specifies the LDAP attribute holding the client name. (The client name is extracted from the client certificate as specified by `ssl-cname-field`.) The default is disabled.

**name** Specifies a unique name for the component. This option is required for the commands `create` and `modify`.

**partition**  
Displays the administrative partition within which the component resides.

**port** Specifies the port number or name for the LDAP service. Port 389 is typically used for non-SSL and port 636 is used for an SSL-enabled LDAP service. The default value is `ldap`.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

**scope**  
Specifies the search scope. The default value is `sub`. The possible values are:

**base** The search scope is base object. The base value is almost never useful for name service lookups.

**one** The search scope is one level.

**sub** The search scope is a subtree.

**search-base-dn**  
Specifies the search base distinguished name. The default value is `none`.

**search-timeout**  
Specifies the search timeout, in seconds. The default value is 30.

**servers**  
Specifies the LDAP servers that the system must use to obtain authentication information. You must specify a server when you create an LDAP configuration object.

**ssl** Enables or disables SSL functionality. The default is disabled.

Note that when you use `tmsh` to enable SSL for an LDAP service, the system does not change the port number from 389 to 636, as is required. To change the port number from the command line, use the `port` option, for example, `ldap [name] ssl enabled port 636`.

**ssl-ca-cert-file**  
Specifies the name of an SSL CA certificate using the full path to the file. The default value is `none`.

**ssl-check-peer**  
Specifies whether the system checks an SSL peer. The default value is disabled.

**ssl-ciphers**  
Specifies SSL ciphers. The default value is `none`.

**ssl-client-cert**  
Specifies the name of an SSL client certificate. The default value is `none`.

**ssl-client-key**  
Specifies the name of an SSL client key. The default value is `none`.

**ssl-cname-field**  
Specifies the value from the client certificate that provides the client name. The client name must appear in either the `subjectName` or `subjectAltName` (SAN) fields in the X.509v3 certificate. If it appears in the `subjectName` field, the client name must be the `commonName` (CN). If the client name appears in the SAN, it will have the specified type. If `san-other` is specified, the `ssl-cname-otheroid` must provide the OID of the UTF8 string containing the client name. The choices are: `subjectname-cn`, `san-other`, `san-email`, `san-dns`, `san-x400`, `san-dirname`, `san-ediparty`, `san-uri`, `san-ipadd`, or `san-rid`. The default value is `subjectname-cn`.

**ssl-cname-otheroid**  
Specifies the OID in dotted-decimal format of the UTF8 string in the client's X.509v3 `subjectAltName` "other" attribute. This value is required when `ssl-cname-field` is `san-other`. The default value is `none`.

**sso** Enables or disables Single Sign On (SSO) functionality. SSO eliminates the need to administer and maintain multiple user logons and eliminates the need for users to enter their credentials multiple times. When SSO is disabled, the user will be prompted to authenticate into the BIG-IP. The default is `off`.

**user-template**  
Specifies a user template for the LDAP application to use for authentication. The default value is `none`.

**version**  
Specifies the version number of the LDAP application. The default value is 3.

**warnings**  
Enables or disables warning messages. The default value is `enabled`.

### DESCRIPTION

LDAP authentication is useful when the BIG-IP system users authentication or authorization data is stored on a remote LDAP server or a Microsoft(r) Windows(r) Active Directory(r) server, and you want the user credentials to be based on basic HTTP authentication (that is, user name and password).

To authenticate BIG-IP system users when their authentication data is stored on a remote LDAP server, you create an LDAP configuration object, and then activate the object.

The following steps describe how to configure LDAP authentication for

BIG-IP system users:

1. Use the ldap component in the auth module to configure an LDAP configuration object.
2. To activate LDAP authentication for BIG-IP system users, run the command sequence modify / auth source type ldap

#### EXAMPLES

```
create ldap bigip_ldap_auth servers add {my_ldap_server}
```

Creates a configuration object named bigip\_ldap\_auth

```
delete ldap bigip_ldap_auth
```

Deletes the configuration object named bigip\_ldap\_auth.

#### OPTIONS

bind-dn

Specifies the distinguished name of an account to which to bind to perform searches. This search account is a Read-only account. You can also use the admin account as the search account. If an administrative distinguished name is not specified, then a bind is not attempted. The default value is none.

Note that if the remote server is a Microsoft Windows Active Directory server, the distinguished name must be in the form of an email address.

bind-pw

Specifies the password for the search account created on the LDAP server. This option is required if you enter a value for the bind-dn option. The default value is none.

bind-timeout

Specifies a bind timeout limit, in seconds. The default value is 30.

check-host-attr

Confirms the password for the bind distinguished name. This option is optional. The default value is disabled.

check-roles-group

Specifies whether to verify a user's group membership given in the remote-role definitions, formatted as \*member\*of="group-dn". The default value is disabled.

debug

Enables or disables syslog-ng debugging information at the LOG DEBUG level. The default value is disabled. F5 Networks does not recommend using this option for normal configuration.

description

User defined description.

filter

Specifies a filter. Use this option for authorizing client traffic. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

group-dn

Specifies the group distinguished name. The system uses this option for authorizing client traffic. The default value is none.

group-member-attribute

Specifies a group member attribute. The system uses this option for authorizing client traffic. The default value is none.

idle-timeout

Specifies the idle timeout, in seconds, for connections. The default value is 3600 seconds.

ignore-auth-info-unavail

Specifies whether the system ignores authentication information if it is not available. The default value is no.

ignore-unknown-user

Specifies whether the system ignores a user that is unknown. The default value is disabled.

login-attribute

Specifies a logon attribute. Normally, the value for this option is uid; however, if the server is a Microsoft Windows Active Directory server, the value must be the account name samaccountname (not case-insensitive). The default value is none.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which the component resides.

port Specifies the port number or name for the LDAP service. Port 389 is typically used for non-SSL and port 636 is used for an SSL-enabled LDAP service. The default value is ldap.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**scope**  
Specifies the search scope. The default value is sub. The possible values are:

**base** The search scope is base object. The base value is almost never useful for name service lookups.

**one** The search scope is one level.

**sub** The search scope is a subtree.

**search-base-dn**  
Specifies the search base distinguished name. The default value is none.

**search-timeout**  
Specifies the search timeout, in seconds. The default value is 30.

**servers**  
Specifies the LDAP servers that the system must use to obtain authentication information. You must specify a server when you create an LDAP configuration object.

**ssl** Enables or disables SSL functionality. The default is disabled.

Note that when you use tmsh to enable SSL for an LDAP service, the system does not change the port number from 389 to 636, as is required. To change the port number from the command line, use the port option, for example, ldap [name] ssl enabled port 636.

**ssl-ca-cert-file**  
Specifies the name of an SSL CA certificate using the full path to the file. The default value is none.

**ssl-check-peer**  
Specifies whether the system checks an SSL peer. The default value is disabled.

**ssl-ciphers**  
Specifies SSL ciphers. The default value is none.

**ssl-client-cert**  
Specifies the name of an SSL client certificate. The default value is none.

**ssl-client-key**  
Specifies the name of an SSL client key. The default value is none.

**user-template**  
Specifies a user template for the LDAP application to use for authentication. The default value is none.

**version**  
Specifies the version number of the LDAP application. The default value is 3.

**warnings**  
Enables or disables warning messages. The default value is enabled.

## auth login-failures

**NAME**  
login-failures - Displays or resets the status of the accounts of users whose attempts to log in to the BIG-IP(r) system have failed.

**MODULE**  
auth

**SYNTAX**  
Configure the login-failures component within the auth module using the following syntax.

**MODIFY**

```
reset-stats login-failures
  options:
    username

DISPLAY
show login-failures
  options:
    field-fmt
    username

DESCRIPTION
  Users assigned a role of Administrator can reset the status of a user
  who is locked out of the BIG-IP system due to enforcement of a
  company's security requirements. Users assigned other roles can only
  view login failures.

EXAMPLES
  show login-failures

  Displays the login failure status of all users.

  show login-failures joe

  Displays login failure status for the user joe.

  reset-stats login-failures

  Resets the failed login counters for all users to zero and unlocks all
  users.

  reset-stats login-failures joe

  Resets the failed login counter for the user joe to zero and unlocks
  the user joe.

OPTIONS
  show For information about the options that you can use with the show
  command, see help show.

  username
  Specifies a user account to display or reset.

SEE ALSO
  auth user, reset-stats, show, tmsh

COPYRIGHT

## auth partition

```
NAME
  partition - Configures administrative partitions that implement access
  control for BIG-IP(r) system users.

MODULE
  auth

SYNTAX
  Configure the partition component within the auth module using the
  syntax shown in the following sections.

  CREATE/MODIFY
  create partition [name]
  modify partition [name]
  options:
    default-route-domain [ID]
    description [string]

  DISPLAY
  list partition
  list partition [ [ [name] | [glob] | [regex] ] ...]
  show running-config partition
  show running-config partition [ [ [name] | [glob] | [regex] ] ...]
  options:
    all-properties
    non-default-properties
    one-line

  DELETE
  delete partition [name]
  options:
    all
```

## DESCRIPTION

An administrative partition is a logical container that you create, containing a defined set of BIG-IP system objects, such as virtual servers, pools, and profiles. When a specific set of objects resides in a partition, you can then give certain users the authority to view and manage the objects in that partition only, rather than all objects on the BIG-IP system. This gives a finer degree of administrative control.

You can configure administrative partitions, only if the Administrator user role is assigned to your user account.

## EXAMPLES

```
create partition partition_A description "Repository for application_A
objects"
```

Creates a partition named `partition_A` that contains objects related to `application_A`.

```
delete partition partition_B
```

Deletes the partition named `partition_B`.

## OPTIONS

`description`

Describes the contents of the partition. If you use spaces in the description, you must put quotation marks around the descriptive text, for example, "This partition contains local traffic management objects for managing HTTP traffic."

`default-route-domain`

Specifies the ID of the route domain that is associated with the IP addresses that reside in the partition. For more information, see `help net route-domain`.

`glob` Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create` and `modify`.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

## SEE ALSO

`auth user`, `create`, `delete`, `glob`, `list`, `modify`, `net route-domain`, `regex`, `show`, `tmsh`

## auth password-policy

### NAME

`password-policy` - Specifies the parameters of the valid passwords for the BIG-IP(r) system.

### MODULE

`auth`

### SYNTAX

Configure the `password-policy` component within the `auth` module using the syntax shown in the following sections.

#### MODIFY

```
modify password-policy
```

```
options:
```

```
expiration-warning [integer]
max-duration [integer]
max-login-failures [integer]
min-duration [integer]
minimum-length [integer]
password-memory [integer]
policy-enforcement [disabled | enabled]
required-lowercase [integer]
required-numeric [integer]
required-special [integer]
required-uppercase [integer]
```

#### DISPLAY

```
list password-policy
list password-policy
show running-config password-policy
show running-config password-policy
options:
  all-properties
  non-default-properties
  one-line
```

#### DESCRIPTION

Users assigned a role of Administrator or Resource Administrator can modify a password policy for the BIG-IP system to enforce a company's security requirements by defining the parameters for valid passwords. Users assigned other roles can view password policies.

#### EXAMPLES

```
password-policy max-duration 90 min-duration 30 minimum-length 6
required-lowercase 2 required-uppercase 2 required-special 1 required-
numeric 1 expiration-warning 5
```

Creates a password policy that specifies that passwords are valid for a maximum of 90 days and a minimum of 30 days. Also specifies that to be valid, a password must contain at least 6 characters, but not more than 10 characters, including 2 lowercase alpha characters, 2 uppercase alpha characters, and 1 number. Additionally, this policy specifies that the system automatically warns users five days before their passwords expire.

```
list password-policy
```

Displays the password policy.

#### OPTIONS

**expiration-warning**

Specifies the number of days before a password expires. Based on this value, the BIG-IP system automatically warns users when their password is about to expire. The default value is 7 days.

**max-duration**

Specifies the maximum number of days a password is valid. The default value is 99999.

**max-login-failures**

Specifies the number of consecutive unsuccessful login attempts that the system allows before locking out the user. The default value is 0 (zero - disabled).

**min-duration**

Specifies the minimum number of days a password is valid. The default value is 0 (zero).

**minimum-length**

Specifies the minimum number of characters in a valid password. The default value is 6.

**password-memory**

Specifies whether the user has configured the BIG-IP system to remember a password on a specific computer. The default value is 0 (zero).

**policy-enforcement**

Enables or disables the password policy on the BIG-IP system. The default value is disabled.

**required-lowercase**

Specifies the number of lowercase alpha characters that must be present in a password for the password to be valid. The default value is 0 (zero).

**required-numeric**

Specifies the number of numeric characters that must be present in a password for the password to be valid. The default value is 0 (zero).

**required-special**

Specifies the number of special characters that must be present in a password for the password to be valid. The default value is 0 (zero).

**required-uppercase**

Specifies the number of uppercase alpha characters that must be present in a password for the password to be valid. The default value is 0 (zero).

## auth password

**NAME**  
password - Prompts for modification of a password, and asks for a confirmation of the new password.

**MODULE**  
auth

**SYNTAX**  
Configure the password component within the auth module using the syntax shown in the following sections.

**USAGE**  
modify password

**DESCRIPTION**  
If you are assigned the user role of Administrator or User Manager, you can change another user's password.

For example, from within the auth module, run the following command sequence: modify password [user name].

The system prompts you for a new password for the specified user, and then to confirm the new password.

If you are assigned any other user role, the system prompts you to change your own password, and then confirm the new password.

To change a password from within another module, use the full path to the password.

**EXAMPLES**  
(tmos.auth)# modify password  
From within the auth module, displays the new password: prompt.  
(tmos.gtm)# modify / auth password  
From within the gtm module, displays the new password: prompt.

**SEE ALSO**  
auth user, modify, tmsh

**COPYRIGHT**

---

## auth radius-server

**NAME**  
radius-server - Configures a RADIUS server for implementing remote RADIUS-based authentication of BIG-IP(r) system users.

**MODULE**  
auth

**SYNTAX**  
Configure the radius-server component within the auth module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create radius-server [name]  
modify radius-server [name]  
options:  
  app-service [[string] | none]  
  description [string]  
  port [ [name] | [number] ]  
  secret [none | ["string"] ]  
  server [ [hostname] | [IP address] | none]  
  timeout [integer]

edit radius-server [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

```
DISPLAY
list radius-server
list radius-server [ [name] | [glob] | [regex] ] ...]
show running-config radius-server
show running-config radius-server [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete radius-server [name]
```

#### DESCRIPTION

To authenticate BIG-IP system users when their authentication data is stored on a remote RADIUS server, you configure a RADIUS server, configure a RADIUS configuration object that references that RADIUS server, and then activate RADIUS authentication for the BIG-IP system. In this case, client credentials are based on basic HTTP authentication (that is, user name and password).

To configure RADIUS authentication for the BIG-IP system:

1. Use the radius-server component in the auth module to configure a RADIUS server.
2. Use the radius component in the auth module to create a RADIUS configuration object that references the RADIUS server you created in the Step 1. For more information about creating a RADIUS configuration object, see help radius.
3. To activate RADIUS authentication for BIG-IP system users, type the following command sequence: modify / auth source type radius

#### EXAMPLES

```
create radius-server bigip_auth_radius_server secret "This is the
secret." server 10.1.1.1

Creates a RADIUS server component named bigip_auth_radius_server.

delete radius-server bigip_auth_radius_server

Deletes the RADIUS server component named bigip_auth_radius_server.
```

#### OPTIONS

```
app-service
Specifies the name of the application service to which the RADIUS
server belongs. The default value is none. Note: If the strict-
updates option is enabled on the application service that owns the
object, you cannot modify or delete the RADIUS server. Only the
application service can modify or delete the RADIUS server.

description
User defined description.

glob Displays the items that match the glob expression. See help glob
for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required
for the commands create and modify.

partition
Displays the partition in which the radius server resides.

port Specifies the port for RADIUS authentication traffic. The default
value is 1812.

regex
Displays the items that match the regular expression. The regular
expression must be preceded by an at sign (@[regular expression])
to indicate that the identifier is a regular expression. See help
regex for a description of regular expression syntax.

secret
Specifies the secret key the system uses to encrypt and decrypt
packets sent from or received by the server. This option is
required.

server
Specifies the host name or IP address of the RADIUS server. This
option is required.

timeout
Specifies the timeout value in seconds. The default value is 3.
```

```
delete radius [name]
```

### DESCRIPTION

To authenticate BIG-IP system users when their authentication data is stored on a remote RADIUS server, you configure a RADIUS server, configure a RADIUS configuration object that references that RADIUS server, and then activate RADIUS authentication for the BIG-IP system. In this case, client credentials are based on basic HTTP authentication (that is, user name and password).

To configure RADIUS authentication for the BIG-IP system:

1. Use the radius-server component in the auth module to configure a RADIUS server. For more information about creating a RADIUS server, see help radius-server.

2. Use the radius component in the auth module to create a RADIUS configuration object that references the RADIUS server you created in Step 1.

3. To activate RADIUS authentication for BIG-IP system users, type the following command sequence: modify / auth source type radius

### EXAMPLES

```
create radius bigip_radius_auth servers add {myradiusserver}
```

Creates a RADIUS configuration object named bigip\_radius\_auth.

```
delete radius bigip_radius_auth
```

Deletes the RADIUS configuration component named bigip\_radius\_auth.

### OPTIONS

accounting-bug

Enables or disables validation of the accounting response vector. This option is necessary only on older servers. The default value is disabled.

app-service

Specifies the name of the application service to which the RADIUS configuration object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the RADIUS configuration object. Only the application service can modify or

delete the RADIUS configuration object.

**client-id**

Sends a NAS-Identifier RADIUS attribute with string bar. If you do not specify a value for this option, the system uses the pluggable authentication module (PAM) service type. You can disable this feature by specifying a blank client ID.

**debug**

Enables or disables syslog-ng debugging information at the LOG DEBUG level. F5 Networks does not recommend this option for normal use. The default value is disabled.

**description**

User defined description.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**partition**

Displays the partition within which the component resides.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**retries**

Specifies the number of authentication retries that the BIG-IP local traffic management system allows before authentication fails. The default value is 3.

**service-type**

Specifies the type of service used for the RADIUS server. The default is default, which behaves as authenticate-only.

**servers**

Specifies the host names or IP addresses of existing RADIUS servers that the BIG-IP system uses to obtain authentication data.

SEE ALSO

---

## auth remote-role

NAME

remote-role - Creates remote role information in a file that an LDAP, Active Directory(r), RADIUS, or TACACS+ server reads to determine the specific access rights to grant to groups of remotely-authenticated users.

MODULE

auth

SYNTAX

Configure the remote-role component within the auth module using the syntax shown in the following sections.

MODIFY

modify remote-role

options:

```
description [string]
role-info [add | delete | modify | replace-all-with] {
  [group-name] {
    options:
      attribute [string]
      console [disabled | tmsh]
      description [string]
      deny [enabled | disabled]
      line-order [integer]
      role [acceleration-policy-editor | admin | fraud-protection-manager |
application-editor | auditor | certificate-manager |
firewall-manager | guest | irule-manager | manager |
no-access | operator | resource-admin | user-manager |
```

```

web-application-security-administrator |
web-application-security-editor]
user-partition [all | Common | [name] ]
user-partition [%string]
}
}
role-info none

DISPLAY
list remote-role
show running-config remote-role
options:
all-properties
non-default-properties
one-line

```

#### DELETE

You cannot delete the remote-role defaults, you can only modify the values of the options.

#### DESCRIPTION

You can use the remote-role component to grant access to a specific group of remotely-authenticated users without creating a local user account on the BIG-IP(r) system for each user in the group.

Users assigned the role of Administrator can modify remote roles. Users assigned all other roles can view remote roles.

You can use the variable substitution feature to assign access rights for a group of remote users by specifying a text string variable that is preceded by a leading % character for the options attribute, console, role and user-partition. For example, if you define the remote role for the groups DC1 and DC2 as follows:

```

remote-role {
  role info {
    dc1 {
      attribute "F5-LTM-User-Info-1=DC1"
      console %F5-LTM-User-Console
      line-order 1
      role %F5-LTM-User-Role
      user-partition %F5-LTM-User-Partition
    }
    dc2 {
      attribute "F5-LTM-User-Info-1=DC2"
      line-order 2
    }
  }
}
}

```

The BIG-IP(r) system attempts to match the value of the attribute option, F5-LTM-User-Info-1=DC1, and then pulls the value of the console, role and user-partition options from the other variables.

Note: If a variable includes an incorrect value, the system does not authorize the user. Additionally, if you have not defined the variables, as with the group DC2 above, the system authenticates the user with the following access rights:

```

console = disabled
role = none
user-partition = none

```

#### EXAMPLES

```

modify remote-role role-info add { my_managers { attribute
"memberOF=cn=BigIPmanagerGroup,cn=users,dc=mydept,dc=mycompany,dc=com"
console disabled line-order 1000 role 100 user-partition all } }

```

Configures a remote role, named my\_managers, for LDAP authentication, by creating the 1000th line of the /config/bigip/auth/remoterole file, and granting the Manager role (100) in all partitions to the remote users assigned this role.

```

modify remote-role role-info add { my_admins { attribute "NS-Admin-
Privilege" console tmsh line-order 1000 role 0 user-partition all } }

```

Configures a remote role, named my\_admins, for LDAP authentication, by creating the 2000th line of the /config/bigip/auth/remoterole file, and granting the Administrator role (0) in all partitions to the remote users assigned this role.

```

modify remote-role role-info add { my_managers { attribute
"manager_group=manager" console tmsh line-order 3000 user-partition all
} }

```

Configures a remote role, named my\_managers, for RADIUS or TACACS+ authentication, by creating the 3000th line of the /config/bigip/auth/remoterole file, and granting the Administrator role (0) in all partitions to the remote users assigned this role:

#### OPTIONS

**description**  
Specifies a user-defined description.

**role-info**  
Configures the access rights for a specific group of remotely-authenticated users. You can configure the following information for a role:

**attribute**  
Specifies an attribute-value pair that an authentication server supplies to the BIG-IP system to match against entries in /config/bigip/auth/remoterole. The specified pair typically identifies users with access rights in common. This

option is required.

Alternatively, you can use the variable substitution feature (described in the Description section above), and specify a text string variable that is preceded by a leading % character.

**console**  
Enables or disables console access for the specified group of remotely-authenticated users. The default value is disabled.

When using variable substitution, as described in the Description section of this man page, the variable for the console option must be: tmsh.

**deny** Enables or disables remote access for the specified group of remotely-authenticated users. The default value is disabled.

**description**  
Specifies a user-defined description.

**group-name**  
Specifies the name of the remote role that you are configuring. This option is required.

**line-order**  
Specifies the number of the first populated line in the file, /config/bigip/auth/remoterole. The LDAP, Active Directory, RADIUS, and TACACS+ servers read this file line by line. The order of the information is important; therefore, F5 Networks recommends that you set the first line at 1000. This allows you, in the future, to insert lines before the first line. This option is required.

**role** Specifies the role that you want to grant to the specified group of remotely-authenticated users. The default value is no-access. The available roles are:

- admin
- fraud-protection-manager
- application-editor
- certificate-manager
- firewall-manager
- guest
- manager
- no-access
- operator
- resource-admin
- web-application-security-administrator
- web-application-security-editor
- user-manager

When using variable substitution, as described in the Description section above, the variable for the role option must evaluate to one of these values: 0 (admin), 20 (resource admin), 40 (user manager), 80 (auditor), 100 (manager), 300 (application editor), 350 (advanced operator), 400 (operator), 450 (firewall manager), 500 (certificate manager), 510 (irule manager), 700 (guest), 800 (web application security administrator), 810 (web application security editor), 850 (acceleration policy editor), 900 (no-access).

**user-partition**  
Specifies the user partition to which you are assigning access to the specified group of remotely-authenticated users. The default value is Common. This option is required.

Alternatively, you can use the variable substitution feature (described in the Description section above) and specify a text string variable that is preceded by a leading % character.

## auth remote-user

### NAME

remote-user - Configures the default role, partition access, and console access for all remotely authenticated user accounts that have not been added as local user accounts on the BIG-IP(r) system.

### MODULE

auth

### SYNTAX

Configure the remote-user component within the auth module using the syntax shown in the following sections.

#### MODIFY

modify remote-user

##### options:

default-partition [all | Common | [partition name] ]  
default-role [acceleration-policy-editor | admin |  
fraud-protection-manager | application-editor |  
auditor | firewall-manager | guest |  
irule-manager | manager | no-access |  
operator | resource-admin | user-manager |  
web-application-security-administrator |  
web-application-security-editor ]  
description [string]  
remote-console-access [disabled | tmsh]

#### DISPLAY

list remote-user

show running-config remote-user

##### options:

all-properties  
non-default-properties  
one-line

#### DELETE

You cannot delete the remote-user defaults, you can only modify the values of the options.

### DESCRIPTION

You can use the remote-user component to configure the default parameters for all the remote user accounts on the BIG-IP system as a group. To assign a different access level to a specific remote user, you must create a local user account for that user on the BIG-IP system. See the auth user man page for more information.

Users assigned the role of Administrator or Resource Administrator can modify the parameters of the remote-user component. Users assigned all other roles can view the parameters of the remote-user component.

### EXAMPLES

```
modify remote-user default-partition Common default-role no access  
remote-console-access disabled
```

For all remote users, sets the default partition access to partition Common, the default role to no-access, and the default remote console access to disabled.

```
modify remote-user default-partition all default-role no access  
remote-console-access disabled
```

For all remote users, sets the default partition access to all partitions, the default role to no-access, and the default remote console access to disabled.

### OPTIONS

#### default-partition

Specifies the default partition for all remote user accounts. The default value is all.

#### default-role

Specifies the default role for all remote user accounts. The default value is no-access.

#### description

Specifies a user-defined description.

#### remote-console-access

Specifies whether you are granting this user access to tmsh or disabling remote console access for this user. The default value is disabled.

### SEE ALSO

auth remote-role, auth user, list, modify, show, tmsh

## auth source

**NAME**  
source - Configures the authorization source type for a BIG-IP(r) system.

**MODULE**  
auth

**SYNTAX**  
Configure the source component within the auth module using the syntax in the following sections.

**MODIFY**  
modify source  
options:  
type [active-directory | ldap | local | radius | tacacs | cert-ldap | apm-auth]  
fallback [true | false]

**DISPLAY**  
list source  
list source [option]  
options:  
all-properties  
non-default-properties  
one-line

**DESCRIPTION**  
You can use the source component to set up the authorization source type for the BIG-IP system. The fallback setting enables system auth fallback from remote to local.

**EXAMPLES**  
modify auth source type tacacs  
  
Sets up the authorization source type as tacacs.  
  
list auth source type  
  
Displays the authorization source type.

**OPTIONS**  
type Specifies the default user authorization source. The default value is local. When user accounts that access the system reside on a remote server, the value of the this option is the type of server that you are using for authentication, for example, ldap.  
  
fallback  
When true and type is set to a remote authentication source, if the remote server is unavailable, authentication will fall back to local authentication. The default value is false.

**SEE ALSO**  
list, modify, tmsh

**COPYRIGHT**

## auth tacacs

**NAME**  
tacacs - Configures a TACACS+ configuration object for implementing remote authentication of BIG-IP(r) system users based on TACACS+.

**MODULE**  
auth

**SYNTAX**

Configure the tacacs component within the auth module using the syntax shown in the following sections.

```
CREATE/MODIFY
create tacacs [name]
modify tacacs [name]
options:
  accounting [send-to-first-server | send-to-all-servers]
  app-service [[string] | none]
  authentication [use-first-server | use-all-servers]
  debug [disabled | enabled]
  description [string]
  encryption [disabled | enabled]
  protocol [none | [protocol] ]
  secret [ "[string]" ]
  servers
    [add | delete | replace-all-with] {
  [ [hostname[:port]] | [ip address[:port]] ] ... ]
  }
  service [ [name] | none]
  timeout [integer]
```

```
edit tacacs [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list tacacs
list tacacs [ [ [name] | [glob] | [regex] ] ... ]
show running-config tacacs
show running-config tacacs [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete tacacs [name]
```

#### DESCRIPTION

To authenticate BIG-IP system users when their authentication data is stored on a remote TACACS+ server, you create a TACACS+ configuration object, and then activate the object.

To configure TACACS+ authentication for BIG-IP system users:

1. Use the tacacs component in the auth module to configure a TACACS+ configuration object.
2. To activate TACACS+ authentication for BIG-IP system users, run the following command sequence: `modify / auth source type tacacs`

#### EXAMPLES

```
create tacacs bigip_tacacs_auth servers add {my_tacacs_server}
```

Creates a TACACS+ configuration object named `bigip_tacacs_auth`.

```
delete tacacs bigip_tacacs_auth
```

Deletes the TACACS+ configuration object named `bigip_tacacs_auth`.

#### OPTIONS

##### accounting

If multiple TACACS+ servers are defined and pluggable authentication module (PAM) session accounting is enabled, sends accounting start and stop packets to the first available server or to all servers. The default value is `send-to-first-server`.

Possible values are:

##### send-to-all-servers

The system sends accounting start and stop packets to all servers.

##### send-to-first-server

The system sends accounting start and stop packets to the first available server.

##### app-service

Specifies the name of the application service to which the TACACS+ configuration object belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the TACACS+ configuration object. Only the application service can modify or delete the TACACS+ configuration object.

##### authentication

Specifies the process the system employs when sending authentication requests. The default value is `use-first-server`.

Possible values are:

##### use-all-servers

The system sends an authentication request to each server until authentication succeeds, or until the system has sent a request to all servers in the list.

##### use-first-server

The system sends authentication requests to only the first server in the list.

##### debug

Enables syslog-ng debugging information at the LOG DEBUG level. F5 Networks does not recommend this option for normal use. The default value is disabled.

**description**  
User defined description.

**encryption**  
Enables or disables encryption of TACACS+ packets. F5 Networks recommends this option for normal use. The default value is enabled.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**partition**  
Displays the administrative partition within which the component resides.

**protocol**  
Specifies the protocol associated with the value specified in the service option, which is a subset of the associated service being used for client authorization or system accounting.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**secret**  
Sets the secret key used to encrypt and decrypt packets sent or received from the server. This option is required.

**servers**  
Specifies the host name or IPv4 address of the TACACS+ server. For each server, a port may optionally be specified in the format hostname:port or IPv4:port. If no port is specified, the default port 49 is used. This option is required.

**service**  
Specifies the name of the service that the user is requesting to be authenticated to use. Identifying the service enables the TACACS+ server to behave differently for different types of authentication requests. This option is required.

**timeout** Specifies the connect timeout in seconds. The default value is 10 seconds. Zero indicates no timeout.

---

## auth user

**NAME**  
user - Configures user accounts for the BIG-IP(r) system.

**MODULE**  
auth

**SYNTAX**  
Modify the user component within the auth module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create user [name]
modify user [name]
```

#### options:

```
description [text...]
partition-access [add | modify | delete |replace-all-with { [partition-name] { role [role-name] } } ]
password [text]
prompt-for-password
shell [name]
```

```
where [role-name]: [acceleration-policy-editor | admin | fraud-
protection-manager |
```

```
application-editor | auditor | certificate-manager |
firewall-manager | guest | irule-manager | manager |
no-access | operator | resource-admin | user-manager |
web-application-security-administrator |
web-application-security-editor]
```

#### DISPLAY

```
list user
list user [ [ [name] | [glob] | [regex] ] ... ]
show running-config user
show running-config user [ [ [name] | [glob] | [regex] ] ... ]
options:
  encrypted-password
  one-line
  partition
show user
options:
  field-fmt
```

#### DELETE

```
delete user [name]
```

#### DESCRIPTION

You can create user accounts where the user names differ only by case-sensitivity (for example, david and DAVID).

You can configure the partition-access property to grant a user access to more than one partition on the system. In the case where you do not grant the user access to all partitions, you can assign the user a different user role for each partition. A user can have only one role per partition. Any user with a role of Administrator, Resource Administrator, Web Application Security Administrator, or Auditor always has access to all partitions and can have no other role on the system.

Only users with the Administrator or User Manager roles are allowed to create or modify user accounts.

Additionally, only users with the Administrator, Resource Administrator, or User Manager user role can view all of the user accounts in all of the partitions to which the user has access. Therefore, if you have a user role other than one of these roles, you can only view your own user account.

#### EXAMPLES

```
create user nwinters partition-access add { all-partitions { role guest
} }
```

Creates a new user named nwinters with a role of Guest in all partitions.

```
create user tknox password aBcD007 partition-access add { partition1 {
role operator } }
```

Creates a new user named tknox with a role of operator in partition named partition1 and sets the user's login password.

```
list user
```

Displays the viewable properties of all user accounts.

```
show user
```

Displays each user role and the corresponding partition access that is currently assigned to the user.

#### OPTIONS

description

Describes the user account in free form text.

encrypted-password

Displays the encrypted password for the user account.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

Note: User account names are case-sensitive.

partition

Displays the name of the administrative partition in which the user account resides.

partition-access

Specifies the administrative partitions to which the user currently has access. Note that in addition to these partitions, the user also has read access to the shared partitions Common and Root. An exception to this is any user with the role No Access.

role Specifies the user role that pertains to the partition specified by the partition-access property. If you do not want to assign a user role to the user account, specify the value no-access. This prevents the user from accessing the system.

password

Sets the user password during creation or modification of a user account without prompting or confirmation. May not be used with prompt-for-password. Passwords are hidden in log and history files.

prompt-for-password

Indicates that when the account is created or modified, the BIG-IP

system prompts the administrator or user manager for both a password and a password confirmation for the account.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### shell

Specifies the shell to which the user has access. Valid values are:

**bash** Provides an unrestricted system prompt. You can assign access to the bash shell only to users with the Administrator or Resource Administrator role. However, F5 Networks recommends that you do not give bash shell access to users with the Resource Administrator user role unless they use the tcpdump, ssldump, or qkview utilities, or if they manage certificate and key files using the console. Instead, F5 Networks recommends that you give these users tmsh access.

**none** Specifies no shell access. The user must use the Configuration utility.

**tmsh** Provides access to the Traffic Management shell.

## cli

### cli admin-partitions

#### NAME

admin-partitions - Set the administrative partition for a BIG-IP(r) configuration file.

#### MODULE

cli

#### SYNTAX

Configure the admin-partitions component within the cli module using the syntax in the following sections.

#### MODIFY

admin-partitions

options:

update-partition [name]

#### DESCRIPTION

You can use the admin-partitions component to set the administrative partition in which configuration will be loaded when a configuration file is being loaded.

This component is only available from a configuration file that is being loaded via the sys config component with the file option.

#### EXAMPLES

```
cli admin-partitions { update-partition partition_A }
```

Sets the administrative partition in which configuration will be loaded. Configuration that follows this directive will be placed in partition\_A.

#### OPTIONS

update-partition

Sets the administrative partition in which you can configure objects.

#### SEE ALSO

load, sys config, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express

written permission of F5 Networks, Inc.

## cli alias private

**NAME**  
private - Configures a user private alias.

**MODULE**  
cli alias

**SYNTAX**  
Configure the alias component within the cli alias module using the syntax in the following sections.

**CREATE/MODIFY**

```
create private [name]
  options:
    command [commandSyntax]
    command ["command syntax"]
    command "[command syntax]; [command syntax]; ..."
    app-service [[string] | none]
    description [string]

edit private [name]
  options:
    all

modify alias [name]
  options:
    command [commandSyntax]
    command ["command syntax"]
    command "[command syntax]; [command syntax]; ..."
```

**DISPLAY**

```
list private
list alias [ [name] | [glob] | [regex] ] ...]
show running-config private
show running-config private [ [name] | [glob] | [regex] ] ...]
  options:
    all-properties
    one-line
    non-default-properties
```

**DELETE**

```
delete private [all | [name ... name] ]
```

**DESCRIPTION**

You can use the private component to create a shortcut that runs a tmsh command sequence. The name of the private alias is what you type on the command line to run the command. If the command sequence for which you are creating an alias contains spaces, it must be enclosed in quotation marks. Command aliases are not case-sensitive.

You can create a private alias that runs multiple commands by entering the command sequences separated by semi-colons.

Private aliases can be used only by the user who created them.

When a batch mode transaction is active, commands that operate on the private component are run immediately and are not added to the transaction.

For more information about aliases, see the Traffic Management Shell (tmsh) Reference Guide.

**EXAMPLES**

```
create private save command "save config"
```

Creates an alias that saves the running configuration in the stored configuration files from anywhere within tmsh.

```
create private stats command "show /sys traffic"
```

Creates an alias that displays traffic statistics from anywhere within tmsh.

```
create private nodemonitor command "list /ltm node; list /ltm monitor"
```

Creates an alias that displays the Local Traffic Manager nodes and monitors.

```
create private myalias command "show /sys provision ; show /sys license"
```

Creates an alias that displays license and provisioning information.

```
create private ltmpool command "list /ltm pool"
```

Creates an alias that displays the Local Traffic Manager pools from anywhere within tmsh.

#### OPTIONS

##### command syntax

Specifies the command for which you are creating an alias. To create an alias that runs multiple commands, enter the command sequences separated by semi-colons.

##### app-service

Specifies the name of the application service to which the alias belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the alias. Only the application service can modify or delete the alias.

##### description

Specifies the purpose of the alias. If you enable cli preference show-aliases, tmsh displays the description in context-sensitive help (?).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a name for the alias. This is what you type in tmsh to run the command for which you are creating an alias.

##### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### SEE ALSO

create, delete, edit, glob, list, modify, regex, show, shared, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2012. All rights reserved.

## cli alias shared

#### NAME

shared - Configures a shared alias.

#### MODULE

cli alias

#### SYNTAX

Configure the shared alias component within the cli alias module using the syntax in the following sections.

##### CREATE/MODIFY

```
create shared [name]
```

##### options:

```
command [commandSyntax]
command ["command syntax"]
command "[command syntax]; [command syntax]; ..."
app-service [[string] | none]
description [string]
```

```
edit shared [name]
```

##### options:

```
all
```

```
modify alias [name]
```

##### options:

```
command [commandSyntax]
command ["command syntax"]
command "[command syntax]; [command syntax]; ..."
```

##### DISPLAY

```
list shared
```

```
list alias [ [ [name] | [glob] | [regex] ] ...]
```

```
show running-config shared
```

```
show running-config shared [ [ [name] | [glob] | [regex] ] ...]
```

##### options:

```
all-properties
one-line
non-default-properties
```

##### DELETE

```
delete shared [all | [name ... name] ]
```

#### DESCRIPTION

You can use the shared component to create a shortcut to run a tmsh command sequence. The name of the shared alias is what you type on the command line to run the command. If the command sequence for which you are creating an alias contains spaces, it must be enclosed in quotation marks. Command aliases are not case-sensitive.

You can create a shared alias that runs multiple commands by entering the command sequences separated by semi-colons.

Shared aliases can be used by all users.

When a batch mode transaction is active, commands that operate on the shared component are run immediately and are not added to the transaction.

For more information about aliases, see the Traffic Management Shell (tmsh) Reference Guide.

#### EXAMPLES

```
create shared save command "save config"
```

Creates an alias that saves the running configuration in the stored configuration files from anywhere within tmsh.

```
create shared stats command "show /sys traffic"
```

Creates an alias that displays traffic statistics from anywhere within tmsh.

```
create shared nodemonitor command "list /ltm node; list /ltm monitor"
```

Creates an alias that displays the Local Traffic Manager nodes and monitors.

```
create shared myalias command "show /sys provision ; show /sys license"
```

Creates an alias that displays license and provisioning information.

```
create shared ltmpool command "list /ltm pool"
```

Creates an alias that displays the Local Traffic Manager pools from anywhere within tmsh.

#### OPTIONS

**command syntax**

Specifies the command for which you are creating an alias. To create an alias that runs multiple commands, enter the command sequences separated by semi-colons.

**app-service**

Specifies the name of the application service to which the alias belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the alias. Only the application service can modify or delete the alias.

**description**

Specifies the purpose of the alias. If you enable cli preference show-alias, tmsh displays the description in context-sensitive help (?).

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**name** Specifies a name for the alias. This is what you type in tmsh to run the command for which you are creating an alias.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### SEE ALSO

create, delete, edit, glob, list, modify, regex, show, shared, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2012. All rights reserved.

BIG-IP 2015-12-28 cli alias shared(1)

**NAME**  
 global-settings - Configures settings for tmsh

**MODULE**  
 cli

**SYNTAX**  
 Configure the global-settings component within the cli module using the syntax shown in the following sections.

**MODIFY**  
 edit global-settings  
 options:  
 all-properties  
 non-default-properties

modify global-settings  
 options:  
 audit [disabled | enabled]  
 description [string]  
 idle-timeout [disabled | integer]  
 scf-backup-number [integer]  
 service [number | name]

**DISPLAY**  
 list global-settings  
 list global-settings [option]  
 options:  
 all-properties  
 non-default-properties  
 one-line

**DELETE**  
 You cannot delete the default global settings.

**DESCRIPTION**  
 You can use the global-settings component to configure multiple settings for tmsh.

**EXAMPLES**  
 modify global-settings audit enabled  
 Enables auditing for tmsh.  
 modify global-settings idle-timeout 15  
 Sets the user idle timeout from tmsh to 15 minutes.

**OPTIONS**  
 audit  
 Specifies the global audit level for tmsh. The audited commands are stored in /var/log/audit. The default value is enabled. The audit levels are:  
 disabled  
 tmsh does not log commands that users enter.  
 enabled  
 tmsh audits only commands that users enter. Note that the system does not audit the commands that the command load runs.  
 description  
 User defined description.  
 idle-timeout  
 If not disabled, log a user in tmsh interactive mode out automatically after a specified set of minutes. An administrator may change the timeout value at any time and the new policy will take place immediately.  
 scf-backup-number  
 Specifies the number of backup single configuration files that the system stores when you enter the following command sequence in tmsh:  
 load sys config file  
 When you run the command, the system saves the single configuration file. By default, the system saves two backup single configuration files. For example, if you set the scf-backup-number option to 3, after you run the command sequence tmsh load sys config file for the third time, the system has three versions of the single configuration file: /var/local/scf/backup.scf, /var/local/scf/backup-1.scf, and /var/local/scf/backup-2.scf. The newest file is /var/local/scf/backup.scf.  
 service  
 Specifies the format in which tmsh displays a service. The default value is name. The options are:  
 name Displays a service using a protocol name, for example, http.  
 number  
 Displays a service using a numeric value, for example, 192.168.10.20:80, where 80 indicates http.

**SEE ALSO**  
 edit, list, modify, run, tmsh

**COPYRIGHT**

## cli history

**NAME**  
history - Displays a list of commands in the order in which you ran the commands.

**MODULE**  
cli

**SYNTAX**  
Use the history component within the cli module to display a numbered list of commands in the order the commands were issued.

**DISPLAY**  
show history  
!  
!!  
![string]

**DESCRIPTION**  
You can use the history component to display a numbered list of the commands that you have run in tmsh. The commands display in the order in which you ran the commands, and each command is identified by an entry ID. The larger the entry ID of the command, the more recently you ran the command.

To rerun a command from the history list, type q to close the list and return to the tmsh prompt, and then enter an exclamation point (!) followed by the entry ID of the command that you want to run.

**EXAMPLES**  
!

show history

Either of the two previous commands, displays the command history list.

!5

Runs the fifth command in the command history list.

!!

Runs the previously issued command.

!create

Runs the last command that begins with create.

**SEE ALSO**  
show, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## cli preference

**NAME**  
preference - Configures tmsh preferences.

## MODULE

cli

## SYNTAX

Configure the preference component within the cli module using the syntax shown in the following sections.

### MODIFY

edit preference

modify preference [option]

options:

alias-path [string list]  
app-service [[string] | none]  
confirm-edit [disabled | enabled]  
display-threshold [integer]  
editor [nano | vi]  
history-date-time [disabled | enabled]  
history-file-size [integer]  
history-size [integer]  
keymap [default | emacs | vi]  
list-all-properties [disabled | enabled]  
pager [disabled | enabled]  
prompt { [avc-count config-sync-status current-folder  
fully-qualified-host host mcp-load-status  
mcp-state multi-line status user user-role] | none }  
show-aliases [disabled | enabled]  
stat-units [default | exa | gig | kil | meg | peta | raw |  
tera | yotta | zetta]  
suppress-warnings [ all | config-version | none ]  
table-indent-width [integer]  
tcl-syntax-highlighting [disabled | enabled]  
video [disabled | enabled]  
warn [bell | disabled | visual-bell]

edit preference

options:

all-properties

### DISPLAY

list preference

list preference [option]

show running-config preference

show running-config preference [option]

options:

all-properties

one-line

## DESCRIPTION

You can use the preference component to configure tmsh to meet your specific needs.

## EXAMPLES

modify preference display-threshold 500

Configures tmsh to retrieve up to 500 objects before requiring a user response to the question, "Display all items? (y/n)."

modify preference history-file-size 80

Configures the maximum number of commands that a user can view in the command history list to be 80.

modify preference history-size 1000

Configures the maximum number of commands that tmsh saves in a user's .tmsh\_history file to be 1000 commands.

modify preference suppress-warnings config-version

Configures tmsh to suppress warning messages for configuration version related (for backward compatibility of configuration).

## OPTIONS

alias-path

Specifies the search paths for shared aliases. The shared aliases could be in multiple locations, only ones on the search paths can be used. If a folder is deleted from the system it will be automatically remove from the alias-path.

app-service

Specifies the name of the application service to which the preference belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the preference. Only the application service can modify or delete the preference.

confirm-edit

Specifies whether the command edit prompts for confirmation before saving changes. The default value is enabled.

Note that the value of this option does not affect the behavior of the editor if the changes made in the editor result in a failed update. In this case, tmsh always prompts the user to either re-edit the file or discard the changes. The options are:

enabled

tmsh prompts a user to either submit (y), discard (n), or edit (e) the changes made to a component within the editor.

disabled

tmsh does not prompt the user, but instead, immediately submits the changes made in the editor.

display-threshold

Specifies the maximum number of objects that tmsh displays without requiring a user response to the question, "Display all [number] items? (y/n)." You can specify from 0 (zero) through 4,294,967,265 objects. If you set this option to 0 (zero), tmsh displays an unlimited number of objects without requesting a response.

#### editor

Specifies the editor that the command edit invokes. Users assigned the user role of Administrator can select nano or vi. Users assigned other user roles must use nano.

#### history-date-time

Specifies whether tmsh displays in the command history the date and time that each command was issued. The default value is disabled.

Note that the command history file, `~/.tmsh-history-[user]`, always contains the date and time that a command was issued.

#### history-file-size

Specifies the maximum number of tmsh commands that the system saves in each user's `.tmsh_history` file. If you set this option to 0 (zero), the system does not save tmsh commands in the file. The maximum value is 100,000. For performance reasons, the system does not truncate the file after a user enters a command. Instead, the system truncates the file after a user exits tmsh.

#### history-size

Specifies the number of commands that a user can view or search in the command history list. The maximum number of commands is 100,000. The default value is 500.

If you set this option to 0 (zero), the system does not add commands to the list of commands in memory; however, the system does write commands to the `.tmsh_history` file, unless the `history-file-size` option is set to 0 (zero).

When you change the value of this option, the system renumbers the commands listed in memory; however, the commands remain in the same order.

#### keymap

Specifies the keyboard bindings that you want tmsh to use. The default value is default. The options are default, emacs, and vi.

#### list-all-properties

Specifies whether the system displays all of the properties of a component by default when you run the command list. The default value is disabled.

#### pager

Specifies whether the system sends the output of the tmsh commands list and show to less. The default value is enabled.

#### prompt

Specifies the information that you want to display in the tmsh prompt. By default the prompt displays `user_name@host_name(tmos-current_module)#`. The options are:

#### avc-count

Displays the current SELinux Access Vector Cache in the tmsh prompt. The value displayed in the prompt indicates the number of times SELinux has denied access to a protected resource. The default is to not display this information.

#### config-sync-status

Displays global sync status in the tmsh prompt. The status displayed in the prompt indicates the rolled-up sync status of all the device groups where the local device resides. The default is to display this information.

#### current-folder

Displays the current working folder in the tmsh prompt. The default is to not display this information.

#### fully-qualified-host

Displays the fully qualified host name in the tmsh prompt. The default is to not display this information.

host Displays the host name in the tmsh prompt. The default is to display the host name in the prompt.

#### mcp-load-status

Displays the configuration file load status in the tmsh prompt. This information is also available in the Last Configuration Load Status of the show sys mcp command output. The default is to not display this information.

#### mcp-state

Displays the running phase of the mcpd service in the tmsh prompt. This information is also available in the Running Phase of the show sys mcp command output. The default is to not display this information.

#### multi-line

Displays the tmsh prompt on multiple lines, with information on the first line, and a pound sign (#) on the second line, for example:

```
(Common:all) operator1@6400(tmos.cli)
```

#

The multi-line option is disabled by default.

none Sets the tmsh prompt to display (tmos.current\_module)#, where the system replaces current\_module with the name of the module within which you are working.

status  
Displays the system status in the tmsh prompt. The default is to display system status in the prompt.

user Displays the user name in the tmsh prompt. The default value is to display the user name in the prompt.

user-role  
Display the user's current role in the tmsh prompt. By default the user role is not displayed in the prompt.

show-aliases  
Specifies whether the system displays aliases in the results of the command completion and context-sensitive help features. The default value is enabled.

suppress-warnings  
Specifies the type of warning messages which needs to be suppressed. The default value is none.

stat-units  
Specifies the default unit in which the system displays statistics. The options are:

default  
Displays data in the simplest units. For example, if the value of the data is 1,200,001, the system displays 1.20M; however, if the value of the data is 1,200, the system displays 1.2K.

exa Display data in parts per quintillion.

gig Displays data in parts per billion.

kil Displays data in parts per thousand.

meg Displays data in parts per million.

peta Displays data in parts per quadrillion.

raw Displays raw data.

tera Displays data in parts per trillion.

yotta  
Displays data in parts per septillion.

zetta  
Displays data in parts per sextillion.

table-indent-width  
Specifies the indent width when tmsh displays the child object tables in a show command. You can specify from 0 (zero) through 10. If you set this option to 0 (zero), tmsh displays child object tables without any indent.

tcl-syntax-highlighting  
Specifies whether Tcl syntax highlighting will be enabled in the editor. This setting only applies if your editor preference is set to vi. The default value is disabled.

video  
Enables or disables any video features used to highlight text. The default value is enabled.

warn Specifies how the system warns you when you make an incorrect keystroke. The default value is bell.

The options are:

bell Sounds a bell.

disabled  
Disables the warning function.

visual-bell  
Displays a visual warning.

## cli script

**NAME**  
script - Automates tmsh using Tool Command Language (Tcl).

**MODULE**  
cli

**SYNTAX**  
Configure the script component within the cli module using the syntax shown in the following sections.

**EDIT**  
create script [name]  
modify script [name]  
options:  
  app-service [[string] | none]  
  description [string]  
  ignore-verification [true | false]  
  script-checksum [[string] | none]  
  script-signature [[string] | none]  
edit script [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties

**DISPLAY**  
list script  
list script [ [name] | [glob] | [regex] ] ... ]  
show running-config script  
show running-config script [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties

**DELETE**  
delete script [name]

**GENERATE**  
Note: generate cryptographic signature or checksum based on cli script text.  
generate cli script [name]  
options:  
  checksum  
  signature

**RUN**  
run script [name] [options ...]  
options:  
  file [file name] [options ...]  
  verbatim-arguments [file option] [file name] [options ...]  
The options that are available depend on which script you are running.  
The file option is limited to users with the role of administrator.

**DESCRIPTION**  
You can use the script component to build Tcl scripts to automate management of the BIG-IP(r) system. By combining command aliases with scripts, you can extend tmsh to build commands that are customized to your environment.  
To do this, place the content of the script inside one or more Tcl procedures. The content of a script cannot exceed 65,000 bytes. However, a script can include other scripts. For more information about including scripts in other scripts, see tmsh::include following.  
Starting with BIGIP 11.5.0, tmsh commands are versioned. The tmsh active version should be specified in scripts. This will avoid breaking scripts due to changes in tmsh syntax in the different versions. See examples below for how to use it in a script. Without tmsh active version specified, scripts will run on the current active version. By default, the active version will be the latest cli version.  
You can use the following procedures in the manner specified:  
script::run  
tmsh invokes the procedure script::run when you issue the command sequence run / cli script [name]. A script is run relative to the module in which the run command is invoked.  
The script::run procedure must be defined in the script named by the run command. Scripts that are included by tmsh::include are not required to implement the procedure script::run.  
script::help  
Provides context sensitive help. A script is not required to implement script::help.  
script::tabc  
Provides context sensitive help. A script is not required to implement script::tabc.  
script::init  
tmsh calls the procedure script::init before calling one of the following procedures: script::run, script::help, or script::tabc. The script::init procedure can use the Tcl variable tmsh::csh to determine which one of these three procedures tmsh invokes after

tmsh:init.

Additionally, you can use the procedure script::init to initialize global variables. A script is not required to implement script::init.

#### EXAMPLES

```
edit script myscript
```

Creates or modifies the script myscript.

```
edit script myscript yourscrip
```

Creates or modifies the scripts myscript and yourscrip at the same time.

```
list script myscript
```

Displays the contents of the script myscript.

```
delete script [name]
```

Deletes the script myscript from the system.

```
run script myscript [arguments ...]
```

Runs the script myscript. The system passes arguments to the script in the following Tcl variables:

- o tmsh::argc contains the number of arguments including the name of the script.

- o tmsh::argv contains the list of argument values. The first item in tmsh::argv is always the name of the script.

Tip: You can create an alias for the command sequence run / cli script [name] using the cli alias component. For more information, see help cli alias.

```
run script verbatim-arguments myscript [arguments ...]
```

Runs the same commands as run script myscript [arguments...] above, except the system passes all arguments specified in the command as one argument to the script. Note that you do not need to enclose the argument list in double quotes, and you do not need to escape special characters.

```
generate my_script checksum
```

Generate a checksum for the script text and add the checksum as a property.

```
generate my_script signature signing-key my_key
```

Generate a signature for the script text using the specified private key and add the signature as a property.

Note: For a script which includes a checksum or signature to successfully load, the script text contents must match the stored checksum or signature. To temporarily stop the verification of signature or checksum and still retain the checksum or signature, the ignore-verification attribute must be set to true. This is done by editing the script and adding the ignore-verification attribute.

To completely clear the signature or checksum, simply set the attribute script-signature or script-checksum to empty string "". By doing so, the script will be processed as if it was never signed or checksummed.

```
modify script /Common/my_script { proc script::init {} { }
```

```
proc script::run {} { }
```

```
proc script::help {} { }
```

```
proc script::tabc {} { }
```

```
ignore-verification true  
script-checksum 74778e7b13016e0b9329a17f8d2da601  
total-signing-status checksum  
verification-status checksum-verified }
```

#### OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

Generate a checksum for the script text and add the checksum to the script as a property. Only for use with the generate command.

description

A user defined description.

file Specifies that the script to be run should come from a file located on the file system rather than a script from the configuration.

glob Displays the scripts that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the script. This option is required for the edit and delete commands.

#### regex

Displays the scripts that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### signature

Generate a signature for the script text using the specified private key and add the signature to the script as a property. Only for use with the generate command.

#### signing-key

The private key to use for signing the script. Only for use with the signature option.

#### verbatim-arguments

Specifies that the arguments at the end of the command should not be tokenized by tmsh prior to being sent to the script. This is useful when the script is wrapping another utility that takes arguments.

### CONFIGURATION AND STATUS ACCESSORS

The following Tcl commands mirror tmsh commands. For example, the Tcl tmsh::create command accepts the same components, object identifiers, and properties that the tmsh create command accepts.

tmsh::cd [args...]

Runs the cd command using the specified arguments.

tmsh::cp [args...]

Runs the cp command using the specified arguments.

tmsh::create [args...]

Runs the create command using the specified arguments.

tmsh::delete [args...]

Runs the delete command using the specified arguments.

tmsh::install [args...]

Runs the install command using the specified arguments.

tmsh::generate [args...]

Runs the generate command using the specified arguments.

tmsh::list [args...]

Runs the list command using the specified arguments. The system returns the results as a string.

tmsh::load [args...]

Runs the load command using the specified arguments.

tmsh::modify [args...]

Runs the modify command using the specified arguments.

tmsh::publish [args...]

Runs the publish command using the specified arguments.

tmsh::pwd

Runs the pwd command.

tmsh::reset-stats [args...]

Runs the reset-stats command using the specified arguments.

tmsh::restart [args...]

Runs the command restart using the specified arguments.

tmsh::run [args...]

Runs the run command using the specified arguments.

tmsh::save [args...]

Runs the save command using the specified arguments.

tmsh::show [args...]

Runs the show command using the specified arguments. The system returns the results as a string.

tmsh::start [args...]

Runs the command start using the specified arguments.

tmsh::stop [args...]

Runs the command stop using the specified arguments.

The following Tcl commands provide structured access for retrieving configuration, statistics, and status information.

tmsh::get\_config [args...]

Returns a list of Tcl objects. Each of these objects can be passed to the commands that accept an \$obj argument. The arguments for this command are the same as for the tmsh list command.

tmsh::get\_status [component] [args...]

Returns a list of Tcl objects that can be passed to the following commands that accept an \$obj argument. The arguments to this command are the same as the tmsh show command.

This command can only be used on components that accept the field-fmt option. The field-fmt option is automatically appended to the argument list. The tmsh help pages identify if a component supports the field-fmt option.

That there are very few components that have status and statistics that do not support the field-fmt option, and in those cases you

can use the Tcl `tmsh::show` command to retrieve the object in the form of a Tcl string object.

A component must be specified, for example, `tmsh::get_status ltm pool`.

`tmsh::get_type $obj`

Returns the type identifier associated with the object. The `$obj` argument must be an object that was returned by either of the Tcl `tmsh::get_config` or `tmsh::get_status` commands.

`tmsh::get_name $obj`

Returns the object identifier associated with the object. The `$obj` argument must be an object that was returned by either of the Tcl commands `tmsh::get_config` or `tmsh::get_status`.

`tmsh::get_field_names [value | nested] $obj`

Returns a list of field names (not the value associated with a field) that are present in an object. The value fields are simple values or lists (for example, an integer or a string). The nested fields are a collection of zero or more nested objects, where the nested objects have their own fields (for example, pool members, and virtual server profiles).

The `$obj` argument must be an object that was returned by the Tcl `tmsh::get_config` or `tmsh::get_status` commands. If the object was retrieved using the Tcl `tmsh::get_config` command, the field names are identical to those that are displayed by the `tmsh list` command. If the object was retrieved using the Tcl `tmsh::get_status` command, the fields are identical to those that the system displays using the `tmsh show` command with the `field-fmt` option.

`tmsh::get_field_value $obj [field name] [Tcl variable]`

Retrieves the value of field name.

The Tcl variable is optional. The behavior of this command depends on whether field name is present in `$obj` and a Tcl variable is present in the command.

- o If field name is present in `$obj`, and a Tcl variable is present, the Tcl variable is set to the value of field name and the command returns 1.
- o If field name is not present in `$obj`, and a Tcl variable is present, the command returns 0 (zero).
- o If field name is present in `$obj`, and a Tcl variable is not present, the command returns the field value.
- o If field name is not present in `$obj`, and a Tcl variable is not present, the command raises an error that causes the script to stop. You can use the Tcl command `catch` to recognize the error and continue to run the script.

The `$obj` argument must be an object that was returned by the Tcl `tmsh::get_config` or `tmsh::get_status` commands, or a nested object obtained from the Tcl `tmsh::get_field_value` command.

If the field is a set of nested objects, the Tcl object that the system returns is a list of objects, where each of the objects can contain fields. Each of the objects can be passed to the Tcl `tmsh::get_field_value` command. If the field is not a nested object the system returns a single Tcl string object.

#### TRANSACTION CONTROL

The following Tcl commands are specific to the `tmsh` Tcl API. There are no corresponding commands available in `tmsh`.

`tmsh::begin_transaction`

Begins an update transaction. The Tcl `tmsh::create`, `tmsh::delete`, and `tmsh::modify` commands that are issued before the next Tcl `tmsh::commit_transaction` command are submitted as a single update.

The system rolls back all of the commands if any of the commands fail.

`tmsh::commit_transaction`

Runs the commands that have been issued since the last Tcl `tmsh::begin_transaction` command. The system validates all of the commands against the running configuration. If any one of the commands fail, the system does not apply any of the commands to the running configuration.

`tmsh::cancel_transaction`

Cancels all commands that you have issued since the last Tcl `tmsh::begin_transaction` command.

**Important:** You cannot use these Tcl commands inside an active transaction:

- o `tmsh::list`
- o `tmsh::show`
- o `tmsh::get_config`
- o `tmsh::get_status`

#### LOGGING

You can use the following Tcl commands to generate log events. These commands affect the behavior of the script and do not affect `tmsh`. These commands are available only to users who have been assigned either the Administrator or Resource Administrator role.

`tmsh::log_dest [screen | file]`  
Specifies whether the system sends events to the screen or to log files. If file is selected, log messages will be directed to `/var/log/ltm`.

`tmsh::log_level [level]`  
Specifies the default severity level. The system does not log events below the specified level. The options, listed in decreasing order of severity, are:

- o emerg
- o alert
- o crit
- o err
- o warning
- o notice
- o info
- o debug

`tmsh::log [level] "message..."`  
Logs the specified message. The level parameter is optional. The level can be one of those described in the Tcl `tmsh::log_level` command.

#### CUSTOM ISTATS

Custom counter, gauge, and string fields may be created, modified, and retrieved using iRules or tmsh scripts. These custom fields are created on first write and do not need to be declared separately.

Each custom field has a "key" that can be associated with a tmsh configuration object. This key is composed of a tmsh component dotted path, a specific object name or ID, the field type, and the field name. The entire key must be enclosed in quotes.

For example, `"ltm.pool /Common/my_pool counter num_hits"` refers to the `num_hits` counter associated with the LTM pool named `my_pool`, located in the Common folder.

These custom fields are displayed with the `tmsh show` command on the associated object.

`istats::incr [key] [amount]`  
Increments a custom counter by amount.

`istats::set [key] [value]`  
Sets a custom gauge or string to value. Setting a counter to an exact value will only set it in the local segment, but `istats::get` will always read the aggregated (not local) value.

`istats::get [key]`  
Returns the latest aggregated value of the custom field or 0 (zero) if it does not exist ("" for string fields).

`istats::remove [key]`  
Removes the custom field from all segments on all blades. Effectively resets a counter to 0.

#### UTILITIES

The following commands are TCL utility commands.

`tmsh::clear_screen`  
Clears the screen and places the cursor at the upper left of the screen.

`tmsh::display [variable | command output]`  
Provides access to the tmsh pager. Output generated with the Tcl `puts` command is not paged.

`tmsh::display_threshold [integer]`  
When a script is run, the system disables the option `cli preference display-threshold`.

You can use the Tcl `tmsh::display_threshold` command to re-enable the threshold. Re-enabling the threshold in this way causes the script to generate a prompt if you issue the `tmsh::list`, `tmsh::show`, `tmsh::get_config`, or `tmsh::get_status` commands, and the output that is generated exceeds the threshold. See `help cli preference` for a description of this option and valid ranges for its value.

`tmsh::expand_macro [macro_text] options...`  
Expands a macro and returns the resulting string. A macro is a string containing macro syntax which can be used for parameter substitution, script and iRule templatization, etc. The Macro Syntax includes the following delimiters:

`<%` The beginning of an expansion code block.

`<%=` The beginning of an expansion code block. Spool the output after evaluating.

`<%D[0-9][0-9]` The beginning of a debug/logging code block with the debug threshold set to 0 thru 99.

`<%D[0-9][0-9]=` The beginning of a debug/logging code block with the debug threshold set to 0 thru 99. Spool the output after

evaluating.

%> The end of the current block (works for all types).

Typically, the result of the `expand_macro` command is used as the input to another command (eg. `lrm rule create`). The command can be called multiple times within an `iApp` implementation to expand multiple macros.

`macro_text` is the blob of text to expand. If not specified, the command will expand the Macro section of the `iApp`. If no `macro_text` argument is specified and no Macro section exists for the `iApp`, an error will be issued.

`-vars name_value_pair_list`

Specifies a list of additional variables (name/value pairs) which can be referenced within the macro and expanded by the command. All APL variables are automatically available from within the macro, so the `-vars` option allows a way to specify additional variables from the `iApp` Implementation section. Since the variables are defined within a Tcl list the format is: { name1 value1 name2 ... nameN valueN }

`-debug debug_levels`

Specifies a single debug level or list of debug levels for controlling which debug messages get rendered in the expanded output.

`-debuginclusive debug_level`

Specifies a debug level for controlling which debug messages get rendered in the expanded output. Since it's "inclusive" all messages with a level at the specified level and below will get rendered in the expanded output.

The following example expands the macro defined in the Macro section of the `iApp`, and sets the debug level to render all debug messages with a level of 11, 33 or 66:

```
tmsh::expand_macro -debug {11 33 66}
```

The following example expands the macro defined via a Tcl variable (`mac`), adds two variables (`foo` and `enable_mything`), and sets the debug level to render all messages of level 66 and below:

```
tmsh::expand_macro $mac -vars {foo bar enable_mything true}
-debuginclusive 66
```

```
tmsh::get_ifile_text [iFile name]
```

Retrieve the text contained in the specified `iFile`. When used on an `iFile` containing characters which are non-ascii or are not printable/space, an error will be returned.

```
tmsh::include [script name]
```

Runs the Tcl `eval` command on the specified script. The system evaluates the script at a global level, and all procedures in the included script are available to any other procedure. You must have previously created the script that is being included using the `tmsh edit / cli script [name]` command. If a full path is not given for the script name, `tmsh` will attempt to first locate the script from the same folder as the including script, then the root partition folder of the including script, and finally the `/Common` folder.

```
tmsh::run_proc [script_name:proc_name] options...
```

Runs the Tcl `eval` command on the specified script and process. The script `script_name` is loaded as if `tmsh::include` was called. After the script is loaded, the Tcl `eval` command is run on the specified Tcl process. Any options that were specified are passed to the Tcl process. This is essentially a short form of running `tmsh::include script_name`, followed by running one of the Tcl processes contained in the script that was included.

The following example invokes the `display_pool_status` proc that is contained in the `pool_utils` script:

```
tmsh::run_proc pool_utils:display_pool_status
```

```
tmsh::stateless [disabled | enabled]
```

Modifies the behavior of `tmsh::create` and `tmsh::delete`.

When `stateless` mode is disabled, an attempt to create an object that already exists in the configuration results in an error, and an attempt to delete an object that does not exist in the configuration is an error.

When `stateless` mode is enabled, an attempt to create an object that already exists in the configuration does not result in an error, and an attempt to delete an object that does not exist in the configuration does not result in an error.

Enabling `stateless` mode enables scripts to successfully run multiple times with the same input.

The default value is disabled.

```
tmsh::version
```

Returns the version number of the BIG-IP system as a Tcl string. The version consists of three digits: a major, minor, and maintenance version, separated by periods. For example, 10.1.0 indicates minor version 1 of major version 10.

## CONTEXT SENSITIVE HELP

Use the following commands to create a script that provides context sensitive help when a user types Tab or question mark (?).

### script::help

Scripts can provide the script::help procedure. tmsh invokes the procedure when a user types a question mark (?) while entering the command sequence run / cli script [name]. If the specified script includes the script::init procedure, tmsh invokes it before the script::help procedure. The script can add context sensitive help by calling the tmsh::add\_help and tmsh::builtin\_help procedures. tmsh formats the help and displays it.

### script::tabc

Scripts can provide the script::tabc procedure. The system invokes this procedure when the user types Tab while entering the command sequence run / cli script. If the script::init procedure is included in the script, that procedure is invoked before the script::tabc procedure. The script can add tab completion datasets to the script by calling the tmsh::add\_tabc and tmsh::builtin\_tabc procedures. tmsh either formats and displays the tab completion datasets, or if possible, completes the current argument.

### tmsh::csh

tmsh::csh is a Tcl string variable that can be used in the script::init procedure to determine the context in which the script::init procedure was invoked.

tmsh::csh is set to one of the following:

question mark (?)

Indicates that the user typed a question mark (?).

TABC Indicates the user pressed the Tab key.

an empty string ""

Indicates the script is being run.

tmsh::add\_help [ [category item description] | [description] ]  
Displays context sensitive help when the user types a question mark (?). If you supply one argument, that argument displays as-is with no formatting applied to the description.

If you supply three arguments, one or more datasets are constructed. The first argument is the name of the dataset. The second argument is an item in the dataset. The third argument is a description of the item. This command has an effect only if the Tcl tmsh::csh variable is set to question mark (?).

tmsh::builtin\_help ["tmsh command" args...]

Presents the same results as typing a question mark (?) while entering a tmsh command. The system stores a set of possible completions and displays the possibilities when the script::help procedure returns. This command has an effect only if the Tcl tmsh::csh variable is set to question mark (?).

tmsh::add\_tabc [ [category item] | [item] ]

Adds tab completion datasets. If you supply one argument, the system adds that argument to an anonymous dataset. If you supply two arguments, the system constructs one or more datasets. The first argument is the name of the dataset. The second argument is an item in the dataset. Potential completions are displayed in groups based on category. This command has an effect only if the Tcl \$tmsh::csh variable is set to TABC.

tmsh::builtin\_tabc ["tmsh command" args...]

Many of the tmsh commands that are available for scripting are also available in the interactive shell. A script can use the tmsh::builtin\_tabc command to present the same tab completion results as a built-in command. The command does not return a value. The set of possible completions are stored internally and displayed when the script::tabc procedure returns. This command has an effect only if the Tcl \$tmsh::csh variable is set to TABC.

## THIRD PARTY TCL LIBRARY USAGE

A selection of third party libraries have been tested to work within the CLI script environment, including MD5, BASE64, SHA1/SHA256, HTTP, TLS, TCL Perl, LDAP client, and XML parser. The TCL packages can only reside in the directory of /usr/share/compat-tcl8.4.

Important: Only these tested packages are supported currently.

This example demonstrates the use of a Tcl package command to make use of tls/https. The TLS package is installed in the directory /usr/share/compat-tcl8.4/tls in the form of two files: tls.tcl and libtls1.6.1.so.

Modify script /Common/use\_tls {

```
proc script::run {} {
    set pkg_name tls
    set pkg_version 1.6
    package require http
    if {[catch {package require $pkg_name $pkg_version}]} {
        puts "No package found: $pkg_name!\n"
    } else {
        puts "Found package: $pkg_name!\n"
        http::register https 443 tls::socket
        set token [http::geturl https://172.27.42.161/]
        upvar #0 $token state
        puts $state(http)
        puts $state(body)
    }
}
```

```
}  
}
```

This example uses the callback function to handle http data.

```
cli script /Common/use_http2 {  
proc script::httpCallback {token} {  
  upvar #0 $token state  
  puts $state(http)  
  puts $state(body)  
  incr ::got_something  
}  
proc script::run {} {  
  namespace eval :: {  
    set got_something 0  
  }  
  set pkg_name http  
  set pkg_version 2.4.5  
  if {[catch {package require $pkg_name $pkg_version}]} {  
    puts "No package found: $pkg_name!\n"  
  } else {  
    puts "Found package: $pkg_name!\n"  
    http::geturl http://172.27.42.22/index.htm -command script::httpCallback  
    vwait ::got_something  
  }  
}
```

This example uses the LDAP client package to query data.

```
cli script /Common/use_ldap {  
proc script::run {} {  
  set pkg_name ldap  
  if {[catch {package require $pkg_name 1.8}]} {  
    puts "No package found: $pkg_name!\n"  
  } else {  
    puts "Found package: $pkg_name!\n"  
    set handle [ldap::connect 172.27.1.2]  
    ldap::bind $handle  
    set results [ldap::search $handle "dc=f5,dc=com" "(uid=test)" {}]  
    foreach result $results {  
      puts $result  
    }  
    ldap::unbind $handle  
    ldap::disconnect $handle  
  }  
}
```

Here are some additional examples:

```
cli script /Common/use_parray {  
proc script::run {} {  
  puts [info patch]  
  namespace eval :: {  
    set pkg_location /usr/share/compat-tcl8.4/  
    source [file join $pkg_location package.tcl]  
  }  
  puts "NS: [namespace current]"  
  set pkg_location $::pkg_location  
  source [file join $pkg_location parray.tcl]  
  parray ::tcl_platform  
}
```

```
cli script /Common/use_sha2 {  
proc script::run {} {  
  set pkg_name sha256  
  if {[catch {package require $pkg_name}]} {  
    puts "No package found: $pkg_name!\n"  
  } else {  
    puts "Found package: $pkg_name!\n"  
    puts "TCL does SHA2 now:"  
    puts [sha2::sha256 "TCL does SHA2"]  
  }  
}
```

```
cli script /Common/use_tclperl {  
proc script::run {} {  
  set pkg_name tclperl  
  if {[catch {package require $pkg_name}]} {  
    puts "No package found: $pkg_name!\n"  
  } else {  
    puts "Found package: $pkg_name!\n"  
    set interpreter [perl::interp new]  
    $interpreter eval {print "Hello World\n"}  
    perl::interp delete $interpreter  
  }  
}
```

#### SPECIAL CHARACTERS

There are several characters that are part of both Tcl and tmsh syntax. You must escape these characters in a shell script so that Tcl passes them to tmsh. You can use standard Tcl escape characters, such as quotes and back slashes. You must escape curly braces ({}), for example, "{ " }".

```
tmsh::create ltm pool my_pool members add "{ 10.1.2.3:80 }"  
Creates a Local Traffic Manager pool named my_pool.
```

#### DISABLED COMMANDS

The following commands are disabled for users that have not been

assigned a user role of Administrator or Resource Administrator:

- o auto\_execok
- o auto\_import
- o auto\_load
- o auto\_mkindex
- o auto\_mkindex\_old
- o auto\_qualify
- o auto\_reset
- o bgerror
- o cd
- o close
- o eof
- o exec
- o fblocked
- o fconfigure
- o fcopy
- o file
- o filevent
- o filename
- o flush
- o glob
- o http
- o interp
- o load
- o memory
- o open
- o package
- o pid
- o pkg:create
- o pkg\_mkindex
- o pwd
- o seek
- o socket
- o source
- o tcl\_findLibrary
- o tell
- o unknown
- o updates
- o vwait

#### EXAMPLES

The following example demonstrates the use of all tmsh Tcl commands. The script displays all configuration property values or all status and statistic values for the specified component, depending on the specified arguments. The system displays all configuration settings if you replace [tmsh::get\_config \$comp all-properties] with [tmsh::get\_config / all-properties]. The use of the all-properties option ensures that all options are displayed.

This command sequence is an example of how to run the following script:  
run / cli script example.tcl config ltm pool.

```
cli script example.tcl {  
    proc script::init { } {  
set ::field_fmt "%-25s %s"  
set ::usage_string "usage: [lindex $tmsh::argv 0] \  
    }  
  
    proc script::help { } {  
if { $tmsh::argc < 2 } {  
    tmsh::add_help Options: config "Display configuration"  
    tmsh::add_help Options: status \  
    "Display status and statistics"  
}  
}
```

```

else {
    build_csh tmsh::builtin_help
}
}

proc script::tabc { } {
if { $tmsh::argc < 2 } {
    tmsh::add_tabc config
    tmsh::add_tabc status
}
else {
    build_csh tmsh::builtin_tabc
}
}

proc script::run { } {
if { $tmsh::argc < 3 } {
    usage
}
set opt [lindex $tmsh::argv 1]
if { $opt != "config" && $opt != "status" } {
    usage
}
set comp ""
for {set idx 2} {$idx < $tmsh::argc} {incr idx} {
    append comp "[lindex $tmsh::argv $idx] "
}

if { $opt == "config" } {
    set objs [tmsh::get_config $comp all-properties]
}
else {
    set objs [tmsh::get_status $comp]
}

set idx 0
set total [llength $objs]

while { $idx < $total } {
    set obj [lindex $objs $idx]
    print_object obj
    puts ""
    incr idx;
}
}

proc print_fields { objVar } {
upvar $objVar obj
set fdx 0
set fields [tmsh::get_field_names value $obj]
set field_count [llength $fields]
while { $fdx < $field_count } {
    set field [lindex $fields $fdx]
    puts [format $::field_fmt $field \
[tmsh::get_field_value $obj $field]]
    incr fdx
}
}

proc print_object { objVar } {
upvar $objVar obj
puts "[tmsh::get_type $obj] [tmsh::get_name $obj]"

# name/value pairs
print_fields obj

# nested objects
set fdx 0
set fields [tmsh::get_field_names nested $obj]
set count [llength $fields]
while { $fdx < $count } {
    set field [lindex $fields $fdx]
    set nested_objects [tmsh::get_field_value $obj $field]
    set ndx 0
    set n_count [llength $nested_objects]
    while { $ndx < $n_count } {
        set nobj [lindex $nested_objects $ndx]
        print_object nobj
        incr ndx
    }
    if { $n_count == 0 } {
        puts [format $::field_fmt $field "none"]
    }
    incr fdx
}
}

proc build_csh { command } {
# generate context sensitive help, tab completion or "?"
set args ""
for {set idx 2} {$idx < $tmsh::argc} {incr idx} {
    lappend args [lindex $tmsh::argv $idx]
}
set opt [lindex $tmsh::argv 1]
if { $opt == "config" } {
    $command list $args
}
elseif { $opt == "status" } {
    $command show $args
}
else {
    puts "\nunexpected argument: $opt"
}
return $args
}

```

```

}
proc usage { } {
puts $::usage_string
exit
}
}

```

#### EXAMPLES

The following example demonstrates the scripts using 11.6.0 tmsh syntax.

```

cli script example_ver.tcl {
...
proc script::run {} {
tmsh::modify cli version active 11.6.0
# the tmsh command in the section below should contain 11.6.0 tmsh syntax
puts stdout [tmsh::list ltm pool mypool]
...
}
}

```

The following example demonstrates the scripts that are using multiple tmsh syntaxes.

```

cli script example_multi_ver.tcl {
....
proc script::run {} {
tmsh::modify cli version active 11.5.0
# the tmsh command in the section below should contain 11.5.0 tmsh syntax
puts stdout [tmsh::list ltm pool mypool]
...

tmsh::modify cli version active 11.6.0
# the tmsh command in the section below should contain 11.6.0 tmsh syntax
puts stdout [tmsh::list ltm pool mypool]
...
}
}

```

## cli transaction

#### NAME

transaction - Opens batch mode within which you can submit a set of commands as a single transaction.

#### MODULE

cli

#### SYNTAX

Use the transaction component within the cli module to open batch mode, enter a series of commands, and then submit the commands as a single transaction.

#### CREATE/MODIFY

create transaction

modify transaction

options:

delete [entry\_id]

submit transaction [validate-only]

#### DISPLAY

list transaction

#### DELETE

delete transaction

#### DESCRIPTION

tmsh parses each command that you enter in batch mode. If the command passes a syntax check, tmsh saves it as part of the transaction you are creating and returns a confirmation. After you finish adding commands, you submit the transaction to change the running configuration of the system. You must run the save config command to save the changes to the stored configuration files.

If, while creating a transaction, you decide you do not want to change the running configuration, you can delete the transaction rather than submit it. However, you can recreate a transaction that you have deleted by using the cli history component.

There are a few commands that you can enter on the command line that the system immediately runs, rather than adding the commands to a transaction. These commands are list and show. Additionally, tmsh immediately runs the command sequence run bigpipe, but does not add it to the transaction.

#### EXAMPLES

The following example shows the commands that you enter from within the ltm module to create and submit a transaction that creates a Local Traffic Manager pool and virtual server, and then associates the two.

1. Open tmsh batch mode:  
create /cli transaction

2. Add a command to the transaction that creates pool1 for the Local Traffic Manager using the default values for a pool:  
create pool pool1

3. Add a command to the transaction that creates the virtual server virtual1 for the Local Traffic Manager using the default values for a virtual server, and associates it with pool1.  
create virtual virtual1 pool pool1

4. Display, in a numbered list, the current set of commands in the transaction:  
list /cli transaction

Note: You can use the preceding command to determine the entry ID of a command. Then, you can use this ID to remove or replace a command in the transaction, or to identify a command before which you want to insert another command.

5. Submit the transaction:  
submit /cli transaction

#### OPTIONS

**command**  
Specifies, in quotation marks, the full path to a command to add to or delete from the transaction that you are creating. You can also replace an existing command with another command or insert a command before a command in the transaction.

**create**  
Opens batch mode.

**delete**  
Deletes the transaction that you are creating and closes batch mode.

**list** Displays, in a numbered list, the current set of commands in the transaction that you are creating.

**modify**  
Specifies a previously entered line in the transaction that you want to change. The options are:

**delete**  
Deletes the specified entries from the transaction that you are creating.

**entry\_id**  
Specifies the number of a command in the list of commands in the transaction that you want to delete.

**submit [validate-only]**  
Submits the transaction that you are entering and closes batch mode. The transaction is submitted in the context of the cli admin-partitions settings that are active when the submit command is issued.

**validate-only**  
Validates the configuration changes without putting them in production.

#### SEE ALSO

cli admin-partitions, create, delete, list, modify, submit, tmsh

## cli version

**NAME**  
version - Displays and Configures tmsh versions.

**MODULE**  
cli

**SYNTAX**  
Configure the version component within the cli module using the syntax shown in the following sections.

**MODIFY**  
modify version [option]  
options:  
active [string ]

**DISPLAY**  
show version

**DESCRIPTION**  
You can use the version component to configure tmsh to run the specified version.

**EXAMPLES**  
modify cli version active 11.5.0  
Configures tmsh run 11.5.0 version.  
show cli version  
Displays the latest, active and supported versions of TMSH.

**OPTIONS**  
active  
Specifies the active version of TMSH.  
latest  
Displays TMSH the latest version. This is used as the default version.  
supported  
Displays the current supported TMSH versions on the system.  
imported  
Displays the imported TMSH versions on the system. An imported TMSH version will be imported from a UCS created from TMSH version which is not supported in the current system - a very rare case. Be aware, for an imported TMSH version, only syntax is supported, if it requires other handling other than syntax change, it will not be supported. So, for an imported TMSH version, it is not fully supported. By default, this entry will not be displayed unless preference is set.

**SEE ALSO**

## cm

### cm add-to-trust

**NAME**  
add-to-trust - Add a device to a trust domain.

**MODULE**  
cm

## SYNTAX

Run the add-to-trust program within the cm module using the syntax in the following section. The trust-domain name 'Root' is optional beginning version 13.0.0.

## MODIFY

```
run add-to-trust [Root]
options:
  [ ca-device | non-ca-device ]
  device [string]
  port [ port_number ]
  device-name [string]
  password [string]
  username [string]
```

## DESCRIPTION

You can use the add-to-trust command to add a device to a trust domain. This is an alternate helper command to the modify trust-domain ca-devices|non-ca-devices add ... command.

## EXAMPLES

```
run add-to-trust ca-device device 10.20.30.40 device-name peer1
username homer password illiad
```

Adds a device to the list of ca-devices in the trust domain.

## OPTIONS

### ca-device

Indicates that the added device is a certificate authority device.

### device

Indicates the FQDN or the management-ip of the device being added to the trust domain

port Device port number if other than 443 when adding new device. This parameter is optional.

### device-name

Used to specify the name of a new device.

### md5-fingerprint

SSL certificate md5 fingerprint is deprecated beginning version 13.0.0. Use sha1-fingerprint.

### non-ca-device

Indicates that the added device is a subordinate device. The target device cannot be used as a signing authority.

### password

Specifies the password for a new device.

### serial

SSL certificate serial number is deprecated beginning version 13.0.0. Use sha1-fingerprint.

### sha1-fingerprint

Specifies the SSL certificate (DER format) sha1 fingerprint when verifying the identity of a new device. This field is optional.

### signature

SSL certificate signature is deprecated beginning version 13.0.0. Use sha1-fingerprint.

### username

Specifies the user name required to log on to a device when adding the device to the trust domain. The user "root" is invalid, and will be disallowed. Any user that has administrator privileges and can use iControl can be used here.

## SEE ALSO

## cm cert

### NAME

cert - Manages a CM trust certificate file.

### MODULE

cm

## SYNTAX

Display the cert component within the cm module using the syntax shown in the following sections.

```
DISPLAY
list cert
list cert [ [ [name] | [glob] | [regex] ] ... ]
show running-config cert
show running-config cert [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  certificate-key-size
  checksum
  create-time
  created-by
  email
  expiration-date
  expiration-string
  fingerprint
  is-bundle
  issuer
  key-type
  last-update-time
  mode
  non-default-properties
  one-line
  partition
  recursive
  revision
  serial-number
  size
  source-path
  subject
  subject-alternative-name
  system-path
  updated-by
  version
```

## DESCRIPTION

You can use the cert component to display CM trust certificates.

## OPTIONS

**app-service**  
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

**certificate-key-size**  
Displays the number of bits in the key associated with this certificate.

**checksum**  
Displays a cryptographic hash or checksum of the file contents for use in verification of file integrity.

**create-time**  
Displays the time at which the trust certificate was created.

**created-by**  
Displays the name of the person, who originally created the trust certificate.

**email**  
Displays the email of the person, who originally created the trust certificate.

**expiration-date**  
Displays the date at which the trust certificate expires. The date is stored as a POSIX time.

**expiration-string**  
Displays a string representation of the trust certificate expiration date.

**fingerprint**  
Specifies the cryptographic fingerprint of the trust certificate.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**is-bundle**  
Indicates whether the trust certificate file is a bundle (that is, whether it contains more than one certificate).

**issuer**  
Displays the X.509 information for the issuer of the trust certificate. If the trust certificate is a bundle, then this displays the issuer information for the primary (first) trust certificate in the bundle.

**key-type**  
Displays the type of cryptographic key associated with this trust certificate.

**last-update-time**  
Displays the last time the trust certificate was modified.

**mode** Displays the UNIX(r) file permissions mode for the file associated with this trust certificate as a numerical value.

**partition**

Displays the partition within which the trust certificate file resides.

**recursive**

Displays all objects of the specified type and the folder that contains the object.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**revision**

Displays the number of the latest revision of the trust certificate. The revision starts with 1 and increments on each update.

**serial-number**

Displays the serial number of the trust certificate.

**size** Displays the size (in bytes) of the file associated with the trust certificate.

**source-path [URL]**

Displays the path to the source of the trust certificate as a URL, for example:

source-path http://cert-server/cert\_store/certs/vs\_132.key

source-path https://cert-server/cert\_store/certs/vs\_132.key

source-path

ftp://username:password@server/cert\_store/certs/vs\_132.key

**subject**

Displays X.509 information about the subject of the trust certificate. If the certificate is a bundle, then the subject information for the primary (first) trust certificate in the bundle displays.

**subject-alternative-name**

Displays a standard X.509 extension as shown in RFC 2459.

**system-path**

Displays the path to the trust certificate.

**updated-by**

Displays the name of the person, who last updated the trust certificate.

**version**

Displays the X.509 version of the trust certificate.

## cm config-sync

NAME

config-sync - Manually synchronizes the configuration between devices.

MODULE

cm

SYNTAX

Run the config-sync program within the cm module using the syntax in the following section.

MODIFY

run config-sync

options:

from-group

recover-sync

to-group

force-full-load-push

DESCRIPTION

This command starts a configuration synchronization job. One of the from-group, to-group, or recover-sync options must be used to specify

the direction of the synchronization.

#### EXAMPLES

```
run config-sync from-group my_dg
```

Updates the configuration on the local device with the configuration from the remote device in the device group /Common/my\_dg with the newest configuration. If the local device already has the newest configuration, then the configuration synchronization does nothing.

```
run config-sync to-group my_dg
```

Updates the configurations on the remote devices in the device group /Common/my\_dg with the configuration on the local device. If the local device does not have the newest configuration, then the configuration synchronization does nothing.

```
run config-sync recover-sync
```

Resets the local device configuration and restores the trust domain, device, and device-group information to default settings.

#### OPTIONS

**from-group**

Updates the configuration of the local device with the configuration of the remote device in the specified device group that has the newest configuration. If the local device already has the newest configuration, then the configuration synchronization does nothing. This option is mutually exclusive of the to-group and recover-sync options.

**recover-sync**

Resets the local device configuration and restores the trust domain, device, and device-group information to default settings. After this recovery, you can sync the local device with its peers by running config-sync on a peer device and specifying the device group in which the local device is a member. This option is mutually exclusive of the from-group and to-group options.

**to-group**

Updates the configurations of the remote devices in the specified device group with the configuration of the local device. If the local device does not have the newest configuration, then the configuration synchronization does nothing. This option is mutually exclusive of the from-group and recover-sync options.

**force-full-load-push**

This option may only be used if to-group has also been specified. It forces all other devices to pull all synchronizable configuration from this device, even if those devices have the same or newer configuration. It will always send the entire configuration, rather than just the changes, regardless of the device group's full-load-on-sync setting.

You may lose configuration by using this option. This happens if you force a push even when another device in the device group has newer configuration.

## cm device-group

#### NAME

device-group - Configures device groups. The device groups that are created and maintained by the system cannot be modified by the user.

#### MODULE

cm

#### SYNTAX

Modify the device-group component within the cm module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create device-group [name]
modify device-group [name]
options:
  app-service [[string] | none]
```

```

asm-sync [ enabled | disabled ]
auto-sync [ enabled | disabled ]
description [string]
devices [add | delete | modify | replace-all-with] {
    [ device_name ]
}
full-load-on-sync [true | false]
incremental-config-sync-size-max [integer]
network-failover [ enabled | disabled ]
save-on-auto-sync [true | false]
type [ sync-only | sync-failover ]
clear-incremental-config-sync-cache

edit device-group [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list device-group
list device-group [ [ [name] | [glob] | [regex] ] ... ]
show running-config device-group
show running-config device-group [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    app-service
    non-default-properties
    partition
    recursive

show device-group
show device-group [name]
options:
    field-fmt

DELETE
delete device-group [name]

```

Note: The device group must be empty, and you must remove all references to the device group, before you can delete the device group.

#### DESCRIPTION

You can use the device-group component to manage sets of devices used for configuration synchronization and failover.

#### EXAMPLES

```

create device-group my_device_group devices add {
    /Common/device1
    /Common/device2
}

```

Creates a sync-only device group named my\_device\_group with two devices, device1 and device2.

```
delete device-group my_device_group
```

Deletes the device group named my\_device\_group.

```
list device-group my_device_group
```

Displays properties of the device group named my\_device\_group.

```
modify device-group my_device_group clear-incremental-config-sync-cache
```

Warning: Do not use this option without assistance from the F5 Technical Support team.

Clears the incremental configuration synchronization cache. The next configuration synchronization for my\_device\_group that pulls configuration from this device will be a full load.

#### OPTIONS

##### app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

##### asm-sync

Specifies whether to synchronize ASM configurations of device group members. The default value is disabled. A device can be a member of only one ASM-enabled device group.

##### auto-sync

Specifies whether the device group automatically synchronizes configuration data to its members. The default value is disabled. Configuration will be saved on remote devices after receiving configuration updates if save-on-auto-sync is enabled.

##### clear-incremental-config-sync-cache

Warning: Do not use this option without assistance from the F5 Technical Support team.

The incremental configuration synchronization mechanism keeps a cache of transactions in each device group. Specifying this option will remove all transactions from the cache for the given device groups. This will not remove configuration from the device group, but will cause the next load in that group from the current device to be a full load.

##### description

Specifies a user-defined description of the device group.

**devices**  
Adds, deletes, or replaces a set of devices to a device group by specifying the device name(s). When the local device is removed from a device group then all of the sys folders that are associated with the device group are reset to have no device group and the name of each folder that was updated is logged to /var/log/ltn.

**full-load-on-sync**  
Specifies that the entire configuration for a device group is sent when configuration synchronization is performed. The default value is false.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**incremental-config-sync-size-max**  
Specifies the maximum size (in KB) to devote to incremental config sync cached transactions. The default is 1024 KB."

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**network-failover**  
When the device group type is failover, specifies whether network failover is used.

**partition**  
Displays the administrative partition within which the device group resides.

**recursive**  
Displays all objects of the specified type and the folder that contains the object.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**save-on-auto-sync**  
Specifies whether to save the configuration on the remote devices following an automatic configuration synchronization. A device group configured for manual synchronization will always save on the remote devices regardless of this setting.

**type** Specifies the type of device group. You can use this option only when you create a device group. You cannot modify the type of a device group. The default value is sync-only.

#### DESCRIPTION

You can use the device component to manage devices.

Warning: To add or remove devices on the BIG-IP system, modify the Root trust domain. For more information, see help trust-domain.

#### OPTIONS

**active-modules**  
Displays the licensed modules that are currently active on the device.

**app-service**  
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify the object. Only the Application Service can modify the object.

**base-mac**  
Displays the base MAC address for the device.

**build**  
Displays the software build number.

**cert** Displays the identity certificate used for device trust.

**chassis-id**  
Displays the chassis identifier.

**chassis-type**  
Displays the chassis type. The possible values are individual and viprion.

**comment**  
Specifies user comments about the device.

**configsync-ip**  
Specifies the IP address used for configuration synchronization. If you specify a self IP address, the self IP address object must be located in the Common folder.

**contact**  
Specifies administrator contact information.

**description**  
Specifies a user-defined description of the device.

**edition**  
Displays the software edition.

**failover-state**  
Displays the device failover state.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ha-capacity**  
Specifies a number that represents the relative capacity of the device to be active for a number of traffic groups. This value along with the traffic group's ha-load-factor is used by the failover daemon to make traffic groups active amongst the available devices. The value is zero by default which means the device may run any number of traffic groups. The value must be within a valid range: 0 - 100000 inclusive.

**hostname**  
Displays the hostname of the device.

**inactive-modules**  
Displays the licensed modules that are currently inactive on the device.

**key** Displays the identity key used for device trust.

**location**  
Specifies the physical location of the device.

**marketing-name**  
Displays the marketing name of the device platform.

**mirror-ip**  
Specifies the IP address used for state mirroring. If you specify a self IP address, the self IP address object must be located in the Common folder.

**mirror-secondary-ip**  
Specifies the secondary IP address used for state mirroring. If you specify a self IP address, the self IP address object must be located in the Common folder.

**multicast-interface**  
Specifies the interface name used for the failover multicast IP address.

**multicast-ip**  
Specifies the multicast IP address used for failover.

**multicast-port**  
Specifies the multicast port used for failover.

**optional-modules**  
Displays the modules that are available for the current platform, but are not currently licensed.

**platform-id**  
Displays the device platform identifier.

**product**  
Displays the software product name.

**recursive**  
Displays all objects of the specified type and the folder that contains the object.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**self-device**  
Displays true, when the device is the self device.

**time-limited-modules**  
Displays the licensed modules that are time-limited.

**time-zone**  
Displays the time zone configured on the device.

**unicast-address**  
Displays the set of unicast IP addresses used for failover. If you specify a self IP address, the self IP address object must be located in the Common folder.

**version**  
Displays the software version number.

## cm failover-status

**NAME**  
failover-status - Display the failover status of the local device.

**MODULE**  
cm

**SYNTAX**  
Display failover-status component within the cm module using the syntax in the following section.

**DISPLAY**  
show failover-status  
options:  
field-fmt

**DESCRIPTION**  
You can use the failover-status component to display the failover status of the local device.

For information about the options that you can use with the command show, see help show.

**EXAMPLE**  
show failover-status

Displays the failover status of the local device.

**SEE ALSO**  
show, tmsh

## cm key

**NAME**  
key - Manages a CM trust certificate private key file.

**MODULE**  
cm

**SYNTAX**  
Display or delete a key component within the cm module using the syntax shown in the following sections.

**DISPLAY**  
list key  
list key [ [ [name] | [glob] | [regex] ] ... ]  
show running-config key  
show running-config key [ [ [name] | [glob] | [regex] ] ... ]  
options:

created-by  
key-size  
key-type  
last-update-time  
mode  
non-default-properties  
one-line  
partition  
recursive  
revision  
security-type  
size  
source-path  
system-path  
updated-by

**DISPLAY**  
delete key [name]

=head1 DESCRIPTION

You can use the following options with the key component.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

checksum

Displays a cryptographic hash or checksum of the key for use in verification of key integrity.

create-time

Displays the time at which the key was created.

created-by

Displays the user who originally created the key.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

key-size

Displays the size of the cryptographic key, in bits.

key-type

Displays the cryptographic algorithm that this key is compatible with. A key can be one of two types:

rsa-private

The key is an RSA private key.

dsa-private

The key is a DSA based private key.

last-update-time

Displays the time at which the key was last modified.

mode Displays the UNIX file permissions mode for the file associated with this key. The mode is expressed in numerical form.

name Specifies the name of the key you want to delete.

partition

Displays the partition within which the key resides.

recursive

Displays all objects of the specified type and the folder that contains the object.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

revision

Displays the latest revision of the key. The revision starts with 1 increments on each update.

security-type

Displays the type of security used to handle or store the key. There are four mutually exclusive options:

normal

Indicate the key resides in a standard form on the file-system. This is the default security type.

fips Indicates that the key is protected by a FIPS device on the system, and is only applicable to devices with FIPS support.

password

Indicates that the key is protected by a passphrase and stored in encrypted form.

nethsm

Indicates that the key is protected by a FIPS device outside the system.

size Displays the size (in bytes) of the file associated with this file object.

source-path [URL]

Displays the path to the source of the key. This option takes a URL, for example:

source-path http://cert-server/cert\_store/certs/vs\_132.key

source-path https://cert-server/cert\_store/certs/vs\_132.key

source-path

ftp://user\_name:user\_password@user\_server/cert\_store/certs/vs\_132.key

system-path

Displays the location where the key is stored on the system.

updated-by

Displays the name of the user who last updated the key.

## cm remove-from-trust

**NAME**  
remove-from-trust - Remove a device from a trust domain.

**MODULE**  
cm

**SYNTAX**  
Run the remove-from-trust program within the cm module using the syntax in the following section. The trust-domain name 'Root' is optional beginning version 13.0.0.

**MODIFY**  
run remove-from-trust [Root]  
options:  
[ca-device | non-ca-device]  
device-name [string]

**DESCRIPTION**  
You can use the remove-from-trust command to remove a device from a trust domain. This is an alternate helper command to the modify trust-domain ca-devices|non-ca-devices delete ... command.

**EXAMPLES**  
run remove-from-trust ca-device device-name peer1  
  
Removes a device from the list of ca-devices in the trust domain Root.

**OPTIONS**  
ca-device  
Indicates that the added device is a certificate authority device.  
  
device-name  
Used to specify the name of a new device.  
  
non-ca-device  
Indicates that the added device is a subordinate device.

**SEE ALSO**  
run, tmsh

#### COPYRIGHT

## cm sha1-fingerprint

**NAME**  
sha1-fingerprint - Display SHA1 fingerprint of the local device SSL certificate in DER format.

**MODULE**  
cm

**SYNTAX**  
Run the sha1-fingerprint command sequence within the cm module using the syntax in the following section.

DISPLAY  
show shal-fingerprint  
options:  
field-fmt

DESCRIPTION

You can use the shal-fingerprint component to display the local box SSL SHA1 checksum and provide this value to a remote authority device that is trying to add the local device to a trust domain. This allows the remote device to verify the identity of the local device when establishing the SSL connection.

For information about the options that you can use with the command show, run the command sequence help show.

EXAMPLE

```
show shal-fingerprint
```

Display SHA1 fingerprint of the local device SSL certificate in DER format.

OPTIONS

field-fmt

Formats the shal fingerprint output in command syntax.

SEE ALSO

show, tmsh

COPYRIGHT

## cm sniff-updates

NAME

sniff-updates - Displays the commit ID updates that occur over the CMI communications channel

MODULE

cm

SYNTAX

```
run cm sniff-updates  
options:  
[-v]
```

DESCRIPTION

You can use the sniff-updates program to monitor the internal CMI communications channel for commit ID updates. The system displays each update as it arrives, one per line.

```
(1) (2) (3) (4) (5) (6) (7) (8) (9) (10)  
[15:35:57] bigipl (v0.0.0) -> device_trust_group: CID 105.105 (bigip2) at 15:34:39 FORCE_SYNC
```

Output fields:

- 1) Time that update arrived from network
- 2) Source device
- 3) Version of source device
- 4) Destination devicegroup
- 5) CommitId ID
- 6) DeviceData CommitId ID
- 7) CommitId originator
- 8) CommitId timestamp
- 9) FORCE\_SYNC if set (nothing if not)
- 10) Last sync error message (nothing if last sync was successful)

OPTIONS

You can use the following option when you run the sniff-updates program:

-v Formats the update output using fully-qualified device and device group names and exact time64\_t timestamps.

SEE ALSO

run, tmsh

COPYRIGHT

## cm sync-status

**NAME**  
sync-status - Displays the configuration synchronization status of the local device.

**MODULE**  
cm

**SYNTAX**  
Run the sync-status command sequence within the cm module using the syntax in the following section.

**DISPLAY**  
show sync-status  
options:  
field-fmt

**DESCRIPTION**  
You can use the sync-status component to display the configuration synchronization status of the local device.  
  
For information about the options that you can use with the command show, run the command sequence help show.

**EXAMPLE**  
show sync-status  
  
Displays the configuration synchronization status of the local device:

**OPTIONS**  
field-fmt  
  
Formats the status output in command syntax.

**SEE ALSO**  
show, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## cm traffic-group

**NAME**  
traffic-group - Manages a CM traffic group.

**MODULE**  
cm

**SYNTAX**  
Manage the traffic-group component within the cm module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create traffic-group [name]  
modify traffic-group [name]  
options:  
app-service [[string] | none]  
auto-failback-enabled [ enabled | disabled ]  
auto-failback-time [ integer ]  
description [string ]  
failover-method [ ha-score | ha-order ]

```

    ha-group [string]
    ha-load-factor [ integer ]
    ha-order [ string ... ]
    mac [mac address]
    monitor { ha-group [string] }

edit traffic-group [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list traffic-group
list traffic-group [ [ [name] | [glob] | [regex] ] ... ]
show running-config traffic-group
show running-config traffic-group [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    app-service
    is-floating
    non-default-properties
    one-line
    partition
    recursive
    unit-id [integer]

show traffic-group
show traffic-group [name]
options:
    all-properties
    details
    failover-objects
    field-fmt

DELETE
delete traffic-group [name]

DESCRIPTION
    You can use the traffic-group component to specify the failover
    behavior for devices in a failover device group.

EXAMPLES
    create traffic-group my_traffic_group

    Creates a traffic group named my_traffic_group.

    create traffic-group my_traffic_group ha-order { my_device }

    Creates a traffic group named my_traffic_group with a preferred device
    named my_device.

OPTIONS
    app-service
    Specifies the application service to which the object belongs. The
    default value is none. Note: If the strict-updates option is
    enabled on the Application Service that owns the object, you
    cannot modify or delete the object. Only the Application Service
    can modify or delete the object.

    auto-failback-enabled
    Specifies whether the traffic group fails back to the default
    device.

    auto-failback-time
    Specifies the time required to fail back. The value must be within
    a valid range: 0 - 300 inclusive.

    details
    Only usable with the show command. Displays the active or next-
    active devices for this traffic group.

    failover-method
    Specifies the method used to decide if the current device needs to
    failover the traffic-group to another device. If the failover-
    method is set to ha-score, a score is calculated for each device
    in the monitoring HA group; and the highest score is the current
    active device while the next highest score will be the device that
    takes over if the current one fails. If the failover-method is set
    to ha-order, a list of devices and their respective HA load is
    used to decide the next one to take over if the current devices
    fails.

    failover-objects
    Only usable with the show command. Tells it to display all of the
    objects associated with that traffic group.

    ha-group
    Deprecated since v13.0.0. Use monitor and failover-method instead.
    This specifies a ha-group for the traffic group to decide the
    active device within the traffic group. The HA group must exist
    first. Note: This attribute is only specific to the local device
    i.e. not sync'ed to its peers in the traffic group. If you use
    this deprecated command attribute, it will also set the failover-
    method to ha-score.

    ha-order
    This list of devices specifies the order in which the devices will
    become active for the traffic group when a failure occurs. This
    list may contain zero, one or more entries up to the number of
    devices in the failover device group. If auto-failback enabled is
    set to true, this list must contain at least one entry for the
    auto-failback device.

    ha-load-factor

```

Specifies a number for this traffic group that represents the load this traffic group presents to the system relative to other traffic groups. This allows the failover daemon to load balance the active traffic groups amongst the devices. The value is one by default. The value must be within a valid range: 1 - 1000 inclusive.

`monitor { ha-group [string] }`  
This specifies a ha-group monitor for the traffic group to decide the active device within the traffic group. The HA group must exist first. Note: This attribute is only specific to the local device i.e. not sync'ed to its peers in the traffic group.

`description`  
Specifies a user-defined description.

`glob` Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

`is-floating`  
Indicates whether the traffic group can fail over to other devices in the device group.

`mac` Specifies a MAC address for the traffic group.

`partition`  
Displays the administrative partition within which the device group resides.

`regex`  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

`recursive`  
Displays all objects of the specified type and the folder that contains the object.

`unit_id`  
Displays the unit ID for the traffic group. The unit ID is set automatically when you create a traffic group. The value is between 1 and 15.

## cm trust-domain

**NAME**  
trust-domain - Manages a CM trust domain by providing control of object failover.

**MODULE**  
cm

**SYNTAX**  
Manage the trust-domain component within the cm module using the syntax shown in the following sections. The trust-domain name 'Root' is optional beginning with version 13.0.0. The 'create cm trust-domain' command is not allowed beginning version 13.0.0.

**MODIFY**  
modify trust-domain [Root]  
options:  
add-device {  
    [ ca-device [true | false] | non-ca-device [true | false] ]  
    device-ip [string]  
    device-port [port\_number]  
    device-name [string]  
    username [string]  
    password [string]  
    shal-fingerprint [string]  
}  
devices delete {  
    [ device names ]  
}  
remove-device [string]

```

deprecated since v13.0.0:
ca-devices [add | delete | modify | replace-all-with] {
  [ device_name | ip address ]
}
md5-fingerprint [string]
name [string]
non-ca-devices [add | delete | modify | replace-all-with] {
  [ device_name | ip address ]
}
password [string]
serial [string]
shal-fingerprint [string]
username [string]

```

#### DISPLAY

```

list trust-domain
list trust-domain [ [ [name] | [glob] | [regex] ] ... ]
show running-config trust-domain
show running-config trust-domain [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  ca-cert
  ca-cert-bundle
  ca-key
  ca-devices
  non-ca-devices
  non-default-properties
  one-line
  partition
  recursive
status
  trust-group

```

#### DELETE/RESTART

```

restart trust-domain
delete trust-domain
options:
  keep-current-certificate-authority
  import-user-defined-cert [string]
  import-user-defined-key [string]

```

#### DESCRIPTION

You can use the trust-domain component to manage the behavior of objects during fail over.

#### DELETE/RESTART operations

When applied to a trust-domain these operations reset the trust and make this device standalone.

#### EXAMPLES

Adds a certificate authority:

```

modify trust-domain add-device { ca-device true device-ip 192.168.1.245
device-name myDevice1 device-port 1234 username admin password admin }

```

Adds a non-authoritative certificate:

```

modify trust-domain add-device { ca-device false ip 192.168.1.248
device-name myDevice2 username admin password admin shal-fingerprint
ab7012e8d834e639f497b2b1c9f1e855a4dbe232}

```

Removes a device from the trust domain:

```

modify trust-domain devices delete { myDevice1 myDevice2}

```

Resets the trust and makes this device standalone:

```

restart cm trust-domain

```

or

```

delete cm trust-domain

```

#### EXAMPLES (deprecated since V13.0.0)

Adds a certificate authority:

```

modify trust-domain Root ca-devices add { 192.168.1.245 } name
myDevice1 username admin password admin

```

Adds a non-authoritative certificate:

```

modify trust-domain Root non-ca-devices add { 192.168.1.245 } name
myDevice1 username admin password admin

```

Removes a device from the trust domain:

```

modify trust-domain Root ca-devices delete { myDevice1 }

```

#### OPTIONS

add-device

Adds a device to the trust domain.

device-ip

Device IP address when adding new device.

device-port

Device port number if other than 443 when adding new device. This parameter is optional.

device-name

Device name when adding new device.

username

Specifies the user name required to log on to a device when adding the device to the trust domain.

**password**  
Specifies the password corresponding to the username required to log on to a device when adding the device to the trust domain.

**shal-fingerprint**  
Specifies the SSL certificate (DER format) sha1 fingerprint when verifying the identity of a new device. This field is optional.

**app-service**  
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

**ca-cert**  
Displays the certificate authority device trust certificate.

**ca-cert-bundle**  
Displays the bundled certificate authority device trust certificates used to authenticate incoming connections.

**ca-devices**  
Create and modify operations are deprecated since v13.0.0. List operation is still supported. Set of certificate authority devices in the trust domain.

**ca-key**  
Displays the certificate authority device trust key. This key only displays for certificate authorities.

**devices**  
Removes one or more devices from the trust domain. It takes the name of the device as the identifier.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**import-user-defined-cert**  
Specifies the certificate to import and use as the trust domain's new certificate authority. You must also use the import-user-defined-key option to specify the corresponding key. This option cannot be specified alongside keep-current-certificate-authority.

**import-user-defined-key**  
Specifies the key to import and use as the trust domain's new certificate authority key. You must also use the import-user-defined-cert option to specify the corresponding certificate. This option cannot be specified alongside keep-current-certificate-authority.

**keep-current-certificate-authority**  
By default, resetting trust will generate a new certificate authority. Adding this option to the delete command will instead keep the current certificate authority. This option cannot be specified alongside import-user-defined-cert or import-user-defined-key.

**md5-fingerprint**  
Deprecated since v13.0.0. Specifies the SSL certificate fingerprint when verifying the identity of a new device.

**name** Deprecated since v13.0.0. Option used to specify the name of a new device.

**non-ca-devices**  
Create and modify operations are deprecated since v13.0.0. List operation is still supported. Set of subordinate devices in the trust domain.

**password**  
Deprecated since v13.0.0. Specifies the password for a new device.

**recursive**  
Displays all objects of the specified type and the folder that contains the object.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**remove-device**  
Removes a single device from the trust domain. It takes the name of the device as the identifier.

**serial**  
Deprecated since v13.0.0. Specifies the SSL certificate serial number when verifying the identity of a new device.

**shal-fingerprint**  
Deprecated since v13.0.0. Specifies the SSL certificate fingerprint when verifying the identity of a new device.

**signature**  
Deprecated since v13.0.0. Specifies the SSL certificate signature, when verifying the identity of a new device.

status  
Displays the status of the trust domain.

trust-group  
Displays the device group associated with the trust domain.

username  
Deprecated since v13.0.0. Specifies the user name required to log on to a device when adding the device to the trust domain.

## cm watch-devicegroup-device

NAME

watch-devicegroup-device - Displays information about the devices in the device group to which the local device belongs.

MODULE

B

SYNTAX

Run the watch-devicegroup-device program within the cm module using the syntax shown in the following sections.

RUN

run watch-devicegroup-device

DISPLAY

By default, multiple devices with identical information are collapsed into a single row that displays in green. The devices column identifies the devices by the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16. Use the c (collapse) command to deactivate/activate this behavior.

DESCRIPTION

You can use the watch-devicegroup-device program to view dynamic information about the synchronization of the devices in the device group to which the local device belongs. You can use this information to monitor or troubleshoot the devices.

For example, when you make a change to a device, the change is identified by a commit ID (cid.id) that displays when you run the watch-devicegroup-device program.

Within the program, you can use the following keys:

Press h to see a list of available commands.  
Press the back tick key (`) to exit the help page.  
Press c to toggle the view from a collapsed view to a full view. The command gathers information from every device in the trust group. When all devices in the trust group report the same information the view is collapsed and one line, highlighted in green, displays the information. The devices included in the line are shown in the devices column. You can press c to see the full view, which displays each device on a separate line.  
Press Ctrl-C to exit the program.  
Press the arrow keys to navigate across the columns or down the rows.

The content in the columns includes:

devices

Displays the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the config-sync IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16.

devgroup

Displays the name of the device group to which the device belongs.  
Note: This can be a sync-only, failover, or trust device group.

device

Displays the device object name.

cid.id

Displays the commit ID, which is a configuration change identifier.

cid-orig  
Displays the name of the device on which the configuration change was made.

cid.time  
Displays the time the configuration change was made.

last\_sync  
Displays the time the device configuration was last synchronized with the device group.

The devices in the to-group of a configuration synchronization display the same time in this column. The local device that pushes the configuration to the other devices in the device group (to-group) has a different value in this column.

The devices in the from-group of a configuration synchronization display the same time in this column. The local device that receives the configuration from the other devices has a different value in this column. You can use this information to determine a rollback strategy.

## cm watch-sys-device

NAME  
watch-sys-device - Displays information about the local device.

MODULE  
B

SYNTAX  
Run the watch-sys-device program within the cm module using the syntax shown in the following sections.

RUN  
run watch-sys-device

DISPLAY  
By default, multiple devices with identical information are collapsed into a single row that displays in green. The devices column identifies the devices by the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16. Use the c (collapse) command to deactivate/activate this behavior.

DESCRIPTION  
You can use the watch-sys-device program to view dynamic information about the local device.

Within the program, you can use the following keys:

Press h to see a list of available commands.  
Press the back tick key (`) to exit the help page.  
Press c to toggle the view from a collapsed view to a full view. The command gathers information from every device in the trust group. When all devices in the trust group report the same information the view is collapsed and one line, highlighted in green, displays the information. The devices included in the line are shown in the devices column. You can press c to see the full view, which displays each device on a separate line.  
Press Ctrl-C to exit the program.  
Press the arrow keys to navigate across the columns or down the rows.

The content in the columns includes:

devices  
Displays the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16.

name Displays the device object name.

platform

Displays the device platform.

build

Displays the software build installed on the device.

failover\_state

Displays the high availability state (active or standby) of the device.

mgmt\_ip

Displays the IP address of the management port on the device.

configsync\_ip

Displays the IP address on the device that is used for configuration synchronization.

unicast\_ip

Displays the unicast IP address of the device.

multicast\_ip

Displays the multicast IP address of the device.

mirror\_ip

Displays the IP address used for configuration mirroring for the device.

mirror\_secondary\_ip

Displays the secondary IP address used for configuration mirroring for the device.

desc Displays a description of the device.

SEE ALSO

run, tmsh, watch-devicegroup-device, watch-trafficgroup-device

## cm watch-trafficgroup-device

NAME

watch-trafficgroup-device - Displays information about the traffic groups associated with devices in a device group.

MODULE

cm

SYNTAX

Run the watch-trafficgroup-device program within the cm module using the syntax shown in the following sections.

RUN

run watch-trafficgroup-device

DISPLAY

By default, multiple devices with identical information are collapsed into a single row that displays in green. The devices column identifies the devices by the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16. Use the c (collapse) command to deactivate/activate this behavior.

DESCRIPTION

You can use the watch-trafficgroup-device program to view dynamic information about the failover status of the devices in a device group to which the local device belongs. You can use this information to monitor or troubleshoot the devices in the device group.

Within the program, you can use the following keys:

Press h to see a list of available commands.

Press the back tick key (`) to exit the help page.

Press c to toggle the view from a collapsed view to a full view. The command gathers information from every device in the device group. When all devices in the device group report the same information the view is collapsed and one line, highlighted in green, displays the information. The devices included in the line are shown in the devices column. You can press c to see the full view, which displays each device on a separate line.

Press Ctrl-C to exit the program.

Press the arrow keys to navigate across the columns or down the rows.

The content in the columns includes:

`devices`

Displays the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16.

`traffic_group`

Displays the name of the traffic group associated with the device.

`device_name`

Displays the device object name.

`failover_state`

Displays the high availability state (active or standby) of the device.

`next_active`

Displays True for the device that becomes active if the active traffic group fails over.

`score`

Displays a system-generated high availability score used to select the next active device.

SEE ALSO

`run`, `tmsh`, `watch-sys-device`, `watch-devicegroup-device`

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## gtm

### gtm datacenter

NAME

`datacenter` - Configures a Global Traffic Manager(tm) data center.

MODULE

`gtm`

SYNTAX

Configure the datacenter component within the `gtm` module using the syntax in the following sections.

CREATE/MODIFY

`create datacenter [name]`

`modify datacenter [name]`

options:

`app-service` [[string] | none]

`contact` [ [name] | none]

`description` [string]

[disabled | enabled]

`location` [none | [physical location] ]

`prober-fallback` [ any-available | inside-datacenter | outside-datacenter | pool | none ]

`prober-pool` [none | name]

`prober-preference` [ inside-datacenter | outside-datacenter | pool ]

metadata

[add | delete | modify] {

[metadata name ... ] {

value [ "value content" ]

persist [ true | false ]

}

}

`edit datacenter [ [ [name] | [glob] | [regex] ] ... ]`

options:

`all-properties`

`non-default-properties`

`one-line`

`reset-stats datacenter`

`reset-stats datacenter [ [ [name] | [glob] | [regex] ] ... ]`

DISPLAY

`list datacenter`

`list datacenter [ [ [name] | [glob] | [regex] ] ... ]`

`show running-config datacenter`

`show running-config datacenter [ [ [name] | [glob] | [regex] ] ... ]`

options:

all-properties  
non-default-properties

show datacenter  
show datacenter [name]  
options:  
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)  
detail  
field-fmt

DELETE  
delete datacenter [name]

#### DESCRIPTION

You can use the datacenter component to create, modify, display, or delete a data center.

#### EXAMPLES

create datacenter DC1  
  
Creates a data center named DC1 with options set to the default values.  
  
list datacenter DC1 all-properties  
  
Displays all properties of the data center named DC1.

#### OPTIONS

app-service  
Specifies the name of the application service to which the data center belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the data center. Only the application service can modify or delete the data center.

contact  
Specifies the name of the administrator or the name of the department that manages the data center. The default value is none.

description  
User defined description.

[disabled | enabled]  
Specifies whether the data center and its resources are available for load balancing. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

location  
Specifies the physical location of the data center. The default value is none.

metadata  
Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

prober-fallback  
Specifies the type of prober to use to monitor servers defined in this data center when the preferred type is not available. The default value is any-available.

prober-pool  
Specifies a prober pool to use to monitor servers defined in this data center.

prober-preference  
Specifies the type of prober to use to monitor servers defined in this data center. The default value is inside-datacenter.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### SEE ALSO

create, delete, glob, gtm link, gtm prober-pool, gtm server, list, modify, regex, reset-stats, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

# gtm distributed-app

**NAME**  
distributed-app - Configures a Global Traffic Manager(tm) distributed application.

**MODULE**  
gtm

**SYNTAX**  
Configure the distributed-app component within the gtm module using the syntax in the following sections.

```
CREATE/MODIFY
create distributed-app [name]
modify distributed-app [name]
options:
  app-service [[string] | none]
  dependency-level [datacenter | link | none | server | wideip]
  description [string]
  disabled-contexts
    [add | delete | modify | replace-all-with] {
      [datacenter | link | server] [name] ...
    }
  disabled-contexts none
  persistence [enabled | disabled]
  persist-cidr-ipv4 [integer]
  persist-cidr-ipv6 [integer]
  ttl-persistence [integer]
  wideips
    [add | delete | replace-all-with] {
      [name] ...
    }
  wideips [default | none]

edit distributed-app
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

reset-stats distributed-app
reset-stats distributed-app
[ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list distributed-app
list distributed-app [ [ [name] | [glob] | [regex] ] ... ]
show running-config distributed-app
show running-config distributed-app
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show distributed-app
show distributed-app [name]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  detail
  field-fmt

DELETE
delete distributed-app [name]
```

**DESCRIPTION**  
You can use the distributed-app component to create, modify, display, or delete a distributed application.

**EXAMPLES**  
create distributed-app DA1  
  
Creates a distributed application named DA1 with options set to the default values.  
  
list distributed-app DA1 all-properties  
  
Displays all properties of the distributed application named DA1.

**OPTIONS**

**app-service**  
Specifies the name of the application service to which the distributed application belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the distributed application. Only the application service can modify or delete the distributed application.

**dependency-level**  
Specifies the resources that must be in the available state before this distributed application is considered available. The options are:

**datacenter**  
All of the data centers on the member list of this distributed application must be in an available state before the system considers the distributed application available.

**link** All of the links on the member list of this distributed

application must be in an available state before the system considers the distributed application available.

none The distributed application has no dependencies. This value effectively disables this option. This is the default value.

#### server

All of the servers on the member list of this distributed application must be in an available state before the system considers the distributed application available.

#### wideip

All of the Wide IPs on the member list of this distributed application must be in an available state before the system considers the distributed application available.

#### description

User defined description.

#### disabled-contexts

Specifies the components that you want to add to or delete from this distributed application as disabled-contexts. You can also replace all of the components that are currently listed as disabled-contexts for this distributed application with other components. The default value is none.

The possible values are:

#### datacenter

Specifies the datacenters, by name, to which the system does not send traffic from this distributed application.

link Specifies the links, by name, to which the system does not send traffic from this distributed application.

none There are no components to which the system does not send traffic from this distributed application. This value effectively disables this option.

#### server

Specifies the servers, by name, to which the system does not send traffic from this distributed application.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which this object resides.

#### persistence

When enabled, if a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### ttl-persistence

Specifies, in seconds, the length of time for which the persistence entry is valid. The default value is 3600.

#### wideips

Specifies the Wide IPs, by name, that you want to add to or delete from this distributed application. You can also replace all of the Wide IPs that are currently associated with this distributed application with other Wide IPs. The default value is none.

A Wide IP is a collection of one or more domain names that maps to one or more groups of virtual servers managed either by BIG-IP(r) systems, or by host servers. The Global Traffic Manager load balances name resolution requests across the virtual servers that are defined in the Wide IP that is associated with the requested domain name.

#### SEE ALSO

create, delete, glob, gtm link, gtm server, create, list, modify, regex, reset-stats, show, tmsh

#### COPYRIGHT

## gtm global-settings general

**NAME**  
general - Configures the general settings for the Global Traffic Manager.

**MODULE**  
gtm global-settings

**SYNTAX**  
Modify or display the general component within the gtm global-settings module using the syntax in the following sections.

**MODIFY**  
modify general  
options:  
automatic-configuration-save-timeout [integer]  
auto-discovery [no | yes]  
auto-discovery-interval [integer]  
cache-ldns-servers [no | yes]  
domain-name-check [allow-underscore | none]  
drain-persistent-requests [no | yes]  
forward-status [enable | disable]  
gtm-sets-recursion [no | yes]  
heartbeat-interval [integer]  
monitor-disabled-objects [no | yes]  
nethsm-timeout [integer]  
peer-leader [name]  
send-wildcard-rrs [enable | disable]  
static-persist-cidr-ipv4 [integer]  
static-persist-cidr-ipv6 [integer]  
synchronization [no | yes]  
synchronization-group-name [name]  
synchronization-time-tolerance [integer]  
synchronization-timeout [integer]  
synchronize-zone-files [no | yes]  
synchronize-zone-files-timeout [integer]  
topology-allow-zero-scores [no | yes]  
virtuals-depend-on-server-state [no | yes]

edit general  
options:  
all-properties  
non-default-properties  
one-line

**DISPLAY**  
list  
list general  
show running-config general  
show running-config general [option name]  
options:  
all-properties  
non-default-properties

**DESCRIPTION**  
You can use the general component to modify or display the General Traffic Manager settings.

**EXAMPLES**  
modify general auto-discovery no  
  
Turns off auto-discovery for the Global Traffic Manager.  
  
list general all-properties  
  
Displays all properties of the general settings for the Global Traffic Manager.

**OPTIONS**  
automatic-configuration-save-timeout  
Sets the timeout, in seconds, indicating how long to wait after a GTM configuration change before automatically saving the GTM configuration to the bigip\_gtm.conf. A timeout of -1 will cause the GTM configuration to NEVER be saved. A value of 0 will cause the GTM configuration to be saved immediately. The default value is 15 seconds.  
  
auto-discovery  
Specifies whether the auto-discovery process is activated for this system. The default value is no.  
  
auto-discovery-interval  
Specifies the frequency, in seconds, between system attempts to discover network components. The default value is 30.  
  
cache-ldns-servers  
Specifies whether the system retains, in cache, all local DNS

servers that make requests. The default value is yes.

You must enable this option if you want the system to store and use the LDNS path information.

**domain-name-check**  
Specifies the parameters for the Global Traffic Manager to use when performing domain name checking. The default value is allow-underscore.

The possible values are:

**allow-underscore**

The Global Traffic Manager checks domain names according to the specifications in RFC 1123 Requirements for Internet Hosts - Application and Support, except that underscores are allowed.

**none**

No validation is performed. Anything is allowed.

**idn-compatible**

Deprecated since v12.1.0. Equivalent to allow-underscore. Value of idn-compatible will be saved as allow-underscore.

**strict**

Deprecated since v12.1.0. Equivalent to allow-underscore. Value of strict will be saved as allow-underscore.

**drain-persistent-requests**

Specifies, when set to yes, that when you disable a pool, load-balanced, persistent connections remain connected until the TTL expires. The default value is yes. If you set this option to no, any persistent connections terminate immediately when a pool is disabled.

**forward-status**

Specifies, when set to enabled, that the availability status change for GTM objects will be shared with subscribers. This option will enable iControl clients to receive event notifications when a change occurs.

**gtm-sets-recursion**

Specifies, when set to yes, that the system enables recursive DNS queries, regardless of whether the requesting local DNS enabled recursive queries. The default value is no.

**heartbeat-interval**

Specifies the frequency at which the Global Traffic Manager queries other BIG-IP(r) systems for updated data. When configuring monitors for BIG-IP systems, F5 Networks recommends that the probe-interval option for the monitor be equal to or greater than the this option. The default value is 10.

**monitor-disabled-objects**

Specifies, when set to yes, that the system will continue to monitor objects even if the objects are disabled. The default value is no.

**nethsm-timeout**

Time to wait on a NetHSM key creation operation for DNSSEC before retry. Default is 20 seconds.

**peer-leader**

Specifies the name of a GTM server to be used for executing certain features, such as creating DNSSEC keys.

**send-wildcard-rrs**

Specifies, when set to enable, that WideIPs or WideIP aliases that contain wildcards will autogenerate Resource Records in the BIND database. The default value is disable.

**static-persist-cidr-ipv4**

Specifies the number of bits of the IPv4 address that the system considers when using the Static Persist load balancing mode. The default value is 32.

**static-persist-cidr-ipv6**

Specifies the number of bits of the IPv6 address that the system considers when using the Static Persist load balancing mode. The default value is 128.

**synchronization**

Specifies whether this system is a member of a synchronization group. The default value is no.

Members of the synchronization group continuously share configuration and metrics collection information. The synchronization group can contain Global Traffic Managers and Link Controllers.

**synchronization-group-name**

Specifies the name of the synchronization group to which the system belongs. The default name is default.

**synchronization-time-tolerance**

Specifies the number of seconds that one system clock can be out of sync with another system clock, in the synchronization group. If the variance between the clock times is higher than the time tolerance setting, the system logs the time difference once per hour.

Possible values are 0 (zero), and 5 - 600. (Values 1 through 4 are automatically set to 5, and 0 (zero) turns time synchronization

off.) The default value is 10 seconds.

Note: If you are using NTP to synchronize the clock with a time server, select a time tolerance other than 0 (zero). When you do this, the system uses the synchronization-time-tolerance option as a fail-over mechanism if NTP is disabled for any reason.

#### synchronization-timeout

Specifies the number of seconds that the system attempts to synchronize the Global Traffic Manager configuration with a synchronization group member. If the synchronization times out, the system tries again. The default value is 180.

#### synchronize-zone-files

Specifies whether the system synchronizes zone files among the synchronization group members. The default value is no.

#### synchronize-zone-files-timeout

Specifies the number of seconds that a synchronization group member attempts to synchronize its zone files with a synchronization group member. If the synchronization times out, the system tries again. The default value is 300.

#### topology-allow-zero-scores

Specifies if topology load-balancing or QoS load-balancing with topology enabled will return pool members with zero topology scores. The default value is yes.

#### virtuals-depend-on-server-state

Specifies whether the system marks a virtual server down when the server on which the virtual server is configured can no longer be reached via iQuery. The default value is yes.

## gtm global-settings load-balancing

#### NAME

load-balancing - Configures the load balancing settings for the Global Traffic Manager(tm).

#### MODULE

gtm global-settings

#### SYNTAX

Modify or display the load-balancing component within the gtm global-settings module using the syntax in the following sections.

#### MODIFY

modify load-balancing

#### options:

failure-rcode [noerror | formerr | servfail | nxdomain | notimpl | refused]  
failure-rcode-ttl [integer]  
failure-rcode-response [disabled | enabled]  
ignore-path-ttl [no | yes]  
respect-fallback-dependency [no | yes]  
topology-longest-match [no | yes]  
verify-vs-availability [no | yes]

edit load-balancing

#### options:

all-properties  
non-default-properties

#### DISPLAY

list

list load-balancing  
show running-config load-balancing  
show running-config load-balancing [option]

#### options:

all-properties  
non-default-properties  
one-line

#### DESCRIPTION

You can use the load-balancing component to modify or display the load balancing settings for the Global Traffic Manager.

## EXAMPLES

```
modify load-balancing ignore-path-ttl yes
```

Specifies that dynamic load balancing methods can use path data, even after the time-to-live (TTL) for the path data expires.

```
list load-balancing all-properties
```

Displays all properties of the load balancing settings for the Global Traffic Manager.

## OPTIONS

**failure-rcode**  
Specifies the DNS RCODE used when failure-rcode-response is enabled. Default is noerror. Options include noerror (no type exists at this name), formerr (format error in query), servfail (unable to process query), nxdomain (name does not exist), notimpl (no support for this kind of query), and refused (refuse to process based on policy). If failure-rcode-ttl is non-zero, only the Authority section of the noerror or nxdomain response will include a SOA record.

**failure-rcode-response**  
When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This affects all Wide IPs and may only be overridden by a more specific enabled configuration of a Wide IP. This response is an authoritative empty answer from the system for record requests. With this option enabled, the system responds faster to requests for which it does not have viable answers configured. The default value is disabled.

**failure-rcode-ttl**  
Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

**ignore-path-ttl**  
Specifies, when set to yes, that dynamic load balancing methods can use path data, even after the time-to-live (TTL) for the path data expires. The default value is no.

**respect-fallback-dependency**  
Specifies, when set to yes, that the system accepts virtual server status when the load balancing mode changes to the mode specified by the fallback-mode option of the pool. The default value is no.

**topology-longest-match**  
Specifies, when set to yes, that the system evaluates all topology records in the topology statement, and then selects the topology record that most specifically matches the IP address in an LDNS request (in other words, has the longest match). When this option is set to no, the system selects the first record in the topology statement that matches the request.

**verify-vs-availability**  
Specifies, when set to yes, that the system checks the availability of virtual servers before sending a connection to those virtual servers. The default value is no.

## gtm global-settings metrics-exclusions

### NAME

metrics-exclusions - Configures the IP addresses that you want to exclude from the Global Traffic Manager(tm) metrics.

### MODULE

gtm global-settings

### SYNTAX

Modify or display the metrics-exclusions within the gtm global-settings module using the syntax in the following sections.

### MODIFY

```

modify metrics-exclusions
  options:
    addresses [add | delete | none | replace-all-with] {
      [ip address]...
    }
}

edit metrics-exclusions
  options:
    all-properties

    DISPLAY
list
list metrics-exclusions
show running-config metrics-exclusions
  addresses
  options:
    all-properties
    one-line

DESCRIPTION
  You can use the metrics-exclusions component to exclude IP addresses
  from the Global Traffic Manager metrics.

EXAMPLES
  modify metrics-exclusions addresses add {10.10.10.1}

  Excludes the IP address 10.10.10.1 from inclusion in the Global Traffic
  Manager metrics.

  list metrics-exclusions

  Displays the IP addresses that are excluded from the Global Traffic
  Manager metrics.

OPTIONS
  ip address
  Specifies the IP addresses that you want to add to or delete from
  the exclusion list, or with which you want to replace all existing
  IP addresses that are currently on the exclusion list.

SEE ALSO

## gtm global-settings metrics

```

NAME
  metrics - Configures metrics for the Global Traffic Manager(tm).

MODULE
  gtm global-settings

SYNTAX
  Modify or display the metrics component within the gtm global-settings
  module using the syntax in the following sections.

MODIFY
  modify metrics
  options:
    default-probe-limit [integer]
    hops-ttl [integer]
    hops-packet-length [integer]
    hops-sample-count [integer]
    hops-timeout [integer]
    inactive-ldns-ttl [integer]
    ldns-update-interval [integer]
    inactive-paths-ttl [integer]
    max-synchronous-monitor-requests [integer]
    metrics-caching [integer]
    metrics-collection-protocols none
    metrics-collection-protocols
      [add | delete | replace-all-with] {
        [dns-dot | dns-rev | icmp | tcp | udp] ...
      }
    path-ttl [integer]
    paths-retry [integer]

  edit metrics
  options:

```

all-properties  
non-default-properties  
one-line

DISPLAY  
list  
list metrics  
show running-config metrics  
show running-config metrics [option]  
options:  
all-properties  
non-default-properties

DESCRIPTION  
You can use the metrics component to modify or display the Global Traffic Manager metrics settings.

EXAMPLES  
modify metrics default-probe-limit 10  
  
Sets the default probe limit for the Global Traffic Manager to 10.  
  
list metrics all-properties  
  
Displays all properties of the metrics settings for the Global Traffic Manager.

OPTIONS  
default-probe-limit  
Specifies the number of probe attempts that the system performs before removing the path from the metrics. The default value is 12.  
  
hops-ttl  
Specifies the number of seconds that the system considers traceroute utility data to be valid for name resolution and load balancing. The default value is 604800. Note that this option must be greater than the hops-timeout option.  
  
hops-packet-length  
Specifies the length of packets, in bytes, that the system sends to a local DNS server to determine the path information between the two systems. Valid values are 64 - 500. The default value is 64.  
  
hops-sample-count  
Specifies the number of packets that the system sends to a local DNS server to determine the path information between those two systems. Valid values are 1 - 10. The default value is 3.  
  
hops-timeout  
Specifies the number of seconds that the big3d daemon waits for a probe. Valid values are 1 - 10. The default value is 3.  
  
inactive-ldns-ttl  
Specifies the number of seconds that an inactive LDNS remains in the cache. Each time an LDNS makes a request, the clock starts again. Valid values are 60 - 31536000 (1 year). The default value is 2419200 (28 days).  
  
ldns-update-interval  
Specifies the number of seconds that a tmm will wait before sending an update for a LDNS which has been accessed. The default value is 20 seconds.  
  
inactive-paths-ttl  
Specifies the number of seconds that a path remains in the cache after its last access. Valid values are 60 - 31536000 (1 year). The default value is 604800 (7 days).  
  
max-synchronous-monitor-requests  
Specifies how many monitors can attempt to verify the availability of a given resource at the same time. The default value is 20.  
  
metrics-caching  
Specifies the interval (in seconds) at which the system dumps path and other metrics data. Valid values are 0 through 604800. The default value is 3600; 0 (zero) turns this feature off.  
  
metrics-collection-protocols  
Specifies the protocols that the system uses to collect metrics information relevant to LDNS servers.  
  
path-ttl  
Specifies the number of seconds that the system considers path data to be valid for name resolution and load balancing purposes. The default value is 2400. Note that this option must be greater than the paths-retry option and less than or equal to 2419200 (28 days).  
  
paths-retry  
Specifies the interval (in seconds) at which the system retries the path data. Valid values are 1 - 600 (10 minutes). The default value is 120.

## gtm iquery

**NAME**  
iquery - Displays information about iQuery.

**MODULE**  
gtm

**SYNTAX**  
Display the iquery component within the gtm module using the syntax in the following sections.

**DISPLAY**  
show iquery  
options:  
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)  
field-fmt  
global

**DESCRIPTION**  
You can use the iquery component to display iQuery statistics.

**EXAMPLES**  
show iquery  
Displays iQuery statistics in the system default units.  
show iquery field-fmt  
Displays iQuery statistics in field format.

**OPTIONS**  
For information about options for the command show, see show.

**SEE ALSO**  
show, tmsh

**COPYRIGHT**

## gtm ldns

**NAME**  
ldns - Displays local domain name system (LDNS) statistics for the Global Traffic Manager(tm).

**MODULE**  
gtm

**SYNTAX**  
Display the ldns component within the gtm module using the syntax in the following section.

**DISPLAY**  
show ldns  
options:  
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)  
field-fmt

**DESCRIPTION**  
You can use the ldns component to display LDNS statistics.

## EXAMPLES

```
show ldns
```

Displays LDNS statistics in the system default units.

```
show ldns field-fmt
```

Displays LDNS statistics in field format.

## SEE ALSO

```
show, tmsh
```

## gtm link

### NAME

link - Configures Global Traffic Manager(tm) links.

### MODULE

gtm

### SYNTAX

Configure the link component within the gtm module using the syntax in the following sections.

#### CREATE/MODIFY

```
create link [name]
modify link [name]
options:
  app-service [[string] | none]
  cost-segments {
    { [up-to-bps [integer] ] [dollars-per-mbps [integer] ] }...
  }
  datacenter [string]
  description [string]
  [disabled | enabled]
  duplex-billing [disabled | enabled]
  limit-max-inbound-bps [integer]
  limit-max-inbound-bps-status [disabled | enabled]
  limit-max-outbound-bps [integer]
  limit-max-outbound-bps-status [disabled | enabled]
  limit-max-total-bps [integer]
  limit-max-total-bps-status [disabled | enabled]
  link-ratio [integer]
  monitor [none | [name] [and [name] ]... ]
  monitor min [integer] of { [name]... }
  prepaid-segment [integer]
  router-addresses
    [add | delete | modify | replace-all-with] {
  [ip address] {
    app-service [[string] | none]
    description [string]
    device-name [[string] | none]
    translation [disabled | enabled]
  }
  }
  service-provider [name]
  uplink-address [ip address]
  weighting [price | ratio]

edit link [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

reset-stats link
reset-stats link [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY

show link [name]
options:
```

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)  
detail  
field-fmt

DELETE  
delete link [name]

#### DESCRIPTION

You can use the link component to create, display, modify, or delete a link.

A link is a physical device that connects the network to the rest of the Internet. You can logically attach links to a collection of servers in order to manage access to the data sources on the network.

#### EXAMPLES

```
create link my_link datacenter DC1 router-addresses add {10.10.1.1}
```

Creates a link named `my_link` in the DC1 data center and adds the IP address of the router that uses this link.

```
list link non-default-properties
```

Displays all non-default properties for all links.

```
delete link my_link
```

Deletes the link named `my_link`.

```
show link my_link detail
```

Show the servers and virtual servers associated with `my_link`.

```
show link all detail
```

Show the servers and virtual servers associated with each respective link in the system.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the link belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the link. Only the application service can modify or delete the link.

##### cost-segments

Specifies the cost of each incremental segment of bandwidth. This option is valid only when the `weighting` option is set to `price`. Note that you cannot modify the list, only replace all of the options in the list.

By default, the list is empty. The options are:

##### dollars-per-mps

Specifies the cost in dollars per megabytes per second. By default this value is not specified.

##### up-to-bps

Specifies the cost in dollars per bytes per second. By default this value is not specified.

##### datacenter

Specifies the data center to which the link belongs.

##### description

User defined description.

##### detail

The `detail` option is used with the `show display` command. This shows the server IP addresses and virtual servers associated with this link. A server can have multiple server IP addresses, however, only the server IP addresses that use this link will be displayed. Assignment information for servers and virtuals will not be displayed if there are not any servers or virtuals that use this link. By default, links are automatically matched to server IP addresses and virtual servers according to their IP addresses. Explicit links may also be defined. How this link was assigned is displayed under the Link Assignment column: `auto` means that the system automatically assigned this link, and `explicit` means that the link was explicitly set by the user.

##### [disabled | enabled]

Specifies whether the link and its resources are available for load balancing. The default value is `enabled`.

##### duplex-billing

Enables or disables duplex billing for this link. The default value is `enabled`. This option is valid only when the `weighting` option is set to `price`.

##### disabled

The internet service provider (ISP) that supplies this link bills for bandwidth usage based on the total amount of inbound plus outbound traffic on the link.

##### enabled

The ISP that supplies this link bills for bandwidth usage based on the maximum amount of either inbound or outbound traffic on the link (whichever is higher), rather than billing for bandwidth usage based on the total amount of inbound plus outbound traffic on the link.

`glob` Displays the items that match the `glob` expression. See `help glob`

for a description of glob expression syntax.

**limit-max-inbound-bps**  
Specifies the threshold for inbound traffic on the link. The default value is 0 (zero).

**limit-max-inbound-bps-status**  
Enables or disables the limit-max-inbound-bps option for this link. The default value is disabled.

**limit-max-outbound-bps**  
Specifies the threshold for inbound traffic on the link. The default value is 0 (zero).

**limit-max-outbound-bps-status**  
Enables or disables the limit-max-outbound-bps option for this link. The default value is disabled.

**limit-max-total-bps**  
Specifies the threshold as a sum of inbound and outbound traffic on the link. The default value is 0 (zero).

**limit-max-total-bps-status**  
Enables or disables the limit-max-total-bps option for this link. The default value is disabled.

**link-ratio**  
Specifies the frequency at which the system sends traffic through the link. The default value is 1.

**Important:** When you set this option, you must also set the weighting option to ratio.

**monitor**  
Specifies the health monitors that the system uses to determine whether this link is available for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this link to be declared up. The default value is none.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**prepaid-segment**  
Specifies the amount of bandwidth for which the system is prepaid. This option is valid only when the weighting option is set to price. The default value is 0 (zero).

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**router-addresses**  
Specifies the IP addresses of the routers that use this link. A router address can be associated with only one link. You can use the following options:

**app-service**  
Specifies the name of the application service to which the link belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the link. Only the application service can modify or delete the link.

**description**  
User defined description.

**device-name**  
Deprecated in v13.0.0 Specifies the name of the device associated with this link. Defaults to none.

**translation**  
Specifies the address that the link uses for translation when communicating between the network and the Internet. The default value is any6.

**service-provider**  
Specifies the Internet Service Provider (ISP) or vendor that supplies this link. This allows you to provide a name or description that helps identify this link out of your data center. This is an optional field.

**uplink-address**  
Specifies the IP address the system uses to gather Simple Network Management Protocol (SNMP) metrics from the router interface. When you configure an uplink address, the system sends SNMP requests to the IP addresses configured using the router-addresses option for this link.

**weighting**  
Specifies the weighting methodology the system uses to select a link to which to send traffic. The default value is ratio. The options are:

**price**  
The system continuously checks the performance of each link, and sends traffic through the link with the best performance data.

**ratio**  
The system uses the value that you set in the link-ratio option to determine the link to which to send traffic.

    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
    field-fmt
```

```
DELETE
delete listener [name]
```

#### DESCRIPTION

You can use the listener component to create, display, modify, or delete a listener.

A listener is an object that listens for DNS queries. Listeners are defined for specific IP addresses, and are always associated with port 53.

**Important:** When you create, modify, or delete a listener, the system saves the running configuration in the stored configuration files.

#### EXAMPLES

```
create listener my_listener address 10.10.1.1 persist replace-all-with
{ source_addr }
```

Creates a listener named `my_listener` with an IP address of 10.10.1.1, which uses the source address persistence method.

```
modify listener my_listener profiles replace-all-with { dns }
```

Replaces the profiles associated with the listener `my_listener`.

**Note:** To replace the profile associated with a listener, you must enclose the name of the new profile in curly brackets.

```
list listener non-default-properties
```

Displays all non-default properties for all listeners.

```
delete listener my_listener
```

Deletes the listener named `my_listener`.

#### OPTIONS

**address**  
Specifies the IP address on which the system listens. The system receives traffic sent to this IP address and processes it as needed. This option is required.

**advertise**  
Specifies whether to advertise the listener address to surrounding routers. The options are `yes` or `no`. The default value is `no`.

**app-service**  
Specifies the name of the application service to which the listener belongs. The default value is `none`. **Note:** If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the listener. Only the application service can modify or delete the listener.

**context**  
Specifies that the protocol profile is either a `clientside` or `serverside` profile. If not specified, the default value is `all` for both sides.

**description**  
User defined description.

**(enabled | disabled)**  
Specifies the state of the listener. The default value is `enabled`.

**Note:** When you disable a listener, the listener no longer accepts new connection requests. However, it allows current connections to finish processing before going to a down state.

**fallback-persistence**  
Specifies a fallback persistence profile for the listener to use when the default persistence profile is not available. The default value is `none`.

**glob** Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

**ip-protocol**  
Specifies the protocol on which this listener receives network traffic. The options are `udp` or `tcp`. The default value is `udp`.

**last-hop-pool**  
Specifies the name of the last hop pool that you want the listener to use to direct reply traffic to the last hop router. The default value is `none`.

**mask** Specifies the netmask for a network listener only. This setting is required for a network listener.

The netmask clarifies whether the host bit is an actual zero or a wildcard representation. The default value is `255.255.255.255` for IPv4 or `ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff` for IPv6.

**name** Specifies a unique name for the component. This option is required for the commands `create` and `modify`.

**partition**  
Displays the administrative partition within which the listener resides.

#### persist

Specifies a list of profiles separated by spaces that the listener uses to manage connection persistence. The default value is none.

To enable persistence, typically you specify a single profile. However, you can specify multiple profiles in conjunction with `iRules(r)` that define a persistence strategy based on incoming traffic. In the case of multiple profiles, the default option specifies which profile you want the listener to use if an `iRule` does not specify a persistence method. When you specify multiple profiles, the default value of the default property is `no`. You can set the value of the default property to `yes` for only one of the profiles.

`pool` Specifies a default pool to which you want the listener to automatically direct traffic. The default value is none.

`port` Specifies the service port on which the listener listens for connections. When you create a listener, the default value is 53 if no port number is specified.

#### profiles

Specifies the DNS, statistics and protocol profiles to use for this listener. When a listener is created, if a DNS profile is not specified, the generic "dns" profile is added. If a protocol profile is not specified, then the generic "tcp" profile is added for TCP and the "udp\_gtm\_dns" profile is added for UDP. A listener always has DNS and protocol profiles once it is created. Only a statistics profile can be added to or deleted from a listener.

The `replace-all-with` command replaces the profiles with the specified ones. The unspecified DNS and protocol profiles are not changed. If statistics profiles are not specified, the `replace-all-with` command removes the existing statistics profile from the listener. When the protocol is modified, if profiles are not specified, a default protocol profile is used. DNS and statistics profiles will not change.

#### rules

Specifies a list of `iRules`, separated by spaces, that customize the listener to direct and manage traffic. The default value is none.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

#### source-address-translation

Specifies the type of source address translation enabled for the listener as well as the pool that the source address translation will use.

`pool` Specifies the name of a SNAT pool used by the specified listener.

`type` Specifies the type of source address translation associated with the specified listener.

The options are:

#### automap

Specifies the use of self IP addresses for listener source address translation.

`none` Specifies no source address translation to be used by the listener.

`snat` Specifies the use of a SNAT pool of translation addresses for listener source address translation.

#### source-port

Specifies whether the system preserves the source port of the connection. The default value is `preserve`.

The options are:

#### change

Obfuscates internal network addresses.

#### preserve

Preserves the source port of the connection.

#### preserve-strict

Use this value only for UDP under very special circumstances, such as `nPath` or `transparent` (that is, no translation of any other L3/L4 field), where there is a 1:1 relationship between virtual IP addresses and node addresses, or when clustered multi-processing (CMP) is disabled.

#### translate-address

Enables or disables address translation for the listener. Disable address translation for a listener if you want to use the listener to load balance connections to any address. This option is useful when the system is load balancing devices that have the same IP address. The default value is `disabled`.

#### translate-port

Enables or disables port translation. Disable port translation for a listener, if you want to use the listener to load balance connections to any service. The default value is `disabled`.

#### vlans

Specifies a list of VLANs on which traffic is either disabled or enabled, based on whether the vlans-disabled or vlans-enabled option is specified.

**vlans-disabled**

Specifies that traffic is not accepted by this listener on the VLANs specified in the vlans option. This option is mutually exclusive with the vlans-enabled option.

**vlans-enabled**

Specifies that traffic is accepted by this listener on only the VLANs specified in the vlans option. This option is mutually exclusive with the vlans-disabled option.

## gtm monitor bigip-link

NAME

bigip-link - Configures a BIG-IP(r) Link monitor.

MODULE

gtm monitor

SYNTAX

Configure the bigip-link component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create bigip-link [name]
modify bigip-link [name]
options:
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  destination [ip address]
  ignore-down-response [enabled | disabled]
  interval [integer]
  timeout [integer]
```

```
edit bigip-link [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list bigip-link
list bigip-link [ [name] | [glob] | [regex] ] ... ]
show running-config bigip-link
show running-config bigip-link [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete bigip-link [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the bigip-link component to configure a custom monitor, or you can use the default BIG-IP Link monitor that the Global Traffic Manager provides. This type of monitor acquires data captured through monitors managed by a BIG-IP Link Controller.

EXAMPLES

```
create bigip-link my_bigip-link defaults-from bigip_link
```

Creates a monitor named my\_bigip-link that inherits properties from the default BIG-IP Link monitor.

```
list bigip-link
```

Displays the properties of all of the BIG-IP Link monitors.

## OPTIONS

### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is bigip\_link.

### description

User defined description.

### destination

Specifies the IP address of the resource that is the destination of this monitor. The default value is \*.

Possible values are:

\* Specifies to perform a health check on the IP address of the node.

### IP address

Specifies to perform a health check on the IP address that you specify, route the check through the IP address of the associated node, and mark the IP address of the associated node up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

### interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

### partition

Displays the administrative partition within which the component resides.

### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

## SEE ALSO

## gtm monitor bigip

### NAME

bigip - Configures a BIG-IP(r) monitor.

### MODULE

gtm monitor

### SYNTAX

Configure the bigip component within the gtm monitor module using the syntax in the following sections.

```

CREATE/MODIFY
create bigip [name]
modify bigip [name]
options:
  aggregate-dynamic-ratios [average-members | average-nodes | none |
    sum-members | sum-nodes]
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  ignore-down-response [enabled | disabled]
  interval [integer]
  timeout [integer]

edit bigip [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default properties

DISPLAY
list bigip
list bigip [ [name] | [glob] | [regex] ] ... ]
show running-config bigip
show running-config bigip [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete bigip [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the bigip component in the gtm monitor module to configure a custom monitor, or you can use the default BIG-IP(r) monitor that the Global Traffic Manager(tm) provides. The BIG-IP monitor is both a health and performance monitor. This type of monitor acquires data captured through monitors managed by a BIG-IP Local Traffic Manager(tm).

You can monitor only the following components with a BIG-IP monitor:

- Global Traffic Manager server
- Global Traffic Manager virtual server
- Local Traffic Manager server
- Local Traffic Manager virtual server

#### EXAMPLES

```
create bigip my_bigip defaults-from bigip
```

Creates a monitor named my\_bigip that inherits properties from the default BIG-IP monitor.

```
list bigip
```

Displays the properties of all of the BIG-IP monitors.

#### OPTIONS

**aggregate-dynamic-ratios**

Specifies the monitor's response to a query. By default, the BIG-IP monitor uses the gtm\_score value as the vs\_score for a Local Traffic Manager virtual server.

You can use this option to override the default behavior using the following values:

**average-members**

Specifies that the monitor uses the average of the dynamic ratio values of the pool members associated with the pools that are associated with the virtual server as a response to a query.

**average-nodes**

Specifies that the monitor uses the average value of all of the nodes associated with the pool members that are associated with the pools that are associated with the virtual server as a response to a query.

**none** This is the default value.

**sum-members**

Specifies that the monitor uses the sum of the pool members as a response to a query.

**sum-nodes**

Specifies that the monitor uses the sum of the dynamic ratios of all of the nodes as a response to a query.

**app-service**

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is bigip.

**description**

User defined description.

**destination**  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the address and port supplied by a virtual server.

\*:port  
Specifies to perform a health check on the virtual server with the IP address supplied by the virtual server and the port you specify.

IP address:port  
Specifies to mark a pool member up or down based on the response of the virtual server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 90 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

## gtm monitor external

**NAME**  
external - Configures an external monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the external component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create external [name]  
modify external [name]  
options:  
args [ [arguments] | none]  
defaults-from [name]  
description [string]  
destination [ip address][port]

```

ignore-down-response [enabled | disabled]
interval [integer]
probe-timeout [integer]
run [none | [path] ]
timeout [integer]
user-defined [ [name] [value] | [name] none ]

edit external [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list external
list external [ [ [name] | [glob] | [regex] ] ... ]
show running-config external
show running-config external [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete external [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the external component to configure a custom monitor, or you can use the default external monitor that the Global Traffic Manager provides. You can use this type of monitor to monitor services using your own programs.

#### EXAMPLES

```
create external my_external defaults-from external
```

Creates a monitor named `my_external` that inherits properties from the default external monitor.

```
list external
```

Displays the properties of all of the external monitors.

#### OPTIONS

`args` Specifies any command-line arguments that the external program requires. The default value is none.

`defaults-from`  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `external`.

`description`  
User defined description.

`destination`  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

`*:port`  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`ignore-down-response`  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

`interval`  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`  
Displays the administrative partition within which the component resides.

`probe-timeout`  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

`regex`  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`run` Specifies the path and file name of a program to run as the external monitor, for example `/config/monitors/myMonitor`. The

default value is none.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### user-defined

Specifies any user-defined command-line arguments and variables that the external program requires. Use the following syntax to specify a user defined parameter.

```
modify external my_external user-defined my_param_name
my_param_value
```

Use the following syntax to remove a user defined parameter.

```
modify external my_external user-defined my_param_name none
```

#### SEE ALSO

create, delete, edit, glob, gtm pool, list, modify, regex, show, tmsh,

#### COPYRIGHT

## gtm monitor firepass

#### NAME

firepass - Configures a FirePass(r) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the firepass component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create firepass [name]
```

```
modify firepass [name]
```

##### options:

```
app-service [[string] | none]
```

```
cipherlist [list]
```

```
concurrency-limit [integer]
```

```
defaults-from [name]
```

```
description [string]
```

```
destination [ip address][port]
```

```
ignore-down-response [enabled | disabled]
```

```
interval [integer]
```

```
max-load-average [floating point value]
```

```
password [none | [password] ]
```

```
probe-timeout [integer]
```

```
timeout [integer]
```

```
username [name]
```

```
edit firepass [ [ [name] | [glob] | [regex] ] ... ]
```

##### options:

```
all-properties
```

```
non-default-properties
```

##### DISPLAY

```
list firepass
```

```
list firepass [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config firepass
```

```
show running-config firepass [ [ [name] | [glob] | [regex] ] ... ]
```

##### options:

```
all-properties
```

```
non-default-properties
```

```
one-line
```

```
partition
```

##### DELETE

```
delete firepass [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the firepass component to configure a custom monitor, or

you can use the default FirePass monitor that the BIG-IP(r) Global Traffic Manager(tm) provides. The FirePass monitor is both a health and performance monitor.

For more information about configuring monitors, refer to the Configuration Guide for BIG-IP(r) Global Traffic Management.

#### EXAMPLES

```
create firepass my_firepass defaults-from firepass_gtm
```

Creates a monitor named my\_firepass that inherits properties from the default FirePass monitor.

```
list firepass
```

Displays the properties of all of the FirePass monitors.

#### OPTIONS

**app-service**

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

**cipherlist**

Specifies the list of ciphers for this monitor. The default value is HIGH:!ADH.

**concurrency-limit**

Specifies the maximum percentage of licensed connections currently in use under which the monitor marks the FirePass system up. The default value is 95.

For example, a value of 95 percent means that the monitor marks the FirePass system up until 95 percent of licensed connections are in use. When the number of in-use licensed connections exceeds 95 percent, the monitor marks the FirePass system down.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is firepass\_gtm.

**description**

User defined description.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the address you supply.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**max-load-average**

Specifies the number that the monitor uses to mark the FirePass system up or down. The system compares value of this option against a one-minute average of the FirePass system load. When the FirePass system-load average falls within the specified value, the monitor marks the FirePass system up. When the average exceeds the setting, the monitor marks the system down.

The default value is 12.0.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**

Displays the administrative partition within which the component resides.

**password**

Specifies the password, if the monitored target requires authentication. The default value is none.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help

regex for a description of regular expression syntax.

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 90 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**

Specifies the username, if the monitored target requires authentication. The default value is gtmuser.

**SEE ALSO**

create, delete, edit, glob, gtm pool, list, modify, regex, show, tmsh

**COPYRIGHT**

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

---

## gtm monitor ftp

**NAME**

ftp - Configures a File Transfer Protocol (FTP) monitor.

**MODULE**

gtm monitor

**SYNTAX**

Configure the ftp component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**

```
create ftp [name]
modify ftp [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  filename [ [filename] | none]
  ignore-down-response [enabled | disabled]
  interval [integer]
  mode [passive | port]
  password [none | [password] ]
  probe-timeout [integer]
  timeout [integer]
  username [name]
```

```
edit ftp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

**DISPLAY**

```
list ftp
list ftp [ [ [name] | [glob] | [regex] ] ... ]
show running-config ftp
show running-config ftp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

**DELETE**

```
delete ftp [name]
```

Note: You cannot delete default monitors.

**DESCRIPTION**

You can use the ftp component to configure a custom monitor, or you can use the default FTP monitor that the Global Traffic Manager provides. This type of monitor verifies the FTP service by attempting to download a specific file to the /var/tmp directory on the system. Once downloaded successfully, the file is not saved.

**EXAMPLES**

```
create ftp my_ftp defaults-from ftp
```

Creates a monitor named `my_ftp` that inherits properties from the default FTP monitor.

`list ftp`

Displays the properties of all of the FTP monitors.

#### OPTIONS

`debug`

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

`no` Specifies that the system does not redirect error messages and additional information related to this monitor.

`yes` Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

`defaults-from`

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `ftp`.

`description`

User defined description.

`destination`

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the address and port supplied by a pool member.

`*:port`

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

`filename`

Specifies the full path and file name of the file that the system attempts to download. The health check is successful if the system can download the file. The default value is none.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`ignore-down-response`

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

`interval`

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

`mode` Specifies the data transfer process (DTP) mode. The default value is `passive`. The options are:

`passive`

Specifies that the monitor sends a data transfer request to the FTP server. When the FTP server receives the request, the FTP server then starts and establishes the data connection.

`port` Specifies that the monitor starts and establishes the data connection with the FTP server.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`password`

Specifies the password, if the monitored target requires authentication. The default value is none.

`partition`

Displays the administrative partition within which the component resides.

`probe-timeout`

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`timeout`

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a

RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

SEE ALSO

## gtm monitor gateway-icmp

**NAME**  
gateway-icmp - Configures a Gateway Internet Control Message Protocol (ICMP) monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the gateway-icmp component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create gateway-icmp [name]  
modify gateway-icmp [name]  
options:  
defaults-from [name]  
description [string]  
destination [ip address][port]  
ignore-down-response [enabled | disabled]  
interval [integer]  
probe-attempts [integer]  
probe-interval [integer]  
probe-timeout [integer]  
timeout [integer]  
transparent [enabled | disabled]  
  
edit gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list gateway-icmp  
list gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]  
show running-config gateway-icmp  
show running-config gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DELETE**  
delete gateway-icmp [name]

Note: You cannot delete default monitors.

**DESCRIPTION**

You can use the gateway-icmp component to configure a custom monitor, or you can use the default Gateway ICMP monitor that the Global Traffic Manager provides. You can use a Gateway ICMP type of monitor for a virtual server, a server (that is, all of the virtuals on a specified server), a pool member, a pool (that is, all of the pool members of a specified pool), or a link.

**EXAMPLES**

```
create gateway-icmp my_icmp defaults-from gateway_icmp
```

Creates a monitor named my\_icmp that inherits properties from the default Gateway ICMP monitor.

```
list gateway-icmp
```

Displays the properties of all of the Gateway ICMP monitors.

**OPTIONS**

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is gateway\_icmp.

**description**  
User defined description.

**destination**  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)  
Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**probe-attempts**  
Specifies the number of times the BIG-IP(r) system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 3 attempts.

**probe-interval**  
Specifies the frequency at which the BIG-IP system probes the host server. The default value is 1 second.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**transparent**  
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

## gtm monitor gtp

**NAME**  
gtp - Configures a GPRS Tunneling Protocol (GTP) monitor. This monitor operates over UDP.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the gtp component within the gtm monitor module using the syntax in the following sections.

### CREATE/MODIFY

```
create gtp [name]
modify gtp [name]
options:
  defaults-from [name]
  description [string]
  destination [ip address][port]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-attempts [integer]
  probe-interval [integer]
  probe-timeout [integer]
  protocol-version [integer]
  timeout [integer]
```

```
edit gtp [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

### DISPLAY

```
list gtp
list gtp [ [name] | [glob] | [regex] ] ... ]
show running-config gtp
show running-config gtp [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete gtp [name]
```

Note: You cannot delete default monitors.

### DESCRIPTION

You can use the gtp component to configure a custom monitor, or you can use the default GTP monitor that the Global Traffic Manager provides. This type of monitor verifies the GPRS tunneling service by attempting to send GTP Echo Requests to a pool, pool member, or virtual server, and verifying the receipt of a well-formed Echo Response packet. This monitor supports GTP version 1 and version 2 over UDP.

For more information about configuring monitors, refer to the Configuration Guide for BIG-IP(r) Global Traffic Management.

### EXAMPLES

```
create gtp my_gtp defaults-from gtp
```

Creates a monitor named my\_gtp that inherits properties from the default GTP monitor.

```
list gtp
```

Displays the properties of all of the GTP monitors.

### OPTIONS

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is gtp.

**description**

User defined description.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**

Displays the administrative partition within which the component resides.

**probe-attempts**

Specifies the number of times the BIG-IP system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 3.

**probe-interval**

Specifies the frequency at which the BIG-IP system probes the host server. The default value is 1.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**protocol-version**

Specifies the GTP protocol version used to perform the exchange. GTP version 1 and GTP version 2 are supported. The default is version 1.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a non-conforming Echo Reply, the system immediately flags the target as down without waiting for the timeout interval to expire.

## gtm monitor http

NAME

http - Configures a Hypertext Transfer Protocol (HTTP) monitor.

MODULE

gtm monitor

SYNTAX

Configure the http component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY

create http [name]

modify http [name]

options:

defaults-from [name]

description [string]

destination [ip address][port]

ignore-down-response [enabled | disabled]

interval [integer]

password [none | [password] ]

probe-timeout [integer]

recv [none | [string] ]

reverse [enabled | disabled]

send [none | [string] ]

timeout [integer]

```

transparent [enabled | disabled]
username [ [name] | none]

edit http [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list http
list http [ [ [name] | [glob] | [regex] ] ... ]
show running-config http
show running-config http [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete http [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the http component to configure a custom monitor, or you can use the default HTTP monitor that the Global Traffic Manager provides. This type of monitor verifies the HTTP service by attempting to receive specific content from a Web page.

#### EXAMPLES

```
create http my_http defaults-from http
```

Creates a monitor named my\_http that inherits properties from the default HTTP monitor.

```
list http
```

Displays the properties of all of the HTTP monitors.

#### OPTIONS

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is http.

**description**

User defined description.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**IP address:port (with the transparent option enabled)**

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**

Displays the administrative partition within which the component resides.

**password**

Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is

included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object.

The default setting is GET /, which retrieves a default HTML file for a web site. To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html.

Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

#### username

Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

create, delete, gtm pool, gtm server, list, modify, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## gtm monitor https

#### NAME

https - Configures a Hypertext Transfer Protocol over Secure Socket Layer (HTTPS) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the https component within the gtm monitor module using the syntax in the following sections.

#### CREATE/MODIFY

```
create https [name]
modify https [name]
options:
  cert [ [cert list] | none]
  cipherlist [string]
  compatibility [enabled | disabled]
```

```

defaults-from [name]
description [string]
destination [ip address][port]
ignore-down-response [enabled | disabled]
interval [integer]
key [ [key] | none]
password [none | [password] ]
probe-timeout [integer]
recv [none | [string] ]
reverse [enabled | disabled]
send [none | [string] ]
timeout [integer]
transparent [enabled | disabled]
username [ [name] | none]

edit https [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list https
list https [ [ [name] | [glob] | [regex] ] ... ]
show running-config https
show running-config https [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete https [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the http component to configure a custom monitor, or you can use the default HTTPS monitor that the Global Traffic Manager provides. This type of monitor verifies the HTTPS service by attempting to receive specific content from a Web page protected by Secure Socket Layer (SSL) security.

#### EXAMPLES

```
create https my_https defaults-from https
```

Creates a monitor named my\_https that inherits properties from the default HTTPS monitor.

```
list https
```

Displays the properties of all of the HTTPS monitors.

#### OPTIONS

**cert** Specifies a fully-qualified path for a client certificate that the monitor sends to the target SSL server. The default value is none.

##### cipherlist

Specifies the list of ciphers for this monitor. The default list DEFAULT:+SHA:+3DES:+kEDH is located in the file base\_monitors.conf.

##### compatibility

Specifies, when enabled, that the SSL options setting (in OpenSSL) is set to ALL. The default value is enabled.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is https.

##### description

User defined description.

##### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*.\* Specifies to perform a health check on the IP address and port supplied by a pool member.

##### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

##### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

##### IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

#### interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**key** Specifies the RSA private key if the monitored target requires authentication. The key must be surrounded by quotation marks, for example, `key \"client.key\"`. Note that if you specify a key, you must also specify a value for the `cert` option. The default value is `none`.

**name** Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

#### partition

Displays the administrative partition within which the component resides.

#### password

Specifies the password if the monitored target requires authentication. The default value is `none`.

#### probe-timeout

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is `none`.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for both the `send` and `recv` options, the monitor performs a simple service check and `connect` only.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

#### reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the `this` mode only if you configure both the `send` and `recv` options.

The default value is `disabled`, which specifies that the monitor does not operate in reverse mode. The `enabled` value specifies that the monitor operates in reverse mode.

**send** Specifies the text string that the monitor sends to the target object. The default value is `GET /`, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, `GET /www/company/index.html`. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is `null`, then a valid connection suffices to determine that the service is up. In this case, the system does not need the `recv` option and ignores the option even if not `null`.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a `RESET` packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is `disabled`.

#### username

Specifies the username, if the monitored target requires authentication. The default value is `none`.

#### SEE ALSO

`create`, `delete`, `edit`, `glob`, `gtm pool`, `list`, `modify`, `regex`, `show`, `tms`

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## gtm monitor imap

**NAME**  
imap - Configures an Internet Message Access Protocol (IMAP) monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the imap component within the gtm monitor module using the syntax in the following sections.

### CREATE/MODIFY

```
create imap [name]
modify imap [name]
```

#### options:

```
debug [no | yes]
defaults-from [name]
description [string]
destination [ip address][port]
folder [ [name] | none]
ignore-down-response [enabled | disabled]
interval [integer]
password [none | [password] ]
probe-timeout [integer]
timeout [integer]
transparent [enabled | disabled]
username [ [name] | none]
```

```
edit imap [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
```

### DISPLAY

```
list imap
```

```
list imap [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config imap
```

```
show running-config imap [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
one-line
partition
```

### DELETE

```
delete imap [name]
```

Note: You cannot delete default monitors.

### DESCRIPTION

You can use the imap component to configure a custom monitor, or you can use the default IMAP monitor that the Global Traffic Manager provides. This type of monitor verifies IMAP by attempting to open a specified mail folder on a server. This monitor is similar to the POP3 monitor.

### EXAMPLES

```
create imap my_imap defaults-from imap
```

Creates a monitor named `my_imap` that inherits properties from the default IMAP monitor.

```
list imap
```

Displays the properties of all of the IMAP monitors.

### OPTIONS

#### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

`no` Specifies that the system does not redirect error messages and additional information related to this monitor.

`yes` Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

#### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `imap`.

#### description

User defined description.

#### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**folder**  
Specifies the name of the folder on the IMAP server that the monitor tries to open. The default value is INBOX.

**ignore-down-response**  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**password**  
Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**transparent**  
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

## gtm monitor ldap

**NAME**  
ldap - Configures a Lightweight Directory Access Protocol (LDAP) monitor.

**MODULE**  
gtm monitor

## SYNTAX

Configure the ldap component within the gtm monitor module using the syntax in the following sections.

### CREATE/MODIFY

```
create ldap [name]
modify ldap [name]
options:
  base [none | [string] ]
  chase-referrals [ no | yes ]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  filter [ [LDAP key] | none]
  ignore-down-response [enabled | disabled]
  interval [integer]
  mandatory-attributes [no | yes]
  password [none | [password] ]
  probe-timeout [integer]
  security [none | ssl | tls]
  timeout [integer]
  username [ [name] | none]

edit ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

### DISPLAY

```
list ldap
list ldap [ [ [name] | [glob] | [regex] ] ... ]
show running-config ldap
show running-config ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete ldap [name]
```

Note: You cannot delete default monitors.

## DESCRIPTION

You can use the ldap component to configure a custom monitor, or you can use the default LDAP monitor that the Global Traffic Manager provides. This type of monitor verifies the LDAP service by attempting to authenticate the specified user.

## EXAMPLES

```
create ldap my_ldap defaults-from ldap
```

Creates a monitor named my\_ldap that inherits properties from the default LDAP monitor.

```
list ldap
```

Displays the properties of all of the LDAP monitors.

## OPTIONS

**base** Specifies the location in the LDAP tree from which the monitor starts the health check. A sample value is dc=bigip-test,dc=net. The default value is none.

### chase-referrals

Specifies whether the monitor upon receipt of an LDAP referral entry chases that referral. The default value is yes.

The options are:

**no** Specifies that the system will treat a referral entry as a normal entry and refrain from querying the remote LDAP server(s) pointed to by the referral entry.

**yes** Specifies that the system upon receiving any referral entry from the monitored LDAP server query, the system will then query the corresponding LDAP server(s) pointed to by the LDAP query. If the query for the referral is unsuccessful the system will mark the monitored LDAP server down.

### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is ldap.

### description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

filter

Specifies an LDAP key for which the monitor searches. A sample value is objectclass=\*. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

mandatory-attributes

Specifies whether the target must include attributes in its response to be considered up. The default value is no. The options are:

no Specifies that the system performs only a one-level search (based on the value of the filter option), and does not require that the target returns any attributes.

yes Specifies that the system performs a sub-tree search, and if the target returns no attributes, the target is considered down.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

security

Specifies the secure communications protocol that the monitor uses to communicate with the target. The default value is none.

The options are:

none Specifies that the system does not use a security protocol for communications with the target.

ssl Specifies that the system uses the SSL protocol for communications with the target.

tls Specifies that the system uses the TLS protocol for communications with the target.

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor mssql

**NAME**  
mssql - Configures a Microsoft(r) Windows(r) Structured Query Language (MSSQL) monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the mssql component within the gtm monitor module using the syntax in the following sections.

```
CREATE/MODIFY
create mssql [name]
modify mssql [name]
options:
  count [0 | 1]
  database [ [name] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  ignore-down-response [enabled | disabled]
  interval [integer]
  password [none | [password] ]
  probe-timeout [integer]
  recv [none | [string] ]
  recv-column [none | [string] ]
  recv-row [none | [string] ]
  send [none | [string] ]
  timeout [integer]
  username [ [name] | none]

edit mssql [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list mssql
list mssql [ [ [name] | [glob] | [regex] ] ... ]
show running-config mssql
show running-config mssql [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete mssql [name]
```

Note: You cannot delete default monitors.

**DESCRIPTION**  
You can use the mssql component to configure a custom monitor, or you can use the default MSSQL monitor that the Global Traffic Manager provides. This type of monitor verifies Microsoft Windows SQL-based services.

**EXAMPLES**  
create mssql my\_mssql defaults-from mssql  
  
Creates a monitor named my\_mssql that inherits properties from the default MSSQL monitor.  
  
list mssql  
  
Displays the properties of all of the MSSQL monitors.

**OPTIONS**  
count  
Specifies the number of instances for which the system keeps a connection open. By default, when you assign instances of this monitor to a resource, the system keeps the connection to the database open. With this option you can assign multiple instances to the database while reducing the overhead that multiple open connections can cause.  
  
A value of 0 (zero), the default, keeps the connection open for all instances. A value of 1 opens a new connection for each

instance. Any other positive value keeps the connection open for that many instances; for example, a value of 5 keeps the connection open for five instances of this monitor.

**database**

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

**debug**

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mssql.

**description**

User defined description.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**

Displays the administrative partition within which the component resides.

**password**

Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

**recv-column**

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**recv-row**

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**send** Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(\*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**

Specifies the username, if the monitored target requires authentication. The default value is none.

**SEE ALSO**

create, delete, edit, glob, gtm pool, list, modify, regex, show, tmsh

## gtm monitor mysql

**NAME**

mysql - Configures a MySQL(r) monitor.

**MODULE**

gtm monitor

**SYNTAX**

Configure the mysql component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**

create mysql [name]

modify mysql [name]

**options:**

count [0 | 1]

database [ [name] | none]

debug [no | yes]

defaults-from {name}

description [string]

destination [ip address][port]

ignore-down-response [enabled | disabled]

interval [integer]

password [none | [password] ]

probe-timeout [integer]

recv [none | [string] ]

recv-column [none | [string] ]

recv-row [none | [string] ]

send [none | [string] ]

timeout [integer]

username [ [name] | none]

edit mysql [ [ [name] | [glob] | [regex] ] ... ]

**options:**

all-properties

non-default-properties

**DISPLAY**

list mysql

list mysql [ [ [name] | [glob] | [regex] ] ... ]

show running-config mysql

show running-config mysql [ [ [name] | [glob] | [regex] ] ... ]

**options:**

all-properties

non-default-properties

one-line

partition

**DELETE**

delete mysql [name]

Note: You cannot delete default monitors.

**DESCRIPTION**

You can use the mysql component to configure a custom monitor, or you can use the default MySQL monitor that the Global Traffic Manager provides. This type of monitor verifies Microsoft(r) Windows(r) SQL-

based services.

#### EXAMPLES

```
create mysql my_mysql defaults-from mysql
```

Creates a monitor named `my_mysql` that inherits properties from the default MySQL monitor.

```
list mysql
```

Displays the properties of all of the MySQL monitors.

#### OPTIONS

`count`

Specifies the number of instances for which the system keeps a connection open. By default, when you assign instances of this monitor to a resource, the system keeps the connection to the database open. With this option you can assign multiple instances to the database while reducing the overhead that multiple open connections can cause.

A value of 0 (zero), the default, keeps the connection open for all instances. A value of 1 opens a new connection for each instance. Any other positive value keeps the connection open for that many instances; for example, a value of 5 keeps the connection open for five instances of this monitor.

`database`

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

`debug`

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

`no` Specifies that the system does not redirect error messages and additional information related to this monitor.

`yes` Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

`defaults-from`

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `mysql`.

`description`

User defined description.

`destination`

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

`*:port`

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`ignore-down-response`

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

`interval`

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`

Displays the administrative partition within which the component resides.

`password`

Specifies the password if the monitored target requires authentication. The default value is none.

`probe-timeout`

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

`recv` Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the `send` and `recv` options, the monitor performs a

simple service check and connect only.

**recv-column**

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**recv-row**

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**send** Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(\*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**

Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor nntp

**NAME**

nntp - Configures a Network News Transfer Protocol (NNTP) monitor.

**MODULE**

gtm monitor

**SYNTAX**

Configure the nntp component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**

```
create nntp [name]
modify nntp [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  ignore-down-response [enabled | disabled]
  interval [integer]
  newsgroup [ [name] | none]
  password [none | [password] ]
  probe-timeout [integer]
  timeout [integer]
  username [ [name] | none]
```

```
edit nntp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

**DISPLAY**

```
list nntp
```

```
list nntp [ [ [name] | [glob] | [regex] ] ... ]
show running-config nntp
show running-config nntp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

#### DELETE

```
delete nntp [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the nntp component to configure a custom monitor, or you can use the default NNTP monitor that the Global Traffic Manager provides. This type of monitor verifies the Usenet News protocol service by attempting to retrieve a newsgroup identification string from the server.

#### EXAMPLES

```
create nntp my_nntp defaults-from nntp
```

Creates a monitor named my\_nntp that inherits properties from the default NNTP monitor.

```
list nntp
```

Displays the properties of all of the NNTP monitors.

#### OPTIONS

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is nntp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*.\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

newsgroup

Specifies the name of the newsgroup that you are monitoring, for example alt.car.mercedes. The default value is none.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### username

Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

create, delete, edit, glob, gtm pool, list, modify, regex, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2010, 2013-2014. All rights reserved.

BIG-IP 2014-07-10 gtm monitor nntp(1)

---

## gtm monitor none

#### NAME

none - A base level NULL monitor used to indicate that no monitoring will be performed.

#### MODULE

gtm monitor

#### SYNTAX

The none component within the gtm monitor module can be used only with the syntax described in the following sections.

#### DISPLAY

```
list none
list none [ [ [name] | [glob] | [regex] ] ... ]
show running-config none
show running-config none [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

#### CREATE/MODIFY/DELETE

Note: You cannot create a custom monitor based off of the none monitor nor can you modify or delete the existing default none monitor.

#### DESCRIPTION

The none component is used to configure a GTM pool member that explicitly does not inherit its parent pool's monitor and remains un-monitored, regardless of the monitor setting on the parent pool.

#### EXAMPLES

```
create gtm pool a test_pool monitor http members add { test:vs_1 {
monitor none } test:vs_2 { } }
```

Creates a gtm pool with an http monitor that has two members, vs\_1 and vs\_2. The pool member vs\_1 is configured with the none monitor so it does not inherit http monitoring from its parent pool, whereas pool member vs\_2 will inherit and use its parent's http monitor.

#### OPTIONS

Note: While the following options are specified as part of the definition of the none monitor, they cannot be changed since the none monitor is used to define the absence of a monitor, not an actual monitor.

#### defaults-from

Specifies the name of the monitor from which this monitor inherits settings. The default value is none.

#### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*:6666, also shown as \*:ircu-2.

**ignore-down-response**  
Specifies whether this monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 0 seconds.

**partition**  
Displays the administrative partition within which the component resides. The default value is Common.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 0 seconds.

**time-until-up**  
Specifies the amount of time in seconds after the first successful response before a node is marked up. A value of 0 causes a node to be marked up immediately after a valid response is received from the node. The default value is 86500.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 0 seconds.

**up-interval**  
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0, which specifies that the system uses the value of the interval option whether the resource is up or down.

SEE ALSO

## gtm monitor oracle

**NAME**  
oracle - Configures an Oracle(r) monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the oracle component within the gtm monitor module using the syntax in the following sections.

```
CREATE/MODIFY
create oracle [name]
modify oracle [name]
options:
  count [0 | 1]
  database [ [name] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  ignore-down-response [enabled | disabled]
  interval [integer]
  password [none | [password] ]
  probe-timeout [integer]
  recv [none | [string] ]
  recv-column [none | [string] ]
  recv-row [none | [string] ]
  send [none | [string] ]
  timeout [integer]
  username [ [name] | none]

edit oracle [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list oracle
list oracle [ [ [name] | [glob] | [regex] ] ... ]
show running-config oracle
show running-config oracle [ [ [name] | [glob] | [regex] ] ... ]
options:
```

all-properties  
non-default-properties  
one-line  
partition

#### DELETE

delete oracle [name]

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the oracle component to configure a custom monitor, or you can use the default Oracle monitor that the Global Traffic Manager provides. This type of monitor verifies services based on Oracle by attempting to perform an Oracle login to a service.

#### EXAMPLES

```
create oracle my_oracle defaults-from oracle
```

Creates a monitor named my\_oracle that inherits properties from the default Oracle monitor.

```
list oracle
```

Displays the properties of all of the Oracle monitors.

#### OPTIONS

##### count

Specifies the number of instances for which the system keeps a connection open. By default, when you assign instances of this monitor to a resource, the system keeps the connection to the database open. With this option you can assign multiple instances to the database while reducing the overhead that multiple open connections can cause.

A value of 0 (zero), the default, keeps the connection open for all instances. A value of 1 opens a new connection for each instance. Any other positive value keeps the connection open for that many instances; for example, a value of 5 keeps the connection open for five instances of this monitor.

##### database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

##### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is oracle.

##### description

User defined description.

##### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

##### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

##### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

##### interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

##### partition

Displays the administrative partition within which the component resides.

##### password

Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

**recv-column**

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**recv-row**

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**send** Specifies the SQL query that the monitor sends to the target database, for example, `SELECT count(*) FROM mytable`.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**

Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor pop3

**NAME**

pop3 - Configures a Post Office Protocol version 3 (POP3) monitor.

**MODULE**

gtm monitor

**SYNTAX**

Configure the pop3 component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**

```
create pop3 [name]
modify pop3 [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  ignore-down-response [enabled | disabled]
```

```

interval [integer]
password [none | [password] ]
probe-timeout [integer]
timeout [integer]
username [ [name] | none]

edit pop3 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list pop3
list pop3 [ [ [name] | [glob] | [regex] ] ... ]
show running-config pop3
show running-config pop3 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete pop3 [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the pop3 component to configure a custom monitor, or you can use the default POP3 monitor that the Global Traffic Manager provides. This type of monitor verifies the POP3 service by attempting to connect to a pool, pool member, or virtual server, log on as the specified user, and log off.

#### EXAMPLES

```
create pop3 my_pop3 defaults-from pop3
```

Creates a monitor named my\_pop3 that inherits properties from the default POP3 monitor.

```
list pop3
```

Displays the properties of all of the POP3 monitors.

#### OPTIONS

**debug**  
Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

**defaults-from**  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is pop3.

**description**  
User defined description.

**destination**  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*.\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**password**

Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**

Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor postgresql

NAME

postgresql - Configures a PostgreSQL(r) monitor.

MODULE

gtm monitor

SYNTAX

Configure the postgresql component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY

create postgresql [name]  
modify postgresql [name]

options:

count [0 | 1]  
database [ [name] | none]  
debug [no | yes]  
defaults-from [name]  
description [string]  
destination [ip address][port]  
ignore-down-response [enabled | disabled]  
interval [integer]  
password [none | [password] ]  
probe-timeout [integer]  
recv [none | [string] ]  
recv-column [none | [string] ]  
recv-row [none | [string] ]  
send [none | [string] ]  
timeout [integer]  
username [ [name] | none]

edit postgresql [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties  
non-default-properties

DISPLAY

list postgresql  
list postgresql [ [ [name] | [glob] | [regex] ] ... ]  
show running-config postgresql  
show running-config postgresql [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

## DELETE

delete postgresql [name]

Note: You cannot delete default monitors.

## DESCRIPTION

You can use the postgresql component to configure a custom monitor, or you can use the default PostgreSQL monitor that the Global Traffic Manager provides. This type of monitor verifies Microsoft(r) Windows(r) SQL-based services.

## EXAMPLES

```
create postgresql my_postgresql defaults-from postgresql
```

Creates a monitor named my\_postgresql that inherits properties from the default PostgreSQL monitor.

```
list postgresql
```

Displays the properties of all of the PostgreSQL monitors.

## OPTIONS

### count

Specifies the number of instances for which the system keeps a connection open. By default, when you assign instances of this monitor to a resource, the system keeps the connection to the database open. With this option you can assign multiple instances to the database while reducing the overhead that multiple open connections can cause.

A value of 0 (zero), the default, keeps the connection open for all instances. A value of 1 opens a new connection for each instance. Any other positive value keeps the connection open for that many instances; for example, a value of 5 keeps the connection open for five instances of this monitor.

### database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is postgresql.

### description

User defined description.

### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

### interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

### partition

Displays the administrative partition within which the component resides.

### password

Specifies the password if the monitored target requires authentication. The default value is none.

### probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-column Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

recv-row Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

regex Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(\*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

timeout Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

username Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor radius-accounting

NAME radius-accounting - Configures a RADIUS accounting monitor for the BIG-IP(r) Global Traffic Manager.

MODULE gtm monitor

SYNTAX Configure the radius-accounting component within the gtm monitor module using the syntax shown in the following sections.

```
CREATE/MODIFY
create radius-accounting [name]
modify radius [name]
options:
  app-service [[string] | none]
  check-until-up [disabled | enabled]
  debug [no | yes]
  defaults-from [ [name] | none]
  description [string]
  destination [ip address]
  interval [integer]
  manual-resume [disabled | enabled]
```

```

nas-ip-address [ip address]
secret [string]
time-until-up [integer]
timeout [integer]
username [none | [string] ]

edit radius-accounting [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  non-default-properties

DISPLAY
list radius-accounting
list radius-accounting [ [ [name] | [glob] | [regex] ] ...]
show running-config radius
show running-config radius [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete radius-accounting [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the radius-accounting component to configure a custom monitor, or you can use the default RADIUS accounting monitor that the Global Traffic Manager provides. This type of monitor provides information about the usage of the RADIUS service for accounting purposes.

#### EXAMPLES

```
create radius-accounting my_radius_acct defaults-from radius_accounting
```

Creates a monitor named `my_radius_acct` that inherits properties from the default RADIUS accounting monitor.

```
list radius-accounting
```

Displays the properties of all of the RADIUS accounting monitors.

#### OPTIONS

##### app-service

Specifies the name of the application service to which this monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this monitor. Only the application service can modify or delete this monitor.

##### check-until-up

When enabled, specifies that when an active and passive (inband) monitor are combined in an AND type of rule, the active monitor performs health checks only when the pool member is down, or until the pool member is marked as up. When the passive monitor marks the pool member down, the active monitor resumes health checks.

The default value is disabled.

##### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

`no` Specifies that the system does not redirect error messages and additional information related to this monitor.

`yes` Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is radius.

##### description

User defined description.

##### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

##### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

##### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

`glob` Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

**manual-resume**  
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**nas-ip-address**  
Specifies the network access server IP address that the system uses to identify itself to the RADIUS server. Using this option, multiple BIG-IP(r) systems can appear as a single network access device to the RADIUS server. The default value is none.

**partition**  
Displays the administrative partition within which the component resides.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**secret**  
Specifies the secret the monitor needs to communicate with the resource. The default value is none.

**time-until-up**  
Specifies the amount of time in seconds after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor radius

**NAME**  
radius - Configures a Remote Access Dial-in User Service (RADIUS) monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the radius component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create radius [name]  
modify radius [name]  
options:  
app-service [[string] | none]  
debug [no | yes]  
defaults-from [name]

```

description [string]
destination [ip address][port]
ignore-down-response [enabled | disabled]
interval [integer]
nas-ip-address [ [ip address] | none]
password [none | [password] ]
probe-timeout [integer]
secret [none | [secret] ]
timeout [integer]
username [ [name] | none]

edit radius [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list radius
list radius [ [ [name] | [glob] | [regex] ] ... ]
show running-config radius
show running-config radius [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete radius [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the radius component to configure a custom monitor, or you can use the default RADIUS monitor that the Global Traffic Manager provides. This type of monitor verifies the RADIUS service by attempting to authenticate the specified user.

#### EXAMPLES

```
create radius my_radius defaults-from radius
```

Creates a monitor named `my_radius` that inherits properties from the default RADIUS monitor.

```
list radius
```

Displays the properties of all of the RADIUS monitors.

#### OPTIONS

##### app-service

Specifies the name of the application service to which this monitor belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete this monitor. Only the application service can modify or delete this monitor.

##### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

`no` Specifies that the system does not redirect error messages and additional information related to this monitor.

`yes` Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `radius`.

##### description

User defined description.

##### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

##### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

##### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

`glob` Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

##### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

##### interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**nas-ip-address**  
Specifies the network access server IP address that the system uses to identify itself to the RADIUS server. Using this option, multiple BIG-IP(r) systems can appear as a single network access device to the RADIUS server. The default value is none.

**partition**  
Displays the administrative partition within which the component resides.

**password**  
Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**secret**  
Specifies the secret the monitor needs to communicate with the resource. The default value is none.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor real-server

**NAME**  
real-server - Configures a RealServer(r) monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the real-server component within the gtm monitor module using the syntax in the following sections.

#### CREATE/MODIFY

```
create real-server [name]
modify real-server [name]
```

#### options:

```
defaults-from [name]
description [string]
ignore-down-response [enabled | disabled]
interval [integer]
metrics [ [metrics] | none]
probe-timeout [integer]
timeout [integer]
```

```
edit real-server [ [ [name] | [glob] | [regex] ] ... ]
options:
all-properties
```

## non-default-properties

### DISPLAY

```
list real-server
list real-server [ [ [name] | [glob] | [regex] ] ... ]
show running-config real-server
show running-config real-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  agent
  all-properties
  command
  method
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete real-server [name]
```

Note: You cannot delete default monitors.

### DESCRIPTION

You can use the real-server component to configure a custom monitor, or you can use the default RealServer monitor that the Global Traffic Manager provides. This type of monitor checks the performance of a pool, pool member, or virtual server that is running the RealServer data collection agent, and then dynamically load balances traffic accordingly.

### EXAMPLES

```
create real-server my_real-server defaults-from real_server
```

Creates a monitor named my\_real-server that inherits properties from the default RealServer monitor.

```
list real-server
```

Displays the properties of all of the RealServer monitors.

### OPTIONS

#### agent

Displays the agent for the monitor. The default agent is Mozilla/4.0 (compatible: MSIE 5.0; Windows NT). You cannot modify the agent.

#### command

Displays the command that the system uses to obtain the metrics from the resource. See the documentation for this resource for information on available commands. You cannot modify the command.

#### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is real\_server.

#### description

User defined description.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

#### interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### method

Displays the GET method. You cannot modify the method.

#### metrics

Specifies the performance metrics that the commands collect from the target. The default value is ServerBandwidth:1.5, CPUPercentUsage, MemoryUsage, TotalClientCount.

#### partition

Displays the administrative partition within which the component resides.

#### probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

## SEE ALSO

## gtm monitor scripted

### NAME

scripted - Configures a Scripted monitor.

### MODULE

gtm monitor

### SYNTAX

Configure the scripted component within the gtm monitor module using the syntax in the following sections.

#### CREATE/MODIFY

```
create scripted [name]
modify scripted [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  filename [ [filename] | none]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-timeout [integer]
  timeout [integer]
```

```
edit scripted [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list scripted
list scripted [ [name] | [glob] | [regex] ] ... ]
show running-config scripted
show running-config scripted [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

#### DELETE

```
delete scripted [name]
```

Note: You cannot delete default monitors.

### DESCRIPTION

You can use the scripted component to configure a custom monitor, or you can use the default scripted monitor that the Global Traffic Manager provides.

### EXAMPLES

```
create scripted my_scripted defaults-from scripted
```

Creates a monitor named my\_scripted that inherits properties from the default Scripted monitor.

```
list scripted
```

Displays the properties of all of the scripted monitors.

### OPTIONS

**debug**  
Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the

/var/log/monitors/--.log file.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is scripted.

**description**

User defined description.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**filename**

Specifies the name of a file in the /config/eav/ directory on the system. The user-created file contains the send and expect data that the monitor uses for the monitor check. The default value is none.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**

Displays the administrative partition within which the component resides.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

## gtm monitor sip

NAME

sip - Configures a Session Initiation Protocol (SIP) monitor.

## MODULE

gtm monitor

## SYNTAX

Configure the sip component within the gtm monitor module using the syntax in the following sections.

### CREATE/MODIFY

```
create sip [name]
modify sip [name]
options:
  cert [ [cert list] | none]
  cipherlist [list]
  compatibility [enabled | disabled]

  non-default-properties
  one-line
  partition
```

### DELETE

```
delete sip [name]
```

Note: You cannot delete default monitors.

## DESCRIPTION

You can use the sip component to configure a custom monitor, or you can use the default SIP monitor that the Global Traffic Manager provides. This type of monitor checks the status of SIP Call-ID services on a device. The SIP protocol enables real-time messaging, voice, data, and video.

## EXAMPLES

```
create sip my_sip defaults-from sip
```

Creates a monitor named my\_sip that inherits properties from the default SIP monitor.

```
list sip
```

Displays the properties of all of the SIP monitors.

## OPTIONS

**cert** Specifies a fully-qualified path for a client certificate that the monitor sends to the target SSL server. The default value is none.

**cipherlist**  
Specifies the list of ciphers for this monitor. The default value is none.

**compatibility**  
Specifies, when enabled, that the SSL options setting (in OpenSSL) is set to ALL. The default value is enabled.

**debug**  
Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

**defaults-from**  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is sip.

**description**  
User defined description.

**destination**  
Specifies the IP address and service port of the resource that is

the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

filter  
Specifies the SIP status codes that the target can return to be considered up. By default the system always accepts status codes whose value is in the 100s, 200s, or 300s.

The options are:

any Specifies that the monitor accepts any SIP status codes.

none Specifies that the monitor does not accept any other SIP status codes. This is the default value.

status  
Specifies one or more status codes that you want to add to the monitor.

filter-neg  
Specifies the SIP status codes that the target can return to be considered down. By default the system always accepts status codes according to sip-monitor.filter. After checking that, the status code is checked against this key. If a code is also in sip-monitor.filter, the node is marked up.

The options are:

any Specifies that the monitor rejects all SIP status codes that are not in sip-monitor.filter.

none Specifies that the monitor does not specifically reject any other SIP status codes. This is the default value.

status  
Specifies one or more status codes that you want to add to the monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

headers  
Specifies the set of SIP headers in the SIP message that is sent to the target. Separate each header with a new line. The default value is none.

ignore-down-response  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

key Specifies the key if the monitored target requires authentication. The default value is none.

mode Specifies the protocol that the monitor uses to communicate with the target. The options are:

sips Specifies that the monitor uses SIPS to communicate with the target.

tcp Specifies that the monitor uses TCP to communicate with the target.

tls Specifies that the monitor uses TLS to communicate with the target, and the SIP URI is SIPS.

udp Specifies that the monitor uses UDP to communicate with the target.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

probe-timeout  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

request

Specifies the SIP request line in the SIP message that is sent to the target. The default value is none.

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**SEE ALSO**

## gtm monitor smtp

**NAME**

smtp - Configures a Simple Mail Transport Protocol (SMTP) monitor.

**MODULE**

gtm monitor

**SYNTAX**

Configure the smtp component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**

```
create smtp [name]
modify smtp [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  domain [ [name] | none]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-timeout [integer]
  timeout [integer]

edit smtp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

**DISPLAY**

```
list smtp
list smtp [ [ [name] | [glob] | [regex] ] ... ]
show running-config smtp
show running-config smtp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

**DELETE**

```
delete smtp [name]
```

Note: You cannot delete default monitors.

**DESCRIPTION**

You can use the smtp component to configure a custom monitor, or you can use the default SMTP monitor that the Global Traffic Manager provides. This type of monitor checks the status of a pool, pool member, or virtual server by issuing standard SMTP commands.

**EXAMPLES**

```
create smtp my_smtp defaults-from smtp
```

Creates a monitor named my\_smtp that inherits properties from the default SMTP monitor.

```
list smtp
```

Displays the properties of all of the SMTP monitors.

## OPTIONS

### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is smtp.

### description

User defined description.

### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*.\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

### domain

Specifies the domain name to check, for example, bigipinternal.com. The default value is none.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

### interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

### partition

Displays the administrative partition within which the component resides.

### probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

## gtm monitor snmp-link

**NAME**  
snmp-link - Configures a Simple Network Management Protocol (SNMP) link monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the snmp-link component within the gtm monitor module using the syntax in the following sections.

### CREATE/MODIFY

```
create snmp-link [name]
```

```
modify snmp-link [name]
```

#### options:

```
app-service [[string] | none]
community [[name] | none]
defaults-from [name]
description [string]
destination [ip address]
ignore-down-response [enabled | disabled]
interval [integer]
port [ [integer] | none]
probe attempts [integer]
probe-interval [integer]
probe-timeout [integer]
timeout [integer]
version [ [integer] | none]
```

```
edit snmp-link [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
```

### DISPLAY

```
list snmp-link
```

```
list snmp-link [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config snmp-link
```

```
show running-config snmp-link [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
one-line
partition
```

### DELETE

```
delete snmp-link [name]
```

Note: You cannot delete default monitors.

### DESCRIPTION

You can use the snmp-link component to configure a custom monitor, or you can use the default SNMP Link monitor that the Global Traffic Manager provides. This type of monitor checks the current CPU, memory, and disk usage of a pool, pool member, or virtual server that is running an SNMP data collection agent, and then dynamically load balances traffic accordingly.

### EXAMPLES

```
create snmp-link my_snmp-link defaults-from snmp_link
```

Creates a monitor named my\_snmp-link that inherits properties from the default SNMP Link monitor.

```
list snmp-link
```

Displays the properties of all of the SNMP Link monitors.

### OPTIONS

#### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

#### community

Specifies the community name that the BIG-IP(r) system must use to authenticate with the host server through SNMP. The default value is public.

#### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is snmp\_link.

#### description

User defined description.

#### destination

Specifies the IP address of the resource that is the destination of this monitor. The default value is \*.

Possible values are:

\* Specifies to perform a health check on the IP address of the node.

#### IP address

Specifies to perform a health check on the IP address that you specify, route the check through the IP address of the associated node, and mark the IP address of the associated node up or down accordingly.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

#### interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### partition

Displays the administrative partition within which the component resides.

**port** Specifies the port number to which this monitor sends SNMP traps. The default value is 161.

#### probe-attempts

Specifies the number of times the BIG-IP system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 3.

#### probe-interval

Specifies the frequency at which the BIG-IP system probes the host server. The default value is 0.

#### probe-timeout

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### version

Specifies the SNMP version the monitor uses. The default value is none.

#### SEE ALSO

create, delete, edit, glob, list, ltm node, modify, regex, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

---

## gtm monitor snmp

#### NAME

snmp - Configures a Simple Network Management Protocol (SNMP) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the snmp component within the gtm monitor module using the syntax in the following sections.

#### CREATE/MODIFY

create snmp [name]

```

modify snmp [name]
  options:
    app-service [(string) | none]
    community [ [name] | none]
    defaults-from [name]
    description [string]
    destination [ip address] [port]
    ignore-down-response [enabled | disabled]
    interval [integer]
    port [integer]
    probe-attempts [integer]
    probe-interval [integer]
    probe-timeout [integer]
    timeout [integer]
    version [ [integer] | none]

edit snmp [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

DISPLAY
list snmp
list snmp [ [ [name] | [glob] | [regex] ] ... ]
show running-config snmp
show running-config snmp [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition

DELETE
delete snmp [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the snmp component to configure a custom monitor, or you can use the default SNMP monitor that the Global Traffic Manager provides. The SNMP monitor is both a health and performance monitor. This type of monitor checks the performance of a server running an SNMP agent such as UC Davis, for the purpose of load balancing traffic to that server.

#### EXAMPLES

```
create snmp my_snmp defaults-from snmp_gtm
```

Creates a monitor named my\_snmp that inherits properties from the default SNMP monitor.

```
list snmp
```

Displays the properties of all of the SNMP monitors.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

##### community

Specifies the community name that the BIG-IP(r) system must use to authenticate with the host server through SNMP. The default value is public.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is snmp\_gtm.

##### description

User defined description.

##### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

##### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

##### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

##### interval

Specifies the frequency at which the system issues the monitor check. The default value is 90 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

port Specifies the port number to which this monitor sends SNMP traps. The default value is 161.

probe-attempts  
Specifies the number of times the BIG-IP system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 1.

probe-interval  
Specifies the frequency at which the BIG-IP system probes the host server. The default value is 1.

probe-timeout  
Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 180 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

version  
Specifies the SNMP version the monitor uses. The default value is v1.

#### SEE ALSO

## gtm monitor soap

NAME  
soap - Configures a Simple Object Access Protocol (SOAP) monitor.

MODULE  
gtm monitor

SYNTAX  
Configure the soap component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY  
create soap [name]  
modify soap [name]  
options:  
debug [no | yes]  
defaults-from {name}  
description [string]  
destination [ip address][port]  
expect-fault [no | yes]  
ignore-down-response [enabled | disabled]  
interval [integer]  
method [string]  
namespace [ {name} | none]  
parameter-name [ {name} | none]  
parameter-type [bool | int | long | [string] ]  
parameter-value [none | [integer] | [string] ]  
password [none | [password] ]  
probe-timeout [integer]  
protocol [[none] | [protocol] ]  
return-type [bool | char | double | int | long | short | [string] ]

```

return-value [none | [integer] | [string] ]
soap-action [string]
timeout [integer]
url-path [none | [string] ]
username [ [name] | none]

edit soap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list soap
list soap [ [ [name] | [glob] | [regex] ] ... ]
show running-config soap
show running-config soap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete soap [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the soap component to configure a custom monitor, or you can use the default SOAP monitor that the Global Traffic Manager provides. This type of monitor tests a Web service based on SOAP.

#### EXAMPLES

```
create soap my_soap defaults-from soap
```

Creates a monitor named `my_soap` that inherits values from the system default SOAP monitor.

```
list soap
```

Displays the properties of all of the SOAP monitors.

#### OPTIONS

`debug`

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

`no` Specifies that the system does not redirect error messages and additional information related to this monitor.

`yes` Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

`defaults-from`

Specifies the type of monitor you want to use to create the new monitor. The default value is `soap`.

`description`

User defined description.

`destination`

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

`*:port`

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

`expect-fault`

Specifies whether the value of the `method` option causes the monitor to expect a SOAP fault message. The default value is no.

`glob` Displays the items that match the `glob` expression. See help `glob` for a description of `glob` expression syntax.

`ignore-down-response`

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

`interval`

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

`method`

Specifies the method by which the monitor contacts the resource.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`namespace`

Specifies the name space for the Web service you are monitoring,

for example, `http://example.com/`. The default value is none.

**parameter-name**  
If the method has a parameter, specifies the name of that parameter. The default value is `bool`.

**parameter-type**  
Specifies the parameter type. The default value is none.

**parameter-value**  
Specifies the value for the parameter. The default value is none.

**partition**  
Displays the administrative partition within which the component resides.

**password**  
Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**protocol**  
Specifies the protocol that the monitor uses to communicate with the target. The default value is none.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

**return-type**  
Specifies the type for the returned parameter. The default value is `bool`.

**return-value**  
Specifies the value for the returned parameter. The default value is none.

**soap-action**  
Specifies the value for the SOAPAction header. The default value is the empty string.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**url-path**  
Specifies the URL for the Web service that you are monitoring, for example, `/services/myservice.aspx`. The default value is none.

**username**  
Specifies the user name if the monitored target requires authentication. The default value is none.

#### SEE ALSO

`create`, `delete`, `edit`, `glob`, `gtm pool`, `list`, `modify`, `regex`, `show`, `tmsh`

#### COPYRIGHT

## gtm monitor tcp-half-open

**NAME**  
`tcp-half-open` - Configures a Transmission Control Protocol (TCP) Half Open monitor.

**MODULE**  
`gtm monitor`

**SYNTAX**  
Configure the `tcp-half-open` component within the `gtm monitor` module using the syntax in the following sections.

```

CREATE/MODIFY
create tcp-half-open [name]
modify tcp-half-open [name]
options:
  defaults-from [name]
  description [string]
  destination [ip address][port]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-attempts [integer])
  probe-interval [integer])
  probe-timeout [integer]
  timeout [integer]
  transparent [disabled | enabled]

edit tcp-half-open [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list tcp-half-open
list tcp-half-open [ [name] | [glob] | [regex] ] ... ]
show running-config tcp-half-open
show running-config tcp-half-open [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete tcp-half-open [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the tcp-half-open component to configure a custom monitor, or you can use the default TCP Half Open monitor that the Global Traffic Manager provides.

For more information about configuring monitors, refer to the Configuration Guide for BIG-IP(r) Global Traffic Management.

#### EXAMPLES

```

create tcp-half-open my_tcp-half-open defaults-from tcp_half_open

Creates a monitor named my_tcp-half-open that inherits properties from
the default TCP Half Open monitor.

list tcp-half-open

Displays the properties of all of the TCP Half Open monitors.

```

#### OPTIONS

**defaults-from**  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is tcp\_half\_open.

**description**  
User defined description.

**destination**  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)  
Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**probe-attempts**  
Specifies the number of times the BIG-IP system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 3.

**probe-interval**  
Specifies the frequency at which the BIG-IP system probes the host server. The default value is 1.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**transparent**  
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

**SEE ALSO**

create, delete, edit, glob, gtm pool, gtm server, list, modify, regex, show, tmsh

---

## gtm monitor tcp

**NAME**  
tcp - Configures a Transmission Control Protocol (TCP) monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the tcp component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create tcp [name]  
modify tcp [name]  
options:  
defaults-from [name]  
description [string]  
destination [ip address][port]  
ignore-down-response [enabled | disabled]  
interval [integer]  
probe-timeout [integer]  
recv [none | [string] ]  
reverse [enabled | disabled]  
send [none | [string] ]  
timeout [integer]  
transparent [disabled | enabled]

edit tcp [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list tcp  
list tcp [ [ [name] | [glob] | [regex] ] ... ]  
show running-config tcp  
show running-config tcp [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

one-line  
partition

DELETE  
delete tcp [name]

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the tcp component to configure a custom monitor, or you can use the default TCP monitor that the Global Traffic Manager provides.

#### EXAMPLES

```
create tcp my_tcp defaults-from tcp
```

Creates a monitor named my\_tcp that inherits properties from the default TCP monitor.

```
list tcp
```

Displays the properties of all of the TCP monitors.

#### OPTIONS

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is tcp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object. The default setting is GET /, which retrieves a default

HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

SEE ALSO

create, delete, edit, glob, gtm pool, gtm server, list, modify, regex, show, tmsh

## gtm monitor udp

NAME

udp - Configures a User Datagram Protocol (UDP) monitor.

MODULE

gtm monitor

SYNTAX

Configure the udp component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create udp [name]
modify udp [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-attempts [integer]
  probe-interval [integer]
  probe-timeout [integer]
  reverse [enabled | disabled]
  send [none | [string] ]
  timeout [integer]
  transparent [disabled | enabled]
```

```
edit udp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list udp
list udp [ [ [name] | [glob] | [regex] ] ... ]
show running-config udp
show running-config udp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete udp [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the `udp` component to configure a custom monitor, or you can use the default UDP monitor that the Global Traffic Manager provides. This type of monitor verifies the UDP service by attempting to send UDP packets to a pool, pool member, or virtual server, and receiving a reply.

For more information about configuring monitors, refer to the Configuration Guide for BIG-IP(r) Global Traffic Management.

#### EXAMPLES

```
create udp my_udp defaults-from udp
```

Creates a monitor named `my_udp` that inherits properties from the default UDP monitor.

```
list udp
```

Displays the properties of all of the UDP monitors.

#### OPTIONS

`debug`

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is `no`.

The options are:

`no` Specifies that the system does not redirect error messages and additional information related to this monitor.

`yes` Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

`defaults-from`

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `udp`.

`description`

User defined description.

`destination`

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

`*:port`

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

`IP address:port (with the transparent option enabled)`

Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

`glob` Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

`ignore-down-response`

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

`interval`

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`

Displays the administrative partition within which the component resides.

`probe-attempts`

Specifies the number of times the BIG-IP system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 3.

`probe-interval`

Specifies the frequency at which the BIG-IP system probes the host server. The default value is 1.

`probe-timeout`

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

#### reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object. The default value is "default send string".

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the value of the recv option and ignores the option even if not null.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

#### SEE ALSO

create, delete, edit, glob, gtm pool, gtm server, list, modify, regex, show, tmsb

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## gtm monitor wap

#### NAME

wap - Configures a Wireless Application Protocol (WAP) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the wap component within the gtm monitor module using the syntax in the following sections.

#### CREATE/MODIFY

```
create wap [name]
```

```
modify wap [name]
```

#### options:

```
accounting-node [none | [RADIUS server name] ]
accounting-port [ [integer] | none]
call-id [none | [RADIUS server 11 digit phone number] ]
check-until-up [enabled | disabled]
debug [no | yes]
defaults-from [name]
description [string]
destination [ip address][port]
framed-address [none | [RADIUS framed IP address] ]
ignore-down-response [enabled | disabled]
interval [integer]
probe-timeout [integer]
recv [none | [string] ]
secret [none | [password] ]
send [none | [string] ]
server-id [none | [RADIUS NAS-ID] ]
session-id [none | [RADIUS session ID] ]
timeout [integer]
```

```
edit wap [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
```

## non-default-properties

### DISPLAY

```
list wap
list wap[ [ [name] | [glob] | [regex] ] ... ]
show running-config wap
show running-config wap[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete wap [name]
```

Note: You cannot delete default monitors.

## DESCRIPTION

You can use the wap component to configure a custom monitor, or you can use the default WAP monitor that the Global Traffic Manager provides. This type of monitor requests the URL specified in the send option, and finds the string specified in the recv option somewhere in the data returned by the URL response.

## EXAMPLES

```
create wap my_wap defaults-from wap
```

Creates a monitor named my\_wap that inherits properties from the default WAP monitor.

```
list wap
```

Displays the properties of all of the WAP monitors.

## OPTIONS

### accounting-node

Specifies the RADIUS server that provides authentication for the WAP target. Note that if you configure the accounting-port option, but you do not configure the this option, the system assumes that the RADIUS server and the WAP server are the same system.

### accounting-port

Specifies the port that the monitor uses for RADIUS accounting. The default value is none. A value of 0 (zero) disables RADIUS accounting.

### call-id

Specifies the 11-digit phone number for the RADIUS server. The default value is none.

### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is wap.

### description

User defined description.

### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

### framed-address

Specifies the RADIUS framed IP address. The default value is none.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

### interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names. If you do not specify both a value for both the send and recv options, the monitor performs a simple service check and connect only. The default value is none.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**secret**  
Specifies the password the monitor needs to communicate with the resource. The default value is none.

**send** Specifies the text string that the monitor sends to the target object. The default setting is GET /, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if it is not null. The default value is none.

**server-id**  
Specifies the RADIUS NAS-ID for this system when configuring a RADIUS server. The default value is none.

**session-id**  
Specifies the RADIUS session identification number when configuring a RADIUS server. The default value is none.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### SEE ALSO

## gtm monitor wmi

**NAME**  
wmi - Configures a Windows(r) Management Instrumentation (WMI) monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the wmi component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY

```

create wmi [name]
modify wmi [name]
options:
  command [[command] | none]
  defaults-from [name]
  description [string]
  ignore-down-response [enabled | disabled]
  interval [integer]
  metrics [ [integer] | none]
  password [none | [password] ]
  probe-timeout [integer]
  timeout [integer]
  url [none | [URL]]
  username [ [name] | none]

edit wmi [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list wmi
list wmi [ [ [name] | [glob] | [regex] ] ... ]
show running-config wmi
show running-config wmi [ [ [name] | [glob] | [regex] ] ... ]
options:
  agent
  all-properties
  method
  non-default-properties
  one-line
  partition
  post

DELETE
delete wmi [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the wmi component to configure a custom monitor, or you can use the default WMI monitor that the Global Traffic Manager provides. This type of monitor checks the performance of a pool, pool member, or virtual server that is running the WMI data collection agent, and then dynamically load balances traffic accordingly.

#### EXAMPLES

```
create wmi my_wmi defaults-from wmi
```

Creates a monitor named my\_wmi that inherits properties from the default WMI monitor.

```
list wmi
```

Displays the properties of all of the WMI monitors.

#### OPTIONS

##### agent

Displays the agent for the monitor. The default agent is Mozilla/4.0 (compatible: MSIE 5.0; Windows NT). You cannot modify the agent.

##### command

Specifies the command that the system uses to obtain the metrics from the resource. See the documentation for this resource for information on available commands.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is wmi.

##### description

User defined description.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

##### interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

##### method

Displays the GET method. You cannot modify the method.

##### metrics

Specifies the performance metrics that the commands collect from the target. The default value is LoadPercentage, DiskUsage, PhysicalMemoryUsage:1.5, VirtualMemoryUsage:2.0.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

##### partition

Displays the administrative partition within which the component resides.

##### password

Specifies the password if the monitored target requires authentication. The default value is none.

**post** Specifies the mechanism that the monitor uses for posting. The default value is `RespFormat=HTML`. You cannot change the post format for WMI monitors.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**url** Specifies the URL that the monitor uses. The default value is `/scripts/f5Isapi.dll`.

**username**  
Specifies the user name if the monitored target requires authentication. The default value is none.

## gtm path

**NAME**  
`path` - Displays or resets path statistics for the Global Traffic Manager(tm).

**MODULE**  
`gtm`

**SYNTAX**  
Configure the path component within the `gtm` module using the syntax in the following section.

**DISPLAY**  
`show path`  
options:  
(`default` | `exa` | `gig` | `kil` | `meg` | `peta` | `raw` | `tera` | `yotta` | `zetta`)  
`field-fmt`

**DESCRIPTION**  
You can use the path component to display path statistics for the Global Traffic Manager. You can also reset the path statistics to zero at any time.

SEE ALSO  
`show`, `tmsh`

COPYRIGHT

## gtm persist

**NAME**  
persist - Displays persistence records for the Global Traffic Manager(tm).

**MODULE**  
gtm

**SYNTAX**  
Display statistics for the persist component within the gtm module using the syntax in the following section.

**DISPLAY**  
show persist  
options:  
destination [ [name] | none]  
key [ip address | string]  
level [application | wideip]  
max-results [integer]  
target-name [ [name] | none]  
target-type [datacenter | link | pool-member | server]

**DESCRIPTION**  
You can use the persist component to display various persistence records based on the filtering options that you use.

**EXAMPLES**  
show persist  
Displays all Global Traffic Manager persistence records.  
show persist level wideip  
Displays persistence records only for wideip persistence.

**OPTIONS**  
destination  
Displays persistence records for the specified destination.  
key Displays persistence records for the specified LDNS address or generic key.  
level  
Displays persistence records for the specified level (destination type), either wideip or application.  
max-results  
Specifies the maximum number of persistence records that you want the system to return.  
target-name  
Displays persistence records for the specified target name.  
If target-type pool-member is specified, then a valid target-name filter for a terminal pool member is the full path virtual server name, for example /Common/vs-dns-1. Do not include the server name in the target-name filter field.  
For a non-terminal member the valid target-name filter is the non-pathed DNS name, for example www.alt.example.com.  
Please refer to the EXAMPLES section below for more info.  
target-type  
Displays persistence records for the specified type of target.

**EXAMPLES**  
All persistence records:  
[root@bigip-1:Active:Standalone] config # tmsh show gtm persist  
Value Level:Destination -> Target Expiration  
10.2.4.4 wideip:A:/Common/www.example.com -> pool-member:www.alt.example.com 11-03 17:23:54  
10.2.4.1 wideip:A:/Common/www.example.com -> pool-member:/Common/gtm-server-1:/Common/vs-dns-1 11-03 17:23:54  
10.2.4.3 wideip:A:/Common/www.example.com -> pool-member:/Common/gtm-server-1:/Common/vs-dns-2 11-03 17:  
10.2.4.5 wideip:A:/Common/www.example.com -> pool-member:www.alt.example.com 11-03 17:23:54

DELETE
delete pool a [name]

```

Note: You must remove all references to a pool before you can delete the pool.

#### DESCRIPTION

You can use the pool component to configure the A pool definitions on the Global Traffic Manager. You use a pool to group member servers together to use a common load balancing algorithm.

#### EXAMPLES

```

create pool a mypool members add {
member myServer:myVs
}
monitor http

```

Creates a Global Traffic Manager A pool with one member myServer:myVs using the Round Robin load balancing method, and default HTTP monitor checks for member availability.

```
delete pool a my_pool
```

Deletes the pool my\_pool.

```
show pool a
```

Displays statistics for all A pools.

```
list pool a my_pool
```

Displays settings of pool my\_pool.

#### OPTIONS

##### alternate-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

##### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

##### fallback-ip

Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

##### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

none Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

`packet-rate`

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

`ratio`

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

`return-to-dns`

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

`round-robin`

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

`static-persistence`

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

`topology`

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

`virtual-server-capacity`

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

`virtual-server-score`

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

`app-service`

Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

`description`

User defined description.

`[disabled | enabled]`

Specifies whether this pool is available for load balancing. The default value is enabled.

`dynamic-ratio`

Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

`fallback-ip`

Specifies the IPv6 address of the server to which the system directs requests in the event that the load balancing methods configured for this pool fail to return a valid virtual server. The default value is ::.

`fallback-mode`

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

`completion-rate`

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

`cpu` Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

`drop-packet`

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

`fallback-ip`

Specifies that the Global Traffic Manager returns the IP

address that you specify as an answer to the query.

#### fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

#### kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

#### least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

#### lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

none Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### limit-max-bps

Specifies the maximum allowable data throughput rate, in bits per second, for the virtual servers in the pool. If the network traffic volume exceeds this value, the system marks the pool as unavailable. The default value is 0 (zero).

#### limit-max-bps-status

Enables or disables the limit-max-bps option for this pool. The default value is disabled.

#### limit-max-connections

Specifies the number of current connections allowed for the virtual servers in the pool. If the current connections exceed this value, the system marks the pool as unavailable. The default value is 0 (zero).

#### limit-max-connections-status

Enables or disables the limit-max-connections option for this pool. The default value is disabled.

limit-max-pps

Specifies the maximum allowable data transfer rate, in packets per second, for the virtual servers in the pool. If the network traffic volume exceeds this value, the system marks the pool as unavailable. The default value is 0 (zero).

limit-max-pps-status

Enables or disables the limit-max-pps option for this pool. The default value is disabled.

load-balancing-mode

Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

fallback-ip

Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### manual-resume

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

#### max-answers-returned

Specifies the maximum number of available virtual servers that the system lists in a response. The default value is 1.

#### members

Specifies the vs-name of the pool members. The default value is none.

You can also use the following options with pool members:

#### app-service

Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

#### depends-on

Specifies the name of the virtual server on which this pool member depends.

#### description

User defined description.

#### [enabled | disabled]

Specifies whether this pool member is available for load balancing. The default value is enabled.

#### limit-max-bps

Specifies the maximum allowable data throughput rate, in bits per second, for the pool member. If the network traffic volume exceeds this value, the system marks the pool member as unavailable.

#### limit-max-bps-status

Enables or disables the limit-max-bps option for this pool member. The default value is disabled.

#### limit-max-connections

Specifies the number of current connections allowed for this pool member. If the current connections exceed this value, the system marks this pool member as unavailable.

#### limit-max-connections-status

Enables or disables the limit-max-connection option for this pool member. The default value is disabled.

#### limit-max-pps

Specifies the maximum allowable data transfer rate, in packets per second, for this pool member. If the network traffic volume exceeds this value, the system marks this pool member as unavailable.

#### limit-max-pps-status

Enables or disables the limit-max-pps option for this pool member. The default value is disabled.

#### member-order

Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

#### monitor

Specifies the health monitors that the system uses to determine whether it can use this pool member for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this pool member to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probes that should be used. The default value is none.

#### ratio

Specifies the weight of the pool member for load balancing purposes.

#### vs-name

Displays the name of the corresponding virtual server.

#### metadata

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

#### monitor

Specifies the health monitors that the system uses to determine

whether it can use this pool for load balancing. Multiple monitors may be specified with the `and` keyword. The `min` keyword is used to specify the minimum number of monitors that must succeed for this pool to be declared up. The `require` keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probes that should be used. The default value is none.

`name` Specifies a unique name for the component. This option is required for the commands `create` and `modify`.

`partition`  
Displays the partition within which the component resides.

`qos-hit-ratio`  
Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

`qos-hops`  
Assigns a weight to the Hops performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 0 (zero).

`qos-kilobytes-second`  
Assigns a weight to the Kilobytes per Second performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 3.

`qos-lcs`  
Assigns a weight to the Link Capacity performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 30.

`qos-packet-rate`  
Assigns a weight to the Packet Rate performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 1.

`qos-rtt`  
Assigns a weight to the Round Trip Time performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 50.

`qos-topology`  
Assigns a weight to the Topology performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 0 (zero).

`qos-vs-capacity`  
Assigns a weight to the Virtual Server performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 0 (zero).

`qos-vs-score`  
Assigns a weight to the Virtual Server Score performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 0 (zero).

`regex`  
Displays the items that match the regular expression. The regular expression must be preceded by an `@` sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`ttl` Specifies the number of seconds that the IP address, once found, is valid. Once the time-to-live (TTL) expires, the client has to request the IP address resolution again. The valid values are 0 through 4294967295; the default value is 30.

`verify-member-availability`  
Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

Note: You must remove all references to a pool before you can delete the pool.

#### DESCRIPTION

You can use the pool component to configure the AAAA pool definitions on the Global Traffic Manager. You use a pool to group member servers together to use a common load balancing algorithm.

#### EXAMPLES

```

create pool aaaa mypool members add {
member myServer:myVs
}
monitor http

```

Creates a Global Traffic Manager AAAA pool with one member myServer:myVs using the Round Robin load balancing method, and default HTTP monitor checks for member availability.

```
delete pool aaaa my_pool
```

Deletes the pool my\_pool.

```
show pool aaaa
```

Displays statistics for all AAAA pools.

```
list pool aaaa my_pool
```

Displays settings of pool my\_pool.

#### OPTIONS

**alternate-mode**  
Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

**drop-packet**  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

**fallback-ip**  
Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

**global-availability**  
Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

**none** Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

**packet-rate**  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

**ratio**  
Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

**return-to-dns**  
Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

**round-robin**  
Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

**static-persistence**  
Specifies that the Global Traffic Manager consistently maps

an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### app-service

Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

#### description

User defined description.

#### [disabled | enabled]

Specifies whether this pool is available for load balancing. The default value is enabled.

#### dynamic-ratio

Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

#### fallback-ip

Specifies the IPv6 address of the server to which the system directs requests in the event that the load balancing methods configured for this pool fail to return a valid virtual server. The default value is ::.

#### fallback-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

#### completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

**cpu** Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

#### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

#### fallback-ip

Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

#### fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

#### kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

#### least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

#### lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest

measured round trip time between a data center and a client LDNS.

none Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

packet-rate Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

quality-of-service Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

ratio Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

return-to-dns Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

round-robin Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

static-persistence Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

topology Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

virtual-server-capacity Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

virtual-server-score Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

limit-max-bps Specifies the maximum allowable data throughput rate, in bits per second, for the virtual servers in the pool. If the network traffic volume exceeds this value, the system marks the pool as unavailable. The default value is 0 (zero).

limit-max-bps-status Enables or disables the limit-max-bps option for this pool. The default value is disabled.

limit-max-connections Specifies the number of current connections allowed for the virtual servers in the pool. If the current connections exceed this value, the system marks the pool as unavailable. The default value is 0 (zero).

limit-max-connections-status Enables or disables the limit-max-connections option for this pool. The default value is disabled.

limit-max-pps Specifies the maximum allowable data transfer rate, in packets per second, for the virtual servers in the pool. If the network traffic volume exceeds this value, the system marks the pool as unavailable. The default value is 0 (zero).

limit-max-pps-status Enables or disables the limit-max-pps option for this pool. The default value is disabled.

load-balancing-mode Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

completion-rate Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual

server that currently has the most CPU processing time available to handle name resolution requests.

#### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

#### fallback-ip

Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

#### fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

#### kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

#### least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

#### lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### manual-resume

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

#### max-answers-returned

Specifies the maximum number of available virtual servers that the system lists in a response. The default value is 1.

#### members

Specifies the vs-name of the pool members. The default value is none.

You can also use the following options with pool members:

#### app-service

Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

#### depends-on

Specifies the name of the virtual server on which this pool member depends.

#### description

User defined description.

#### [enabled | disabled]

Specifies whether this pool member is available for load balancing. The default value is enabled.

#### limit-max-bps

Specifies the maximum allowable data throughput rate, in bits per second, for the pool member. If the network traffic volume exceeds this value, the system marks the pool member as unavailable.

#### limit-max-bps-status

Enables or disables the limit-max-bps option for this pool member. The default value is disabled.

#### limit-max-connections

Specifies the number of current connections allowed for this pool member. If the current connections exceed this value, the system marks this pool member as unavailable.

#### limit-max-connections-status

Enables or disables the limit-max-connection option for this pool member. The default value is disabled.

#### limit-max-pps

Specifies the maximum allowable data transfer rate, in packets per second, for this pool member. If the network traffic volume exceeds this value, the system marks this pool member as unavailable.

#### limit-max-pps-status

Enables or disables the limit-max-pps option for this pool member. The default value is disabled.

#### member-order

Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

#### monitor

Specifies the health monitors that the system uses to determine whether it can use this pool member for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this pool member to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probes that should be used. The default value is none.

#### ratio

Specifies the weight of the pool member for load balancing purposes.

#### vs-name

Displays the name of the corresponding virtual server.

#### metadata

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

#### monitor

Specifies the health monitors that the system uses to determine whether it can use this pool for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this pool to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probes that should be used. The default value is none.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the partition within which the component resides.

#### qos-hit-ratio

Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

#### qos-hops

Assigns a weight to the Hops performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-kilobytes-second

Assigns a weight to the Kilobytes per Second performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 3.

#### qos-lcs

Assigns a weight to the Link Capacity performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 30.

#### qos-packet-rate

Assigns a weight to the Packet Rate performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 1.

#### qos-rtt

Assigns a weight to the Round Trip Time performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 50.

#### qos-topology

Assigns a weight to the Topology performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-vs-capacity

Assigns a weight to the Virtual Server performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-vs-score

Assigns a weight to the Virtual Server Score performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**ttl** Specifies the number of seconds that the IP address, once found, is valid. Once the time-to-live (TTL) expires, the client has to request the IP address resolution again. The valid values are 0 through 4294967295; the default value is 30.

#### verify-member-availability

Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

## gtm pool cname

#### NAME

**cname** - Configures CNAME load balancing pools for the Global Traffic Manager(tm).

#### MODULE

gtm pool

#### SYNTAX

Modify the Global Traffic Manager pool cname component within the gtm module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create pool cname [name]
modify pool cname [name]
```

#### options:

```
alternate-mode [drop-packet | global-availability
| none | packet-rate | ratio | return-to-dns | round-robin

DELETE
delete pool cname [name]

Note: You must remove all references to a pool before you can delete
the pool.

DESCRIPTION
You can use the pool component to configure the CNAME pool definitions
on the Global Traffic Manager. You use a pool to group member names
together to use a common load balancing algorithm.

EXAMPLES
create pool cname mypool members add {
canonical.mydomain.com
}

Creates a Global Traffic Manager CNAME pool with one member
canonical.mydomain.com using the Round Robin load balancing method.

delete pool cname my_pool

Deletes the pool my_pool.

show pool cname

Displays statistics for all CNAME pools.

list pool cname my_pool

Displays settings of pool my_pool.

```

## OPTIONS

### alternate-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

none Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

### virtual-server-capacity

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

### app-service

Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

### description

User defined description.

[disabled | enabled]

Specifies whether this pool is available for load balancing. The default value is enabled.

### dynamic-ratio

Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

### fallback-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

`completion-rate`

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

`cpu` Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

`drop-packet`

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

`fewest-hops`

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

`global-availability`

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

`kilobytes-per-second`

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

`least-connections`

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

`lowest-round-trip-time`

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

`none` Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the `fallback-mode` option is `return-to-dns`.

`packet-rate`

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

`quality-of-service`

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

`ratio`

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

`return-to-dns`

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

`round-robin`

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

`static-persistence`

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

`topology`

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

`virtual-server-capacity`

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

`virtual-server-score`

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

`load-balancing-mode`

Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is `round-robin`.

The options are:

`completion-rate`

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

`cpu` Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

`drop-packet`

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

`fewest-hops`

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

`global-availability`

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

`kilobytes-per-second`

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

`least-connections`

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

`lowest-round-trip-time`

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

`packet-rate`

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

`quality-of-service`

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

`ratio`

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

`return-to-dns`

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

`round-robin`

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

`static-persistence`

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

`topology`

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

`virtual-server-capacity`

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

`virtual-server-score`

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

`manual-resume`

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

`members`

Specifies the member-dname of the pool members. The default value is none.

You can also use the following options with pool members:

**app-service**  
Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

**description**  
User defined description.

[enabled | disabled]  
Specifies whether this pool member is available for load balancing. The default value is enabled.

**member-order**  
Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

**ratio**  
Specifies the weight of the pool member for load balancing purposes.

**static-target**  
Specifies the member's name specifies a static DNAME rather than a name linked to a Wide IP defined on the system. This may be required if the target DNAME is not owned by the organization or configured on GTM. One side-effect of using a static target is that the member is always considered available for load balancing. The default value is no.

**member-dname**  
Displays the member's DNAME.

**metadata**  
Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**partition**  
Displays the partition within which the component resides.

**qos-hit-ratio**  
Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

**qos-hops**  
Assigns a weight to the Hops performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-kilobytes-second**  
Assigns a weight to the Kilobytes per Second performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 3.

**qos-lcs**  
Assigns a weight to the Link Capacity performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 30.

**qos-packet-rate**  
Assigns a weight to the Packet Rate performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 1.

**qos-rtt**  
Assigns a weight to the Round Trip Time performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 50.

**qos-topology**  
Assigns a weight to the Topology performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-vs-capacity**  
Assigns a weight to the Virtual Server performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-vs-score**  
Assigns a weight to the Virtual Server Score performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**ttl** Specifies the number of seconds that the answer, once found, is valid. Once the time-to-live (TTL) expires, the client has to request name resolution again. The valid values are 0 through 4294967295; the default value is 30.

verify-member-availability  
Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

## gtm pool mx

NAME

mx - Configures MX load balancing pools for the Global Traffic Manager(tm).

MODULE

gtm pool

SYNTAX

Modify the Global Traffic Manager pool mx component within the gtm module using the syntax shown in the following sections.

CREATE/MODIFY

```
create pool mx [name]
modify pool mx [name]
options:
  alternate-mode [drop-packet | global-availability
    | none | packet-rate | ratio | return-to-dns | round-robin
    | static-persistence | topology | virtual-server-capacity
    | virtual-server-score]
  app-service [[string] | none]
  description [string]
  [disabled | enabled]
  dynamic ratio [disabled | enabled]
  fallback-mode [completion-rate | cpu | drop-packet
    | fewest-hops | global-availability | kilobytes-per-second
    | least-connections | lowest-round-trip-time | none
    | packet-rate | quality-of-service | ratio | return-to-dns
    | round-robin | static-persistence | topology
    | virtual-server-capacity | virtual-server-score]
  load-balancing-mode [completion-rate | cpu | drop-packet
    | fewest-hops | global-availability
    | kilobytes-per-second | least-connections
    | lowest-round-trip-time | packet-rate | quality-of-service
    | ratio | return-to-dns | round-robin | static-persistence
    | topology | virtual-server-capacity | virtual-server-score]
  manual-resume [disabled | enabled]
  max-answers-returned [integer]
  members none
  members
    [ add | delete | modify | replace-all-with ] {
      [member-dname] {
options:
  app-service [[string] | none]
  description [string]
  [disabled | enabled]
  member-order [integer]
  priority [integer]
  ratio [integer]
  }...
}

  detail
  field-fmt

DELETE
delete pool mx [name]

```

Note: You must remove all references to a pool before you can delete the pool.

#### DESCRIPTION

You can use the pool component to configure the MX pool definitions on the Global Traffic Manager. You use a pool to group member names together to use a common load balancing algorithm.

#### EXAMPLES

```

create pool mx mypool members add {
  maill.mydomain.com {
    priority 20
  }
}

```

Creates a Global Traffic Manager MX pool with one member maill.mydomain.com with priority 20 using the Round Robin load balancing method.

```
delete pool mx my_pool
```

Deletes the pool my\_pool.

```
show pool mx
```

Displays statistics for all MX pools.

```
list pool mx my_pool
```

Displays settings of pool my\_pool.

#### OPTIONS

**alternate-mode**

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

**drop-packet**

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

**global-availability**

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

**none** Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

**packet-rate**

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

**ratio**

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

**return-to-dns**

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### app-service

Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

#### description

User defined description.

#### [disabled | enabled]

Specifies whether this pool is available for load balancing. The default value is enabled.

#### dynamic-ratio

Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

#### fallback-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

#### completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

#### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

#### fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

#### kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

#### least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

#### lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

none Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

packet-rate  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

quality-of-service  
Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

ratio  
Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

return-to-dns  
Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

round-robin  
Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

static-persistence  
Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

topology  
Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

virtual-server-capacity  
Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

virtual-server-score  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

load-balancing-mode  
Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

completion-rate  
Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

drop-packet  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

fewest-hops  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

global-availability  
Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

kilobytes-per-second  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

least-connections  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

lowest-round-trip-time  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### manual-resume

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

#### max-answers-returned

Specifies the maximum number of available virtual servers that the system lists in a response. The default value is 1.

#### members

Specifies the member-dname of the pool members. The default value is none.

You can also use the following options with pool members:

#### app-service

Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

#### description

User defined description.

[enabled | disabled]

Specifies whether this pool member is available for load balancing. The default value is enabled.

#### member-order

Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

#### priority

Specifies the response resource record's priority RDATA field value when this member is picked. The default value is 10.

#### ratio

Specifies the weight of the pool member for load balancing purposes.

#### member-dname

Displays the member's DNAME.

#### metadata

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

**name** Specifies a unique name for the component. This option is required for the commands `create` and `modify`.

**partition**  
Displays the partition within which the component resides.

**qos-hit-ratio**  
Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

**qos-hops**  
Assigns a weight to the Hops performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 0 (zero).

**qos-kilobytes-second**  
Assigns a weight to the Kilobytes per Second performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 3.

**qos-lcs**  
Assigns a weight to the Link Capacity performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 30.

**qos-packet-rate**  
Assigns a weight to the Packet Rate performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 1.

**qos-rtt**  
Assigns a weight to the Round Trip Time performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 50.

**qos-topology**  
Assigns a weight to the Topology performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 0 (zero).

**qos-vs-capacity**  
Assigns a weight to the Virtual Server performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 0 (zero).

**qos-vs-score**  
Assigns a weight to the Virtual Server Score performance factor when the value of the either the `load-balancing-mode` or `fallback-mode` options is `quality-of-service`. The default value is 0 (zero).

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

**t1** Specifies the number of seconds that the answer, once found, is valid. Once the time-to-live (TTL) expires, the client has to request name resolution again. The valid values are 0 through 4294967295; the default value is 30.

**verify-member-availability**  
Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

DELETE
delete pool naptr [name]
```

Note: You must remove all references to a pool before you can delete the pool.

## DESCRIPTION

You can use the pool component to configure the NAPTR pool definitions on the Global Traffic Manager. You use a pool to group member names together to use a common load balancing algorithm.

## EXAMPLES

```
create pool naptr mypool members add {
  _sip_udp.a.mydomain.com {
    flags "s"
    order 20
    preference 100
    service "sip+d2u"
  }
  _sip_udp.b.mydomain.com {
    flags "s"
    order 20
    preference 110
    service "sip+d2u"
  }
}
```

Creates a Global Traffic Manager NAPTR pool with two members using the Round Robin load balancing method.

```
delete pool naptr my_pool
```

Deletes the pool my\_pool.

```
show pool naptr
```

Displays statistics for all NAPTR pools.

```
list pool naptr my_pool
```

Displays settings of pool my\_pool.

## OPTIONS

### alternate-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

none Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

### virtual-server-capacity

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

### app-service

Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

description  
User defined description.

[disabled | enabled]  
Specifies whether this pool is available for load balancing. The default value is enabled.

dynamic-ratio  
Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

fallback-mode  
Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

completion-rate  
Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

drop-packet  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

fewest-hops  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

global-availability  
Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

kilobytes-per-second  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

least-connections  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

lowest-round-trip-time  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

none Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

packet-rate  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

quality-of-service  
Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

ratio  
Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

return-to-dns  
Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

round-robin  
Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

**static-persistence**  
Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

**topology**  
Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

**virtual-server-capacity**  
Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

**virtual-server-score**  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**load-balancing-mode**  
Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

**completion-rate**  
Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

**cpu** Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

**drop-packet**  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

**fewest-hops**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

**global-availability**  
Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

**kilobytes-per-second**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

**least-connections**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

**lowest-round-trip-time**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

**packet-rate**  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

**quality-of-service**  
Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

**ratio**  
Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

**return-to-dns**  
Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

**round-robin**  
Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

**static-persistence**  
Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### manual-resume

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

#### max-answers-returned

Specifies the maximum number of available virtual servers that the system lists in a response. The default value is 1.

#### members

Specifies the member-dname of the pool members. The default value is none.

You can also use the following options with pool members:

#### app-service

Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

#### description

User defined description.

#### [enabled | disabled]

Specifies whether this pool member is available for load balancing. The default value is enabled.

#### flags

Specifies the response resource record's flags RDATA field value when this member is picked. Either 'a' or 's' may be specified for this attribute as GTM supports only these record types.

#### member-order

Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

#### order

Specifies the response resource record's order RDATA field value when this member is picked. The default value is 10.

#### preference

Specifies the response resource record's preference RDATA field value when this member is picked. The default value is 10.

#### ratio

Specifies the weight of the pool member for load balancing purposes.

#### service

Specifies the response resource record's service RDATA field value when this member is picked.

#### member-dname

Displays the member's DNAME.

#### metadata

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the partition within which the component resides.

#### qos-hit-ratio

Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

#### qos-hops

Assigns a weight to the Hops performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-kilobytes-second**  
Assigns a weight to the Kilobytes per Second performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 3.

**qos-lcs**  
Assigns a weight to the Link Capacity performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 30.

**qos-packet-rate**  
Assigns a weight to the Packet Rate performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 1.

**qos-rtt**  
Assigns a weight to the Round Trip Time performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 50.

**qos-topology**  
Assigns a weight to the Topology performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-vs-capacity**  
Assigns a weight to the Virtual Server performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-vs-score**  
Assigns a weight to the Virtual Server Score performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**t1** Specifies the number of seconds that the answer, once found, is valid. Once the time-to-live (TTL) expires, the client has to request name resolution again. The valid values are 0 through 4294967295; the default value is 30.

**verify-member-availability**  
Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

DELETE
delete pool srv [name]

```

Note: You must remove all references to a pool before you can delete the pool.

#### DESCRIPTION

You can use the pool component to configure the SRV pool definitions on the Global Traffic Manager. You use a pool to group member names together to use a common load balancing algorithm.

#### EXAMPLES

```

create pool srv mypool members add {
  imap.mydomain.com {
port 143
priority 20
  }
}

```

Creates a Global Traffic Manager SRV pool with one member `imap.mydomain.com` with port 143 and priority 20 using the Round Robin load balancing method.

```
delete pool srv my_pool
```

Deletes the pool `my_pool`.

show pool srv

Displays statistics for all SRV pools.

list pool srv my\_pool

Displays settings of pool my\_pool.

#### OPTIONS

alternate-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

none Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

virtual-server-capacity

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

app-service

Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

description

User defined description.

[disabled | enabled]

Specifies whether this pool is available for load balancing. The default value is enabled.

dynamic-ratio

Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

fallback-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

none Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

glob Displays the items that match the glob expression. See help glob

for a description of glob expression syntax.

**load-balancing-mode**  
Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

**completion-rate**  
Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

**cpu** Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

**drop-packet**  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

**fewest-hops**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

**global-availability**  
Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

**kilobytes-per-second**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

**least-connections**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

**lowest-round-trip-time**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

**packet-rate**  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

**quality-of-service**  
Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

**ratio**  
Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

**return-to-dns**  
Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

**round-robin**  
Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

**static-persistence**  
Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

**topology**  
Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

**virtual-server-capacity**  
Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

**virtual-server-score**  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

**manual-resume**  
Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you

manually re-enable it.

**max-answers-returned**  
Specifies the maximum number of available virtual servers that the system lists in a response. The default value is 1.

**members**  
Specifies the member-dname of the pool members. The default value is none.

You can also use the following options with pool members:

**app-service**  
Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

**description**  
User defined description.

[enabled | disabled]  
Specifies whether this pool member is available for load balancing. The default value is enabled.

**member-order**  
Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

**port** Specifies the response resource record's port RDATA field value when this member is picked.

**priority**  
Specifies the response resource record's priority RDATA field value when this member is picked. The default value is 10.

**ratio**  
Specifies the relative weight of the pool member for load balancing purposes.

**weight**  
Specifies the response resource record's weight RDATA field value when this member is picked. The default value is 10.

**member-dname**  
Displays the member's DNAME.

**metadata**  
Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**partition**  
Displays the partition within which the component resides.

**qos-hit-ratio**  
Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

**qos-hops**  
Assigns a weight to the Hops performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-kilobytes-second**  
Assigns a weight to the Kilobytes per Second performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 3.

**qos-lcs**  
Assigns a weight to the Link Capacity performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 30.

**qos-packet-rate**  
Assigns a weight to the Packet Rate performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 1.

**qos-rtt**  
Assigns a weight to the Round Trip Time performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 50.

**qos-topology**  
Assigns a weight to the Topology performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-vs-capacity**  
Assigns a weight to the Virtual Server performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-vs-score**  
Assigns a weight to the Virtual Server Score performance factor

when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**ttl** Specifies the number of seconds that the answer, once found, is valid. Once the time-to-live (TTL) expires, the client has to request name resolution again. The valid values are 0 through 4294967295; the default value is 30.

#### verify-member-availability

Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

## DELETE

delete prober-pool [name]

Note: You must remove all references to a prober-pool before you can delete the prober-pool.

## DESCRIPTION

You can use the prober-pool component to configure prober pool definitions on the Global Traffic Manager. You use prober pools to control which BIG-IP servers on your network are utilized by GTM to monitor the up/down state of GTM resources. Once defined, prober pools can be set to monitor whole data centers or individual servers.

## EXAMPLES

```
create prober-pool my_pool members add {
  bigip-dallas
  bigip-london
}
```

Creates a Global Traffic Manager prober pool with two members bigip-dallas and bigip-london. Members are selected using the global-availability load balancing method.

```
delete prober-pool my_pool
```

Deletes the prober pool my\_pool.

```
show prober-pool
```

Displays statistics for all prober pools.

```
list prober-pool my_pool
```

Displays settings of prober pool my\_pool.

## OPTIONS

app-service

Specifies the name of the application service to which this prober pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this prober pool. Only the application service can modify or delete this prober pool.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

load-balancing-mode

Specifies the load balancing mode that the system uses to select members of this pool. The default value is global-availability.

The options are:

global-availability

Specifies that the Global Traffic Manager selects the first available pool member in the order in which they are listed.

round-robin

Specifies that the Global Traffic Manager selects members using a circular, sequential pattern among available pool members.

members

Specifies the BIG-IP server names of the pool members. The default value is none.

You can also use the following options with prober pool members:

app-service

Specifies the name of the application service to which this prober pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this prober pool member. Only the application service can modify or delete this prober pool member.

description

User defined description.

[enabled | disabled]

Specifies whether this pool member is available to issue probes. The default value is enabled.

order

Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members by listed order.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

## SEE ALSO

## gtm region

**NAME**  
region - Configures a Global Traffic Manager(tm) region.

**MODULE**  
gtm

**SYNTAX**  
Configure the region component within the gtm module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create region [name]
modify region [name]
options:
  app-service [[string] | none]
  description [string]
  [name]
  region-members
  options:
    app-service [[string] | none]
    continent [Africa | Antarctica | Asia | Australia | Europe
| North America | South America | unknown]
    country [two-letter abbreviation of country name]
    datacenter [name]
    geoip-isp [name]

```

### DELETE

```
delete region [name]
```

## DESCRIPTION

You can use the region component to create, display, modify, or delete a region. A region is a customized collection of topologies with which you can extend the topology functionality by defining specific geographical regions that have meaning for your network.

## EXAMPLES

```
create region my_region continent Australia
```

Creates a region named `my_region` to populate with resources on the continent of Australia.

```
list region
```

Displays properties for all regions.

```
delete region my_region
```

Deletes the region named `my_region`.

## OPTIONS

### app-service

Specifies the name of the application service to which the region belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the region. Only the application service can modify or delete the region.

**description**  
User defined description.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**region-members**  
Specifies the members that you want to add to, delete from, replace-all-with, or modify for this region.

You can specify the following options for region members:

**app-service**  
Specifies the name of the application service to which the region member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the region member. Only the application service can modify or delete the region member.

**continent**  
Specifies the name of a continent.

**country**  
Specifies the two-letter abbreviation of a country. Use the command completion feature to view the numerous options.

**datacenter**  
Specifies the name of an existing data center.

**geoip-isp**  
An ISP whose IP Address allocation range should be used in matching topologies. Any ISP string may be given as long as it matches the string in the GeoIP-ISP Database. Case is irrelevant.

**isp** Specifies the name of an Internet service provider.

**not** Specifies region-members to exclude from this region.

**pool** Specifies the name of an existing pool.

**region-name**  
Specifies the name of an existing region.

**state**  
Specifies the name of an existing state.

**subnet**  
Specifies an existing subnet.

## gtm rule

**NAME**  
rule - Opens an editor in which you can configure iRules(r) for traffic management system configuration.

**MODULE**  
gtm

**SYNTAX**  
Configure the rule component within the gtm module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create rule [name]

```

modify rule [name]
  option:
    metadata
      [add | delete | modify] {
[metadata_name] {
  value [ "value content" ]
  persist [ true | false ]
}
}
edit rule [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list rule
list rule [ [name] | [glob] | [regex] ] ... ]
show running-config rule
show running-config rule [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

show rule
show rule [ [name] | [glob] | [regex] ] ... ]
  options:
    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
    field-fmt

DELETE
delete rule [name]

```

Note: You can also delete metadata associated with an iRule. See the example section for detail.

#### DESCRIPTION

You can use iRules to direct traffic not only to specific pools, but also to individual pool members, including port numbers and URI paths, either to implement persistence or to meet specific load balancing requirements. The syntax that you use to write iRules is based on the Tools Command Language (TCL) programming standard. Thus, you can use many of the standard Tcl commands, plus a robust set of extensions that the BIG-IP(r) local traffic management system provides to help you further increase load balancing efficiency.

For information about standard Tcl syntax, see <http://tmml.sourceforge.net/doc/tcl/index.html>. For a list of Tcl commands that have been disabled within the traffic management system and therefore cannot be used in the traffic management system, see the Configuration Guide for BIG-IP(r) Local Traffic Management(r). This guide is available at <https://support.f5.com>.

#### EXAMPLES

```
edit rule my_irule
```

Opens the vi editor in which you can edit the iRule named my\_irule. Note that after you close the editor, you must run the command sequence save config to save the configuration changes to the stored configuration files.

The following are example iRules for the Global Traffic Manager(tm).

```
when DNS_REQUEST {
if {[IP::addr [IP::remote_addr]/24 equals 10.10.1.0/24] }
  {cname cname.siterequest.com } else { host 10.20.20.20}}
```

Specifies that requests from 10.10.1.0/24 be directed to cname.siterequest.com, and all other requests be directed to 10.20.20.20.

```
when DNS_REQUEST {
if {[whereis [IP::remote_addr]] contains "Asia"}
  {pool asia_pool} else {pool general_pool}}
```

Specifies that requests that originate in Asia be directed to the pool named asia\_pool, and that all other requests be directed to the pool named general\_pool.

metadata is the user defined key/value pair

Adds new metadata to named my\_meta and modifies existing metadata named my\_meta2 for the iRule named my\_irule.

```
modify rule my_irule {
when DNS_REQUEST {}
metadata replace-all-with {
  my_meta {      persist false      value "hello"
}
  my_meta2 {    persist false    value "hello
2"          }
} }
```

Deletes metadata named my\_meta from the iRule named my\_irule.

```
modify rule my_irule {
when RULE_INIT {}
definition-checksum 7c0dba9aa53e8959042c6cfe041d3d11
metadata delete { my_meta } }
```

#### OPTIONS

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

metadata Specifies a user-defined key/value pair.

name Specifies a unique name for the component. This option is

required.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

DELETE
delete server [name]

DESCRIPTION
  You can use the server component to configure a Global Traffic Manager
  server.

EXAMPLES
  create server my_server devices add { my_device { addresses add {
    10.10.1.1 } } } datacenter my_datacenter

  Creates a server named my_server in my_datacenter with a self IP
  address of 10.10.1.1.

  modify server my_server virtual-servers add {myVs { address
    10.10.10.2:80 } }

  Adds the virtual server myVs with an IP address of 10.10.10.2:80 as a
  resource to the server named my_server.

  list server non-default-properties

  Displays all non-default properties for all servers.

  delete server my_server

  Deletes the server named my_server.

  show server my_server detail

  Shows the link associated with each server IP address for
  my_server.

  show server all detail

  Shows the link assignments for all servers in the system.

  show server my_server virtual-servers

  Shows the regular server information as well as any virtuals on
  my_server. The link associated with a virtual server is displayed,
  or --- is shown to indicate that the virtual is not using a
  configured link.

OPTIONS
  app-service
  Specifies the name of the application service to which the server
  belongs. The default value is none. Note: If the strict-updates

```

option is enabled on the application service that owns the object, you cannot modify or delete the server. Only the application service can modify or delete the server.

**datacenter**

Specifies the data center to which the server belongs. This option is required for the command create.

**description**

User defined description.

**detail**

The detail option is used with the show display command. This shows device statistics, virtual server statistics, and links associated with the server. Only the device addresses that have an associated link are displayed. If this server is not using any links, no link assignment information is printed. By default, links are automatically matched to device addresses according to the smallest subnet match. Explicit links may also be defined. How this link was assigned is displayed in the Link Assignment column: auto means that the system automatically assigned this link, and explicit means that the link was explicitly set by the user.

**devices**

Specifies the names of the devices that represent this server. Every device must have at least one address. The options are:

**addresses**

Specifies the IP addresses that represent the device. If GTM configuration synchronization is enabled and all existing addresses for a device are being replaced, new addresses should be added and synchronized before old addresses are removed, otherwise the changes may fail to synchronize. Alternatively, the address configuration changes can be performed on each GTM. The options are:

**app-service**

Specifies the name of the application service to which the address belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the address. Only the application service can modify or delete the address.

**description**

User defined description.

**explicit-link-name**

Specifies the explicit link name for the device. The default value is none.

**translation**

Specifies the internal IP address that corresponds to the external IP address of this device. The default value is ::.

**app-service**

Specifies the name of the application service to which the device belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the device. Only the application service can modify or delete the device.

**description**

User defined description.

[disabled | enabled]

Enables or disables the server. The default value is enabled.

**expose-route-domains**

Allow the GTM server to auto-discover LTM virtual servers from all route domains. The default value is no.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**iq-allow-path**

Specifies whether the Global Traffic Manager uses this BIG-IP(r) system to conduct a path probe before delegating traffic to it. The default value is yes.

**iq-allow-service-check**

Specifies whether the Global Traffic Manager uses this BIG-IP system to conduct a service check probe before delegating traffic to it. The default value is yes.

**iq-allow-snmp**

Specifies whether the Global Traffic Manager uses this BIG-IP system to conduct an SNMP probe before delegating traffic to it. The default value is yes.

**limit-cpu-usage**

For a server configured as a generic host, specifies the percent of CPU usage, otherwise has no effect. If percent of CPU usage goes above the limit, the system marks the server as unavailable.

**limit-cpu-usage-status**

Enables or disables the limit-cpu-usage option for this server. Only has an effect on a server configured as a generic host. The default value is disabled.

**limit-mem-avail**

For a server configured as a generic host, specifies the available memory required by the virtual servers on the server. If available

memory falls below this limit, the system marks the server as unavailable.

#### limit-mem-avail-status

Enables or disables the limit-mem-avail option for this server. Only used on a server configured as a generic host. The default value is disabled.

#### limit-max-bps

Specifies the maximum allowable data throughput rate, in bits per second, for this server. If the network traffic volume exceeds this limit, the system marks the server as unavailable.

#### limit-max-bps-status

Enables or disables the limit-max-bps option for this server. The default value is disabled.

#### limit-max-connections

Specifies the maximum number of concurrent connections, combined, for this server. If the connections exceed this limit, the system marks the server as unavailable.

#### limit-max-connections-status

Enables or disables the limit-max-connections option for this server. The default value is disabled.

#### limit-max-pps

Specifies the maximum allowable data transfer rate, in packets per second, for this server. If the network traffic volume exceeds this limit, the system marks the server as unavailable.

#### limit-max-pps-status

Enables or disables the limit-max-pps option for this server. The default value is disabled.

#### link-discovery

Specifies whether the system auto-discovers the links for this server. The default value is disabled. The options are:

##### disabled

Specifies that the system does not auto-discover the links that are available for the server.

##### enabled

Specifies that the system auto-discovers the links that are configured on the server. With this option, the system automatically adds, deletes, and modifies link settings in the configuration.

##### enabled-no-delete

Specifies that the system auto-discovers the links that are configured on the server. With this option, the system automatically adds and modifies link settings in the configuration, but does not delete them. This option is useful when you regularly take links in and out of service.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

#### monitor

Specifies the health monitors that the system uses to determine whether this server is available for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this server to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probers that should be used.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the object resides.

#### prober-fallback

Specifies the type of prober to use to monitor this server's resources when the preferred type is not available. If this value is specified, it overrides the prober fallback value on this server's data center. The default value is inherit.

#### prober-pool

Specifies the name of a prober pool to use to monitor this server's resources. If this value is specified, it overrides any prober pool set on this server's data center. The default value is none.

#### prober-preference

Specifies the type of prober to use to monitor this server's resources. If this value is specified, it overrides the prober preference value on this server's data center. The default value is inherit.

#### product

Specifies the server type. The server type determines the metrics that the system can collect from the server. Use the command completion feature to view the types of servers that are available.

#### regex

Displays the items that match the regular expression. The regular

expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### virtual-server-discovery

Specifies whether the system auto-discovers the virtual servers for this server. The default value is disabled. The options are:

##### disabled

Specifies that the system does not auto-discover the virtual servers that are configured on the server. With this option, you must configure the virtual servers for this server.

##### enabled

Specifies that the system auto-discovers the virtual servers that are configured on the server. With this option, the system automatically adds, deletes, and modifies virtual server settings in the configuration.

##### enabled-no-delete

Specifies that the system auto-discovers the virtual servers that are configured on the server. With this option, the system automatically adds and modifies virtual server settings in the configuration, but does not delete them. This option is useful when you regularly take virtual servers in and out of service.

#### virtual-servers

Specifies the name of the virtual servers that are resources for this server. You can include the following options for virtual servers.

##### app-service

Specifies the name of the application service to which the virtual server belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the virtual server. Only the application service can modify or delete the virtual server.

##### depends-on

Specifies the vs-name of the server on which this virtual server depends.

##### description

User defined description.

##### destination

Specifies the IP address and port of the virtual server.

##### [disabled | enabled]

Specifies whether this virtual server is available for load balancing. The default value is enabled.

##### explicit-link-name

Specifies the explicit link name for the virtual server. The default value is none.

##### limit-max-bps

Specifies the maximum allowable data throughput rate, in bits per second, for this virtual server. If the network traffic volume exceeds this value, the system marks the virtual server as unavailable. The default value is 0 (zero).

##### limit-max-bps-status

Enables or disables the limit-max-bps option for this virtual server. The default value is disabled.

##### limit-max-connections

Specifies the number of current connections allowed for this virtual server. If the current connections exceed this value, the system marks this virtual server as unavailable. The default value is 0 (zero).

##### limit-max-connections-status

Enables or disables the limit-max-connections option for this virtual server. The default value is disabled.

##### limit-max-pps

Specifies the maximum allowable data transfer rate, in packets per second, for this virtual server. If the network traffic volume exceeds this limit, the system marks the virtual server as unavailable. The default value is 0 (zero).

##### limit-max-pps-status

Enables or disables the limit-max-pps option for this virtual server. The default value is disabled.

##### ltm-name

The virtual server name found on the LTM. Useful for differentiating between virtuals with same IP and port, but different protocols. The ltm-name used in probe requests.

##### monitor

Specifies the monitor you want to assign to this virtual server. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this server to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probes that should be used. The default value is none.

##### translation-address

Specifies the public address that this virtual server translates into when the Global Traffic Manager communicates between the network and the Internet. The default value is ::.

translation-port  
Specifies the translation port number or service name for the virtual server, if necessary. The default value is 0.

## gtm topology

NAME  
topology - Configures a topology statement.

MODULE  
gtm

SYNTAX  
Configure the topology component within the gtm module using the syntax shown in the following sections.

#### CREATE

```
create topology
options:
  app-service [[string] | none]
  description [[string] | none]
  ldns: [continent | country | geoip-isp | isp | not | region | state | subnet]
  server: [continent | country | datacenter | geoip-isp | isp | not | pool |
          region | state | subnet]
  score [integer]
```

#### MODIFY

```
modify topology [ [name] | [glob] | [regex] ] ... ]
options:
  app-service [[string] | none]
  description [[string] | none]
  score [integer]
```

#### EDIT

```
edit topology [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list topology
list topology [ [name] | [glob] | [regex] ] ... ]
show running-config topology
show running-config topology [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

#### DELETE

```
delete topology all
delete topology
[ldns: [identifier] [value] server: [identifier] [value] ]
```

#### DESCRIPTION

You can use the topology component to configure a topology statement. A topology statement is a set of characteristics that identify the origin of a given name resolution request.

#### EXAMPLES

```
create topology ldns: country US server: datacenter DC1 score 30
```

Creates a topology statement that specifies that the Global Traffic Manager routes any traffic coming from the United States to the datacenter named DC1. Note that the weight of this topology item for load balancing is 30.

```
delete topology ldns: country US server: datacenter DC1
```

Deletes the topology statement mentioned in the previous example.

## OPTIONS

### app-service

Specifies the name of the application service to which the topology belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the topology. Only the application service can modify or delete the topology.

### description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

### ldns:

Specifies the criteria that the Global Traffic Manager uses when matching requests from LDNS servers.

### continent

A continent whose IP address allocation range should be used in matching topologies

### country

A country whose IP address allocation range should be used in matching topologies

### datacenter

A data center to be used in matching topologies

### geoip-isp

An ISP whose IP Address allocation range should be used in matching topologies. Any ISP string may be given as long as it matches the string in the GeoIP-ISP Database. Case is irrelevant.

isp An ISP whose IP address allocation range should be used in matching topologies

not Specify a region member to exclude from the region

pool A pool to be used in matching topologies

### region

Another region to be used in matching topologies

### state

A state whose IP address allocation range should be used in matching topologies

### subnet

A subnet to be used in matching topologies

### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

### score

Specifies the weight of the topology item.

### server:

Specifies the server to which the Global Traffic Manager routes requests.

### continent

A continent whose IP address allocation range should be used as an LDNS routing destination

### country

A country whose IP address allocation range should be used as an LDNS routing destination

### datacenter

A data center to be used as an LDNS routing destination

### geoip-isp

An ISP whose IP Address allocation range should be used in matching topologies. Any ISP string may be given as long as it matches the string in the GeoIP-ISP Database. Case is irrelevant.

isp An ISP whose IP address allocation range should be used as an LDNS routing destination

not Specify an item to exclude from the group

pool A pool to be used as an LDNS routing destination

### region

Another region to be used as an LDNS routing destination

### state

A state whose IP address allocation range be used as an LDNS routing destination

### subnet

A subnet to be used as an LDNS routing destination

DELETE
delete wideip a [all | [name] ]

```

#### DESCRIPTION

You can use the wideip component to create, modify, display, or delete a wide IP that responds to A queries. An A wide IP is a mapping of a fully-qualified domain name (FQDN) to a set of IPv4 virtual servers that host the domain's content, such as a web site or an e-commerce site.

#### EXAMPLES

```

create wideip a www.my_wide_ip.com

Creates a wide IP named www.my_wide_ip.com.

delete wideip a www.my_wide_ip.com

Deletes the wide IP named www.my_wide_ip.

```

#### OPTIONS

##### aliases

Specifies alternate domain names for the web site content you are load balancing. You can use two different wildcard characters, asterisk (\*) and question mark (?), to represent one or more characters. The default value is none.

##### app-service

Specifies the name of the application service to which this wide ip belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this wide ip. Only the application service can modify or delete this wide ip.

##### description

User defined description. Note: Advanced search on the GUI's Wideip list page can be turned on/off by modifying the DB variable ui.advancedsearch via the tmsh command "modify sys db ui.advancedsearch value true/false". This will result in a new description column and the inclusion of that field in the search.

##### [disabled | enabled]

Specifies whether the wide IP and its resources are available for load balancing.

##### failure-rcode

Specifies the DNS RCODE used when failure-rcode-response is enabled. Default is noerror. Options include noerror (no type exists at this name), formerr (format error in query), servfail (unable to process query), nxdomain (name does not exist), notimpl (no support for this kind of query), and refused (refuse to process based on policy). If failure-rcode-ttl is non-zero, only the Authority section of the noerror or nxdomain response will

include a SOA record.

#### failure-rcode-response

When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This response is an authoritative empty answer from the system to A record requests. With this option enabled, the system responds faster to A requests for which it does not have A records configured. The default value is disabled.

#### failure-rcode-ttl

Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### last-resort-pool

Specifies a last resort pool to use when load balancing requests for this wide IP. Any A or CNAME pool type is allowed. The default value is none.

#### load-balancing-decision-log-verbosity

Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default value is none.

#### minimal-response

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the component resides.

#### persistence

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### pools

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pools-cname

Configures the CNAME pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pool-lb-mode

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

#### global-availability

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

#### random

Specifies that the system selects a pool in no pattern or

order.

**ratio**  
Specifies that the system selects a pool based on the ratio that you assign to the pool.

**round-robin**  
Specifies that the system selects pools sequentially.

**topology**  
Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**rules**  
Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

**ttl-persistence**  
Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

DELETE
delete wideip aaaa [all | [name] ]

DESCRIPTION
  You can use the wideip component to create, modify, display, or delete
  a wide IP that responds to AAAA queries. An AAAA wide IP is a mapping
  of a fully-qualified domain name (FQDN) to a set of IPv6 virtual
  servers that host the domain's content, such as a web site or an
  e-commerce site.

EXAMPLES
  create wideip aaaa www.my_wide_ip.com

  Creates a AAAA wide IP named www.my_wide_ip.com.

  delete wideip aaaa www.my_wide_ip.com

  Deletes the AAAA wide IP named www.my_wide_ip.

OPTIONS
  aliases
  Specifies alternate domain names for the web site content you are
  load balancing. You can use two different wildcard characters,
  asterisk (*) and question mark (?), to represent one or more
  characters. The default value is none.

  app-service
  Specifies the name of the application service to which this wide
  ip belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete this wide ip. Only the application
  service can modify or delete this wide ip.

  description
  User defined description. Note: Advanced search on the GUI's
  Wideip list page can be turned on/off by modifying the DB variable
  ui.advancedsearch via the tmsh command "modify sys db
  ui.advancedsearch value true/false". This will result in a new
  description column and the inclusion of that field in the search.

  [disabled | enabled]
  Specifies whether the wide IP and its resources are available for
  load balancing.

  failure-rcode
  Specifies the DNS RCODE used when failure-rcode-response is
  enabled. Default is noerror. Options include noerror (no type
  exists at this name), formerr (format error in query), servfail
  (unable to process query), nxdomain (name does not exist), notimpl
  (no support for this kind of query), and refused (refuse to
  process based on policy). If failure-rcode-ttl is non-zero, only
  the Authority section of the noerror or nxdomain response will
  include a SOA record.

  failure-rcode-response
  When enabled, specifies that the system returns a RCODE response
  to Wide IP requests after exhausting all load-balancing methods.
  This response is an authoritative empty answer from the system to
  AAAA record requests. With this option enabled, the system
  responds faster to AAAA requests for which it does not have AAAA
  records configured. The default value is disabled.

  failure-rcode-ttl
  Specifies the negative caching TTL of the SOA for the RCODE
  response. The default is 0, meaning no SOA is included (i.e. no
  caching).

  glob Displays the items that match the glob expression. See help glob

```

for a description of glob expression syntax.

**last-resort-pool** Specifies a last resort pool to use when load balancing requests for this wide IP. Any AAAA or CNAME pool type is allowed. The default value is none.

**load-balancing-decision-log-verbosity**  
Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option **pool-selection**, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option **pool-traversal**, the log will contain details of all pools traversed during load balancing. With the option **pool-member-selection**, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option **pool-member-traversal**, the log will contain details of all pool members traversed during load balancing. The default value is none.

**minimal-response**

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

**metadata**

Specifies user-defined data to associate with a server. By default the **persist** attribute is set to true. This means the data is saved into the configuration file.

**name** Specifies a unique name for the component. This option is required for the commands **create** and **modify**.

**partition**

Displays the administrative partition within which the component resides.

**persistence**

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

**persist-cidr-ipv4**

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

**persist-cidr-ipv6**

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

**pools**

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

**pools-cname**

Configures the CNAME pools the system uses when load balancing requests for this wide IP. The default value is none.

**pool-lb-mode**

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is **round-robin**.

The available load balancing methods are:

**global-availability**

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

**random**

Specifies that the system selects a pool in no pattern or order.

**ratio**

Specifies that the system selects a pool based on the ratio that you assign to the pool.

**round-robin**

Specifies that the system selects pools sequentially.

**topology**

Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression])

to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### rules

Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

#### ttl-persistence

Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

DELETE
delete wideip cname [all | [name] ]
```

#### DESCRIPTION

You can use the wideip component to create, modify, display, or delete a wide IP that responds to CNAME queries. A CNAME wide IP is a mapping of a fully-qualified domain name (FQDN) to its canonical name.

#### EXAMPLES

```
create wideip cname www.my_wide_ip.com

Creates a CNAME wide IP named www.my_wide_ip.com.

delete wideip cname www.my_wide_ip.com

Deletes the CNAME wide IP named www.my_wide_ip.
```

#### OPTIONS

**aliases**  
Specifies alternate domain names for the web site content you are load balancing. You can use two different wildcard characters, asterisk (\*) and question mark (?), to represent one or more characters. The default value is none.

**app-service**  
Specifies the name of the application service to which this wide ip belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this wide ip. Only the application service can modify or delete this wide ip.

**description**  
User defined description. Note: Advanced search on the GUI's Wideip list page can be turned on/off by modifying the DB variable ui.advancedsearch via the tmsh command "modify sys db ui.advancedsearch value true/false". This will result in a new description column and the inclusion of that field in the search.

**[disabled | enabled]**  
Specifies whether the wide IP and its resources are available for load balancing.

**failure-rcode**  
Specifies the DNS RCODE used when failure-rcode-response is enabled. Default is noerror. Options include noerror (no type exists at this name), formerr (format error in query), servfail (unable to process query), nxdomain (name does not exist), notimpl (no support for this kind of query), and refused (refuse to process based on policy). If failure-rcode-ttl is non-zero, only the Authority section of the noerror or nxdomain response will include a SOA record.

**failure-rcode-response**  
When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This response is an authoritative empty answer from the system to CNAME record requests. With this option enabled, the system responds faster to CNAME requests for which it does not have CNAME records configured. The default value is disabled.

**failure-rcode-ttl**  
Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**last-resort-pool**  
Specifies a last resort pool to use when load balancing requests for this wide IP. Any CNAME pool type is allowed. The default value is none.

**load-balancing-decision-log-verbosity**  
Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default value is none.

#### minimal-response

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the component resides.

#### persistence

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### pools

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pool-lb-mode

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

#### global-availability

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

#### random

Specifies that the system selects a pool in no pattern or order.

#### ratio

Specifies that the system selects a pool based on the ratio that you assign to the pool.

#### round-robin

Specifies that the system selects pools sequentially.

#### topology

Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### rules

Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

#### ttd-persistence

Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

#### SEE ALSO

  field-fmt

DELETE
delete wideip mx [all | [name] ]

```

### DESCRIPTION

You can use the wideip component to create, modify, display, or delete a wide IP that responds to MX queries. An MX wide IP maps a domain's mail address to a set of hosts acting as mail servers.

### EXAMPLES

create wideip mx mydomain.com

Creates an MX wide IP named mydomain.com.

delete wideip mx mydomain.com

Deletes the MX wide IP named mydomain.com.

## OPTIONS

### aliases

Specifies alternate domain names for the web site content you are load balancing. You can use two different wildcard characters, asterisk (\*) and question mark (?), to represent one or more characters. The default value is none.

### app-service

Specifies the name of the application service to which this wide ip belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this wide ip. Only the application service can modify or delete this wide ip.

### description

User defined description. Note: Advanced search on the GUI's Wideip list page can be turned on/off by modifying the DB variable ui.advancedsearch via the tmsh command "modify sys db ui.advancedsearch value true/false". This will result in a new description column and the inclusion of that field in the search.

[disabled | enabled]

Specifies whether the wide IP and its resources are available for load balancing.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

### failure-rcode

Specifies the DNS RCODE used when failure-rcode-response is enabled. Default is noerror. Options include noerror (no type exists at this name), formerr (format error in query), servfail (unable to process query), nxdomain (name does not exist), notimpl (no support for this kind of query), and refused (refuse to process based on policy). If failure-rcode-ttl is non-zero, only the Authority section of the noerror or nxdomain response will include a SOA record.

### failure-rcode-response

When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This response is an authoritative empty answer from the system to MX record requests. With this option enabled, the system responds faster to MX requests for which it does not have MX records configured. The default value is disabled.

### failure-rcode-ttl

Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

### last-resort-pool

Specifies a last resort pool to use when load balancing requests for this wide IP. Any MX or CNAME pool type is allowed. The default value is none.

### load-balancing-decision-log-verbosity

Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default value is none.

### minimal-response

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

### partition

Displays the administrative partition within which the component resides.

#### persistence

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### pools

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pools-cname

Configures the CNAME pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pool-lb-mode

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

#### global-availability

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

#### random

Specifies that the system selects a pool in no pattern or order.

#### ratio

Specifies that the system selects a pool based on the ratio that you assign to the pool.

#### round-robin

Specifies that the system selects pools sequentially.

#### topology

Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### rules

Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

#### ttl-persistence

Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

  (detail | global)
  field-fmt
```

##### DELETE

```
delete wideip naptr [all | [name] ]
```

#### DESCRIPTION

You can use the wideip component to create, modify, display, or delete a wide IP that responds to NAPTR queries. A NAPTR wide IP is a mapping of a fully-qualified domain name (FQDN) to a set of either services or hosts defined under that name.

#### EXAMPLES

```
create wideip naptr example.com

Creates a NAPTR wide IP named example.com.

delete wideip naptr example.com

Deletes the NAPTR wide IP named example.com.
```

#### OPTIONS

##### aliases

Specifies alternate domain names for the web site content you are load balancing. You can use two different wildcard characters, asterisk (\*) and question mark (?), to represent one or more characters. The default value is none.

##### app-service

Specifies the name of the application service to which this wide

ip belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this wide ip. Only the application service can modify or delete this wide ip.

#### description

User defined description. Note: Advanced search on the GUI's Wideip list page can be turned on/off by modifying the DB variable ui.advancedsearch via the tmsh command "modify sys db ui.advancedsearch value true/false". This will result in a new description column and the inclusion of that field in the search.

[disabled | enabled]

Specifies whether the wide IP and its resources are available for load balancing.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### failure-rcode

Specifies the DNS RCODE used when failure-rcode-response is enabled. Default is noerror. Options include noerror (no type exists at this name), formerr (format error in query), servfail (unable to process query), nxdomain (name does not exist), notimpl (no support for this kind of query), and refused (refuse to process based on policy). If failure-rcode-ttl is non-zero, only the Authority section of the noerror or nxdomain response will include a SOA record.

#### failure-rcode-response

When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This response is an authoritative empty answer from the system to NAPTR record requests. With this option enabled, the system responds faster to NAPTR requests for which it does not have NAPTR records configured. The default value is disabled.

#### failure-rcode-ttl

Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

#### last-resort-pool

Specifies a last resort pool to use when load balancing requests for this wide IP. Any NAPTR or CNAME pool type is allowed. The default value is none.

#### load-balancing-decision-log-verbosity

Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default value is none.

#### minimal-response

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the component resides.

#### persistence

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### pools

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

**pools-cname**

Configures the CNAME pools the system uses when load balancing requests for this wide IP. The default value is none.

**pool-lb-mode**

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

**global-availability**

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

**random**

Specifies that the system selects a pool in no pattern or order.

**ratio**

Specifies that the system selects a pool based on the ratio that you assign to the pool.

**round-robin**

Specifies that the system selects pools sequentially.

**topology**

Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**rules**

Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

**ttl-persistence**

Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

    (detail | global)
    field-fmt

```

```

DELETE
delete wideip srv [all | [name] ]

```

#### DESCRIPTION

You can use the wideip component to create, modify, display, or delete a wide IP that responds to SRV queries. An SRV wide IP is a mapping of a fully-qualified domain name (FQDN) specifying a particular service of a domain to a host and port that provides the service.

#### EXAMPLES

```

create wideip srv _imap._tcp.mydomain.com

Creates an SRV wide IP named _imap._tcp.mydomain.com.

delete wideip srv _imap._tcp.mydomain.com

Deletes the SRV wide IP named _imap._tcp.mydomain.com.

```

#### OPTIONS

**aliases**  
Specifies alternate domain names for the web site content you are load balancing. You can use two different wildcard characters, asterisk (\*) and question mark (?), to represent one or more characters. The default value is none.

**app-service**  
Specifies the name of the application service to which this wide ip belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this wide ip. Only the application service can modify or delete this wide ip.

**description**  
User defined description. Note: Advanced search on the GUI's Wideip list page can be turned on/off by modifying the DB variable ui.advancedsearch via the tmsh command "modify sys db ui.advancedsearch value true/false". This will result in a new description column and the inclusion of that field in the search.

[disabled | enabled]  
Specifies whether the wide IP and its resources are available for load balancing.

**failure-rcode**

Specifies the DNS RCODE used when failure-rcode-response is enabled. Default is noerror. Options include noerror (no type exists at this name), formerr (format error in query), servfail (unable to process query), nxdomain (name does not exist), notimpl (no support for this kind of query), and refused (refuse to process based on policy). If failure-rcode-ttl is non-zero, only the Authority section of the noerror or nxdomain response will include a SOA record.

#### failure-rcode-response

When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This response is an authoritative empty answer from the system to SRV record requests. With this option enabled, the system responds faster to SRV requests for which it does not have SRV records configured. The default value is disabled.

#### failure-rcode-ttl

Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### last-resort-pool

Specifies a last resort pool to use when load balancing requests for this wide IP. Any SRV or CNAME pool type is allowed. The default value is none.

#### load-balancing-decision-log-verbosity

Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default value is none.

#### minimal-response

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

name Specifies a unique name for the component. The format of an SRV wide IP name is governed by RFC. The general form is 'service.protocol.domain labels'. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the component resides.

#### persistence

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### pools

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pools-cname

Configures the CNAME pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pool-lb-mode

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

global-availability

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

**random**  
Specifies that the system selects a pool in no pattern or order.

**ratio**  
Specifies that the system selects a pool based on the ratio that you assign to the pool.

**round-robin**  
Specifies that the system selects pools sequentially.

**topology**  
Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**rules**  
Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

**tll-persistence**  
Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

## ilx

### ilx global-settings

**NAME**  
global-settings - system-wide settings for iRules Language Extension (ILX) Plugin.

**MODULE**  
ilx

**SYNTAX**  
The global-settings can be displayed/modified with the following syntax:

**MODIFY**  
modify global-settings [name]  
options:  
debug-port-blacklist add/delete/replace-all-with { [port] }

**DISPLAY**  
list global-settings [name]  
options:  
debug-port-blacklist

**DESCRIPTION**  
An iRules Language Extension (ILX) plugin global-settings profile a way to store system-wide settings.

**EXAMPLES**

list ilx global-settings  
See the current settings

modify global-settings debug-port-blacklist add { 20001 }

Add port 20001 to the list of reserved ports that cannot be used to attach node inspector.

#### OPTIONS

`debug-port-blacklist`  
Specifies the list of reserved ports that cannot be used to attach node inspector in case debugging is enabled.

#### SEE ALSO

`ilx plugin`, `modify`, `list`

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## ilx plugin

#### NAME

`plugin` - Configures an iRules Language Extension (ILX) Plugin.

#### MODULE

`ilx`

#### SYNTAX

Configure the plugin component within the `ilx` module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create plugin [name]
```

```
options:
```

```
  app-service [name]
  description [string]
  disabled
  enabled
  from-workspace [name]
  log-publisher [name]
```

```
modify plugin [name]
```

#### DESCRIPTION

An iRules Language Extension (ILX) plugin provides the following functionality:

An RPC interface that allows an iRule to communicate with an ILX

Node.js(tm) process.

A Streaming interface that allows an ILX Node.js(tm) process to

manage Virtual

Server connections and payload data.

A plugin is created from an ilx workspace. Files from the workspace are copied into a system area and run from the system area. iRule files contained in the workspace are read into the system as ltm rule configuration. The ltm rule configuration objects are created in a sys folder that has the same name as the plugin.

The system will start one or more Node.js(tm) process for each extension (see also concurrency-mode below). Node.js(tm) will look in the extension directory for the file package.json. Node.js(tm) will look in package.json for a main field that identifies the main entry point of the plugin. If the main field is not present node will look for the file index.js.

The status of plugin processes can be viewed with the show command.

```
show plugin my_plugin
```

A plugin can be started, stopped and restarted. When a plugin is initially created the system will start processes for each extension. When a plugin is stopped existing plugin processes associated with active tmm connections are allowed to drain. Draining processes continue to run until the connections are closed. There are several options that control how processes are stopped, drain-existing-connections, immediate and stop-draining, and are describe below.

There are several ILX commands that an iRule may use to communicate with a Node.js(tm) extension process: ILX::init, ILX::call and ILX::notify.

ILX::init [plugin name] [extension name] establishes a communication path from an iRule to the node process. It returns a handle that must be passed to ILX::call and ILX::notify.

ILX::call [ILX handle] [method] [optional arg 1] [optional arg 2] ..... invokes the specified node method in the extension associated with the ILX handle. If the node method returns a javascript array or dictionary then a Tcl list object is returned from ILX::call, otherwise a Tcl string object is returned.

ILX::notify [ILX handle] [method] [optional arg 1] [optional arg 2] ..... sends a message to the node method but does not wait for the method to complete before returning. TCL\_OK is returned if the message was successfully queued. Any other return value indicates the message could not be queued.

#### RPC

The RPC API consists of two primary components, Node.js and Tcl.

The Node.js API contains an ILXServer class. Methods are added to the server using ILXServer.addMethod("method name", function(req, res) { ... }). "req" is an ILXRequest object and "res" is an ILXResponse object. ILXServer.listen will start the server.

A Tcl iRule connects to the Node.js process using the Tcl command  
set plugin [ILX::init "plugin name" "extension name"]

The Javascript methods are invoked from a Tcl iRule using either ILX::call or ILX::notify. The args are user defined and passed to the Node.js method via the ILXRequest object.  
set response [ILX::call \$plugin "method name" args...]

ILX::notify is similar to ILX::call except that the iRule will not wait for a response from the Node.js process.  
ILX::call \$plugin "method name" args...]

Here is a Hello World Node.js script

```
var f5 = require('f5-nodejs');
var server = new f5.ILXServer();
server.addMethod("hello_world", function(req, res) {
console.log("request args: " + JSON.stringify(req));
```

```
res.reply('hello_world');
});
server.listen();
```

Here is the Hello World Tcl iRule that passes some data to the Node.js process, waits for a response and logs the response to /var/log/ltm. The iRule must be associated with an ltm virtual-server.

```
when CLIENT_ACCEPTED {
set plugin [ILX::init rpc example]
set rv [ILX::call $plugin hello_world arg1 val1 arg2 val2]
log local0.debug $rv
}
```

Run the following tmsh commands to create the ilx workspace and ilx plugin configuration for the RPC example above. See also help ilx workspace for more examples describing how to manage a workspace.

```
create ilx workspace rpc
create ilx workspace rpc extension example
edit ilx workspace rpc extension example
```

A file named index.js will be created. Replace the content of index.js with the Node.js Hello World script above. If you have bash shell access you can directly edit the file /var/ilx/workspaces/Common/rpc/extensions/example/index.js.

```
edit ilx workspace rpc rule example
```

A file named rpc\_example.tcl will be created. Replace the content of rpc\_example.tcl with the Tcl iRule Hello World example above. If you have bash shell access you can directly edit the file /var/ilx/workspaces/Common/rpc/rules/hello\_world.tcl.

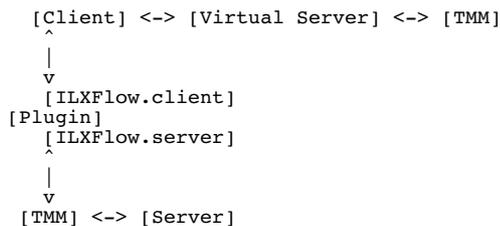

```
create ilx plugin rpc from-workspace rpc
modify ltm virtual [name] rules { rpc/example }
```

You must create a Virtual Server and associate the rpc\_example rule with the Virtual Server. When a client connects to the Virtual Server you should see the output from both the Node.js process and Tcl iRule in /var/log/ltm.

See also the BIG-IP iRulesLX User Guide located in the Programmability Wiki at devcentral.f5.com.

## Streaming

The Streaming API allows a Node.js Plugin process to act as a proxy for connections through a Virtual Server. When a client connects to a Virtual Server an ILXFlow object is created and passed to the plugin. The ILXFlow object contains two Node.js sockets. ILXFlow.client represents the connection from the client to the plugin. ILXFlow.server represents the connection from the plugin to a server. The plugin will use ILXFlow.client to receive or send data to the client. The plugin will use ILXFlow.server to send or receive data from the server. The plugin may inspect or modify any/all client or server data. The ILXFlow.client and ILXFlow.server objects behave as native Node.js sockets. The plugin can also be configured to act as a server and respond directly to the client without completing a connection to a server. The plugin can also be configured as a native Node.js HTTP server.

Note that the plugin sees TCP payload. TCP headers are stripped by the TMM and are not visible to the plugin.

The following is a brief overview of the Javascript classes that make up the Streaming API. These classes contain many more features and options as described in the BIG-IP iRulesLX User Guide located in the Programmability Wiki at devcentral.f5.com.

**ILXPlugin** - Connects to the TMM to accept Virtual Server client connections. When a connection is made an ILXFlow object is passed to the plugin via the "connect" event: plugin.on("connect", function(flow) { ... }).

**ILXPluginOptions** - Options that configure the events and data that a plugin will received.

**ILXFlow** - An object that represents a client socket to Virtual Server and server socket to a server.

**ILXStream** - An object that represents the client side connection from a client to a Virtual Server (ILXFlow.client), the server side connection from a Virtual Server to a server (ILXFlow.server), or a plugin initiated connection to a server (created using ILXStream.connect).

**ILXLbOptions** - Options that allow the plugin to specify which server the client will connect to by calling ILXFlow.lbSelect(ILXLbOptions).

ILXTable - Functions for reading and writing the TMM Session DB. Very similar interface to the Tcl iRule table command.

ILXBufferUtil - Functions for searching and modifying a Node.js Buffer object.

ILXDatagroup - Functions for accessing ltm data-group configuration. The set of data-groups available to a plugin must be specified using the ILXPluginOptions when the plugin is started.

ILXTransaction - If HTTP and ILX profiles are attached to a virtual server then all header and data inspection and modification are done in the context of request and response transaction. An ILXTransaction object is passed to the following events: requestStart, requestComplete, responseStart and responseComplete. The ILXTransaction object contains things like request headers, URI and method, and response headers and status.

The following is a sample streaming plugin that acts as a pass through. Data is read from the client and sent to the server. Data is read from the server and sent to the client. Note that it is important to handle "error" events as the Node.js plugin process will exit if they are not handled.

```
var f5 = require("f5-nodejs");
var plugin = new f5.ILXPlugin();
plugin.on("connect", function(flow) {
  flow.client.on("readable", function() {
    var buffer;
    while (true) {
      buffer = flow.client.read();
      if (buffer === null) {
        break;
      }
      console.log("Client Data");
      console.log(buffer.toString());
      flow.server.write(buffer);
    }
  });
  flow.client.on("error", function(err) {
    console.log("client socket error: " + err);
  });
  flow.server.on("readable", function() {
    var buffer;
    while (true) {
      buffer = flow.server.read();
      if (buffer === null) {
        break;
      }
      console.log("Server Data");
      console.log(buffer.toString());
      flow.client.write(buffer);
    }
  });
  flow.server.on("error", function(err) {
    console.log("server socket error: " + err);
  });
  flow.on("error", function(err) {
    console.log("flow error: " + err);
  });
});
var options = new f5.ILXPluginOptions(); // use defaults
plugin.start(options);
```

The following is a sample streaming HTTP plugin that acts as a pass through. Note that the example above can also be used to manage HTTP traffic. This example requires a Virtual Server with both HTTP and ILX profiles.

```
var f5 = require('f5-nodejs');
var plugin = new f5.ILXPlugin();
plugin.on("connect", function(flow)
{
  flow.client.on("requestStart", function(request) {
    // HTTP request URI, headers and more
    console.log(
      "requestStart: " + JSON.stringify(request.params));
  });
  flow.client.on("readable", function() {
    // HTTP request body, if present
    var buf;
    while (true) {
      buf = flow.client.read();
      if (buf !== null) {
        console.log("request body:" + buf.length + " bytes");
        console.log(buf.toString());
        flow.server.write(buf);
      }
      else {
        break;
      }
    }
  });
  flow.client.on("requestComplete", function(request) {
    // Entire HTTP request received
    console.log(
      "requestComplete: " + JSON.stringify(request.params));
    request.complete();
  });
  flow.client.on("error", function(err) {
    console.error("flow.client error:" + err);
  });

  flow.server.on("responseStart", function(response) {
```

```

// HTTP response headers, status and more
console.log(
  "responseStart: " + JSON.stringify(response.params));
});
flow.server.on("readable", function() {
// HTTP response body, if present
var buf;
while (true) {
  buf = flow.server.read();
  if (buf !== null) {
    console.log(
      "response body:" + buf.length + " bytes");
    console.log(buf.toString());
    flow.client.write(buf);
  }
  else {
    break;
  }
}
});
flow.server.on("responseComplete", function(response) {
// Entire HTTP response received
console.log(
  "responseComplete: " + JSON.stringify(response.params));
response.complete();
});
flow.server.on("error", function(err) {
console.error("flow.server error:" + err);
});
flow.on("error", function(err) {
console.error("flow.error:" + err);
});
});
var options = new f5.ILXPluginOptions(); // use defaults
plugin.start(options);

```

Run the following tmsh commands to create ilx workspace and ilx plugin configuration for a streaming plugin using either of the sample plugins above.

```

create ilx workspace streaming
create ilx workspace streaming extension example
edit ilx workspace streaming extension example

```

A file named index.js will be created. Replace the content of index.js with the Node.js streaming example from above. If you have bash shell access you can directly edit the file /var/ilx/workspaces/Common/streaming/extensions/example/index.js.

```

create ilx plugin streaming from-workspace streaming
modify ilx plugin streaming extensions { example { ilx-logging
  enabled concurrency-mode single } }

```

When ilx-logging is enabled all stdout and stderr from the plugin is sent to /var/log/ilx/.., in this case /var/log/ilx/Common.streaming.example.

```

create ltm profile ilx streaming-profile plugin streaming
modify ltm virtual [name] profiles replace-all-with {
  tcp streaming-profile }

```

You must create a Virtual Server and associate the streaming-profile with the Virtual Server. When a client connects to the Virtual Server the client should receive the server data. The plugin also logs the client and server data that is received to /var/log/ilx/Common.streaming.example. If you are using the HTTP sample you will need to assign an HTTP profile to the virtual server.

#### EXAMPLES

```
create plugin my_plugin from-workspace my_workspace
```

Creates a plugin named my\_plugin. Rule files from the workspace are read into the system configuration and placed in the sys folder my\_plugin.

```
modify plugin my_plugin from-workspace my_workspace
```

Restart the plugin using the current files in my\_workspace.

```
modify plugin my_plugin extensions { my_extension { concurrency-mode
  dedicated } }
```

Modify the concurrency-mode for a specific extension.

```
reset-stats plugin my_plugin
```

Reset all statistics for my\_plugin.

```
reset-stats plugin my_plugin extensions { my_extension }
```

Reset statistics for the extension my\_extension in my\_plugin.

```
delete plugin my_plugin
```

Deletes the plugin named my\_plugin. The iRule configuration in the sys folder named my\_plugin will also be deleted. The sys folder my\_plugin will be deleted if there are no remaining (non-plugin related) configuration items in the folder.

list plugin

List the configuration for all plugins in the current sys folder.

list plugin my\_plugin

List the configuration for my\_plugin.

show plugin my\_plugin

Displays the status of all extension processes running as part of my\_plugin.

show plugin my\_plugin extensions { my\_extension }

Displays the status of processes in extension my\_extension running as part of my\_plugin.

start plugin my\_plugin

Starts all extensions in my\_plugin.

stop plugin my\_plugin

Stops all extensions in my\_plugin. Active processes and connections are allowed to drain.

stop plugin my\_plugin drain-existing-connections

Stops all extension processes in my\_plugin. Active connections that are currently using the plugin are allowed to drain. The plugin processes will be stopped when all associated active connections are closed.

stop plugin my\_plugin immediate

Immediately stops all extension processes associated with my\_plugin. New and existing connections to Virtual Servers that have iRules that interact with the plugin will receive a Tcl error when using the Tcl functions ILX::init and ILX::call.

stop plugin my\_plugin stop-draining

Immediately stops all extension processes in my\_plugin that are draining. Existing connections that have iRules that interact with the plugin and were attached to the draining processes will receive a Tcl error when using the Tcl functions ILX::init and ILX::call.

#### OPTIONS

app-service

Specifies the name of the application service to which the pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the plugin. Only the application service can modify or delete the plugin.

description

User defined description.

disabled

Disable the plugin. All node processes associated with the plugin that are associated with active tmm connections are allowed to continue until the connections close. To immediately stop all processes use the stop command.

enabled

Enable the plugin. Node processes will be started for each plugin extension.

extensions

Modify attributes of plugin extensions.

command-arguments

The optional list of arguments to be passed to the nodejs (after the extension).

Eg.:

```
command-arguments { arg1 arg2 }
```

will result in nodejs process started like this:

```
/usr/bin/nodejs /extensions/ arg1 arg2
```

The plugin must be restarted for this setting to take affect.

command-options

The list of options passed to Node.js before the name of the extension script. These must be valid Node.js options. The Node.js process will fail to start if it is provided with invalid options.

Example:

```
command-options { --debug-brk=12345 }
```

will result in nodejs process started like this:

```
/usr/bin/nodejs --debug-brk=12345 /extensions/
```

Please note the choice of the specified port is not guaranteed. If the specified port is not available, the system will choose another consecutive port (see Debugging section for more details).

The plugin must be restarted for this setting to take affect.

concurrency-mode

Specifies a concurrency mode for the extension.

The value `dedicated` specifies that a node process should be started for each tmm that has been provisioned (see `sys db provision.tmmcountactual`). Each node process will be dedicated to servicing requests from a single tmm.

The value `single` specifies that a single node process should be started. This node process will service requests from all tmm processes in the system.

#### `data-groups`

The set of data-groups that will be made available to the plugin through the `ILXDatagroup` JavaScript class. The default value is `none`.

#### `debug-port-range-high`

When debugging is enabled and the debug port is not specified in `command-options`, ILX will assign the port, searching for an available port to attach the node inspector, see the section on Debugging. It will start searching at the `debug-port-range-low` value and try each port until it reaches the `debug-port-range-high` value.

#### `debug-port-range-low`

When debugging is enabled and the debug port is not specified in `command-options`, ILX will assign the port, searching for an available port to attach the node inspector, see the section on Debugging. It will start searching at the `debug-port-range-low` value and try each port until it reaches the `debug-port-range-high` value.

#### `description`

User defined description.

#### `heartbeat-interval`

Specifies the maximum number of seconds between extension process heartbeats. The extension process heartbeat is updated by the BIG-IP version of `libuv`. The BIG-IP monitors the heartbeat of each extension process. When enabled the system will restart an extension process if the extension does not update its heartbeat over the configured interval. A value of 0 (zero) disables heartbeat checking. The heartbeat should be disabled when the extension is being debugged.

#### `ilx-logging`

Specifies where standard out and standard error generated by the plugin will be logged. A value of `disabled` will cause output to be logged to `/var/log/ltn`. A value of `enabled` will cause output to be logged to `/var/log/ilx/[plugin].[extension]` (enabled). A CPU identifier will be appended to the log file name if the `concurrency-mode` is `dedicated`. Setting the value to `enabled` is intended to aid in debugging a plugin and not overrun `/var/log/ltn` with debug logs. The default value is `disabled`.

#### `max-restarts`

Specifies the maximum number of times an extension process may fail before the system will no longer automatically restart the process. See also `restart-interval`. The default value is 5.

#### `restart-interval`

Specifies the interval, in seconds, over which `max-restarts` may occur. The default value is 60 seconds.

#### `trace-level`

Specifies the global trace level for an extension. This can also be controlled by an extension using the JavaScript function `ILXPlugin.setGlobalTraceLevel` (note that this does not update the extension configuration, only the running extension). An extension may use this setting in JavaScript by calling `ILXPlugin.globalTraceLevel()`. F5 extension internals also use this setting to log interaction between the configuration system, the TMM and the plugin extension. A value of zero will stop trace logging. A value of 1 will log configuration messages. A value of 10 will log general function call location information. A value of 20 will include function call information in the packet path. A value of 30 will include packet content that is sent and received to and from the TMM. Note that if the trace level has been set by JavaScript code in the plugin using `ILXPlugin.setGlobalTraceLevel` and the extension `trace-level` setting is zero then to disable tracing in the plugin you must update the plugin code. See also `ilx-logging`.

#### `from-workspace`

Create or modify a plugin using the set of files in the specified workspace. The workspace files are copied into a system area. New node processes are started using the latest copy of workspace files. Existing node processes continue to run until all tmm connections associated with those processes have closed.

#### `log-publisher`

Specifies the log destination for messages generated by node processes. See `sys log-config publisher`.

`name` Specifies a unique name for the component. This option is required for the `create` and `modify` commands.

#### `staged-directory`

Display the workspace directory that was used to create the plugin.

## Debugging

In order to debug an ILX extension the user must enable debugging via command-options and restart the plugin. Node.js provides three options for enabling remote debugging: `--debug[=]`, `--debug-port=` and `--debug-brk=`.

If a debug port is specified the system will search for an available port starting with the specified port. Please note that the debugging can only be enabled in single concurrency mode.

```
modify ilx plugin my_plugin extension { my_extension { command_options add { --debug } } }
restart ilx plugin my_plugin
```

If a debug port is not specified with either `--debug=`, `--debug-brk=` or `--debug-port=`, the system will search for an available port within the configured `debug-port-range-low` and `debug-port-range-high` range. If a port is specified the system will perform a search for an available port using the specified port instead of the `debug-port-range-low` value. The assignment of the specified port is best-effort and is not guaranteed. In both cases the search for ports is consecutive.

There is a system-wide list of ports that will be skipped during the debug port search:

Eg.

```
# list ilx global-settings
ilx global-settings {
  debug-port-blacklist { 47019 54321 60000 }
}
```

The node-inspector process must be started at the bash command line, specifying a valid IP address that is either a `self-ip` (net `self-ip`) or the management IP address (`sys management-ip`).

```
/usr/lib/node_modules/.bin/node-inspector --web-host --no-inject
```

It will then be possible to connect to the IP address using the port that the system chose. The debug port that the system chose can be seen by running the command `show plugin my_plugin`.

```
show plugin my_plugin extensions { my_extension }
```

```
-----
| Extension Process: my_extension
-----
Status      running
PID         1190
TMM         0
CPU Utilization (%) 0
Debug Port  20000
Memory (bytes)
Total Virtual Size 0
Resident Set Size 0
Connections
Active      0
Total      20
RPC Info
Total      20
Notifies   0
Timeouts   0
Errors     0
Octets In  620
Octets Out 1160
Average Latency 3
Max Latency 20
```

It is then possible to connect with a suitable debugging client, such as the Chrome(tm) browser via:  
`https://:8080/debug?port=20000`

The externally reachable port opened by node-inspector is ":8080". Port "20000" is the port displayed by the `show ilx plugin` command.

## ilx workspace

NAME

workspace - Configures a development workspace for Node.js(tm) iRule Language Extensions.

#### MODULE

ilx

#### SYNTAX

Configure the workspace component within the ilx module using the syntax shown in the following sections.

##### CREATE/MODIFY/EDIT

create workspace [name]

options:

archive [name]  
extension [name]  
file [name]  
from-archive [name]  
from-plugin [name]  
from-uri [uri]  
from-workspace [name]  
rule [name]

modify workspace [name]

options:

from-archive [name]  
from-plugin [name]  
from-uri [uri]  
from-workspace [name]

edit workspace [name]

options:

extension [name]  
file [name]  
rule [name]

##### DISPLAY

list workspace

list workspace [ [name] ... ]

show running-config workspace

show running-config workspace [ [name] ... ]

options:

all-files  
archive [name]  
extension [name]  
file [name]  
one-line

rule [name]  
staged-directory  
version

##### DELETE

delete workspace [name]

options:

archive [name]  
extension [name]  
file [name]  
rule [name]

#### DESCRIPTION

An ILX Workspace is an area of the file system used to store Node.js(tm) and supporting files used to construct an ilx plugin. Workspaces are stored in /var/ilx/workspaces/.../.

A workspace contains several components.

/var/ilx/workspaces/Common//extensions/...  
/var/ilx/workspaces/Common//rules/...  
/var/ilx/workspaces/Common//version

The extensions directory contains sub-directories. Each sub-directory contains files for a specific extension.

/var/ilx/workspaces/Common//extensions//... Each extension directory must contain a package.json file. This is a standard npm package definition file. For more information see [www.npmjs.org/doc/package.json.html](http://www.npmjs.org/doc/package.json.html). When an ilx plugin is started node will look in package.json for a main field that identifies the main entry point of the plugin. If the main field is not present node will look for the file index.js.

The rules directory contains zero or more files that contain iRules (see ltm rule).

/var/ilx/workspaces/Common//rules/.tcl.

ILX iRule commands are used to communicate with a Node.js(tm) process that is running as part of an ILX Plugin. When a new rule is created using either of the following commands a sample iRule file is opened with syntax examples for the ILX iRule commands.

```
create ilx workspace ilx rule test
edit ilx workspace ilx rule test
```

When a new extension is created using the following commands a sample index.js file will be created that contains Node.js(tm) and ILX iRule examples. The extension directory is also populated with the file package.json and locally installed Node.js(tm) modules.

```
tmsh create ilx workspace my_workspace
tmsh create ilx workspace my_workspace extension my_extension
```

The version file indicates the BIG-IP version used to create the workspace.

#### EXAMPLES

```
create workspace my_workspace
```

Creates a workspace named my\_workspace in /var/ilx/workspaces/Common/my\_workspace (assuming your current working

folder is the default BIG-IP folder /Common).

create workspace my\_workspace rule my\_rule

Adds the iRule my\_rule as the file my\_rule.tcl to the workspace directory named /var/ilx/workspaces/Common/my\_workspace/rules/.

edit workspace my\_workspace rule my\_rule

Adds or modifies the iRule my\_rule as the file my\_rule.tcl to the workspace directory named /var/ilx/workspaces/Common/my\_workspace/rules/.

create workspace my\_workspace extension my\_extension

Adds a new extension directory in /var/ilx/workspaces/Common/my\_workspace/extensions/my\_extension and installs node\_modules/f5-nodejs within the directory. my\_extension must be a valid Linux directory name.

edit workspace my\_workspace extension my\_extension

If the extension does not exist a new extension directory is created in /var/ilx/workspaces/Common/my\_workspace/extensions/my\_extension, installs node\_modules/f5-nodejs within the directory and opens the editor on the file within the directory named index.js. If the extension already exists the editor will open index.js.

edit workspace my\_workspace file extensions/my\_extension/my\_file.js

If the extension does not exist a new extension directory is created in /var/ilx/workspaces/Common/my\_workspace/extensions/my\_extension, installs node\_modules/f5-nodejs within the directory and opens the editor on my\_file.js. If the extension already exists the editor will open my\_file.js.

edit workspace my\_workspace file extensions/my\_extension/my\_file.js

The editor is opened on /var/ilx/workspaces/Common/my\_workspace/extensions/my\_extension/my\_file.js. The extension must already exist.

delete workspace my\_workspace

Deletes the workspace named my\_workspace. This removes all disk files associated with the workspace and cannot be undone. You will be prompted to confirm before the workspace is deleted.

delete workspace my\_workspace extension my\_extension

Deletes the extension named my\_extension in my\_workspace.

delete workspace my\_workspace rule my\_rule

Deletes the iRule file named my\_rule in my\_extension in my\_workspace.

delete workspace my\_workspace file extensions/my\_extension/my\_file

Deletes the file named my\_file in my\_extension in my\_workspace.

list workspace my\_workspace

List the content of my\_workspace

list workspace recursive my\_workspace

List all files and directories in my\_workspace.

list workspace my\_workspace rule

List the rules associated with my\_workspace.

list workspace my\_workspace rule my\_rule

List the text content of the rule my\_rule associated with my\_workspace

list workspace my\_workspace file rules/my\_rule.tcl

List the text content of the file rules/my\_rule.tcl associated with my\_workspace

list workspace my\_workspace extension

List the extensions associated with my\_workspace.

list workspace my\_workspace extension my\_extension

List the content of the my\_extension extension directory associated with my\_workspace.

list workspace my\_workspace file extensions/my\_extension/my\_file

List the text content of the file my\_file in extension my\_extension.

#### OPTIONS

archive  
Specifies the name of a workspace archive file. See the section below on archives.

all-files  
Recursively list all directory and file names contained in a workspace.

extension

Specifies the name of a workspace extension.

file For the edit and list commands the file option specifies the name of a file in a workspace to edit or list. For the delete command the file option specifies the name of a workspace file to delete.

from-archive

Specifies the name of a tar or gzipped tar archive file from which to create or update a workspace. See the section below on archives.

from-plugin

Specifies the name of an ilx plugin from which to create or modify a workspace. The files used to create the plugin are copied into the workspace.

from-uri

Specifies the name of a URI from which to create or update a workspace. The URI must refer to a tar or gzipped tar archive file.

from-workspace

Specifies the name of a workspace from which to create or modify a workspace. The files used to create the workspace specified by from-workspace are copied into the new workspace.

one-line

List the content of a workspace on a single line.

recursive

Recursively list all workspaces contained in the current BIG-IP system folder (see sys folder).

rule Specifies the name of a rule file to create, delete, edit or list.

staged-directory

The directory where the workspace and associated files reside. This is a read-only property.

name Specifies the name of a workspace. This option is required for the commands create, delete, edit and modify.

#### ACCESS CONTROL

Workspaces are stored under file system directory /var/ilx/workspaces.

A user with the role of admin can access all workspaces under /var/ilx/workspaces.

Users with the role of irule-manager, manager and resource-admin can manage workspaces under /var/ilx/workspaces/, where is the name of an existing sys folder that the user has permission to access, see also help sys folder and help pwd.

As a convenience workspaces are automatically created in the users' current folder relative to /var/ilx/workspaces. However, workspaces may be created in file system directories that do not correspond to BIG-IP system configuration folders. In this case the workspace must be referred to by full path.

The following creates two workspaces, the first in the file system location /var/ilx/workspaces/Common/my\_workspace and the second in the filesystem location /var/ilx/workspaces/Common/my\_folder/my\_workspace.

```
(tmos)# pwd
/Common
(tmos)# create ilx workspace my_workspace
(tmos)# cd my_folder
(tmos)# pwd
/Common/my_folder
(tmos)# create ilx workspace my_workspace_2
(tmos)# list ilx workspace my_workspace_2

(tmos)# cd ..
(tmos)# pwd
/Common
(tmos)# list ilx workspace my_workspace
```

Full folder paths may be used to refer to a workspace.

```
(tmos)# create ilx workspace /Common/my_folder/my_workspace_2
(tmos)# list ilx workspace /Common/my_folder/my_workspace_2
```

If an auth partition is removed from the BIG-IP configuration the workspace files remain on disk and can be accessed by a user with the role of admin. If a sys folder is removed under an auth partition, such as removing the folder /Common/my\_config, all workspaces under the file system directory /var/ilx/workspaces/Common/my\_config remain accessible to all users that have access to the Common partition.

#### ARCHIVES

A workspace archive is a gzipped tar file of an existing workspace. The archive contains all files in the workspace.

There are two ways to refer to an archive: 1) 2) //.

Workspace archives are stored in /var/ilx/workspaces//archive/. The system looks for archives in /var/ilx/workspaces//archive.

If an auth partition is removed from the BIG-IP configuration, archive files remain on disk and can be accessed by a user with the role of admin. A user with the role of admin can also manage archives under /var/ilx/workspaces in directories that do not correspond to a BIG-IP auth partition.

```

create workspace my_workspace archive my_workspace.tgz

Save the workspace as a gzipped tar file. The workspace must have been
previously created.

create workspace my_workspace archive /my_partition/my_workspace.tgz

Save the workspace as a gzipped tar file to the set of archives in
/my_partition. The workspace must have been previously created.

list workspace my_workspace archive

List all archives in the current auth partition.

list workspace my_workspace archive my_workspace.tgz

List file details for the archive my_workspace.tgz.

list workspace my_workspace archive /my_partition/my_workspace.tgz

List file details for the archive my_workspace.tgz that is in
my_partition.

list workspace my_workspace archive /my_partition

List all archives in /my_partition.

delete workspace archive my_archive.tgz

Delete the workspace archive my_archive.tgz.

delete workspace archive /my_partition/my_archive.tgz

Delete the workspace archive my_archive.tgz in /my_partition.

create workspace my_workspace from-archive my_workspace.tgz

Create a new workspace from the archive my_workspace.tgz.

modify workspace my_workspace from-archive my_workspace.tgz

Update my_workspace from the archive my_workspace.tgz.

```

#### CONFIGURATION FILES

Workspaces are not stored in system config files.

Workspaces are stored in UCS files and are rolled forward to the next product release.

In a bladed system workspaces are clustered among blades.

Workspaces are not synced across device groups.

## ltm

### ltm alg-log-profile

#### NAME

alg-log-profile - Configures an Application-Level Gateway logging profile.

#### MODULE

ltm

#### SYNTAX

```

CREATE/MODIFY
create alg-log-profile [name]
modify alg-log-profile [name | all]
options:
  app-service [[string] | none]
  csv-format [disabled | enabled]
  start-control-channel {
  action [disabled | enabled | backup-allocation-only]
  elements [add | delete | replace-all-with] {

```

```

    destination
}
}
end-control-channel {
action [disabled | enabled | backup-allocation-only]
elements [add | delete | replace-all-with] {
    destination
}
}
start-data-channel {
action [disabled | enabled | backup-allocation-only]
elements [add | delete | replace-all-with] {
    destination
}
}
end-data-channel {
action [disabled | enabled | backup-allocation-only]
elements [add | delete | replace-all-with] {
    destination
}
}
inbound-transaction {
action [disabled | enabled]
}
edit alg-log-profile [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
reset-stats alg-log-profile
reset-stats alg-log-profile [ [ [name] | [glob] | [regex] ] ... ]
DISPLAY
list alg-log-profile
list alg-log-profile [ [ [name] | [glob] | [regex] ] ... ]
show running-config alg-log-profile
show running-config alg-log-profile [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
DELETE
delete alg-log-profile [name | all]

```

#### DESCRIPTION

A ALG log profile allows fine grain control of the logging for ALG events. When attached to an supported ALG profile - currently FTP, RTSP, SIP, you can control the events to log as well as optional elements in the log entry.

#### EXAMPLES

```

create ltm alg-log-profile my_alg_log_profile end-control-channel {
action backup-allocation-only } end-data-channel { action backup-
allocation-only }

```

Creates the ALG log profile `my_alg_log_profile` that generates log entries for both inbound and data-channel when translation is from backup members only.

```

delete alg-log-profile my_lsn_log_profile

```

Deletes the ALG log profile named `my_lsn_log_profile`.

#### OPTIONS

**app-service**

Specifies the name of the application service to which this object belongs. The default value is none.

**Note:** If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

**csv-format**

When enabled, use CSV log format for log entries. The default value is disabled.

**events**

The type of ALG events available for logging control.

**start-control-channel**

Event for start of control channel connection.

**end-control-channel**

Event for end of control channel connection.

**start-data-channel**

Event for start of data channel connection.

**end-data-channel**

Event for end of data channel connection.

**inbound-transaction**

Event for inbound transaction event to an ALG end-point. Inbound transaction log entry could contain both incoming and outgoing messages.

**action**

Specify the logging action to be taken when a particular event is encountered.

**enabled**

Logging is enable for the event, regardless of how the flow is created.

backup-allocation-only  
Logging is enable for the event, when the ALG is proxy with a LSN, and translation is take from backup pool member only.

disabled  
Logging is disable for the event.

elements  
Optional elements that can be added to the log message.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

## ltm auth crldp-server

#### NAME

crldp-server - Creates a Certificate Revocation List Distribution Point (CRDLP) server for implementing a CRLDP authentication module.

#### MODULE

ltm auth

#### SYNTAX

Configure the crldp-server component within the ltm auth module using the syntax in the following sections.

##### CREATE/MODIFY

```
create crldp-server [name]
modify crldp-server [name]
```

##### options:

```
app-service [[string] | none]
base-dn [ [LDAP base directory name] | none]
description [string]
host [ [ip address] | none]
port [ [name] | [number] ]
reverse-dn [disabled | enabled]
```

```
edit crldp-server [ [name] | [glob] | [regex] ] ... ]
```

##### options:

```
all-properties
non-default-properties
```

##### DISPLAY

```
list crldp-server
list crldp-server [ [name] | [glob] | [regex] ] ... ]
show running-config crldp-server
show running-config crldp-server [ [name] | [glob] | [regex] ] ... ]
```

##### options:

```
all-properties
non-default-properties
one-line
partition
```

##### DELETE

```
delete crldp-server [name]
```

#### DESCRIPTION

CRLDP authentication is a mechanism for checking certificate revocation status for client connections passing through the BIG-IP(r) system. This module is useful when your authentication data is stored on a remote CRLDP server.

To implement a CRLDP authentication module and create a CRLDP server:

1. Use the crldp-server component in the ltm auth module to create a CRLDP server.
2. Use the ssl-crldp component in the ltm auth module to configure a CRLDP configuration object and associate it with the server you created in Step 1.
3. Use the profile component in the ltm auth module to create an

authentication profile in which you specify the following options:

- For the configuration option, specify the SSL CRLDP configuration object that you created in Step 2.
- For the defaults-from option, specify a parent profile (either the default profile named `ssl_crl dp` or another custom profile that you created).

#### EXAMPLES

```
create crldp-server my_crldp_server

Creates a CRLDP server named my_crldp_server.

delete crldp-server my_crldp_server

Deletes a CRLDP server named my_crldp_server.
```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the CRLDP server belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the CRLDP server. Only the application service can modify or delete the CRLDP server.

**base-dn**  
Specifies the LDAP base directory name for certificates that specify the CRL distribution point in directory name format (`dirName`). The default value is none.

Use this option when the value of the X509v3 attribute `crldDistributionPoints` is of type `dirName`. In this case, the BIG-IP system attempts to match the value of the `crldDistributionPoints` attribute to the value of the `base-dn` option. An example of a `base-dn` value is `cn=lxxx,dc=f5,dc=com`.

**description**  
User defined description.

**glob** Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

**host** Specifies an IP address for the CRLDP server. This option is required. The default value is none.

**name** Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

**partition**  
Displays the administrative partition within which the component resides.

**port** Specifies the port for CRLDP authentication traffic. The default value is 389.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

**reverse-dn**  
Specifies in which order the system attempts to match the value of the `base-dn` option to the value of the X509v3 attribute `crldDistributionPoints`. When enabled, the system matches the value of the `base-dn` option from left to right, or from the beginning of the DN string, to accommodate `dirName` strings in certificates such as `C=US,ST=WA,L=SEA,OU=F5,CN=xxx`. The default value is disabled.

#### SEE ALSO

```
create, delete, edit, glob, list, ltm auth profile, ltm auth ssl-crldp,
ltm virtual, modify, reset-stats, regex, reset-stats, show, tmsh
```

## ltm auth kerberos-delegation

**NAME**  
kerberos-delegation - Configures a Kerberos delegation profile.

**MODULE**  
ltm auth

## SYNTAX

Configure the kerberos-delegation component within the ltm auth module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create kerberos-delegation [name]
modify kerberos-delegation [name]
```

#### options:

```
app-service [[string] | none]
client-principal [string]
debug-logging [disabled | enabled]
description [string]
protocol-transition [disabled | enabled]
server-principal [string]
```

```
edit kerberos-delegation [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
```

```
reset-stats kerberos-delegation
```

```
reset-stats kerberos-delegation
[ [name] | [glob] | [regex] ] ... ]
```

### DISPLAY

```
list kerberos-delegation
```

```
list kerberos-delegation [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config kerberos-delegation
```

```
show running-config kerberos-delegation
```

```
[ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
one-line
partition
```

```
show kerberos-delegation
```

```
show kerberos-delegation [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global
```

### DELETE

```
delete kerberos-delegation [name]
```

## DESCRIPTION

The Kerberos delegation configuration acts like a proxy for Kerberos credentials. When connecting to a server that is inside its domain, the browser client fetches Kerberos credentials known as delegated credentials. These credentials are passed on to the system. Once the system has these credentials, it retrieves credentials for the RealServer(r) that is on the back end, and passes those credentials back.

Each user is assigned a unique cookie that describes a session on the system. This cookie is encrypted in a cookie key.

To configure a Kerberos authentication module and create a Kerberos configuration object:

1. Use the kerberos-delegation component in the ltm auth module to create a Kerberos configuration object.
2. Use the profile component, in the ltm auth module, to create an authentication profile in which you specify the following options:
  - a. For the configuration option, specify the Kerberos configuration object that you created in Step 1.
  - b. For the defaults-from option, specify a parent profile (either the default Kerberos profile named krbdelegate or another custom Kerberos profile that you created).

## EXAMPLES

```
create kerberos-delegation my_kerberos-delegation_config client-
principal client.net server-principal server.net
```

Creates a Kerberos delegation profile named my\_kerberos-delegation\_config.

```
list kerberos-delegation all-properties
```

Displays all properties for all Kerberos delegation profiles.

## OPTIONS

### app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

### client-principal

Specifies the principal that the client sees. This is usually a value such as HTTP/. This principal may be in a different domain from the server principal. This option is required. There is no default value.

### debug-logging

Specifies whether the system logs debugging actions. The default value is disabled.

### description

User defined description.

glob Displays the items that match the glob expression. See help glob

for a description of glob expression syntax.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which this profile resides.

**protocol-transition**  
Specifies whether associated virtual should transition client certificate authentication into Kerberos credentials.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**server-principal**  
Specifies the principal of the back-end web server. This is usually a value such as HTTP/. This may be in a different domain from the server principal. This setting is required. There is no default value.

## ltm auth ldap

NAME

ldap - Configures an LDAP configuration object for implementing remote LDAP-based client authentication.

MODULE

ltm auth

SYNTAX

Configure the ldap component within the ltm auth module using the syntax shown in the following sections.

CREATE/MODIFY

```
create ldap [name]
modify ldap [name]
options:
  bind-dn [ [account dn] | none]
  bind-pw [ [string] | none]
  bind-timeout [integer]
  check-host-attr [disabled | enabled]
  debug [disabled | enabled]
  description [string]
  filter [ [string] | none]
  group-dn [ [group dn] | none]
  group-member-attr [ [string] | none]
  idle-timeout [integer]
  ignore-auth-info-unavail [no | yes]
  ignore-unknown-user [disabled | enabled]
  login-attribute [ [account name] | none]
  port [ [name] | [integer]]
  scope [base | one | sub]
  search-base-dn [ [search base dn] | none]
  search-timeout [number]
  servers
    [add | delete | replace-all-with] {
[ip address ... ]
}
  servers none
  ssl [disabled | enabled]
  ssl-ca-cert-file [ [name] | none]
  ssl-check-peer [disabled | enabled]
  ssl-ciphers [ [string] | none]
  ssl-client-cert [ [string] | none]
  ssl-client-key [ [string] | none]
  user-template [ [string] | none]
  version [number]
  warnings [disabled | enabled]

edit ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
```

all-properties  
non-default-properties

DISPLAY  
list ldap  
list ldap [ [ [name] | [glob] | [regex] ] ... ]  
show running-config ldap  
show running-config ldap [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

DELETE  
delete ldap [name]

#### DESCRIPTION

LDAP authentication is a mechanism for authenticating or authorizing client connections passing through the system. LDAP authentication is useful when your authentication or authorization data is stored on a remote LDAP server or a Microsoft(r) Windows Active Directory(r) server, and you want the client credentials to be based on basic HTTP authentication (that is, user name and password).

To configure an LDAP authentication module and create an LDAP configuration object:

1. Use the ldap component in the ltm auth module to create an LDAP configuration object.
2. Use the profile component, in the ltm auth module, to create an authentication profile in which you specify the following options:
  - a. For the configuration option, specify the LDAP configuration object that you created in Step 1.
  - b. For the defaults-from option, specify a parent profile (either the default LDAP profile named ldap or another custom profile that you created).

#### EXAMPLES

```
create ldap my_auth_ldap servers add {my_ldap_auth_server}
```

Creates a configuration object named my\_auth\_ldap

```
delete ldap my_auth_ldap
```

Deletes the configuration object named my\_auth\_ldap.

#### OPTIONS

##### bind-dn

Specifies the distinguished name of an account to which to bind, to perform searches. This search account is a Read-only account used to do searches. You can use the admin account as the search account. If no admin DN is specified, then no bind is attempted. The default value is none.

This option is required only when a site does not allow anonymous searches. If the remote server is a Microsoft(r) Windows(r) Active Directory(r) server, the distinguished name must be in the form of an email address.

##### bind-pw

Specifies the password for the search account created on the LDAP server. This option is required if you specify a value for the bind-dn option. The default value is none.

##### bind-timeout

Specifies a bind timeout limit. The default value is 30 seconds.

##### check-host-attr

Confirms the password for the bind distinguished name. This option is optional. The default value is disabled.

##### debug

Enables or disables syslog-ng debugging information at LOG DEBUG level. The default value is disabled. F5 Networks does not recommend using this option for normal configuration.

##### description

User defined description.

##### filter

Specifies a filter. Use this option for authorizing client traffic. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### group-dn

Specifies the group distinguished name. The system uses this option for authorizing client traffic. The default value is none.

##### group-member-attribute

Specifies a group member attribute. The system uses this option for authorizing client traffic. The default value is none.

##### idle-timeout

Specifies the idle timeout, in seconds, for connections. The default value is 3600 seconds.

##### ignore-auth-info-unavail

Specifies whether the system ignores authentication information, if it is not available. The default value is no.

##### ignore-unknown-user

Specifies whether the system ignores a user that is unknown. The default value is disabled.

`login-attribute`

Specifies a logon attribute. Normally, the value for this option is uid; however, if the server is a Microsoft Windows Active Directory server, the value must be the account name samaccountname (not case-sensitive). The default value is none.

`name` Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

`partition`

Displays the administrative partition within which the component resides.

`port` Specifies the port number or name for the LDAP service. Port 389 is typically used for non-SSL and port 636 is used for an SSL-enabled LDAP service. The default value is ldap.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

`scope`

Specifies the search scope. The default value is sub. The options are:

`base` Specifies the search scope is base object. The base value is almost never useful for nameservice lookups.

`one` Specifies the search scope is one level.

`sub` Specifies the search scope is subtree.

`search-base-dn`

Specifies the search base distinguished name. The default value is none.

`search-timeout`

Specifies the search timeout. The default value is 30 seconds.

`servers`

Specifies the LDAP servers that the system must use to obtain authentication information. You must specify a server when you create an LDAP configuration object.

`ssl` Enables or disables SSL functionality. The default is disabled.

Note that when you use the command line interface to enable SSL for an LDAP service, the system does not change the service port number from 389 to 636, as is required. To change the port number from the command line, use the service option of this command (see above), for example, ldap [name] ssl enabled service 636.

`ssl-ca-cert-file`

Specifies the name of an SSL CA certificate using the full path to the file. The default value is none.

`ssl-check-peer`

Specifies whether the system checks an SSL peer. The default value is disabled.

`ssl-ciphers`

Specifies SSL ciphers. The default value is none.

`ssl-client-cert`

Specifies the name of an SSL client certificate. The default value is none.

`ssl-client-key`

Specifies the name of an SSL client key. The default value is none.

`user-template`

Specifies a user template for the LDAP application to use for authentication. The default value is none.

`version`

Specifies the version number of the LDAP application. The default value is 3.

`warnings`

Enables or disables warning messages. The default value is enabled.

## ltm auth ocsponder

**NAME**  
 ocsponder - Configures Online Certificate System Protocol (OCSP) responder objects.

**MODULE**  
 ltm auth

**SYNTAX**  
 Configure the ocsponder component within the ltm auth module using the syntax shown in the following sections.

**CREATE/MODIFY**  
 create ocsponder [name]  
 modify ocsponder [name]  
 options:  
 allow-certs [disabled | enabled]  
 app-service [[string] | none]  
 ca-file [ [file name] | none]  
 ca-path [ [file name] | none]  
 cert-id-digest [md5 | sha1]  
 chain [disabled | enabled]  
 check-certs [disabled | enabled]  
 description [string]  
 explicit [disabled | enabled]  
 ignore-aia [disabled | enabled]  
 intern [disabled | enabled]  
 nonce [disabled | enabled]  
 sign-digest [md5 | sha1]  
 sign-key [ [key] | none]  
 sign-key-pass-phrase [ [pass phrase] | none]  
 sign-other [ [list of certs] | none]  
 signer [ [certificate] | none]  
 status-age [integer]  
 trust-other [disabled | enabled]  
 url [none | [url] ]  
 va-file [ [file name] | none]  
 validity-period [integer]  
 verify [disabled | enabled]  
 verify-cert [disabled | enabled]  
 verify-other [ [file name] | none]  
 verify-sig [disabled | enabled]

edit ocsponder [ [ [name] | [glob] | [regex] ] ... ]  
 options:  
 all-properties  
 non-default-properties

**DISPLAY**  
 list ocsponder  
 list ocsponder [ [ [name] | [glob] | [regex] ] ... ]

 show running-config ocsponder [ [ [name] | [glob] | [regex] ] ... ]  
 options:  
 all-properties  
 non-default-properties  
 one-line  
 partition

**DELETE**  
 delete ocsponder [name]

**DESCRIPTION**  
 To implement the SSL OCSP authentication module, you must create the following objects: one or more OCSP responder objects, an SSL OCSP configuration object, and an SSL OCSP profile.

To implement an SSL OCSP authentication module and create an OCSP responder object:

1. Use the ocsponder component in the ltm auth module to configure an OCSP responder object.
2. Use the ssl-ocsp component in the ltm auth module to configure an SSL OCSP configuration object to which you add the OCSP responder object that you created in Step 1.
3. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:
  - a. For the configuration option, specify the SSL OCSP configuration object that you created in Step 2.
  - b. For the defaults-from option, specify a parent profile (either the default OCSP Responder profile named ssl\_ocsp or another custom profile that you created).

**OPTIONS**  
 allow-certs  
 Enables or disables the addition of certificates to an OCSP request. The default value is enabled.

app-service  
 Specifies the name of the application service to which the OCSP

responder object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the OCSF responder object. Only the application service can modify or delete the OCSF responder object.

#### ca-file

Specifies the name of the file containing trusted CA certificates used to verify the signature on the OCSF response. The default value is none.

#### ca-path

Specifies the name of the path containing trusted CA certificates used to verify the signature on the OCSF response. The default value is none.

#### cert-id-digest

Specifies a specific algorithm identifier, either sha1 or md5. The default value is sha1. The options are:

sha1 is newer and provides more security with a 160-bit hash length.

md5 is older and has only a 128-bit hash length.

The cert ID is part of the OCSF protocol. The OCSF client (in this case, the BIG-IP system) calculates the cert ID using a hash of the Issuer and serial number for the certificate that it is trying to verify.

#### chain

Specifies whether the system constructs a chain from certificates in the OCSF response. The default value is enabled.

#### check-certs

Enables or disables verification of an OCSF response certificate. Use this option for debugging purposes only. The default value is enabled.

#### description

User defined description.

#### explicit

Specifies that the Local Traffic Manager explicitly trusts that the OCSF response signer's certificate is authorized for OCSF response signing. If the signer's certificate does not contain the OCSF signing extension, specification of this option causes a response to be untrusted. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### ignore-aia

Specifies whether the system ignores the URL contained in the certificate's AIA fields, and always uses the URL specified by the responder instead. The default value is disabled.

#### intern

Specifies whether the system ignores certificates contained in an OCSF response when searching for the signer's certificate. To use this option, the signer's certificate must be specified with either the verify-other or va-file option. The default value is enabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### nonce

Specifies whether the system verifies an OCSF response signature or the nonce values. The default value is enabled.

#### partition

Displays the administrative partition within which the component resides.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### sign-digest

Specifies the algorithm for signing the request, using the signing certificate and key. This parameter has no meaning, if request signing is not in effect (that is, both the request signing certificate and request signing key parameters are empty). This parameter is required only when request signing is in effect. The default value is sha1.

#### sign-key

Specifies the key that the system uses to sign an OCSF request. The default value is none.

#### sign-key-pass-phrase

Specifies the passphrase that the system uses to encrypt the sign key. The default value is none.

#### sign-other

Adds a list of additional certificates to an OCSF request. The default value is none.

#### signer

Specifies a certificate used to sign an OCSF request. If the certificate is specified, but the key is not specified, then the private key is read from the same file as the certificate. If

neither the certificate nor the key is specified, then the request is not signed. If the certificate is not specified and the key is specified, then the configuration is considered to be invalid. The default value is none.

**status-age**  
Specifies the age of the status of the OCSF responder. The default value is 0 (zero).

**trust-other**  
Instructs the BIG-IP local traffic management system to trust the certificates specified with the `verify-other` option. The default is value disabled.

**url** Specifies the URL used to contact the OCSF service on the responder. This option is required. The default value is none.

**va-file**  
Specifies the name of the file containing explicitly trusted responder certificates. This parameter is needed in the event that the responder is not covered by the certificates already loaded into the responder's CA store. The default value is none.

**validity period**  
Specifies the number of seconds used to specify an acceptable error range. Use this option when the OCSF responder clock and a client clock are not synchronized, which can cause a certificate status check to fail. This value must be a positive number. The default value is 300 seconds.

**verify**  
Enables or disables verification of an OCSF response signature or the nonce values. Used for debugging purposes only. The default value is enabled.

**verify-cert**  
Specifies that the system makes additional checks to see if the signer's certificate is authorized to provide the necessary status information. Use this option for testing purposes only. The default value is enabled.

**verify-other**  
Specifies the name of the file used to search for an OCSF response signing certificate when the certificate has been omitted from the response. The default value is none.

**verify-sig**  
Specifies that the system checks the signature on the OCSF response. Use this option for testing purposes only. The default value is enabled.

## ltm auth profile

**NAME**  
profile - Configures an authentication profile.

**MODULE**  
ltm auth

**SYNTAX**  
Configure the profile component within the ltm auth module using the syntax shown in the following sections.

**CREATE/MODIFY**  
`create profile [name]`  
`modify profile [name]`  
**options:**  
`app-service [[string] | none]`  
`configuration [ [name] | none]`  
`cookie-key [string]`  
`cookie-name [string]`  
`credential-source [http-basic-auth]`  
`defaults-from [name]`  
`description [string]`  
`enabled [yes | no]`

```

idle-timeout [integer]
rule [iRule name]

edit profile [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

reset-stats profile
reset-stats profile [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list profile
list profile [ [ [name] | [glob] | [regex] ] ... ]
show running-config profile
show running-config profile [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show profile
show profile [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global

DELETE
delete profile [name]

```

Note: You cannot delete default profiles.

#### DESCRIPTION

You can use the profile component to configure a custom authentication profile, or you can use the default profile that the BIG-IP(r) Local Traffic Manager system provides for each type of authentication module.

An authentication profile requires one of the following configuration objects: ltm auth kerberos-delegation, ltm auth ldap, ltm auth radius, ltm auth ssl-cc-ldap, ltm auth ssl-crl dp, ltm auth ssl-ocsp or ltm auth tacacs. The type of profile specified by the defaults-from option must match the type of configuration object.

#### EXAMPLES

```

create profile my_authentication_profile { configuration tacacs
defaults-from tacacs credential-source http-basic-auth enabled yes
idle-timeout 30 rule _sys_auth_tacacs }

```

Creates a profile named my\_authentication\_profile for TACACS+ authentication.

```
list profile
```

Displays the properties of all of the auth profile components.

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

**configuration**  
Specifies the name of an authentication configuration object. This option is required.

**cookie-key**  
Specifies the key that the system uses to encrypt the session cookie assigned to each user using the cookie-name option. The default value is f5auth. This option applies only to KRB Delegate profiles.

**cookie-name**  
Specifies a session cookie that the system assigns to each user. F5 Networks recommends that each virtual server use a different cookie name. The system encrypts the cookie using the value of the cookie-key option. The default value is abc123. This option applies only to KRB Delegate profiles.

**credential-source**  
Specifies the credential source.

**defaults-from**  
Specifies the name of the authentication profile from which you want your custom profile to inherit settings. This option is required.

**description**  
User defined description.

**enabled**  
Specifies whether this authentication profile is enabled. The default value is yes.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**idle-timeout**  
Specifies the idle timeout for the authentication profile. The default value is 300 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rule Specifies the name of the rule that corresponds to the authentication method you want to use.

## ltm auth radius-server

#### NAME

radius-server - Configures a RADIUS server for implementing remote RADIUS-based client authentication.

#### MODULE

ltm auth

#### SYNTAX

Configure the radius-server component within the ltm auth module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create radius-server [name]
modify radius-server [name]
options:
  description [string]
  port [ [name] | [number] ]
  secret [none | ["string" ] ]
  server [ [hostname] | [ip address] | none ]
  timeout [integer]
```

```
edit radius-server [ [ [name] | [glob] | [regex] ] ... ]
```

##### options:

```
all-properties
non-default-properties
```

##### DISPLAY

```
list radius-server
list radius-server [ [ [name] | [glob] | [regex] ] ... ]
show running-config radius-server
show running-config radius-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete radius-server [name]
```

#### DESCRIPTION

You use a RADIUS authentication module when your authentication data is stored on a remote RADIUS server. In this case, client credentials are based on basic HTTP authentication (that is, user name and password).

To configure a RADIUS authentication module and create a RADIUS server:

1. Use the radius-server component in the ltm auth module to configure a RADIUS server.
2. Use the radius component in the ltm auth module to create a RADIUS configuration object that references the RADIUS server you created in Step 1.
3. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:

- a. For the configuration option, specify the radius component that you created in Step 2.
- b. For the defaults-from option, specify a parent profile (either the default RADIUS profile named radius or another custom profile that you created).

#### EXAMPLES

```
create radius-server bigip_auth_radius_server secret "This is the secret." server 10.1.1.1
```

Creates a RADIUS server named my\_radius\_server.

```
delete radius-server my_radius_server
```

Deletes the RADIUS server named my\_radius\_server.

#### OPTIONS

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition in which the component resides.

port Specifies the port for RADIUS authentication traffic. The default value is 1812.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Specifies the secret key the system uses to encrypt and decrypt packets sent or received from the server. This option is required.

server

Specifies the host name or IP address of the RADIUS server. This option is required.

timeout

Specifies the timeout value. The default value is 3 seconds.

#### SEE ALSO

create, delete, edit, glob, list, ltm auth profile, ltm auth radius, ltm virtual, modify, regex, show, tmsh

## ltm auth radius

#### NAME

radius - Configures a RADIUS configuration object for implementing remote RADIUS-based authentication of BIG-IP(r) system users.

#### MODULE

ltm auth

#### SYNTAX

Configure the radius component within the ltm auth module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create radius [name]
```

```
modify radius [name]
```

##### options:

```
accounting-bug [disabled | enabled]
```

```
client-id [none | [string]]
```

```
debug [disabled | enabled]
```

```
description [string]
```

```
retries [integer]
```

```
service-type [default | login | framed | callback-login | callback-framed | outbound | administrative | nas-prompt
```

##### servers

```
[add | delete | replace-all-with] {
```

```

[ [hostname ... ] | [ip address ... ] ]
}
servers [default | none]

edit radius [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list radius
list radius [ [ [name] | [glob] | [regex] ] ... ]
show running-config radius
show running-config radius [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition

DELETE
delete radius [name]

```

#### DESCRIPTION

You use a RADIUS authentication module when your authentication data is stored on a remote RADIUS server. In this case, client credentials are based on basic HTTP authentication (that is, username and password).

To implement a RADIUS authentication module and create a RADIUS configuration object:

1. Use the radius-server component in the ltm auth module to configure a RADIUS server.
2. Use the radius component in the ltm auth module to create a RADIUS configuration object that references the RADIUS server you created in Step 1.
3. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:
  - a. For the configuration option, specify the RADIUS configuration object that you created in Step 2.
  - b. For the defaults-from option, specify a parent profile (either the default RADIUS profile named radius or another custom profile that you created).

#### EXAMPLES

```

create radius my_radius_auth servers add { myradiusserver }

Creates a RADIUS configuration object named my_radius_auth.

delete radius my_radius_auth

Deletes the RADIUS configuration object named my_radius_auth.

```

#### OPTIONS

**accounting-bug**  
Enables or disables validation of the accounting response vector. This option is necessary only on older servers. The default value is disabled.

**client-id**  
Sends a NAS-Identifier RADIUS attribute with string bar. If you do not specify a value for the client-id option, the system uses the pluggable authentication module (PAM) service type. You can disable this feature by specifying a blank client ID.

**debug**  
Enables or disables syslog-ng debugging information at LOG DEBUG level. F5 Networks does not recommend this option for normal use. The default value is disabled.

**description**  
User defined description.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**retries**  
Specifies the number of authentication retries that the Local Traffic Manager allows before authentication fails. The default value is 3.

**service-type**  
Specifies the type of service used for the RADIUS server. The default is default, which behaves as authenticate-only.

**servers**  
Specifies the hostnames or IP addresses of the RADIUS servers that the BIG-IP Local Traffic Manager uses to obtain authentication data.

## ltm auth ssl-cc-ldap

NAME

ssl-cc-ldap - Configures an SSL client certificate configuration object for remote SSL-based LDAP authorization for client traffic passing through the traffic management system.

MODULE

ltm auth

SYNTAX

Configure the ssl-cc-ldap component within the ltm auth module using the syntax shown in the following sections.

CREATE/MODIFY

```
create ssl-cc-ldap [name]
modify ssl-cc-ldap [name]
options:
  admin-dn [ [name] | none]
  admin-password [none | [password] ]
  cache-size [integer]
  cache-timeout [integer]
  certmap-base [none | [search base] ]
  certmap-key [ [name] | none]
  certmap-user-serial [no | yes]
  description [string]
  group-base [none | [search base] ]
  group-key [ [name] | none]
  group-member-key [ [name] | none]
  role-key [ [name] | none]
  search-type [cert | certmap | user]
  secure [no | yes]
  servers
    [add | delete | none | replace-all-with] {
  [ip address ... ]
    }
  user-base [none | [search base] ]
  user-class [ [class] | none]
  user-key [ [key] | none]
  valid-groups
    [add | delete | replace-all-with] {
  [group ... ]
    }
  valid-groups none
  valid-roles
    [add | delete | replace-all-with] {
  [role ... ]
    }
  valid-roles none

options:
  all-properties
  non-default-properties
```

DISPLAY

```
list ssl-cc-ldap
list ssl-cc-ldap [ [ [name] | [glob] | [regex] ] ... ]
show running-config ssl-cc-ldap
show running-config ssl-cc-ldap
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete ssl-cc-ldap [name]
```

DESCRIPTION

You can use the ssl-cc-ldap component to configure SSL client certificate-based remote LDAP authorization for client traffic passing through the traffic management system.

To configure this type of authentication module and create a configuration object:

1. Use the ssl-cc-ldap component in the ltm auth module to create an SSL client certificate LDAP configuration object.
2. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:
  - a. For the configuration option, specify the configuration object that you created in Step 1.
  - b. For the defaults-from option, specify a parent profile (either the default profile named ssl\_cc\_ldap or another custom profile that you created).

## OPTIONS

### admin-dn

Specifies the distinguished name of an account to which to bind to perform searches. This search account is a read-only account used to do searches. The admin account can also be used as the search account. If no admin DN is specified, then no bind is attempted.

This option is required only when an LDAP database does not allow anonymous searches. The default value is none.

### admin-password

Specifies the password for the admin account. See admin-dn above. The default value is none.

### cache-size

Specifies the maximum size, in bytes, allowed for the SSL session cache. Setting this option to 0 (zero) disallows SSL session caching. The default value is 20000 bytes (20KB).

### cache-timeout

Specifies the number of usable lifetime seconds of negotiable SSL session IDs. When this time expires, a client must negotiate a new session. The default value is 300 seconds.

### certmap-base

Specifies the search base for the subtree used by the certmap search method. A typical search base is: ou=people,dc=company,dc=com. The default value is none.

### certmap-key

Specifies the name of the certificate map that the certmap search method uses. This name is found in the LDAP database. The default value is none.

### certmap-user-serial

Specifies whether the system uses the client certificate's subject or serial number (in conjunction with the certificate's issuer) when trying to match an entry in the certificate map subtree.

A value of yes uses the serial number. A value of no uses the subject. The default value is no.

### description

User defined description.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

### group-base

Specifies the search base for the subtree used by group searches. Use this option only when specifying the valid-groups option. The typical search base is similar to: ou=groups,dc=company,dc=com. The default value is none.

### group-key

Specifies the name of the attribute in the LDAP database that specifies the group name in the group subtree. An example of a typical key is cn (common name for the group). The default value is none.

### group-member-key

Specifies the name of the attribute in the LDAP database that specifies members (DNs) of a group. A typical key is member. The default value is none.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

### partition

Displays the administrative partition within which the component resides.

### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

### role-key

Specifies the name of the attribute in the LDAP database that specifies a user's authorization roles. Use this option only when specifying the valid-roles option. A typical role key is authorizationRole. The default value is none.

### search

Specifies the type of LDAP search that is performed based on the client's certificate. Possible values are:

**cert** Searches for the exact certificate.

### certmap

Searches for a user by matching the certificate issuer and the certificate serial number or certificate.

user Searches for a user based on the common name found in the certificate. This is the default value.

#### secure

Specifies whether the system attempts to use secure LDAP (LDAP over SSL). The alternative to using secure LDAP is to use insecure (clear text) LDAP. Secure LDAP is a consideration when the connection between the BIG-IP system and the LDAP server cannot be trusted. The default value is no.

#### servers

Specifies a list of LDAP servers you want to search. You must specify a server when you create an SSL client certificate configuration object.

#### user-base

Specifies the search base for the subtree used when you select for the search option either of the values user or cert. A typical search base is: ou=people,dc=company,dc=com. You must specify a user base when you create an SSL client certificate configuration object. The default value is none.

#### user-class

Specifies the object class in the LDAP database to which the user must belong to be authenticated. The default value is none.

#### user-key

Specifies the key that denotes a user ID in the LDAP database (for example, the common key for the user option is uid). You must specify a user key when you create an SSL client certificate configuration object.

#### valid-groups

Specifies a space-delimited list of the names of groups to which the client must belong in order to be authorized (matches against the group key in the group subtree). The client needs to be a member of only one of the groups in the list. The default value is none.

#### valid-roles

Specifies a space-delimited list of the valid roles that clients must have to be authorized. The default value is none.

#### SEE ALSO

create, delete, edit, glob, list, ltm auth profile, ltm virtual, modify, regex, show, tmsh

## ltm auth ssl-crl dp

#### NAME

ssl-crl dp - Configures a Secure Socket Layer (SSL) Certificate Revocation List Distribution Point (CRLDP) configuration object for implementing SSL CRLDP to manage certificate revocation.

#### MODULE

ltm auth

#### SYNTAX

Configure the ssl-crl dp component within the ltm auth module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create ssl-crl dp [name]
modify ssl-crl dp [name]
```

##### options:

```
cache-timeout [integer]
connection-timeout [integer]
description [string]
```

##### servers

```
[add | delete | replace-all-with] {
[ip address ... ]
}
```

```
servers [default | none]
update-interval [integer]
use-issuer [disabled | enabled]
```

```
edit ssl-crl dp [ [name] | [glob] | [regex] ] ... ]
options:
```

all-properties  
non-default-properties

#### DISPLAY

```
list ssl-crl dp
list ssl-crl dp [ [ [name] | [glob] | [regex] ] ... ]
show running-config ssl-crl dp
show running-config ssl-crl dp
  [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

#### DELETE

```
delete ssl-crl dp [name]
```

#### DESCRIPTION

CRLDP authentication is a mechanism for checking certificate revocation status for client connections passing through the system. This module is useful when your authentication data is stored on a remote CRLDP server.

To implement a CRLDP authentication module and create an SSL CRLDP configuration object:

1. Use the `crl dp-server` component, in the `ltm auth` module, to create a CRLDP server.
2. Use the `ssl-crl dp` component in the `ltm auth` module to configure a CRLDP configuration object that references the server you created in Step 1.
3. Use the profile component in the `ltm auth` module to create an authentication profile in which you specify the following options:
  - a. For the configuration option, specify the SSL CRLDP configuration object that you created in Step 2.
  - b. For the `defaults-from` option, specify a parent profile (either the default profile named `ssl_crl dp` or another custom profile that you created).

#### EXAMPLES

```
create ssl-crl dp my_auth_ssl-crl dp
```

Creates an SSL CRLDP configuration object named `my_auth_ssl-crl dp`.

```
delete ssl-crl dp my_auth_ssl-crl dp
```

Deletes the SSL CRLDP configuration object named `my_auth_ssl-crl dp`.

#### OPTIONS

`cache-timeout`  
Specifies the number of seconds that CRLs are cached. The default value is 86400 (24 hours).

`connection-timeout`  
Specifies the number of seconds before the connection times out. The default value is 15.

`description`  
User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`  
Displays the administrative partition within which the component resides.

`regex`  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`servers`  
Specifies a host name or IP address for the secure CRLDP server. This option is required. The default value is none.

`update-interval`  
Specifies an update interval for CRL distribution points that ensures that CRL status is checked at regular intervals, regardless of the CRL timeout value. This helps to prevent CRL information from becoming outdated before the BIG-IP system checks the status of a certificate. The default value is 0 (zero), which indicates an internal default value is active.

`use-issuer`  
Specifies whether the system extracts the CRL distribution point from the client certificate. The default value is disabled.

#### SEE ALSO

`create`, `delete`, `edit`, `glob`, `list`, `ltm auth profile`, `ltm auth crl dp-server`, `ltm virtual`, `modify`, `regex`, `show`, `tmsh`

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## ltm auth ssl-ocsp

### NAME

ssl-ocsp - Configures OCSF authentication for client traffic passing through the traffic management system.

### MODULE

ltm auth

### SYNTAX

Configure the ssl-ocsp component within the ltm auth module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create ssl-ocsp [name]
modify ssl-ocsp [name]
  options:
    description [string]
    responders
      [add | delete | replace-all-with] {
[name]...
      }
    responders [default | none]

edit ssl-ocsp [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
```

#### DISPLAY

```
list ssl-ocsp
list ssl-ocsp [ [ [name] | [glob] | [regex] ] ... ]
show running-config ssl-ocsp
show running-config ssl-ocsp
  [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition
```

#### DELETE

```
delete ssl-ocsp [name]
```

### DESCRIPTION

Online Certificate Status Protocol (OCSP) is an industry-standard protocol that offers an alternative to a certificate revocation list when using public-key technology. To implement an SSL OCSP authentication module, you must create the following objects: one or more OCSP responder objects, an SSL OCSP configuration object, and an SSL OCSP profile.

To implement an SSL OCSP authentication module and create an SSL OCSP configuration object:

1. Use the ocsf-responder component in the ltm auth module to configure an OCSP responder object.
2. Use the ssl-ocsp component in the ltm auth module to configure an SSL OCSP configuration object to which you add the OCSP responder object that you created in Step 1.
3. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:
  - a. For the configuration option, specify the SSL OCSP configuration object that you created in Step 2.
  - b. For the defaults-from option, specify a parent profile (either the default OCSP Responder profile named ssl\_ocsp or another custom profile that you created).

### EXAMPLES

```
create ssl-ocsp my_auth_ssl-ocsp
```

Creates an SSL OCSP configuration object named my\_auth\_ssl-ocsp.

```
delete ssl-ocsp my_auth_ssl-ocsp
```

Deletes the SSL OCSP configuration object named my\_auth\_ssl-ocsp.

### OPTIONS

description  
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

responders  
Specifies a list of OSCP responders that you configured using the oosp-responder component in the ltm auth module.

SEE ALSO

create, delete, edit, glob, list, ltm auth profile, ltm auth oosp-responder, ltm virtual, modify, regex, show, tmsh

## ltm auth tacacs

NAME  
tacacs - Configures a TACACS+ configuration component for implementing remote TACACS+-based client authentication.

MODULE  
ltm auth

SYNTAX  
Configure the tacacs component within the ltm auth module using the syntax shown in the following sections.

```
CREATE/MODIFY
create tacacs [name]
modify tacacs [name]
options:
  accounting [send-to-all-servers | send-to-first-server]
  authentication [use-all-servers | use-first-server]
  debug [disabled | enabled]
  description [string]
  encryption [disabled | enabled]
  protocol [none | [protocol] ]
  secret [ "[string]" ]
  servers
    [add | delete | replace-all-with] {
    [ [hostname[:port]] | [ip address[:port]] ] ... ]
    }
  service [ [name] | none ] ]

edit tacacs [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list tacacs
list tacacs [ [ [name] | [glob] | [regex] ] ... ]
show running-config tacacs
show running-config tacacs [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete tacacs [name]
```

DESCRIPTION

Using a TACACS+ configuration object and profile, you can implement the TACACS+ authentication module as the mechanism for authenticating client connections passing through the BIG-IP Local Traffic Manager system. You use this module when your authentication data is stored on a remote TACACS+ server. In this case, client credentials are based on basic HTTP authentication (that is, user name and password).

To implement a TACACS+ authentication module and create a TACACS configuration object:

1. Use the tacacs component in the ltm auth module to configure a

TACACS+ configuration object.

2. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:
  - a. For the configuration option, specify the TACACS+ configuration object that you created in Step 1.
  - b. For the defaults-from option, specify a parent profile (either the default TACACS+ profile named tacacs or another custom profile that you created).

#### EXAMPLES

```
create tacacs my_tacacs_auth secret "This is the secret" servers add
{my_tacacs_server} encryption enabled
```

Enables encryption for TACACS+ packets.

```
create tacacs my_tacacs_auth secret "This is the secret" servers add {
my_tacacs_server1 my_tacacs_server2 } accounting send-to-all-servers
```

Provides the ability to send accounting start and stop packets to all servers

#### OPTIONS

accounting

If multiple TACACS+ servers are defined and pluggable authentication module (PAM) session accounting is available, specifies where the system sends accounting start and stop packets. Possible values are:

send-to-all-servers

Sends to all servers.

send-to-first-server

Sends to the first available server.

authentication

Specifies when to use the secret key supplied for the secret option. This option is required. The options are:

use-all-servers

Use the secret key with all servers.

use-first-server

Use the secret key with the first available server.

debug

Enables syslog-ng debugging information at LOG DEBUG level. F5 Networks does not recommend this option for normal use. The default value is disabled.

description

User defined description.

encryption

Enables or disables encryption of TACACS+ packets. F5 Networks recommends this option for normal use. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

protocol

Specifies the protocol associated with the value specified in the service option, which is a subset of the associated service being used for client authorization or system accounting.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Sets the secret key used to encrypt and decrypt packets sent or received from the server. This option is required.

servers

Specifies the host name or IPv4 address of the TACACS+ server. For each server, a port may optionally be specified in the format hostname:port or IPv4:port. If no port is specified, the default port 49 is used. This option is required.

service

Specifies the name of the service that the user is requesting to be authenticated to use. Identifying the service enables the TACACS+ server to behave differently for different types of authentication requests. This option is required.

#### SEE ALSO

create, delete, edit, glob, list, ltm auth profile, ltm virtual, modify, regex, show, tmsh,

#### COPYRIGHT

## ltm cipher group

**NAME**  
group - Configures a cipher group.

**MODULE**  
ltm cipher

**SYNTAX**  
Configure the group component within the cipher module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create group [name]  
modify group [name]  
options:  
allow { add rule1 [ rule2... ] }  
description [string]  
exclude { add rule3 [ rule4... ] }  
require { add rule5 [ rule6... ] }

edit group [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list group  
list group [ [ [name] | [glob] | [regex] ] ... ]  
show group [ [ [name] | [glob] | [regex] ] ... ]

**DELETE**  
delete group [all | [name]]  
options:  
recursive

**DESCRIPTION**  
You can use the group component to create, modify, or delete a custom cipher group, or display a custom cipher group.  
  
Cipher groups are contain sets of cipher rules and are attached to client-ssl or server-ssl profiles.

**EXAMPLES**  
create group my\_group { allow add { f5-default } }  
  
Creates a group named my\_group with a single allowed rule, f5-default.

**OPTIONS**  
allow  
Specifies a list of rules that are allowed in this group.  
  
description  
User defined description.  
  
exclude  
Specifies a list of rules that are excluded from this group.  
  
require  
Specifies a list of rules that are required for this group. The operation is the intersection of allow and require after all excluded rules have been removed.

**SEE ALSO**  
create, delete, edit, glob, list, ltm virtual, modify, mv, regex, reset-stats, show, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

---

## ltm cipher rule

**NAME**  
rule - Configures a cipher rule.

**MODULE**  
ltm cipher

**SYNTAX**  
Configure the rule component within the cipher module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create rule [name]  
modify rule [name]  
options:  
ciphers [string]  
description [string]

edit rule [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list rule  
list rule [ [ [name] | [glob] | [regex] ] ... ]  
show rule [ [ [name] | [glob] | [regex] ] ... ]

**DELETE**  
delete rule [all | [name]]  
options:  
recursive

**DESCRIPTION**  
You can use the rule component to create, modify, or delete a custom cipher rule, or display a custom cipher rule.  
  
Cipher rules are gathered into cipher groups and attached to client-ssl or server-ssl profiles.

**EXAMPLES**  
create rule my\_rule cipher "default"  
  
Creates a rule named my\_rule with a cipher string "default".

**OPTIONS**  
cipher rule  
Specifies the OpenSSL compatible cipher string.  
  
description  
User defined description.

**SEE ALSO**  
create, delete, edit, glob, list, ltm virtual, modify, mv, regex, reset-stats, show, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.  
  
F5 Networks and BIG-IP (c) Copyright 2016. All rights reserved.

**BIG-IP**      2016-03-31      ltm cipher rule(1)

---

## ltm classification application

**NAME**  
application - Configures a custom classification application.

**MODULE**  
ltm classification

**SYNTAX**  
Configure the application within the ltm classification module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create application [name]  
options:

```

app-service [[string] | none]
description [string]
application-id [integer]
category [name]

modify application [name]
options:
  app-service [[string] | none]
  description [string]
  category [name]

edit application [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list application
list application [ [all] | [name] ]
show running-config application
show running-config application [ [all] | [name] ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete application [name]

```

Note: All referring classification-filters (to this application) need to be deleted first; otherwise an error will be reported. Predefined applications cannot be deleted.

#### DESCRIPTION

You can use the application component to create, modify, delete, and display classification application.

#### EXAMPLES

```

create application my_app { application-id 8192 category my_cat }

Creates a new application named my_app.

modify application my_app { category Web description "My description."
}

Modify an application named my_app.

list application

Displays all created applications.

delete application my_app

Deletes the application named my_app.

```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
User defined description.

**application-id**  
Identifies the application. This is set during creation and cannot be changed. Identifiers must be unique across predefined and user-defined applications. Predefined application-ids must be in numeric range [0, 8192), and user defined application-ids must be in numeric range [8192, 16384).

**category**  
Refers to classification category. The referred category [name] should exist already; otherwise an error will be reported.

#### SEE ALSO

create, modify, delete, list, show, tmsh, ltm classification

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2012-2013, 2016. All rights reserved.

## ltm classification category

**NAME**  
category - Configures a custom classification category.

**MODULE**  
ltm classification

**SYNTAX**  
Configure the category within the ltm classification module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create category [name]  
options:  
app-service [[string] | none]  
description [string]

modify category [name]  
options:  
app-service [[string] | none]  
description [string]

edit category [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list category  
list category [ [all] | [name] ]  
show running-config category  
show running-config category [ [all] | [name] ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DELETE**  
delete category [name]

Note: All referring applications/classification-filters (to this category) need to be deleted first; otherwise an error will be reported. Predefined categories cannot be deleted.

**DESCRIPTION**  
You can use the category component to create, modify, delete, and display classification category.

**EXAMPLES**  
create category my\_cat  
Creates a new category named my\_cat.  
modify category my\_cat { description "My description." }  
Modify a category named my\_cat.  
list category  
Displays all created categories.  
delete category my\_cat  
Deletes the category named my\_cat.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
description  
User defined description.

**SEE ALSO**  
create, modify, delete, list, show, tmsh, ltm classification

**COPYRIGHT**

## ltm classification ce

**NAME**  
CE - Classification Engine configuration.

**MODULE**  
ltm classification

**SYNTAX**  
Configure the Classification Engine settings (AKA preset) within the ltm classification module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create ce [name]  
modify ce [name]  
options:  
  app-service [[string] | none]  
  allow-reclassification [on | off]  
  analyze-dns [on | off]  
  analyze-ssl-serverside [on | off]  
  flow-bundling [on | off]  
  cache-results [on | off]  
  policies [add | delete | default | replace-all-with | none]

**DISPLAY**  
list ce [ name ]  
show running-config ce [name]  
options:  
  all-properties  
  non-default-properties  
  one-line

**DELETE**  
delete ce [name]

**DESCRIPTION**  
Use this command to create, modify, display, or delete an Classification Engine configuration.

**EXAMPLES**  
create ce my\_ce { allow-reclassification on flow-bundling on cache-results off }  
  
Creates a new Classification Engine configuration named my\_ce.  
  
modify ce my\_ce { cache-results on allow-reclassification off }  
  
Turn Cache Results on and turn flow reclassification off on my\_ce preset  
  
list ce  
  
Displays all Classification Engines configurations.  
  
delete ce my\_ce  
  
Deletes the Classification Engine configuration named my\_ce.

**OPTIONS**

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
User defined description.

**allow-reclassification**  
Specifies that connection ("flow") allowed to be reclassified, i.e. classification result could be changed.

**analyze-dns**  
Allows classification engine to perform extended analysis of DNS traffic providing extended classification result.

**analyze-ssl-serverside**  
Enables classification engine to process SSL Server Side Hello to inspect ALPN (mostly for HTTP2 / SPDY subclassification).

**flow-bundling**  
Enables / disables flow correlation mechanism (e.g. FTP and FTP-data protocols).

**cache-results**  
Enables / Disables classification result caching.

**policies**  
Specifies a LTM policy that you have configured previously, if you want to configure custom signatures.

**SEE ALSO**  
create, modify, delete, list, show, tmsh, ltm profile classification, ltm policy

## ltm classification signature-definition

**NAME**  
signature-definition - Configure status for classification signature updates.

**MODULE**  
ltm classification

**SYNTAX**  
Configure the signature-definition component within the ltm classification module using the syntax in the following sections.

**DISPLAY**  
list signature-definition  
list signature-definition [ [name] | [glob] | [regex] ]  
options:  
all-properties  
non-default-properties  
one-line  
recursive  
last-attempt-automatic-mode [enabled | disabled]  
last-attempt-datetime [date]  
last-attempt-user [string]  
last-update-automatic-mode [enabled | disabled]  
last-update-datetime [date]  
last-update-user [string]  
message [string]  
progress-status [none | success | failure | in-progress]

**DESCRIPTION**  
You can use the signature-definition component to configure the status for classification signature updates.

**EXAMPLES**  
list signature-definition  
  
Displays classification signature update status configuration.

**OPTIONS**  
last-attempt-automatic-mode  
Indicates whether the last attempt to update the signature file was done manually or automatically by the system.  
  
last-attempt-datetime  
Indicates the date and time of the last attempt to update the signature file.  
  
last-attempt-user  
Indicates the user who is the last one to attempt to update the signature file.  
  
last-update-automatic-mode  
Indicates whether the last successful signature file update was done manually or automatically by the system. The value of the last-update-automatic-mode may be different from the value of the last-attempt-automatic-mode if the last update attempt fails.  
  
last-update-datetime  
Indicates the date and time of the last successful signature file update. The value of the last-update-datetime is different from the value of the last-attempt-datetime if the last update attempt fails.  
  
last-update-user  
Indicates the user who did the last successful signature file update. The value of the last-update-user may be different from the value of the last-attempt-user if the last update attempt fails.  
  
message  
Indicates the error message when it fails to attempt to update the signature file.  
  
progress-status  
Indicates the progress status when attempting to update the signature file. The options are none, success, failure, and in-progress.

## ltm classification signature-update-schedule

#### NAME

signature-update-schedule - Configure schedule for classification signature updates.

#### MODULE

ltm classification

#### SYNTAX

Configure the signature-update-schedule component within the ltm classification module using the syntax in the following sections.

#### MODIFY

```
modify signature-update-schedule [name]
options:
  [auto-update-enabled | auto-update-disabled]
  auto-update-interval [daily | weekly | monthly]
```

```
edit signature-update-schedule [name]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list signature-update-schedule
list signature-update-schedule [ [name] | [glob] | [regex] ]
options:
  all-properties
  non-default-properties
  one-line
  recursive
```

#### DESCRIPTION

You can use the signature-update-schedule component to configure schedule for classification signature updates.

#### EXAMPLES

```
list signature-update-schedule
```

Displays classification signature update schedule configuration.

```
modify signature-update-schedule auto-update-enabled auto-update-
interval daily
```

Updates the scheduler for classification signature updates to run once a day.

```
modify signature-update-schedule auto-update-disabled
```

Disables the scheduler and allows signatures to update via the browser-based Configuration utility only.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### auto-update-disabled

Specifies that the updates scheduler is disabled. The user can update the classification signatures using the browser-based BIG-IP Configuration utility.

##### auto-update-enabled

Specifies that the updates scheduler is enabled.

##### auto-update-interval

Specifies the auto-update frequency for classification signatures. This attribute will only apply in case auto update is enabled. The default value is weekly.

## ltm classification signature-version

**NAME**  
signature-version - Display classification signature version.

**MODULE**  
ltm classification

**SYNTAX**  
Display the signature-version component within the ltm classification module using the syntax in the following sections.

**DISPLAY**  
list signature-version  
options:  
all-properties  
non-default-properties  
one-line  
recursive

**DESCRIPTION**  
You can use the signature-version component to display versions in classification signature updates.

**EXAMPLES**  
list signature-version  
  
Displays classification signature version configuration.

**OPTIONS**

**cec-filename**  
Indicates the cec library filename in the last updated classification signature.

**cec-version**  
Indicates the cec library version in the last updated classification signature.

**classification-version**  
Indicates the classification version in the last updated classification signature.

**conf-filename**  
Indicates the configuration filename in the last updated classification signature.

**conf-version**  
Indicates the configuration version in the last updated classification signature.

**im-version**  
Indicates the im version in the last updated classification signature.

**qm-protocols-filename**  
Indicates the qosmos protocols filename in the last updated classification signature.

**qm-protocols-version**  
Indicates the qosmos protocols version in the last updated classification signature.

**update-time**  
Indicates the update time in the last updated classification signature.

**SEE ALSO**  
list, tmsh

## Itn classification signatures

**NAME**  
signatures - Manages classification engine signatures.

**MODULE**  
ltm classification

**SYNTAX**  
load signatures file [filename]  
Loads classification signatures from a signature update file.  
load signatures default  
Resets classification engine and signatures to the factory defaults.

**DESCRIPTION**  
You can use the signatures component to load the classification signatures from a file. Only admins can run this command.  
You can obtain the latest signature update file (\*.im) (if one is available) from <http://downloads.f5.com>.  
For the filename, if no absolute path is specified, the default path /var/libdata/dpi/im/ is used.  
Use load signatures default to discard and remove any installed upgrades and reset the classification engine and signatures to factory defaults. No user-created signatures will be deleted. By keeping the \*.im file, you will be able to re-apply the update any time later using the load signatures file command.

**EXAMPLES**  
load signatures file my\_sig\_file.im  
Loads signatures from file "my\_sig\_file.im" under the folder: /var/libdata/dpi/im/.  
load signatures file /var/tmp/new\_sig\_file.im  
Loads signatures from file "new\_sig\_file.im" under the folder: /var/tmp/.

## Itn classification stats application

**NAME**  
application - Displays and resets classified application statistics.

**MODULE**  
ltm classification stats

**SYNTAX**  
Display statistics for the application component within the ltm classification stats module using the syntax in the following section.  
**DISPLAY**  
show application  
option:  
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

**DESCRIPTION**  
You can use the application component to display classification

application statistics. The statistics details are described below:

**Name** Specifies the number of the classified application.

**Count**

Specifies a number of classified flows or transactions (in transaction mode) to specific application.

**LTM Policy**

Specifies the number of classification decisions by LTM Policy (cpm).

**Classification Engine**

Specifies the number of classification decisions by classification engine (CEC).

**Qosmos iXengine**

Specifies the number of classification decisions by Qosmos iXengine (ixe).

**Cache**

Specifies the number of classification decisions by Results Cache.

**URI Parameter**

Specifies the number of classification decisions by evaluating HTTP URI query string classification parameter.

**HTTP Header**

Specifies the number of classification decisions by using HTTP classification header.

**iRule**

Specifies the number of classification decisions by iRule.

**Bytes in**

Specifies the bytes in of the classified application.

**Bytes out**

Specifies the bytes out of the classified application.

**Packets in**

Specifies the packets in of the classified application.

**Packets out**

Specifies the packets out of the classified application.

You can reset the classification application statistics using reset-stats command.

#### EXAMPLES

show application

Displays the classified application statistics.

reset-stats application

Resets the classified application statistics.

#### OPTIONS

For information about the options that you can use with the command show, see help show.

#### SEE ALSO

reset-stats, show, tmsh

## ltm classification stats url-category

#### NAME

url-category - Displays and resets classified url-category statistics.

#### MODULE

ltm classification stats

#### SYNTAX

Display statistics for the url-category component within the ltm classification stats module using the syntax in the following section.

#### DISPLAY

show url-category

option:  
(default | exa | gig | kil | meg | peta | raw | tera | yotta |  
zetta)

#### DESCRIPTION

You can use the url-category component to display classification url-category statistics. The statistics details are described below:

Name Specifies the number of the classified url-category.

#### Count

Specifies a number of classified flows or transactions (in transaction mode) to specific url-category.

#### iRule

Specifies the number of url-categorization decision by iRule.

#### Customdb

Specifies the number of url-categorization decision by custom url database.

wrdb Specifies the number of url-categorization decision by webroot database.

#### Bytes in

Specifies the bytes in of the classified url-category.

#### Bytes out

Specifies the bytes out of the classified url-category.

#### Packets in

Specifies the packets in of the classified url-category.

#### Packets out

Specifies the packets out of the classified url-category.

You can reset the classification url-category statistics using reset-stats command.

#### EXAMPLES

```
show url-category
```

Displays the classified url-category statistics.

```
reset-stats url-category
```

Resets the classified url-category statistics.

#### OPTIONS

For information about the options that you can use with the command show, see help show.

#### SEE ALSO

reset-stats, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## ltm classification stats urlcat-cloud

#### NAME

urlcat-cloud - Displays and resets URL category cloud lookup statistics.

#### MODULE

ltm classification stats

#### SYNTAX

Display statistics for the url category lookup within the ltm classification stats module using the syntax in the following section.

#### DISPLAY

```
show urlcat-cloud
```

#### option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta |  
zetta)

#### DESCRIPTION

You can use the urlcat-cloud component to display URL category cloud lookup statistics. The statistics details are described below:

Lookups

Specifies the number of URL look-up happened in cloud cache.

#### Cloud Query

Specifies the number of queries sent to the cloud. This happens if the entry is not present in cloud cache.

#### Cloud Response

Specifies the number of responses received from the cloud lookup. Each TMM gets a response. Hence the total is multiplied by TMM count.

#### Unknown

Specifies the number of unknown responses from the cloud. This means the webroot cloud does not know about the queried URL.

#### Entries

Specifies the number of entries present in the cloud cache. Each TMM has a copy of the cache. This number is cumulative and reset-stats does not reset this number.

Add Specifies the number of entries added to the cloud cache. If the cache is not cleared "adds" and "entries" must be the same.

#### Delete

Specifies the number of entries cleared from the cloud cache.

#### Queue Full

Specifies the number of instances that tmm could not send out a URL query.

You can reset the URL category cloud lookup statistics using reset-stats command. Reset-stats does not reset the number of entries in the cache.

#### EXAMPLES

```
show urlcat-cloud
```

Displays the URL category cloud lookup statistics.

```
reset-stats urlcat-cloud
```

Resets the URL category cloud lookup statistics, except the number of entries in the cache.

#### OPTIONS

For information about the options that you can use with the command show, see help show.

#### SEE ALSO

reset-stats, show, tmsh

#### COPYRIGHT

## ltm classification update-signatures

#### NAME

update-signatures - Run automatic update for classification signatures.

#### MODULE

ltm classification

#### SYNTAX

Run the update-signatures component within the ltm classification module using the syntax in the following sections:

#### RUN

```
run update-signatures
```

#### DESCRIPTION

You can use the update-signatures component to update the classification signatures from F5 download server. Only admins can run this command.

#### SEE ALSO

ltm classification signature-update-schedule, run, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## ltm classification url-cat-policy

**NAME**  
url-cat-policy - Configures an ltm classification url-cat policy. It's comprised of list of urlldb feed lists. This is deprecated since version 13.0.0. Instead of creating url-cat-policy and attaching a feedlist to it, enable the feedlist directly.

**MODULE**  
ltm classification

**SYNTAX**  
Configure the url-cat-policy component within the ltm classification module using the syntax in the following sections.

```
CREATE/MODIFY
create url-cat-policy [name]
modify url-cat-policy [name]
options:
  app-service [name]
  description [string]
  feed-lists [add | delete ] { [name] }

edit url-cat-policy
options:
  all-properties
  non-default-properties

DISPLAY
list url-cat-policy [ [ [name] ] ]
show running-config url-cat-policy
show running-config url-cat-policy [ [ [name] ] ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive

DISPLAY
delete url-cat-policy [name]
```

**DESCRIPTION**  
You can use the url-cat-policy component to configure a shareable and reusable url categorization database feed coming from local files or download feeds. The url-cat-policy can then be enforced on the configuration object of the type: ltm virtual.

**EXAMPLES**  
create ltm classification url-cat-policy POL1  
feed-lists add { FL1 }  
description none }  
  
Creates a url-cat-policy POL1 with urlldb feeds from FL1 feed lists.  
  
list url-cat-policy  
  
Displays the current list of url-categorization policies contents.

**OPTIONS**  
app-service  
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.  
  
description  
User defined description.  
  
partition  
Displays the administrative partition within which the component resides.  
  
feed-lists  
Adds, deletes, or replaces a feed list. Specifies a list of feed lists (see ltm classification urlldb-feed-list) against which the packet will be compared.

**SEE ALSO**  
create, edit, list, modify, ltm classification urlldb-feed-list, tmsh

**COPYRIGHT**

## ltm classification url-category

**NAME**  
url-category - Configures a custom URL category.

**MODULE**  
ltm classification

**SYNTAX**  
Configure the url-category within the ltm classification module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create url-category [name]  
options:  
app-service [[string] | none]  
description [string]  
url-category-id [integer]  
irule-event [enabled | disabled]

modify url-category [name]  
options:  
app-service [[string] | none]  
description [string]  
irule-event [enabled | disabled]

edit url-category [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list url-category  
list url-category [ [all] | [name] ]  
show running-config url-category  
show running-config url-category [ [all] | [name] ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DELETE**  
delete url-category [name]

Note: All referring url-categorization-filters (to this url-category) need to be deleted first; otherwise an error will be reported. Predefined url-categories cannot be deleted.

**DESCRIPTION**  
You can use the url-category component to create, modify, delete, and display classification url-category.

**EXAMPLES**  
create url-category my\_urlcat { url-category-id 28672 irule-event disabled }  
Creates a new url-category named my\_urlcat.  
modify url-category my\_urlcat { irule-event enabled description "My description." }  
Modify a url-category named my\_urlcat.  
list url-category  
Displays all created categories.  
delete url-category my\_urlcat  
Deletes the url-category named my\_urlcat.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
description  
User defined description.

**url-category-id**  
Identifies the url-category. This is set during creation and cannot be changed. Identifiers must be unique across predefined and user-defined categories. Predefined url-category-ids must be in numeric range [24576, 28671), and user defined url-category-ids must be in numeric range [28672-32768).

**irule-event**  
Indicates if the irule is enabled or disabled in result of the classification engine.

## ltm classification urldb-feed-list

NAME

urldb-feed-list - Configures a feed-list to be used for URLDB file loads. A urldb-feed-list is a list of URL feeds (including local file paths) from where URLDB files are downloaded. These files contain URL categorization information.

MODULE

ltm classification

SYNTAX

Configure the urldb-feed-list component within the ltm classification module using the syntax in the following sections.

CREATE/MODIFY

```
create urldb-feed-list [name]
modify urldb-feed-list [[name] | all]
options:
  default-url-category [name]
  url [string]
  poll-interval [integer]
  user [string]
  password [string]
  app-service [name]
  description [string]
```

```
load urldb-feed-list [[name] | all]
```

DISPLAY

```
list urldb-feed-list [[name] | all | [property]]
show running-config urldb-feed-list [[name] | all | [property]]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

DELETE

```
delete urldb-feed-list [[name] | all]
```

DESCRIPTION

You can use the urldb-feed-list component to define reusable lists of feeds. You can use a feed list in an ltm classification url-cat-policy.

EXAMPLES

```
create urldb-feed-list FL1 { url
file:///shared/images/custom_urldb_1.txt }
```

Creates a new feed list, "FL1" with URL category information in the file specified by url.

OPTIONS

**create**  
Creates a new feed list.

**delete**  
Deletes the feed list that you specify next, in curly braces ({}).

**file**  
DEPRECATED since version 11.7.0. Specifies the file object containing the URLDB information.

**url** Specifies the url to fetch the file containing the URLDB information.

**default-url-category**  
The URL category to be used for all the URLs specified in the URLDB file.

**poll-interval**  
Specifies the time interval in seconds at which the url needs to be polled.

**app-service**  
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

**description**  
User defined description for this feed list.

**partition**  
Displays the administrative partition within which the component resides.

SEE ALSO  
edit, list, modify, ltm classification, tmsh

COPYRIGHT  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03ltm classification urldb-feed-list(1)

---

## ltm classification urldb-file

**NAME**  
urldb-file - Manages a custom URLDB file

**MODULE**  
ltm classification

**SYNTAX**  
List the urldb-file component within the ltm classification module using the syntax in the following sections.

**CREATE**  
create urldb-file [name]  
options:  
source-path [string]  
app-service [name]

**DEPRECATED:** create command is deprecated from version 12.0.0. Though this command is visible, this is not meant to be used by the users. The daemons use it internally.

**DISPLAY**  
list urldb-file [[name] | all | [property]]  
show running-config urldb-file [[name] | all | [property]]  
options:  
all-properties  
one-line  
partition

**DELETE**  
delete urldb-file [[name] | all]

**DEPRECATED:** delete command is deprecated from version 12.0.0. Though this command is visible, this is not meant to be used by the users. The daemons use it internally.

**DESCRIPTION**  
You can use the urldb-file component to create, the custom URLDB file in versions before 11.7.0. The urldb-file is created internally using the URL specified in ltm classification urldb-feed-list in later versions.

**EXAMPLES**  
create urldb-file FILE1 { source-path  
file:/shared/images/custom\_urldb\_1.txt }

Creates a new urldb file object, "FILE1" from the source file /shared/images/custom\_urldb\_1.txt

Create works in versions before 11.7.0. Has been deprecated in later versions

list urldb-file [fileobj-name]

Lists the attributes of urldb file object, "FILE1" from the source file /shared/images/custom\_urldb\_1.txt

#### OPTIONS

create

Creates a new file object for custom urlcat db.

delete

Deletes the file object that you specify next, in curly braces ({}).

source-path

Specifies the location from where the URLDB file object sources the file.

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description for this feed list.

partition

Displays the administrative partition within which the component resides.

#### SEE ALSO

## ltm clientssl-proxy cached-certs

#### NAME

cached-certs - Displays and deletes SSL Forward Proxy cached certificates on the BIG-IP(r) system.

#### MODULE

ltm clientssl-proxy

#### SYNTAX

Use the cached-certs component within the ltm.clientssl-proxy module to manage connections using the following syntax.

##### DISPLAY

show cached-certs

options:

virtual [name]

clientssl-profile [name]

##### DELETE

delete cached-certs

options:

virtual [name]

clientssl-profile [name]

#### DESCRIPTION

You can use the cached-certs component to display or delete SSL Forward Proxy cached certificates based on a specified clientssl profile.

#### OPTIONS

virtual

Specifies the name of the virtual server that you want to display or delete cached certificates from.

clientssl-profile

Specifies the name of the clientssl profile that belongs to the virtual selected.

#### SEE ALSO

delete, show, tmsh

#### COPYRIGHT

## ltm clientssl oosp-stapling-responses

**NAME**  
oosp-stapling-responses - Deletes the cached OOSP responses on the BIG-IP(r) system.

**MODULE**  
ltm clientssl

**SYNTAX**  
Use the oosp-stapling-responses component within the ltm.clientssl module to manage connections using the following syntax.

**DELETE**  
delete oosp-stapling-responses  
options:  
  virtual [name]  
  clientssl-profile [name]

**DESCRIPTION**  
You can use the oosp-stapling-responses component to delete the cached OOSP responses based on a specified clientssl profile.

**OPTIONS**  
virtual  
Specifies the name of the virtual server that you want to display or delete cached certificates from.  
  
clientssl-profile  
Specifies the name of the clientssl profile that belongs to the virtual selected.

**SEE ALSO**  
delete, tmsh

## ltm data-group external

**NAME**  
external - Configures an external class.

**MODULE**  
ltm data-group

**SYNTAX**  
Configure the external data-group within the ltm data-group module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create external [name]  
modify external [name]  
options:  
  app-service [[string] | none]  
  description [string]  
  external-file-name [ [file name] | none]  
  separator [string]  
  source-path [URL]  
  type [integer | ip | string ]

edit external [ [ [name] | [glob] | [regex] ] ... ]

```
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list external
list external [ [ name ] | [ glob ] | [ regex ] ] ... ]
show [name] external-records
show running-config external
show running-config external [ [ name ] | [ glob ] | [ regex ] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

#### DELETE

```
delete external [name]
```

#### DESCRIPTION

Data groups are lists of data that you define and use with iRules(r) operators. External data group records are stored in external files that you manage through the sys file data-group component. Note that external data groups can be very large, which is one reason why the groups are saved to external files. For example, a phone company may store a list of thousands of phone numbers in an external data group.

You should consider using an internal data group when the number of records is expected to be small.

An external data group acquires its type from the associated data-group file, which can be a list of IP addresses, strings, or integers.

External data groups are lists that specify:

- o A data-group file where records are stored
- o A description of the class

There are two ways to configure the external data-group object:

- o Create external data-group object, and then specify the source-path and type of the external-file. In one step the external-file will be created within the sys file data-group module and external data-group within the ltm data-group module.
- o Create an external-file within the sys file data-group module, and then create external data-group within the ltm data-group module. See help sys file data-group for information on creating the data-group file.

#### EXAMPLES

```
create external ext-dg1 external-file-name string.dat description
"created for rule xyz"
Creates an external data group named ext-dg1, with the given
description. The records for the data group are loaded from the
data-group file string.dat previously created in the sys file
data-group component.
```

```
create external ext-dg1 description "created for rule xyz" source-path
http://file-server/data-groups/ip.class type ip
Downloads the data-group file from the given URL into file-store
and creates a data-group file named ext-dg1 within the sys file
data-group module. Creates an external data group named ext-dg1,
with the given description. The records for the data group are
loaded from the data-group file ext-dg1.
```

```
create external ext-dg2 source-path file:/shared/save/Test.dat type
string
Creates a data-group file named ext-dg2 within the sys file data-
group module. Creates an external data group named ext-dg2. The
records for the data group are loaded from the data-group file
ext-dg2.
```

```
modify external ext-dg2 description "created for rule abc" source-path
file:/shared/save/Test2.dat
Downloads the file from the given URL into file-store and updates
the source-path of data-group file referenced by external data
group ext-dg2. Modifies the description of external data group
ext-dg2.
```

```
delete external ext-dg1
Deletes the external data group named ext-dg1. Note: the data-
group file referenced by ext-dg1 is not deleted at this time. If
needed, it should be deleted under sys file data-group component.
```

```
show external ext-dg1 external-records Shows a sorted list of external
data group records. Note: We recommend against displaying data-groups
of over two million records due to control-plane resource constraints.
```

#### OPTIONS

```
app-service
Specifies the name of the application service to which the data
group belongs. The default value is none. Note: If the strict-
updates option is enabled on the application service that owns the
object, you cannot modify or delete the data group. Only the
application service can modify or delete the data group.
```

```
description
User defined description.
```

```
external-file-name
Specifies the data-group file where the records are stored.
```

Note: Only source-path or external-file-name may be specified for external data-group configuration item.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**separator**

Specifies a separator to use when defining the data group. The default value is :=.

**source-path [URL]**

This optional attribute takes a URL.

Note: Only source-path or external-file-name may be specified for external data-group configuration item, for example:

```
source-path http://file-server/data-groups/AUL_1.cls
```

```
source-path https://file-server/data-groups/CNN.x
```

```
source-path  
ftp://username:password@server/data-groups/latest.class
```

```
source-path file://shared/save/Test.dat
```

**type** Specifies the kind of data in the group. This option is acquired from the data group file. If the external data group is created with external-file that was previously created within the sys file data-group module, then type option cannot be modified. If the external data group is created with source-path option, then type should be specified. The value for type could be integer or ip or string.

## ltm data-group internal

**NAME**

internal - Configures an internal class.

**MODULE**

ltm data-group

**SYNTAX**

Configure the internal data-group within the ltm data-group module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create internal [name]
options:
  app-service [[string] | none]
  description [string]
  records [add | delete | modify | replace-all-with] {
    [record key] {
      data [value]
    }
  }
  records none
  type [integer | ip | [string] ]

modify internal [name]
options:
  app-service [[string] | none]
  description [string]
  records [add | delete | modify | replace-all-with] {
    [record key] {
      data [value]
    }
  }
  records none

edit internal [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list internal
list internal [ [ [name] | [glob] | [regex] ] ... ]
show running-config internal
show running-config internal [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

#### DESCRIPTION

Data groups are lists of data that you define and use with iRules(r) operators. Consider using an external data group if the number of records is expected to be large.

The BIG-IP(r) system includes a number of predefined lists that you can use. They are:

- o aol
- o default\_accept\_language
- o images
- o private\_net

The above lists are located in the file /config/profile\_base.conf. When you run the load command, the system loads these lists; however, unless you have modified the lists, the system does not save the lists to the bigip.conf file.

The internal data groups are stored in the bigip.conf file.

Internal data groups can be one of three types:

- o A list of IP addresses
- o A list of strings
- o A list of integers

Strings must be surrounded by quotation marks. Numbers can be either positive or negative. These groups define the type of data in the class, which can be IP addresses, strings, or integers>

#### EXAMPLES

```
create internal MyDG records add { 10.0.0.0 } type ip
```

Creates an internal data group named MyDG that contains a single IP address.

```
create internal DG2 records add { 192.1.1.255 192.2.1.255 192.3.1.255 }
type ip
```

Creates an internal data group named DG2 that contains a list of three network addresses: 192.1.1.0/24, 192.2.1.1/24, and 192.3.1.1/24.

```
create internal MyDG records add { my_key { data my_value } } type
string
```

Creates an internal data group named MyDG that contains a single name/value pair.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the data group belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the data group. Only the application service can modify or delete the data group.

##### description

User defined description.

##### records

Configures the data in the group.

##### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

type Specifies the kind of data in the group. The default value is ip. This option is required by the command create.

#### SEE ALSO

## ltm default-node-monitor

**NAME**  
default-node-monitor - Configures the default node monitor for the Local Traffic Manager.

**MODULE**  
ltm

**SYNTAX**  
Configure the default-node-monitor component within the ltm module using the syntax shown in the following sections.

**CREATE/MODIFY**  
modify default-node-monitor  
options:  
rule [rule syntax]

edit default-node-monitor  
options:  
all-properties

**DISPLAY**  
list default-node-monitor  
show running-config default-node-monitor  
options:  
one-line  
all-properties

**DESCRIPTION**  
You can use the default-node-monitor component to modify the default monitor that the system applies to any node address to which a monitor is not explicitly assigned.

**EXAMPLES**  
modify default-node-monitor rule icmp  
Modifies the global default node monitor to use the rule ICMP.  
list default-node-monitor  
Displays the properties of the global default node monitor.

**OPTIONS**  
rule Specifies the rule that the system applies to any node that has not been assigned a monitor rule. The default value is none.  
You can specify:

- o A single monitor, for example, modify default-node-monitor rule icmp.
- o Multiple monitors, for example, modify default-node-monitor rule icmp and tcp\_echo.
- o A minimum number of monitors, for example, modify default-node-monitor rule min 1 of { icmp and tcp\_echo }.

**SEE ALSO**  
list, ltm node, modify, show, tmsh

## ltm dns analytics global-settings

**NAME**  
global-settings - Configures the global settings of all DNS listeners on the BIG-IP(r) system.

**MODULE**  
ltm dns analytics

**SYNTAX**  
Configure the global-settings DNS listeners within the ltm dns analytics module using the syntax in the following sections.

**MODIFY**  
modify global-settings  
options:  
collect-client-ip [enabled | disabled]  
collect-query-name [enabled | disabled]

**DISPLAY**  
list global-settings  
list global-settings  
options:  
all-properties  
non-default-properties  
one-line

**DESCRIPTION**  
You can use the global-settings component to configure and view information about the global settings of all DNS listeners.

**EXAMPLES**  
list global-settings all-properties  
  
Displays the global settings for the DNS listeners on the BIG-IP system.

**OPTIONS**  
collect-client-ip  
When enabled, the client IP addresses of DNS queries will be collected and stored in analytics database. The default value is enabled.

collect-query-name  
When enabled, the domain names of DNS queries will be collected and stored in analytics database. The default value is enabled.

**SEE ALSO**  
list, modify, tmsh

**COPYRIGHT**

## ltm dns cache global-settings

**NAME**  
global-settings - Configures the global settings of all DNS caches on the BIG-IP(r) system.

**MODULE**  
ltm dns cache

**SYNTAX**  
Configure the global-settings DNS cache component within the ltm dns cache module using the syntax in the following sections.

**CREATE/MODIFY**  
modify global-settings [name]  
options:  
cache-maximum-ttl [integer]  
cache-minimum-ttl [integer]  
resolver-edns-buffer-size [integer]

edit global-settings [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list global-settings  
list global-settings [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line

**DESCRIPTION**  
You can use the global-settings component to configure and view information about the global settings of all DNS caches.

**EXAMPLES**

list global-settings all-properties

Displays the global settings for the DNS caches on the BIG-IP system.

#### OPTIONS

cache-maximum-ttl

Specifies the number of seconds after which you want the BIG-IP system to re-query for resource records. This setting allows the BIG-IP system to re-query for resource records sooner than the owner of the records intended.

cache-minimum-ttl

Specifies the minimum number of seconds you want the BIG-IP system to cache DNS resource records. This setting allows the BIG-IP system to cache resource records longer than the owner of the records intended.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

resolver-edns-buffer-size [integer]

Specifies the number of bytes you want the BIG-IP system to advertise as the EDNS buffer size in UDP queries.

#### SEE ALSO

edit, glob, list, modify, regex, tmsh

## ltm dns cache records key

#### NAME

key - Manages the DNSKEY records in the DNS caches on the BIG-IP(r) system.

#### MODULE

ltm dns cache records

#### SYNTAX

Configure the key component within the ltm dns cache records module using the following syntax.

#### DISPLAY

show key cache [cache name]

#### options:

count-only  
owner [domain name]  
slot [integer]  
tmm [integer]

#### DELETE

delete key cache [cache name]

#### options:

owner [domain name]

#### EXAMPLES

show key cache resolver\_cache

Displays the DNSKEY records in the cache named resolver\_cache.

delete key cache v\_resolver\_cache

Deletes the DNSKEY records from the cache named v\_resolver\_cache.

#### DESCRIPTION

You can use the following options with the key component.

#### OPTIONS

cache name

Specifies a DNS cache name from which to display or delete DNSKEY records. This is a required field.

count-only

For a show command, return only a count of the number of matched records.

**owner**  
Specifies a domain name on which to filter the DNSKEY records in the specified DNS cache for a query or deletion.

**slot** Specifies a slot number on a chassis that contains the specified DNS cache. This is a 1 based index.

**tmm** Specifies the number of the TMM that contains the specified DNS cache. Each tmm has essentially the same entries, so which tmm you choose is arbitrary. Use this option only for debugging. This is a 0 based index. If not specified, a random tmm will be used.

SEE ALSO

delete, show, tmsh

## ltm dns cache records msg

NAME

msg - Manages message records in the DNS caches on the BIG-IP(r) system.

MODULE

ltm dns cache records

SYNTAX

Configure the msg component within the ltm dns cache records module using the following syntax.

DISPLAY

```
show msg cache [cache name]
options:
count-only
qname [domain name]
rcode [integer]
slot [integer]
tmm [integer]
```

DELETE

```
delete msg cache [cache name]
options:
qname [domain name]
rcode [integer]
```

DESCRIPTION

The msg component contains full DNS messages. You can display and delete these messages.

EXAMPLES

```
show msg cache resolver_cache
```

Displays the message records in the DNS cache named resolver\_cache.

```
delete msg cache v_resolver_cache
```

Deletes the message records from the DNS cache named v\_resolver\_cache.

OPTIONS

**cache name**

Specifies a DNS cache name. This is a required field.

**count-only**

For a show command, return only a count of the number of matched records.

**qname**

Specifies a domain name on which to filter the DNS messages in the specified DNS cache for a query or deletion.

**rcode**

Specifies the DNS return code on which to filter DNS messages in the specified DNS cache for a query or deletion.

**slot** Specifies a slot number on a chassis that contains the specified DNS cache. This is a 1 based index.

**tmm** Specifies the number of the TMM that contains the specified DNS cache. Each tmm has essentially the same entries, so which tmm you choose is arbitrary. Use this option only for debugging. This is a 0 based index. If not specified, a random tmm will be used.

SEE ALSO  
delete, show, tmsh

COPYRIGHT

## ltm dns cache records nameserver

**NAME**  
nameserver - Manages the nameserver records in the DNS cache resolvers on the BIG-IP(r) system.

**MODULE**  
ltm dns cache records

**SYNTAX**  
Configure the nameserver component within the ltm dns cache records

**DISPLAY**  
show cache [cache name]  
options:  
address [ip address]  
count-only  
has-edns [yes | no]  
has-lame [yes | no]  
rtt-range [min:max]  
slot [integer]  
tmm [integer]  
ttl-range [min:max]  
zone-name [name]

**DELETE**  
delete cache [cache name]  
options:  
address [ip address]  
has-edns [yes | no]  
has-lame [yes | no]  
rtt-range [min:max]  
ttl-range [min:max]  
zone-name [name]

**DESCRIPTION**  
You can use the nameserver component to display or delete nameserver records from a DNS cache. The maximum number of records returned is 1000; therefore, broad searches may not show all records in the cache.

**EXAMPLES**  
show cache my\_cache zone-name com ttl-range 50:500

Displays the nameserver records, in the DNS cache named my\_cache, with the zone name com, where the TTLs of the records are between 50 and 500.

**OPTIONS**  
address  
Specifies the nameserver records, in the specified DNS cache, to select based on the IP address of the nameserver.

cache name  
Specifies a DNS cache name. This is a required field.

count-only  
For a show command, return only a count of the matched records.

has-edns  
Specifies the nameserver records to select from the specified DNS cache, based on whether the nameserver is EDNS lame. An EDNS lame nameserver does not reply to EDNS queries.

has-lame  
Specifies the nameserver records to select from the specified DNS cache, based on whether the nameserver is lame for one or more items.

rtt-range  
Specifies the nameserver records to select from the specified DNS cache, based on RTTs within the specified range (inclusive). A missing value (:500 or 50:) defaults to the minimum or maximum, respectively.

slot  
Specifies a slot number on a chassis that contains the specified DNS cache. This is a 1 based index.

**tmm** Specifies the number of the TMM that contains the specified DNS cache. Each tmm has essentially the same entries, so which tmm you choose is arbitrary. Use this option only for debugging. This is a 0 based index. If not specified, a random tmm will be used.

**ttl-range**  
Specifies the nameserver records to select from the specified DNS cache, based on TTLs within the specified range (inclusive). A missing value (:500 or 50:) defaults to the minimum or maximum, respectively.

**zone-name**  
Specifies the nameserver records to select from the specified DNS cache, based on the specified zone name.

SEE ALSO

delete, show, tmsh

## ltm dns cache records rrset

NAME

rrset - Manages the RRset records in the DNS cache resolvers on the BIG-IP(r) system.

MODULE

ltm dns cache records

SYNTAX

Configure the rrset component within the ltm dns cache records module using the syntax in the following sections.

DISPLAY

```
show cache [cache name]
options:
  class [IN | CH | HS | ANY]
  count-only
  owner [DNS name]
  slot [integer]
  tmm [integer]
  ttl-range [integer:integer]
  type [A | AAAA | CNAME | NS | PTR | RRSIG | DNSKEY | SOA | TXT | ANY | ... ]
```

DELETE

```
delete cache [cache name]
options:
  class [IN | CH | HS | ANY]
  owner [DNS name]
  ttl-range [integer:integer]
  type [A | AAAA | CNAME | NS | PTR | RRSIG | DNSKEY | SOA | TXT | ANY | ... ]
```

DESCRIPTION

You can use the rrset component to display or delete records in the specified DNS cache. The maximum number of records returned is 1000. Broad searches might not show all records in the cache.

EXAMPLES

```
show cache resCache2 class IN type A ttl-range 20:5000 owner .com

Displays RRset records of type A, class IN, with TTLs between 20 and 5000, and an owner of .com.
```

OPTIONS

**cache name**  
Specifies a DNS cache name. This is a required field.

**class**  
Specifies the class of RRset records to select from the specified DNS cache.

**count-only**  
For a show command, return only a count of the matched records.

**owner**  
Specifies the node on which to filter the RRset records in the specified DNS cache for a query or deletion.

**slot**  
Specifies a slot number on a chassis that contains the specified DNS cache. This is a 1 based index.

**tmm**  
Specifies the number of the TMM that contains the specified DNS

cache. Each tmm has essentially the same entries, so which tmm you choose is arbitrary. Use this option only for debugging. This is a 0 based index. If not specified, a random tmm will be used.

#### ttl-range

Specifies the RRset records to select from the specified DNS cache, based on TTLs within the specified range (inclusive). A missing value (:500 or 50:) defaults to the minimum or maximum, respectively.

type Specifies the RRset records to select from the specified DNS cache, based on the specified type. Most record types are supported.

#### SEE ALSO

## ltm dns cache resolver

#### NAME

resolver - Configures a DNS cache with a resolver on the BIG-IP(r) system.

#### MODULE

ltm dns cache

#### SYNTAX

Configure the resolver DNS cache component within the ltm dns cache module using the syntax in the following sections.

#### CREATE/MODIFY

```
create resolver [name]
modify resolver [name]
options:
  allowed-query-time [integer]
  answer-default-zones [yes | no]
  app-service [[string] | none]
  description [[string] | none]
  forward-zones [add | delete | modify | replace-all-with] {
    [ [zone-name] ] {
options:
nameservers [add | delete | replace-all-with] {
  [ [IPv4address:port] | [IPv6address.port] ]
}
nameservers none
}
forward-zones none
local-zones [ [none] ]
[ { { name [dname] type [type] records [none | add { [RR string] ... } ] } ... } ] ]
max-concurrent-queries [integer]
max-concurrent-tcp [integer]
max-concurrent-udp [integer]
msg-cache-size [integer]
nameserver-cache-count [integer]
randomize-query-name-case [yes | no]
response-policy-zones [add | delete | modify] {
  [zone-name] {
action [nxdomain | walled-garden]
walled-garden [local-zone]
}
}
response-policy-zones none
root-hints {
  { [IP address] ... }
}
route-domain [name]
rrset-cache-size [integer]
rrset-rotate [none | query-id]
unwanted-query-reply-threshold [integer]
use-ipv4 [yes | no]
use-ipv6 [yes | no]
use-tcp [yes | no]
use-udp [yes | no]
```

#### DISPLAY

```
list resolver
list resolver [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
one-line
show resolver
show resolver [name]
```

```
DELETE
delete resolver [name]
```

#### DESCRIPTION

You can use the resolver component to configure and view information about a recursive-resolving DNS cache. A resolver cache performs recursive resolution to fill its cache.

**Important:** When sizing caches, consider the total amount of memory available and how you wish to allocate memory for DNS caching. Note that cache sizing values are per-TMM process; therefore, a platform with eight TMMs consumes the amount of memory set for the RRset cache times eight.

#### EXAMPLES

```
list resolver myCache
```

Displays the properties of the recursive-resolving DNS cache myCache.

```
modify resolver myCache local-zones { { name lz.example.net records add
{ "lz.example.net 60 IN A 127.0.0.1" "www.lz.example.net 300 IN A
127.0.0.2" } } }
```

Modifies DNS cache myCache by adding a local-zone lz.example.net with 2 resource records.

#### OPTIONS

**allowed-query-time**

Specifies the time allowed for a query to stay in the queue before it is replaced by a new query when the number of concurrent distinct queries exceeds the limit. The default value is 200 milliseconds.

**answer-default-zones**

Specifies whether the resolver cache answers queries for default zones: localhost, reverse 127.0.0.1 and ::1, and AS112 zones. The default value is no.

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**forward-zones**

Adds, deletes, modifies, or replaces a set of forward zones on a DNS Cache, by specifying zone name(s). A given zone name should only use the symbols allowed for a fully qualified domain name (FQDN), namely ASCII letters a through z, digits 0 through 9, hyphen -, and period .. For example site.example.com would be a valid zone name.

A DNS Cache configured with a forward zone will forward any queries that result in a cache-miss (the answer was not available in the cache) and match a configured zone name, to the nameserver specified on the zone. If no nameservers are specified on the zone, an automatic SERVFAIL is returned. When a forward zone's nameserver returns a valid response to the DNS Cache, that response is cached and then returned to the requester.

**nameservers**

Adds, deletes, modifies, or replaces a set of nameservers in a forward zone on a DNS Cache. A nameserver is represented by an IPaddress and port in the format [IPv4:port] or [IPv6:port], for example 10.10.10.10:53 or 2001::1:ff:53, respectively.

If more than one nameserver is listed for a given forward zone, a matching query will be sent to the nameserver that is currently deemed the most responsive (based on RTTs). If no response is received within a certain window of time, the DNS Cache will resend the query to another nameserver with an increased wait window until a response is received.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**local-zones**

Zones and associated resource records for which the cache will provide Authoritative responses. Default is empty. This is intended for small, simple authoritative data configurations.

The local-zone name must be fully qualified and should be the apex of the zone. The local-zone type may be one of the following: deny, refuse, static, transparent, type-transparent, or redirect. Zero or more resource records must be fully specified: name, ttl, class, type, and record data, separated by spaces, and within double quotes. For example, "www.example.net. 300 IN A 1.2.3.4".

For all local-zones types, if the DNS query matches, it is answered Authoritatively. How a non-matching query is handled depends on the local-zone type.

deny drops the query.

refuse sends a REFUSED response.

static sends either a NoData or NXDOMAIN response (includes SOA if present in local-zone).

transparent performs regular cache operation (i.e. transparent pass-through or iterative resolution) except for those query names which would result in NoData. This is the default local-zone type.

type-transparent Same as transparent but does not return NoData.

redirect returns responses with zone suffix record(s) for queries beneath that suffix. For example, a local-zone for example.com and a single A record for that name; queries for www.example.com or abc.www.example.com would return the single A record (both have the same suffix).

max-concurrent-queries  
Specifies the maximum number of concurrent distinct queries used by the resolver. A query is identified by query name, type and class. If the number of distinct queries exceeds this limit, the resolver replaces the earliest query in the queue with the new query if it has been in the queue longer than the allowed time. The default value is 1024.

max-concurrent-tcp  
Specifies the maximum number of concurrent TCP flows used by the resolver. The default value is 20.

max-concurrent-udp  
Specifies the maximum number of concurrent UDP flows used by the resolver. The default value is 8192.

msg-cache-size  
Specifies the maximum size in bytes of the DNS message cache. The default value is 1048576.

The BIG-IP system caches the messages in a DNS response in the message cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

nameserver-cache-count  
Specifies the maximum number of DNS nameservers for which the BIG-IP system caches connection and capability data. The default value is 16536 entries.

randomize-query-name-case  
When enabled, the resolver randomizes the case of query names. The default value is yes.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

response-policy-zones  
Adds, deletes or modifies the response policy zone to be used by this DNS Cache. Only a DNS Express zone configured as a response policy zone can be added.

The query name of a recursive DNS request without DNSSEC enabled is queried against the data in the response policy zone. If a match is found, the configured response policy action is taken.

action  
The action to take upon a match. nxdomain results in an NXDOMAIN response given to the client. walled-garden results in a response with a CNAME to the walled-garden zone and an A or AAAA response matching the DNS query type. The default action is nxdomain.

walled-garden  
A local zone configured in this cache that contains an A and/or AAAA record. This is typically used to redirect a user that requests resolution of a name contained in the RPZ database to a local server. This local server can display a message to the user and/or record the connection. Only A/AAAA/ANY requests are redirected, a request for any other type is answered with a NoData response. If a request is received for type A or AAAA but there are no records of that type configured, a NoData response is returned instead.

root-hints  
Specifies the IP addresses of DNS servers that the BIG-IP system considers authoritative for the DNS root nameservers.

Important:By default, the BIG-IP system uses the DNS root nameservers published by InterNIC.

Caution:When you add DNS root nameservers, the BIG-IP system no longer uses the default nameservers published by InterNIC, but instead uses the nameservers you add as authoritative for the DNS root nameservers.

route-domain  
Specifies the route domain the resolver uses for outbound traffic. The default value is the default route domain.

rrset-cache-size  
Specifies the maximum size in bytes of the resource records set

cache. The default value is 10485760.

The BIG-IP system caches the supporting records in a DNS response in the resource record cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

#### rrset-rotate

Specifies the resource record rotation method used within cached responses. The default value is none.

none Resource record order is not modified.

query-id Resource record order is a function of the client's query id.

#### unwanted-query-reply-threshold

The system always rejects unsolicited replies. The default value of 0 (off) indicates the system does not generate SNMP traps or log messages when rejecting unsolicited replies.

Change the default value to monitor for unsolicited replies. This alerts you to a potential security attack, such as cache poisoning or DOS. For example, if you specify a value of 1,000,000, each time the system receives 1,000,000 unsolicited replies, it generates an SNMP trap and log message. The default value is 0 (off).

#### use-ipv4

When enabled, the resolver sends DNS queries to IPv4 addresses. The default value is yes.

#### use-ipv6

When enabled, the resolver sends DNS queries to IPv6 addresses. The default value is yes.

#### use-tcp

When enabled, the resolver can send queries over the TCP protocol. The default value is yes.

#### use-udp

When enabled, the resolver can send queries over the UDP protocol. The default value is yes.

BIG-IP 2016-03-14 ltm dns cache resolver(1)

---

## ltm dns cache transparent

#### NAME

transparent - Configures a DNS cache without a resolver on the BIG-IP(r) system.

#### MODULE

ltm dns cache

#### SYNTAX

Configure the transparent DNS cache component within the ltm dns cache module using the syntax in the following sections.

#### CREATE/MODIFY

```
create transparent [name]
modify transparent [name]
options:
  answer-default-zones [yes | no]
  app-service [[string] | none]
  local-zones [ [none] |
  [ { { name [dname] type [type] records [none | add { [RR string] ... } ] } ... } ] ]
  msg-cache-size [integer]
  response-policy-zones [add | delete | modify] {
    [zone-name] {
  action [nxdomain | walled-garden]
  walled-garden [local-zone]
    }
  }
```

```
response-policy-zones none
rrset-cache-size [integer]
rrset-rotate [none | query-id]
```

#### DISPLAY

```
list transparent
list transparent [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
show transparent
show transparent [name]
```

#### DELETE

```
delete transparent [name]
```

#### DESCRIPTION

You can use the transparent component to configure and view information about a transparent DNS cache. A transparent cache does not perform recursive resolution, but instead relies on another DNS resource for this functionality.

**Important:** When sizing caches, consider the total amount of memory available and how you wish to allocate memory for DNS caching. Note that cache sizing values are per-TMM process; therefore, a platform with eight TMMs consumes the amount of memory set for the RRset cache times eight.

#### EXAMPLES

```
list transparent myCache
```

Displays the properties of the transparent DNS cache myCache.

```
modify transparent myCache local-zones { { name lz.example.net records
add { "lz.example.net 60 IN A 127.0.0.1" "www.lz.example.net 300 IN A
127.0.0.2" } } }
```

Modifies DNS cache myCache by adding a local-zone lz.example.net with 2 resource records.

#### OPTIONS

**answer-default-zones**

Specifies whether the resolver cache answers queries for default zones: localhost, reverse 127.0.0.1 and ::1, and AS112 zones. The default value is no.

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**local-zones**

Zones and associated resource records for which the cache will provide Authoritative responses. Default is empty. This is intended for small, simple authoritative data configurations.

The local-zone name must be fully qualified and should be the apex of the zone. The local-zone type may be one of the following: deny, refuse, static, transparent, type-transparent, or redirect. Zero or more resource records must be fully specified: name, ttl, class, type, and record data, separated by spaces, and within double quotes. For example, "www.example.net. 300 IN A 1.2.3.4".

For all local-zones types, if the DNS query matches, it is answered Authoritatively. How a non-matching query is handled depends on the local-zone type.

deny drops the query.

refuse sends a REFUSED response.

static sends either a NoData or NXDOMAIN response (includes SOA if present in local-zone).

transparent performs regular cache operation (i.e. transparent pass-through or iterative resolution) except for those query names which would result in NoData. This is the default local-zone type.

type-transparent Same as transparent but does not return NoData.

redirect returns responses with zone suffix record(s) for queries beneath that suffix. For example, a local-zone for example.com and a single A record for that name; queries for www.example.com or abc.www.example.com would return the single A record (both have the same suffix).

**msg-cache-size**

Specifies the maximum size in bytes of the DNS message cache. The default value is 1048576.

The BIG-IP system caches the messages in a DNS response in the message cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**response-policy-zones**

Adds, deletes or modifies the response policy zone to be used by this DNS Cache. Only a DNS Express zone configured as a response policy zone can be added.

The query name of a recursive DNS request without DNSSEC enabled is queried against the data in the response policy zone. If a match is found, the configured response policy action is taken.

**action**

The action to take upon a match. nxdomain results in an NXDOMAIN response given to the client. walled-garden results in a response with a CNAME to the walled-garden zone and an A or AAAA response matching the DNS query type. The default action is nxdomain.

**walled-garden**

A local zone configured in this cache that contains an A and/or AAAA record. This is typically used to redirect a user that requests resolution of a name contained in the RPZ database to a local server. This local server can display a message to the user and/or record the connection. Only A/AAAA/ANY requests are redirected, a request for any other type is answered with a NoData response. If a request is received for type A or AAAA but there are no records of that type configured, a NoData response is returned instead.

**rrset-cache-size**

Specifies the maximum size in bytes of the resource records set cache. The default value is 10485760.

The BIG-IP system caches the supporting records in a DNS response in the resource record cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

**rrset-rotate**

Specifies the resource record rotation method used within cached responses. The default value is none.

none Resource record order is not modified.

query-id Resource record order is a function of the client's query id.

## ltm dns cache validating-resolver

**NAME**

validating-resolver - Configures a DNS cache with a resolver and validator on the BIG-IP(r) system.

**MODULE**

ltm dns cache

**SYNTAX**

Configure the validating-resolver DNS cache component within the ltm dns cache module using the syntax in the following sections.

**CREATE/MODIFY**

```
create validating-resolver [name]
modify validating-resolver [name]
options:
    allowed-query-time [integer]
```

```

answer-default-zones [yes | no]
app-service [[string] | none]
dlv-anchors {
    { [DNSKEY or DS RR string] ... }
}
forward-zones [add | delete | modify | replace-all-with] {
    [ [zone-name] ] {
options:
nameservers [add | delete | replace-all-with] {
    [ [IPv4address:port] | [IPv6address.port] ]
}
nameservers none
}
forward-zones none
ignore-cd [yes | no]
key-cache-size [integer]
local-zones [ [none] |
[ { { name [dname] type [type] records [none | add { [RR string] ... } ] } ... } ] ]
max-concurrent-queries [integer]
max-concurrent-udp [integer]
max-concurrent-tcp [integer]
msg-cache-size [integer]
nameserver-cache-count [integer]
prefetch-key [yes | no]
randomize-query-name-case [yes | no]
response-policy-zones [add | delete | modify] {
    [zone-name] {
action [nxdomain | walled-garden]
walled-garden [local-zone]
}
}
response-policy-zones none
root-hints {
    { [IP address] ... }
}
route-domain [name]
rrset-cache-size [integer]
rrset-rotate [none | query-id]
trust-anchors {
    { [DNSKEY or DS RR string] ... }
}
unwanted-query-reply-threshold [integer]
use-ipv4 [yes | no]
use-ipv6 [yes | no]
use-tcp [yes | no]
use-udp [yes | no]

```

```

DISPLAY
list validating-resolver
list validating-resolver [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
show validating-resolver [name]

```

```

DELETE
delete validating-resolver [name]

```

#### DESCRIPTION

You can use the validating-resolver component to configure and view information about a validating recursive-resolving DNS cache. A resolving and validating cache performs recursive resolution to fill its cache and uses DNSSEC to ensure the integrity of the data.

**Important:** When sizing caches, consider the total amount of memory available and how you wish to allocate memory for DNS caching. Note that cache sizing values are per-TMM process; therefore, a platform with eight TMMs consumes the amount of memory set for the resource record set cache times eight.

#### EXAMPLES

```
list validating-resolver myCache
```

Displays the properties of the validating recursive-resolving DNS cache myCache.

```
modify validating-resolver myCache local-zones { { name lz.example.net
records add { "lz.example.net 60 IN A 127.0.0.1" "www.lz.example.net
300 IN A 127.0.0.2" } } }
```

Modifies DNS cache myCache by adding a local-zone lz.example.net with 2 resource records.

#### OPTIONS

**allowed-query-time**  
Specifies the time allowed for a query to stay in the queue before it is replaced by a new query when the number of concurrent distinct queries exceeds the limit. The default value is 200 milliseconds.

**answer-default-zones**  
Specifies whether the validating resolver cache answers queries for default zones: localhost, reverse 127.0.0.1 and ::1, and AS112 zones. The default value is no.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**dlv-anchors**

Specifies the DNSKEY or DS resource records the BIG-IP system uses to establish DNSSEC trust with a DLV registry. The resource records must be specified in string format, for example, dig or drill format. The default is none.

#### forward-zones

Adds, deletes, modifies, or replaces a set of forward zones on a DNS Cache, by specifying zone name(s). A given zone name should only use the symbols allowed for a fully qualified domain name (FQDN), namely ASCII letters a through z, digits 0 through 9, hyphen -, and period .. For example site.example.com would be a valid zone name.

A DNS Cache configured with a forward zone will forward any queries that result in a cache-miss (the answer was not available in the cache) and match a configured zone name, to the nameserver specified on the zone. If no nameservers are specified on the zone, an automatic SERVFAIL is returned. When a forward zone's nameserver returns a valid response to the DNS Cache, that response is cached and then returned to the requester.

#### nameservers

Adds, deletes, or replaces a set of nameservers in a forward zone on a DNS Cache. A nameserver is represented by an IP address and port in the format [IPv4:port] or [IPv6.port], for example 10.10.10.10:53 or 2001::1:ff.53, respectively.

If more than one nameserver is listed for a given forward zone, a matching query will be sent to the nameserver that is currently deemed the most responsive (based on RTTs). If no response is received within a certain window of time, the DNS Cache will resend the query to another nameserver with an increased wait window until a response is received.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### ignore-cd

When enabled, the system ignores the Checking Disabled setting on client queries, performs validation, and returns only secure answers. The default value is no.

#### key-cache-size

Specifies the maximum size in bytes of the DNSKEY cache. The default value is 1048576.

#### local-zones

Zones and associated resource records for which the cache will provide Authoritative responses. Default is empty. This is intended for small, simple authoritative data configurations.

The local-zone name must be fully qualified and should be the apex of the zone. The local-zone type may be one of the following: deny, refuse, static, transparent, type-transparent, or redirect. Zero or more resource records must be fully specified: name, ttl, class, type, and record data, separated by spaces, and within double quotes. For example, "www.example.net. 300 IN A 1.2.3.4".

For all local-zones types, if the DNS query matches, it is answered Authoritatively. How a non-matching query is handled depends on the local-zone type.

deny drops the query.

refuse sends a REFUSED response.

static sends either a NoData or NXDOMAIN response (includes SOA if present in local-zone).

transparent performs regular cache operation (i.e. transparent pass-through or iterative resolution) except for those query names which would result in NoData. This is the default local-zone type.

type-transparent Same as transparent but does not return NoData.

redirect returns responses with zone suffix record(s) for queries beneath that suffix. For example, a local-zone for example.com and a single A record for that name; queries for www.example.com or abc.www.example.com would return the single A record (both have the same suffix).

#### max-concurrent-queries

Specifies the maximum number of concurrent distinct queries used by the resolver. A query is identified by query name, type and class. If the number of distinct queries exceeds this limit, the resolver replaces the earliest query in the queue with the new query if it has been in the queue longer than the allowed time. The default value is 1024.

#### max-concurrent-tcp

Specifies the maximum number of concurrent TCP flows used by the resolver. The default value is 20.

#### max-concurrent-udp

Specifies the maximum number of concurrent UDP flows used by the resolver. The default value is 8192.

#### msg-cache-size

Specifies the maximum size in bytes of the DNS message cache. The default value is 1048576.

The BIG-IP system caches the messages in a DNS response in the message cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired

and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**nameserver-cache-count**

Specifies the maximum number of DNS nameservers for which the BIG-IP system caches connection and capability data. The default value is 16536 entries.

**prefetch-key**

When enabled, the validating resolver fetches the DNSKEY early in the validation process. Disable this setting when you want to reduce resolver traffic, but understand that a client may have to wait for the validating resolver to perform a key lookup. The default value is yes.

**randomize-query-name-case**

When enabled, the resolver randomizes the case of query names. The default value is yes.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**response-policy-zones**

Adds, deletes or modifies the response policy zone to be used by this DNS Cache. Only a DNS Express zone configured as a response policy zone can be added.

The query name of a recursive DNS request without DNSSEC enabled is queried against the data in the response policy zone. If a match is found, the configured response policy action is taken.

**action**

The action to take upon a match. nxdomain results in an NXDOMAIN response given to the client. walled-garden results in a response with a CNAME to the walled-garden zone and an A or AAAA response matching the DNS query type. The default action is nxdomain.

**walled-garden**

A local zone configured in this cache that contains an A and/or AAAA record. This is typically used to redirect a user that requests resolution of a name contained in the RPZ database to a local server. This local server can display a message to the user and/or record the connection. Only A/AAAA/ANY requests are redirected, a request for any other type is answered with a NoData response. If a request is received for type A or AAAA but there are no records of that type configured, a NoData response is returned instead.

**root-hints**

Specifies the IP addresses of DNS servers that the BIG-IP system considers authoritative for the DNS root nameservers.

**Important:**By default, the BIG-IP system uses the DNS root nameservers published by InterNIC.

**Caution:**When you add DNS root nameservers, the BIG-IP system no longer uses the default nameservers published by InterNIC, but instead uses the nameservers you add as authoritative for the DNS root nameservers.

**route-domain**

Specifies the route domain the resolver uses for outbound traffic. The default value is the default route domain.

**rrset-cache-size**

Specifies the maximum size in bytes of the resource records set cache. The default value is 10485760.

The BIG-IP system caches the supporting records in a DNS response in the resource record cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

**rrset-rotate**

Specifies the resource record rotation method used within cached responses. The default value is none.

none Resource record order is not modified.

query-id Resource record order is a function of the client's query id.

**trust-anchors**

Specifies the DNSKEY or DS resource records the BIG-IP system uses to establish DNSSEC trust with a specific DNS zone. The resource records must be specified in string format, for example, dig or drill format. The default value is none.

**unwanted-query-reply-threshold**

The system always rejects unsolicited replies. The default value of 0 (off) indicates the system does not generate SNMP traps or

log messages when rejecting unsolicited replies.

Change the default value to monitor for unsolicited DNS replies. This alerts you to a potential security attack, such as cache poisoning or DOS. For example, if you specify a value of 1,000,000, each time the system receives 1,000,000 unsolicited replies, it generates an SNMP trap and log message. The default value is 0 (off).

use-ipv4

When enabled, the resolver sends DNS queries to IPv4 addresses. The default value is yes.

use-ipv6

When enabled, the resolver sends DNS queries to IPv6 addresses. The default value is yes.

use-tcp

When enabled, the resolver can send queries over the TCP protocol. The default value is yes.

use-udp

When enabled, the resolver can send queries over the UDP protocol. The default value is yes.

## ltm dns dns-express-db

NAME

dns-express-db - Loads the DNS Express data file.

MODULE

ltm dns

SYNTAX

load dns-express-db

DESCRIPTION

The dns-express-db component within the ltm dns module is used to load the DNS Express data file /var/db/tmmdns.bin. The file is only loaded if it has been modified.

EXAMPLES

load dns-express-db

Loads the DNS Express file from disk into the running configuration.

SEE ALSO

load, tmsh

## ltm dns dnssec generation

**NAME**  
 generation - Configures a generation on the BIG-IP(r) system.

**MODULE**  
 ltm dns dnssec

**SYNTAX**  
 Configure the generation component within the ltm dns dnssec module using the syntax in the following sections.

**CREATE/MODIFY**  
 modify generation [name]  
 options:  
 app-service [[string] | none]  
 expiration [date and time]  
 rollover [date and time]

edit generation [ [name] | [glob] | [regex] ] ... ]  
 options:  
 all-properties  
 non-default-properties

**DISPLAY**  
 list generation  
 list generation [ [name] | [glob] | [regex] ] ... ]  
 options:  
 all-properties  
 non-default-properties  
 pub-text  
 show generation  
 show generation [ [name] | [glob] | [regex] ] ... ]  
 options:  
 (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

**DELETE**  
 delete generation [name]

**DESCRIPTION**  
 You can use the generation component to configure a generation.

**EXAMPLES**  
 list generation myfirstgen  
 Displays the properties of the generation named myfirstgen.  
 show generation myfirstgen  
 Displays the status of the generation named myfirstgen.

**OPTIONS**  
 app-service  
 Specifies the name of the application service to which this generation belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this generation. Only the application service can modify or delete this generation.

expiration  
 Specifies the date and time that this generation expires.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

pub-text  
 Displays public text generated by the system.

regex  
 Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rollover  
 Specifies the date and time that this generation rolls over to a new generation.

# ltm dns dnssec key

**NAME**  
key - Configures DNSSEC keys on the BIG-IP(r) system.

**MODULE**  
ltm dns dnssec

**SYNTAX**  
Configure the key component within the ltm dns dnssec module using the syntax in the following sections.

**CREATE/MODIFY**  
create key [name]  
modify key [name]  
options:  
algorithm [ rsasha1 | rsasha256 | rsasha512 ]  
app-service [[string] | none]  
bitwidth [ 512 | 1024 | 2048 | 4096 ]  
certificate-file [string]  
description [string]  
[enabled | disabled]  
expiration-period [integer]  
key-file [string]  
key-type [skk | zsk]  
rollover-period [integer]  
signature-pub-period [integer]  
signature-valid-period [integer]  
ttl [integer]  
use-fips [external | internal | none]

edit key [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list key  
list key [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
generation  
non-default-properties  
one-line

**DELETE**  
delete key [name]

**DESCRIPTION**  
You can use the key component to configure DNSSEC zone signing and key signing keys, and to view information about the keys.

**EXAMPLES**  
create key ksk1  
Creates the key signing key, ksk1, using the system default values.  
create key zsk1  
Creates the zone signing key, zsk1, using the system default values.  
list key my\_key  
Displays the properties of the DNS security key my\_key.

**OPTIONS**  
algorithm  
Specifies the algorithm to use to generate the key. The default value is RSASHA1.  
app-service  
Specifies the name of the application service to which the key belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the key. Only the application service can modify or delete the key.  
bitwidth  
Specifies the length of the key you want to generate. The default value is 1024. If a key is manually managed, MCPD will derive this value from the file and override any user defined value.  
certificate-file  
Specifies the file containing the public key. Fields certificate-file and key-file are required for manual DNSSEC key import.  
description  
User defined description.  
[enabled | disabled]  
Specifies whether the key is enabled or disabled.  
expiration-period  
Specifies the life of the key in d:h:m:s, h:m:s, m:s, or seconds. At the end of the period, the system deletes the expired generation of the key. This value must be greater than the value of the rollover-period option. The difference between the two periods must be more than the value of the ttl option.  
The default value is 0 (zero), which indicates unset, and thus the key does not expire.

generation

Displays the generation of the key, including the following:

creator

Hostname of BIG-IP system that created this generation.

expiration

The date and time that this generation of the key expires.

handle

The handle of a generation of a key that is used for interacting with the key subsystem (for example, HSM for FIPS).

key-tag

The hash identifier of the DNSKEY.

pub-text

The text of the randomly-generated public key.

rollover

The date and time that this generation of the key rolls over to a new key.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

key-file

Specifies the file containing the private key. Fields certificate-file and key-file are required for manual DNSSEC key import.

key-type

Specifies whether the key is of type ksk or zsk. The default value is zsk.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rollover-period

Specifies the amount of time, in d:h:m:s, h:m:s, m:s, or seconds, before the system generates another generation of the key. At the end of the period, the system creates a new generation of the key. Two generations of the key exist during the time between the end of the rollover period and the end of the expiration period.

This value must be greater than or equal to one third of the value of the expiration-period option, and less than the value of the expiration period option. The difference between the two periods must be more than the value of the ttl option.

The default value is 0 (zero), which indicates unset, and thus the key does not roll over.

signature-pub-period

Specifies the amount of time, in d:h:m:s, h:m:s, m:s, or seconds, before the system publishes another generation of the signature. At the end of the period, the system creates a new signature.

This value must be less than the value of the signature-valid-period option. The default value is 403200 seconds.

signature-valid-period

Specifies the amount of time, in d:h:m:s, h:m:s, m:s, or seconds, that the signature is valid. At the end of the period, the Global Traffic Manager no longer uses the expired signature. The default value is 604800 seconds.

ttl Specifies the amount of time, in d:h:m:s, h:m:s, m:s, or seconds, that a DNS server can cache the key. The default value is 86400.

The value of the ttl option must be less than the difference between the values of the rollover-period and expiration-period options.

0 seconds indicates that the key is not cached.

use-fips

Specifies the type of FIPS-compliant hardware security module to use when storing, and signing with, the private key. The default value is none. The choice of external attempts to use a network-attached FIPS device if configured; otherwise internal uses the FIPS device within the BIG-IP.

If this option is set to internal or external and a FIPS device is not present, the system automatically resets the value to none.

## ltm dns dnssec zone

**NAME**  
zone - Configures DNSSEC zones on the BIG-IP(r) system.

**MODULE**  
ltm dns dnssec

**SYNTAX**  
Configure the zone component within the ltm dns dnssec module using the syntax in the following sections.

**CREATE/MODIFY**  
create zone [name]  
modify zone [name]  
options:  
app-service [[string] | none]  
description [string]  
[enabled | disabled]  
ds-algorithm [ SHA1 | SHA256 ]  
indicate-authenticated [ enabled | disabled ]  
keys  
[add | delete | modify | replace-all-with] {  
[key name ...]  
}  
keys none  
nsec3-algorithm [ SHA1 ]  
nsec3-iterations [unsigned integer]

edit zone [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

reset-stats zone  
reset-stats zone [ [ [name] | [glob] | [regex] ] ... ]

**DISPLAY**  
list zone  
list zone [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
seps

show zone [ [ [name] | [glob] | [regex] ] ... ]  
options:  
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)  
global  
field-fmt

**DELETE**  
delete zone [name]

**DESCRIPTION**  
You can use the zone component to configure and view information about a DNSSEC zone.

**EXAMPLES**  
list zone mySecureZone  
  
Displays the properties of the DNSSEC zone named mySecureZone.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the zone belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the zone. Only the application service can modify or delete the zone.

description  
User defined description.

ds-algorithm  
Specifies the hash algorithm to use when creating the Delegation Signer (DS) resource record. The default value is SHA1.  
[enabled | disabled]  
Specifies whether the DNSSEC zone is enabled or disabled.

Note: You must associate both a key signing and a zone signing key with the zone before complete signing of client requests can occur.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

indicate-authenticated  
The Authenticated Data (AD) flag is TRUE for DNSSEC zone authoritative answers when this setting is enabled. The default value is disabled.

keys Specifies the keys that you want to configure for the zone.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

nsec3-algorithm  
Specifies the hash algorithm to use when creating the Next Secure (NSEC3) resource record. The default value is SHA1. Other algorithms are not currently supported, so selecting SHA256 will revert to SHA1 with a warning message.

nsec3-iterations  
Specifies the number of times to hash the Next Secure (NSEC3) names. The default value is 1."

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

seps Displays the Secure Entry Point(s) (DS and DNSKEY resource records used as client trust anchors) of the zone, including the following:

dnskey  
String representation of the DNSKEY resource record.

ds String representation of the DS resource record.

generation-id  
ID of DNSSEC Key Generation used to create the SEP.

key-name  
Name of DNSSEC Key which was used to create the SEP.

xfr-primary-soa-serial  
The learned zone SOA serial number from the primary server.

xfr-soa-serial  
The advertised zone SOA serial number to all clients.

## ltm dns nameserver

NAME  
nameserver - Configures DNS nameservers on the BIG-IP(r) system.

MODULE  
ltm dns

SYNTAX  
Configure the nameserver component within the ltm dns module using the syntax in the following sections.

#### CREATE/MODIFY

```
create nameserver [name]
modify nameserver [name]
```

#### options:

```
address [ip address]
app-service [[string] | none]
port [unsigned integer]
route-domain [route-domain name | none]
tsig-key [tsig-key name | none]
```

```
edit nameserver [ [ [name] | [glob] | [regex] ] ... ]
options:
```

```
all-properties
non-default-properties
```

```
reset-stats nameserver
```

```

reset-stats nameserver [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list nameserver
list nameserver [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
show nameserver
show nameserver [ [ [name] | [glob] | [regex] ] ... ]
  options:
    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
    global
    field-fmt

DELETE
delete nameserver [name]

DESCRIPTION
  You can use the nameserver component to configure nameservers and to
  view information about the nameservers.

EXAMPLES
  create nameserver myNameserver address 127.0.0.1 port 53

  Creates the nameserver, myNameserver, given the address and port.

  list nameserver myNameserver

  Displays the properties of the nameserver myNameserver.

OPTIONS
  address
  Specifies the IP address of the nameserver. The default value is
  127.0.0.1.

  app-service
  Specifies the name of the application service to which the
  nameserver belongs. The default value is none. Note: If the
  strict-updates option is enabled on the application service that
  owns the object, you cannot modify or delete the nameserver. Only
  the application service can modify or delete the nameserver.

  glob
  Displays the items that match the glob expression. See help glob
  for a description of glob expression syntax.

  name
  Specifies a unique name for the component. This option is required
  for the commands create, delete, and modify.

  port
  Specifies the service port of the nameserver. The default value is
  53.

  route-domain
  Specifies the route domain that the nameserver uses for outbound
  traffic. The default value is the default route domain.

  tsig-key
  Specifies the TSIG key used to communicate with this nameserver
  for zone transfers. If the nameserver is a client, then this TSIG
  key is used to verify the query and sign the response. If the
  nameserver is a transfer target for DNS Express nameserver, then
  this TSIG key should match that of the master nameserver.

  regex
  Displays the items that match the regular expression. The regular
  expression must be preceded by an at sign (@[regular expression])
  to indicate that the identifier is a regular expression. See help
  regex for a description of regular expression syntax.

SEE ALSO
  create, delete, edit, glob, list, modify, regex, show, tmsh

## ltm dns tsig-key

```

NAME
  tsig-key - Configures TSIG keys on the BIG-IP(r) system.

MODULE
  ltm dns

```

**SYNTAX**

Configure the tsig-key component within the ltm dns module using the syntax in the following sections.

**CREATE/MODIFY**

```
create tsig-key [name]
modify tsig-key [name]
options:
  algorithm [ hmacmd5 | hmacsha1 | hmacsha256 ]
  app-service [[string] | none]
  secret [string]
```

```
edit tsig-key [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

**DISPLAY**

```
list tsig-key
list tsig-key [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

**DELETE**

```
delete tsig-key [name]
```

**DESCRIPTION**

You can use the tsig-key component to configure TSIG keys and to view information about the keys.

**EXAMPLES**

```
create tsig-key myKey algorithm hmacmd5 secret ABCDEFG
```

Creates the TSIG key, myKey, given the algorithm and secret (both required).

```
list tsig-key myKey
```

Displays the properties of the TSIG key myKey.

**OPTIONS**

**algorithm**  
Specifies the algorithm to use to generate the key.

**app-service**  
Specifies the name of the application service to which the TSIG key belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the TSIG key. Only the application service can modify or delete the TSIG key.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**secret**  
Specifies the string representation of the key's shared secret.

**SEE ALSO**

create, delete, edit, glob, list, modify, regex, tmsh

**COPYRIGHT**

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## ltm dns zone

**NAME**

zone - Configures zones on the BIG-IP(r) system.

**MODULE**

ltm dns

## SYNTAX

Configure the zone component within the ltm dns module using the syntax in the following sections.

```
CREATE/MODIFY
create zone [name]
modify zone [name]
options:
  app-service [[string] | none]
  dns-express-allow-notify [add | delete | none | replace-all-with] {
    [IP Address]
  }
  dns-express-enabled [yes | no]
  dns-express-notify-action [ consume | bypass | repeat ]
  dns-express-notify-tsig-verify [yes | no]
  dns-express-server [server name | none]
  response-policy [yes | no]
  server-tsig-key [tsig-key name | none]
  transfer-clients [add | delete | none | replace-all-with] {
    [server name]
  }

edit zone [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

reset-stats zone
reset-stats zone [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list zone
list zone [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
show zone [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete zone [name]
```

## DESCRIPTION

You can use the zone component to configure and view information about a zone.

## EXAMPLES

```
list zone myZone
```

Displays the properties of the zone named myZone.

```
create zone myZone transfer-clients add { nameserver1 nameserver2 }
```

Creates a zone named myZone, which allows zone data to be transferred to nameserver1 and nameserver2.

## OPTIONS

### app-service

Specifies the name of the application service to which the zone belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the zone. Only the application service can modify or delete the zone.

### dns-express-allow-notify

Specifies a list of IP addresses, in addition to the DNS Zone's DNS-Express Server address, which are allowed to notify the BIGIP of DNS Zone changes. A notify message coming from an IP which is neither the address of the zone's DNS Express server nor an address in this list will be dropped by the BIGIP.

### dns-express-enabled [yes | no]

Specifies whether DNS Express is enabled to process queries for this zone. The default value is yes.

### dns-express-notify-action [ consume | bypass | repeat ]

Action to take when a NOTIFY query is received for a configured zone. Options are consume, bypass, and repeat. Default is consume, meaning the NOTIFY query is seen only by DNS Express. bypass means the query will NOT go to DNS Express, but any backend DNS resource (subject to DNS profile unhandled-query-action). repeat means the NOTIFY will go to both DNS Express and any backend DNS resource. If TSIG is configured, the signature is only validated for consume and repeat actions. NOTIFY responses are assumed to be sent by the backend DNS resource, except when the action is consume and DNS Express will generate a response.

### dns-express-notify-tsig-verify

Verify NOTIFY query TSIG for a DNS Express zone. Default is yes.

### dns-express-server

Specifies the server from which to retrieve zone information for DNS Express.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

Note: A successful zone transfer must occur before this zone can

service DNS requests.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**response-policy**

Specifies if this is a response policy zone. If this is set to yes, this zone may be assigned as an RPZ to a DNS Cache. Default is no.

**server-tsig-key**

Specifies the server side TSIG key associated with the DNS zone. It should match the TSIG Key associated with the master name servers.

**transfer-clients**

Specifies the nameservers allowed to transfer the zone from BIGIP.

show eviction-policy [ [ [name] | [glob] | [regex] ] ...]
  options:
    all-properties
    default

```

```

DELETE
delete eviction-policy [name]

```

#### DESCRIPTION

You use the eviction policy to specify which flows to terminate when the connection limits for the box are approached. The eviction policy contains strategies which select the flows to terminate. Additionally, the eviction policy defines parameters used to determine when flows are considered to be slow. Slow flows are terminated according to the policy, even when the Big-IP is not under duress and the connection limits are not approached.

When applied to the global context, the eviction policy low-water and high-water limits are with respect to memory available on the Big-IP. When applied to a virtual server or a route domain, the limits are with respect to the connection limit on the virtual server or route domain, respectively.

It is possible to monitor slow flows, accumulating metrics on the number of flows under the designated slow flow transfer limit. To do so, enable slow-flows, but disable throttling on the slow flow.

Note: Monitoring or killing slow flows will incur a performance penalty.

Note: The strategies applied here work on a cyclic sweep of all connections on the Big-IP. These do not run at the granularity to guarantee eviction of a particular flow or type of flow, but are statistical and opportunistic.

The bias-bytes algorithm attempts to select the flows that have sent and received the fewest bytes on the connection.

The bias-idle algorithm attempts to select the flows that have been idle the longest.

The bias-oldest algorithm attempts to select the oldest flows.

The low-priority-geographies algorithm selects flows that are in low-priority geographies according to the GeoIP database loaded onto the box.

The low-priority-port algorithm selects flows that are in the provided list of low-priority ports and protocols.

The low-priority-route-domain algorithm selects flows that are in the provided list of low-priority route domains.

The low-priority-virtual-server algorithm selects flows that are in the provided list of low-priority virtual servers.

#### EXAMPLES

```

create eviction-policy my_eviction_policy { low-water 70 high-water 80
slow-flow { enabled true threshold-bps 50 throttling disabled }
strategies { bias-idle { enabled true } } }

```

Creates an eviction policy named `my_eviction_policy`, which accumulates statistics on the current number of slow flows but does not terminate any flows that are considered slow. The bias-idle algorithm is used to kill flows when the limits on the context are approached. The aggressive sweeper will activate at 80 percent of capacity, and deactivate when load is reduced to 70 percent of capacity.

```

modify eviction-policy my_eviction_policy { strategies { low-priority-
geographies { enabled true countries replace-all-with { AZ BZ } } } }

```

Modifies the eviction policy named `my_eviction_policy`, enabling the low-priority geography strategy and dropping flows from Azerbaijan (AZ) and Belize (BZ).

```

delete eviction-policy my_eviction_policy

```

Deletes the eviction policy named `my_eviction_policy`.

#### OPTIONS

```

description
Provides a user-defined description for the policy.

```

#### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### low-water

Specifies the aggressive sweeper activation threshold as a percentage of total capacity. The allowable range is 50 - 100, and the low-water value must be lower than or equal to the high-water value. To disable killing flows when limits are met or exceeded, set the low-water and high-water to 100 percent. Default value is 85 percent.

#### high-water

Specifies the target maximum load on the context. The adaptive reaper will be more aggressive as this limit is approached. The allowable range is 50 - 100, and the high-water value must be higher than or equal to the low-water value. To disable killing flows when limits are met or exceeded, set the low-water and high-water to 100 percent. Defaults to 95 percent.

#### slow-flow

Specifies whether to monitor and possibly remove flows considered to be slow.

#### enabled

If true, the slow-flow monitoring and possible removal are activated. If false, the remaining slow-flow attributes are unused. The default value is false.

#### eviction-type

Indicates whether the threshold is based on an absolute count of slow flows, or a percentage of the total flows on the context where the eviction policy is applied. There is no default value.

#### grace-period

Specifies the minimum age of a slow flow before the flow is killed.

#### maximum

Provides the count or percentage at which slow flows will be killed. If eviction-type is count, this value is the absolute number of slow flows allowed; if eviction-type is percent, this is the percentage of flows on the context that are allowed to fall under the threshold-bps before being killed.

#### threshold-bps

Provides the threshold under which flows are considered to be slow, in bytes per second.

#### throttling

Indicates whether to kill flows that are considered slow. If set to enabled, flows that fall under the threshold-bps are subject to being killed according to the defined maximum number of flows.

#### strategies

Defines the strategies to be used to select flows for eviction in the eviction policy.

#### bias-bytes

Defines how to use the bias-bytes eviction strategy.

#### delay

The delay allowed for new flows to transfer content, to prevent killing infant flows.

#### enabled

Specifies whether to use the bias-bytes algorithm. If false, the bias-bytes algorithm is not used. The default value is false.

#### bias-idle

Defines how to use the bias-idle eviction strategy.

#### enabled

Specifies whether to use the bias-idle algorithm. If false, the bias-idle algorithm is not used. The default value is false.

#### bias-oldest

Defines how to use the bias-oldest eviction strategy.

#### enabled

Specifies whether to use the bias-oldest algorithm. If false, the bias-oldest algorithm is not used. The default value is false.

#### low-priority-geographies

Defines how to use the low-priority geographies eviction strategy.

#### countries

Provides a list of country codes considered low-priority candidates to evict, based on GeoIP information.

#### enabled

Specifies whether to use the low-priority-geographies algorithm. If false, the low-priority-geographies algorithm is not used. The default value is false.

`low-priority-port`  
Defines how to use the `low-priority-port` eviction strategy.

`enabled`  
Specifies whether to use the `low-priority-port` algorithm. If false, the `low-priority-port` algorithm is not used. The default value is false.

`ports`  
Provides a list of ports considered low-priority candidates to evict.

`app-service`  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`port-number`  
Specifies the port number considered low-priority. The number provided can be either a number (e.g., 80) or a name (e.g., http).

`protocol`  
Specifies the protocol considered low-priority. The default value is any.

`low-priority-route-domain`  
Defines how to use the `low-priority-route-domain` eviction strategy.

`enabled`  
Specifies whether to use the `low-priority-route-domain` algorithm. If false, the `low-priority-route-domain` algorithm is not used. The default value is false.

`names`  
Specifies a list of route domain names considered to be low-priority candidates to evict.

`low-priority-virtual-server`  
Defines how to use the `low-priority-virtual-server` eviction strategy.

`enabled`  
Specifies whether to use the `low-priority-virtual-server` algorithm. If false, the `low-priority-virtual-server` algorithm is not used. The default value is false.

`names`  
Specifies a list of virtual server names considered to be low-priority candidates to evict.

## ltm global-settings connection

**NAME**  
`connection` - Configures the global settings that pertain to connections for the BIG-IP(r) and VIPRION(r) local traffic management systems.

**MODULE**  
`ltm global-settings`

**SYNTAX**  
Configure the connection component within the `ltm global-settings` module using the syntax shown in the following sections.

**MODIFY**  
`modify connection`  
**options:**  
`adaptive-reaper-hiwater` [integer]  
`adaptive-reaper-lowater` [integer]  
`auto-last-hop` [disabled | enabled]

```
default-vs-syn-challenge-threshold [infinite | integer]
global-flow-eviction-policy [name]
global-syn-challenge-threshold [infinite | integer]
syncookies-threshold [integer]
vlan-keyed-conn [disabled | enabled]
vlan-syn-cookie [disabled | enabled]
```

#### DISPLAY

```
list connection
list connection [option name]
show running-config connection
show running-config connection [option name]
options:
  all-properties
  non-default-properties
  one-line
```

#### DESCRIPTION

You can use the connection component to modify how the system processes connections.

#### EXAMPLES

```
modify connection auto-last-hop disabled
Specifies that the system does not automatically map the last hop
for pools.
```

```
list connection
Displays the global settings for how the system processes
connections.
```

#### OPTIONS

```
adaptive-reaper-hiwater
*IMPORTANT* This command has been deprecated (as of 11.6.0).
Please use ltm eviction-policy instead. Specifies, in a
percentage, the memory usage at which the system stops
establishing new connections. Once the system meets the reaper
high-water mark, the system does not establish new connections
until the memory usage drops below the reaper low-water mark. The
adaptive reaper settings help mitigate the effects of a denial-of-
service attack.
```

The available range is 85 - 100. The default value is 95. To
disable the adaptive reaper, set the high-water mark to 100.

```
adaptive-reaper-lowwater
*IMPORTANT* This command has been deprecated (as of 11.6.0).
Please use ltm eviction-policy instead. Specifies, in percent,
the memory usage at which the system silently purges stale
connections, without sending reset packets (RST) to the client. If
the memory usage remains above the low-water mark after the purge,
then the system starts purging established connections closest to
their service timeout.
```

The available range is 70 - 100. The default value is 85. To
disable the adaptive reaper, set the low-water mark to 100.

```
auto-last-hop
Specifies that the system automatically maps the last hop for
pools. The default value is enabled.
```

```
default-vs-syn-challenge-threshold
Specifies the default value of per-virtual server SYN Cookie
activation threshold per chassis. The default value is infinite.
The valid range is 128 - 1024K or infinite (encoded as 0).
```

```
global-flow-eviction-policy
Specifies the flow eviction policy to use when approaching memory
usage limits. The settings in the policy determine the adaptive
reaper high and low water marks, and help determine which client
connections to terminate when memory limits have exceeded the
"low-water" threshold in the eviction policy. The settings help
mitigate the effects of a denial-of-service attack.
```

```
global-syn-challenge-threshold
Specifies the default value of the global SYN Cookie activation
threshold per TMM. The default value is 64K. The valid range is
2048 - 4096K or infinite (encoded as 0).
```

```
syncookies-threshold
This option is deprecated in version 13.0.0 and is replaced by
default-vs-syn-challenge-threshold. Specifies the number of new
or untrusted TCP connections that can be established before the
system activates the SYN Cookies authentication method for
subsequent TCP connections. The default value is 16384.
```

```
vlan-keyed-conn
Enables or disables VLAN-keyed connections. You use VLAN-keyed
connections when traffic for the same connection must pass through
the system several times, on multiple pairs of VLANs (or in
different VLAN groups). The default value is enabled.
```

```
vlan-syn-cookie
Enables or disables the hardware per-VLAN SYN cookie protection on
platforms with supported firmware. The default value is enabled.
```

## ltm global-settings general

**NAME**  
general - Configures the general properties for the BIG-IP(r) and VIPRION(r) local traffic management systems.

**MODULE**  
ltm global-settings

**SYNTAX**  
Configure the general component within the ltm global-settings module using the syntax shown in the following sections.

**MODIFY**  
modify general  
options:  
gratuitous-arp-rate [integer value: 0 ~ 2147483647]  
l2-cache-timeout [ integer value: 0 ~ 2147483647]  
maintenance-mode [disabled | enabled]  
share-single-mac [unique | global | vmw-compat]  
snat-packet-forward [ disabled | enabled]

**DISPLAY**  
list general  
list general [option name]  
show running-config general  
show running-config general [option name]  
options:  
all-properties  
non-default-properties  
one-line

**DESCRIPTION**  
You can use the general component to modify how the system processes local traffic.

**EXAMPLES**  
modify general maintenance-mode enabled  
Places the Local Traffic Manager system in maintenance mode.  
  
list general  
Displays the general properties of the local traffic management system.

**OPTIONS**  
gratuitous-arp-rate  
Specifies how fast gratuitous ARPs can be sent. If it is 0, then gratuitous ARPs are sent without pause. Otherwise, it specifies how many gratuitous ARPs can be sent every second. The default value is 0. The range is 0 (zero) to 2147483647."  
  
l2-cache-timeout  
Specifies, in seconds, the amount of time that records remain in the Layer 2 forwarding table, when the MAC address of the record is no longer detected on the network.  
  
The default value is 300 seconds. The range is 0 (zero) to 2147483647 seconds.  
  
maintenance-mode  
Specifies, when enabled, that the unit is in maintenance mode. In maintenance mode, the system stops accepting new connections and slowly finishes off existing connections.  
  
The default value is disabled.  
  
share-single-mac  
Specifies the Media Access Control address (MAC address) that the system assigns to a VLAN. The default value is unique, which indicates that a VLAN uses a unique MAC address from the pool of mac addresses assigned to each hardware platform. The global value indicates that all of the VLANs on the system use the same MAC address. The vmw-compat value indicates that the MAC address of a vlan is allocated in a manner compatible with VMware(tm) vSwitch, and restricts vlans to a single interface, with no trunks allowed. Changing the value of this feature requires a manual restart of all TMOS daemons.  
  
snat-packet-forward  
Enables or disables SNAT packet forwarding. The default value is enabled.

## ltm global-settings traffic-control

### NAME

traffic-control - Configures the global settings that pertain to traffic control for the BIG-IP(r) and VIPRION(r) local traffic management systems.

### MODULE

ltm global-settings

### SYNTAX

Configure the traffic-control component within the ltm global-settings module using the syntax shown in the following sections.

#### MODIFY

modify traffic-control

options:

accept-ip-options [disabled | enabled]  
accept-ip-source-route [disabled | enabled]  
allow-ip-source-route [ disabled | enabled]  
continue-matching [ disabled | enabled]  
max-icmp-rate [integer value: 0 ~ 2147483647]  
max-reject-rate [ integer value: 1 ~ 1000]  
max-reject-rate-timeout [ integer value: 0 ~ 300]  
min-path-mtu [ integer value: 68 ~ 1500]  
path-mtu-discovery [disabled | enabled]  
port-find-linear [ integer value: 0 ~ 61439]  
port-find-random [ integer value: 0 ~ 1024]  
port-find-threshold-warning [disabled | enabled]  
port-find-threshold-trigger [integer value: 1 ~ 12]  
port-find-threshold-timeout [integer value: 0 ~ 300]  
reject-unmatched [ disabled | enabled]

#### DISPLAY

list traffic-control  
list traffic-control [option name]  
show running-config traffic-control  
show running-config traffic-control [option name]  
options:  
all-properties  
non-default-properties  
one-line

### DESCRIPTION

You can use the traffic-control component to modify how the system processes local traffic.

### EXAMPLES

modify traffic-control accept-ip-options enabled  
Specifies that the system accepts IPv4 packets with IP options.

list traffic-control  
Displays the local traffic control global settings.

### OPTIONS

accept-ip-options  
Specifies whether the system accepts IPv4 packets with IP options. The default value is disabled.

accept-ip-source-route  
Specifies whether the system accepts IPv4 packets with IP source route options that are destined for Traffic Management Microkernel (TMM). The default value is disabled.

To enable this option, you must also enable the accept-ip-options option.

allow-ip-source-route  
Specifies whether the system allows IPv4 packets with IP source route options enabled to be routed through Traffic Management Microkernel (TMM). The default value is disabled.

To enable this option, you must also enable the accept-ip-options option.

continue-matching  
Specifies whether the system matches against a less-specific virtual server when the more-specific one is disabled. When continue-matching is disabled, the default value, the system drops

connections that request a disabled virtual server. In this case, the system rejects or drops packets depending on the value of the reject-unmatched option.

**max-icmp-rate**

Specifies the maximum rate per second at which the system issues Internet Control Message Protocol (ICMP) errors. The default value is 100 errors per second. The range is from 0 (zero) to 2147483647 errors per second. This option is useful for preventing ICMP-message storms.

**max-reject-rate**

Specifies the maximum rate per second at which the system issues reject packets (TCP RST or ICMP port unreachable). The default value is 250 per second. The range is from 1 to 1000 per second.

**max-reject-rate-timeout**

Specifies the time in seconds which the system ignores icmp port unreachable and tcp rst ratelimits on becoming active after a failover. The default value is 30 seconds. The range is from 0 to 300 seconds.

**min-path-mtu**

Specifies the minimum packet size that can traverse the path without suffering fragmentation, also known as path Maximum Transmission Unit (MTU). The default value is 296. The range is from 68 to 1500.

**path-mtu-discovery**

Specifies, when enabled, that the system discovers the maximum transmission unit (MTU) that it can send over a path, without fragmenting TCP packets. The default value is enabled.

**port-find-linear**

Specifies the maximum of ports to linearly search for outbound connections. The default value is 16. The range is from 0 to 61439.

**port-find-random**

Specifies the maximum of ports to randomly search for outbound connections. The default value is 16. The range is from 0 to 1024.

**port-find-threshold-warning**

Specifies if the ephemeral port-exhaustion threshold warning is to be monitored. The default is enabled.

**port-find-threshold-trigger**

Specifies the threshold warning's trigger which is the value of random port attempts when attempting to find an unused outbound port for a connection. The default is 8. The valid range is 1 - 12.

**port-find-threshold-timeout**

Specifies the threshold warning's timeout. This is the time in seconds since the last trigger value was hit and will drop the tuple if not hit. The default is 30 (1/2 minute) with range from 0 - 300.

**reject-unmatched**

Specifies, when enabled, that the system returns a TCP RESET or ICMP\_UNREACH packet if no virtual servers on the system match the destination address of the incoming packet. When this option is disabled, the system silently drops the unmatched packet. The default value is enabled.

## Itn ifile

NAME

ifile - Configures an iFile.

MODULE

ltm

SYNTAX

Configure the iFile component within the ltm module using the syntax shown in the following sections.

```

CREATE/MODIFY
create ifile [name]
modify ifile [name]
options:
  app-service [[string] | none]
  description [string]
  file-name [ifile file object name]

edit ifile [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

DISPLAY
list ifile
list ifile [ [ [name] | [glob] | [regex] ] ... ]
show running-config ifile
show running-config ifile [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

DELETE
delete ifile [name]

```

**DESCRIPTION**  
 You can use the ifile component to configure an iFile. The iFile can then be referenced from an iRule, to allow loading an external file into an iRule.

**EXAMPLES**

```

create ifile my_ifile file-name ifile_file_object_name

Creates an iFile named my_ifile, that gets its contents from the file
object ifile_file_object_name.

list ifile all-properties

Displays all of the properties of all of the iFiles.

delete ifile my_ifile

Deletes the iFile named my_ifile.

```

**OPTIONS**

```

app-service
Specifies the name of the application service to which the iFile
belongs. The default value is none. Note: If the strict-updates
option is enabled on the application service that owns the object,
you cannot modify or delete the iFile. Only the application
service can modify or delete the iFile.

description
User defined description.

file-name
The name of the iFile File Object that this iFile uses.

```

**SEE ALSO**

DELETE
delete lsn-log-profile [name | all]

DESCRIPTION
A LSN log profile allows fine grain control of the logging for LSN
translation events. When attached to an LSN pool, you can control the
events to enable logging, and the elements in the log entry.

EXAMPLES
create ltm lsn-log-profile my_lsn_log_profile end-inbound-session {
action enabled } end-outbound-session { action enabled }

Creates the LSN log profile my_lsn_log_profile that generates log
entries for both inbound and session when the translation session ends.

delete lsn-log-profile my_lsn_log_profile

Deletes the LSN log profile named my_lsn_log_profile.

OPTIONS
app-service
Specifies the name of the application service to which this object
belongs. The default value is none.

Note: If the strict-updates option is enabled on the application
service that owns the object, you cannot modify or delete this
object. Only the application service can modify or delete this
object.

csv-format
When enabled, use CSV log format for log entries. The default
value is disabled.

events
The type of LSN translation events available for logging control.

start-outbound-session
Event for start of outbound translation session, when the
outbound flow is created.

end-outbound-session
Event for end of outbound translation session, when the
outbound flow is deleted.

start-inbound-session
Event for start of incoming connection to a translated
address.

end-inbound-session
Event for end of incoming connection to a translated address.

quota-exceeded
Event for when client exceeded allocated resource limit.

errors
Event for when LSN encountered errors while attempting
translation for clients.

action
Specify the logging action to be taken when a particular event is
encountered.

```

enabled  
Logging is enable for the event, whether translation is from the primary pool member or backup pool member.

backup-allocation-only  
Logging is enable for the event, when translation is take from backup pool member only.

disabled  
Logging is disable for the event.

elements  
Optional elements that can be added to the log message.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

DELETE
delete lsn-pool [ name | all ]

```

#### DESCRIPTION

A large-scale NAT (LSN) pool is a set of networks and port numbers that the BIG-IP system uses as public-side addresses and ports. When you assign an LSN pool to a virtual server, the virtual server's clients have their private addresses (and/or ports) translated to a public address and/or port from the LSN pool. The public-side addresses and ports in the LSN pool are called translation addresses and ports.

#### EXAMPLES

```

create lsn-pool my_lsn_pool1 mode napt persistence { mode address-port
timeout 600 } members add { 10.10.10.0/24 10.10.20.0/24 } translation-
port-range 4000:5000 client-connection-limit 100

```

Creates the LSN pool `my_lsn_pool1` that contains the translation addresses in the range of (members) `10.10.10.0/24` and `10.10.20.0/24`, translation port range `4000-5000`, with a client connection limit of 100 connections per client. The translated address and port are persisted for 600 seconds. This LSN pool operates in NAT mode (Network Address and Port Translation mode), which is the default mode if not specified.

```

delete lsn-pool my_lsn_pool1

```

Deletes the LSN pool named `my_lsn_pool1`.

#### OPTIONS

##### app-service

Specifies the name of the application service to which this object belongs. The default value is none.

**Note:** If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

##### backup-members

Specifies translation IP addresses available in the backup pool which is used by DNAT translation mode if DNAT mode translation fails and falls back to NAT mode. This is a collection of IP prefixes with their prefix lengths.

##### client-connection-limit

The maximum number of simultaneous translated connections a client or subscriber is allowed to have.

##### description

User defined description.

##### egress-interfaces

The set of interfaces on which the source address translation is allowed or disallowed. If `egress-interfaces-enabled` is specified, the source address translation is allowed only on the specified set of interfaces. If `egress-interfaces-disabled` is specified, source address translation is disabled on specified interfaces.

##### egress-interfaces-disabled

Source address translation is not allowed on the interfaces specified in the `egress-interfaces` set.

##### egress-interfaces-enabled

Source address translation is allowed on the interfaces specified in the `egress-interfaces` set.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

##### hairpin-mode

Enable or disable hairpinning for incoming connections.

When a client sends a packet to another client in the same private network, hairpin mode sends the packet directly to the destination client's private address; the BIG-IP system immediately translates the packet's public-side destination address. Rather than going out to the public network and coming back later for translation, the packet takes a hairpin turn at the BIG-IP device.

`icmp-echo`  
Enable or disable ICMP echo on translated addresses.

`inbound-connections`  
Modifies the inbound-connection mode for incoming connections to translation endpoints. A translation endpoint is the public-side address and port (X':x') for a private-side address (X:x). You can allow one of three algorithms for managing inbound connections:

`Automatic`  
creates inbound mappings automatically from outbound traffic and allows inbound connections. Consider an outbound mapping from X:x to X':x'. If a connection comes from X:x through X':x', the BIG-IP system automatically creates a reverse mapping from X':x' back to X:x. A public-side station can respond through the X':x' address. This allows the BIG-IP system to provide Endpoint Independent Filtering (EIF) as defined in section 5 of RFC 4787  
().

`Explicit`  
only allows inbound connections for mappings that are explicitly created by another party, such as iRules or a PCP request. For example, if a PCP request creates a mapping of X:x to X':x' and the client at X:x uses it, an external caller can respond to the client through X':x'. However, if a client at M:m automatically makes a NAT'ed connection through M':m', the BIG-IP does not support an inbound connection from M':m' back to M:m.

`Disabled`  
disables inbound connections to translation end-points (X':x'). If there is a mapping of X (a private-side IP address) to X' (a public-side IP), connections can only go out from X through X'. If a public-side recipient tries to answer at the client's public-side X' address, the BIG-IP system does not map X' back to X. The inbound connection never happens.

Port Control Protocol (PCP) is not supported if you use this setting.

`log-publisher`  
Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

`log-profile`  
Specify the name of the LSN log profile which controls the logging of translation events. See help ltm lsn-log-profile for more details on the logging profile sub-system. Use the "ltm lsn-log-profile profile" component to set up a LSN log profile.

`members`  
Specifies the set of translation IP addresses available in the pool. This is a collection of IP prefixes with their prefix lengths. All public-side addresses come from the subnets you enter in this property.

`mode` Specifies which kind of translation address mapping is performed when an address is translated. Available options are NATPT, Deterministic, and PBA.

`NAPT` (Network Address Port Translation) assigns translation addresses and ports in round-robin fashion. The algorithm first cycles through translation addresses and then through translation ports.

`Deterministic` (DNAT) is a reversible translation method. A given client address and port always translates to a particular public address and port from the LSN pool. This method has the following restrictions:

it is only available for NAT44 translations,  
it does not support connections through DS-Lite tunnels,  
subscriber connections must be received over a VLAN with the property, `cmp-hash`, set to "source ip,"  
the egress to the Internet must be over a VLAN with the property, `cmp-hash`, set to "dest ip,"  
any virtual server ("ltm virtual") that uses this LSN pool must have a source property set to an IP prefix containing fewer than 231 addresses. For example, the source cannot be 0.0.0.0/0.

`PBA` (Port Block Allocation) assigns 'blocks' of the translation addresses and ports to individual clients. All client connections are restricted to the allocated port blocks. Only block allocations and deallocations are logged in order to reduce the volume of logs.

subscriber connections must be received over a VLAN with the property, `cmp-hash`, set to "source ip,"  
the egress to the Internet must be over a VLAN with the property, `cmp-hash`, set to "dest ip,"

You can access your VLAN configurations through the "net vlan" component. You can find the VLANs used by your virtual server by showing or listing the "ltm virtual" component.

`name` Specifies a unique name for the lsn-pool component. This option is required for the commands create, delete, and modify.

`persistence`

Configure the persistence settings for LSN translation entries. Persistence is the preservation of a public-side IP address for a client from session to session.

`persistence.mode`

Configure the persistence mode for LSN translation entries. You can enter address, address-port, or none.

`address`

causes the BIG IP software to attempt to keep the IP address persistent but not necessarily the port. If a client's private IP address:port combination is X:x, it's public-side address may be X':a in one session, X':b in the next session, X':c in a third session, and so on.

`address-port`

causes the BIG IP software to attempt to keep the IP address and port persistent. If a client's private IP address:port combination is X:x, and it's public-side address is X':x' in the first session, it remains X':x' in all future sessions.

This is called "Endpoint Independent Mapping" in RFC 4787 ().

This is the only supported setting for PCP, which you configure with the `pcp` property.

`none` prevents the BIG IP software from attempting any IP address or port persistence. An address:port combination of X:x is never guaranteed to have the same public-side address or port in two sessions.

`persistence.timeout`

After the most-recent session where address:port X:x translated to X':x' on the public side, a timer begins. If the timer expires before X:x has another session, X' or x' may be used as the public side of another address:port. Use this parameter to set the timeout (in seconds) for address and port persistence.

`pcp` A Port Control Protocol (PCP) client can set (or at least learn) its own translation (public-side) IP address and/or port. It can also set the address and/or port of a third-party client. PCP is defined in RFC 6887 (see ).

`pcp.profile`

Specifies the PCP profile to use for this LSN pool. This PCP profile defines the settings to use for communication with PCP clients. Use the `create ltm profile pcp` command to create a new PCP profile.

PCP requires a profile (defined with this property) and either a `pcp.selfip` or a `pcp.dslite` tunnel where clients can send their PCP requests.

If you remove this profile option, you must specifically remove any `pcp.selfip` or `pcp.dslite` tunnel, too.

`pcp.selfip`

Specifies the PCP Server self-IP address for this LSN pool. The virtual server's clients send their PCP packets to this address. Use the `create net self` command to create a self-IP address, then use that address for this parameter. Choose a self-IP address in a VLAN that is reachable by the virtual server's clients.

`pcp.dslite`

Specifies a DS-LITE tunnel for PCP packets. Whenever a client sends a PCP packet through this tunnel, the BIG-IP device uses the PCP profile you choose with the `pcp.profile` property.

A DS-LITE tunnel places each IPv4 packet into the payload of an IPv6 packet. The IPv6 packet carries the IPv4 packet between customer equipment and the BIG-IP system, which then removes the IPv4 packet, uses NAT to translate its IPv4 addresses, and sends it to its destination.

You cannot use this property if the mode property is set to Deterministic.

`port-block-allocation`

Configures the port block settings for PBA mode.

`port-block-allocation.block-idle-timeout`

Configures the time after the last connection using the block is freed that the block assignment expires. The default value is 3600 seconds.

`port-block-allocation.block-lifetime`

Configures the timeout after which the block is no longer used for new port allocations. The block becomes a zombie block. The default is 0 which corresponds to an infinite timeout.

`port-block-allocation.block-size`

Configures the number of ports in a block. The default value is 64.

`port-block-allocation.client-block-limit`

Configures the number of blocks that can be assigned to a single subscriber IP address. The default value is 1.

`port-block-allocation.zombie-timeout`

Configures the timeout after which connections using the zombie block are killed. After connections are killed zombie block is freed after `port-block-allocation.block-idle-timeout`. This parameter is unused unless the

port-block-allocation.block-lifetime is set. The default value is 0 which corresponds to infinite timeout.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**route-advertisement**

Specifies whether route advertisement is enabled or disabled for translated IP addresses.

**translation-port-range**

Specifies the range of port numbers available for use with translation IP addresses.

## ltm message-routing diameter peer

**NAME**

peer - Configures a peer for routing Diameter protocol messages.

**MODULE**

ltm message-routing diameter

**SYNTAX**

Configure the peer component within the ltm message-routing diameter module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create peer [name]
modify peer [name]
options:
  app-service [[string] | none]
  auto-initialization [ enabled | disabled ]
  auto-initialization-interval [integer]
  connection-mode [ per-peer | per-blade | per-tmm | per-client ]
  description [string]
  number-connections [integer]
  pool [name]
  ratio [integer]
  transport-config [ transport-config ]
```

```
edit peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
```

**DISPLAY**

```
list peer
list peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  one-line
```

**DELETE**

```
delete peer [name]
```

**DESCRIPTION**

You can use the peer component to manage a named Diameter peer. A peer specifies the pool for the Diameter router to use as the destination for Diameter routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

**EXAMPLES**

```
create peer my_peer { pool my_pool transport { type virtual name my_vip } }
```

Creates a Diameter peer named my\_peer which uses the settings of my\_vip to establish a connection with a pool member from pool my\_pool.

**OPTIONS**

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### auto-initialization

If enabled, the BIGIP will automatically create outbound connections to the active pool members in the specified pool using the configuration of the specified transport-config. For auto-initialization to attempt to create a connection, the peer must be included in a route that is attached to a router instance. For each router instance that the peer is contained in, a connection will be initiated. The auto-initialization logic will verify at a configurable interval if the a connection exists between the BIG-IP and the pool members of the pool. If a connection does not exist, it will attempt to reestablish one. The default is disabled.

#### auto-initialization-interval

Specifies the interval (in milliseconds) that attempts to initiate a connection occur. Valid ranges are from 500ms to 65535ms. The default is 5000ms.

#### connection-mode

Specifies how the number of connections per host is limited. Note a host (specified in the referred pool) may exist more than one peer object, and those peer objects may have different settings for connection-mode and number\_connections. Thus, these settings specify how messages routed through this peer are distributed between a set of connections, not the maximum number of connections to a specified host. The default value is per-peer.

#### per-blade

Specifies the number of connections to a remote host per blade in the cluster.

#### per-client

Specifies the number of connections to a remote host per client connection.

#### per-peer

Specifies the number of connections to a remote host.

#### per-tmm

Specifies the number of connections to a remote host per TMM in the system.

#### description

User defined description.

#### number-connections

Specifies the distribution of connections between the BIG-IP system and a remote host. The default value is 1.

**pool** Specifies the name of the pool to which the Diameter parser routes messages.

#### ratio

Specifies the ratio the Diameter router uses to select a peer from a list of peers for the ltm message-routing diameter route. The default value is 1.

#### transport-config

Specifies the name of the transport configuration (ltm message-routing diameter transport-config) the message router uses to create an outgoing connection.

#### SEE ALSO

DELETE
delete router [name]

DESCRIPTION
  You can use the router component to manage a Diameter router profile.

EXAMPLES
  create router my_router_profile defaults-from router

  Creates a Diameter router profile named my_router_profile using the
  system defaults.

  create router my_router_profile routes add { route1 route2 }

  Creates a Diameter profile named my_router_profile with two static
  routes.

OPTIONS
  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  defaults-from
  Specifies the profile that you want to use as the parent profile.
  Your new profile inherits all of the settings and values from the
  specified parent profile. The default value is router.

  description
  User defined description.

  glob Displays the items that match the glob expression. See help glob
  for a description of glob expression syntax.

  ha-message-sweeper-interval
  Specifies the maximum time in milliseconds that a message will be
  held on the standby device as it waits for the active device to
  route the message. Messages on the standby device held for longer
  than the configurable sweeper interval, will be dropped. The
  default value is 1000 milliseconds.

  ignore-peer-port
  If selected (enabled), any connection from a configured peer will
  be suitable for routing a message to, regardless of its remote
  port number. The default value is enabled.

  max-pending-bytes
  Specifies the maximum number of bytes contained within pending
  messages that will be held while waiting for a connection to a
  peer to be created. Once reached any additional messages to the
  peer will be flagged as undeliverable and returned to the
  originator.

  max-pending-messages
```

Specifies the maximum number of pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator.

**max-retries**

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

**mirrored**

If enabled, connection created on the active device of the traffic-group specified, will be mirrored on the standby device. Messages processed on the active device will also be mirrored and perform equivalent processing on the standby device.

**partition**

Displays the administrative partition within which the component resides.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**routes**

Specifies a list of static routes. The ordering of the route entries is insignificant.

**supported-applications**

Defines the list of application ID values that will be supported. If a message is received with an Auth-Application-ID or Acct-Application-ID AVP that does not match any of the values in this list, it will be dropped and the connection will be reset. A value of 0 will match all application IDs. The default value is none.

**traffic-group**

Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

**inherited-traffic-group**

Read-only property that indicates if the traffic-group is inherited from the parent folder.

**transaction-timeout**

Specifies the maximum time (in seconds) between a request and its response. A provisional response restarts the timer. The default value is 10 seconds. Note: This may not affect all transactions. The scenarios where the system waits for response (eg. a final response for REGISTER request), are impacted by dropping any persistent data maintained for the request.

**use-local-connection**

Enables or disables a preference for local connections established by the ingress TMM over connections established by other TMM's when selecting the egress connection to destination peer. By default this attribute is enabled.

**SEE ALSO**

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, tmsh

**COPYRIGHT**

DELETE
delete session [name]

DESCRIPTION
  You can use the session component to manage a Diameter session profile.

EXAMPLES
  create session my_session_profile defaults-from session

  Creates a Diameter session profile named my_session_profile using the
  system defaults.

  create session my_session_profile { reset-on-timeout disabled }

  Creates a Diameter profile named my_session_profile that will not reset
  the connection when watchdog failure exceed maximum-watchdog-failures.

OPTIONS
  acct-application-id
  Specifies as an integer the Accounting identifier for specific
  application, as specified in RFC 6733. This value will be
  appended ot the end of array-acct-application-id in capabilities
  exchange messages if it doesn't already exist in it.

  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  array-acct-application-id
  Specifies as a whitespace separated list of integers the
  Accounting identifier(s) for specific application(s), as specified
  in RFC 6733.

  array-auth-application-id
  Specifies as a whitespace separated list of integers the
  Authentication and Authorization identifier(s) for specific
  application(s), as specified in RFC 6733.

  auth-application-id
  Specifies as an integer the Authentication and Authorization
  identifier for specific application, as specified in RFC 6733.

```

This value will be appended at the end of array-auth-application-id in capabilities exchange messages if it doesn't already exist in it.

**defaults-from**

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is `diametersession`.

**description**

User defined description.

**dest-host-rewrite**

Specifies the destination host AVP to which the specified value on the egress will be rewritten.

**dest-realm-rewrite**

Specifies the destination realm AVP to which the specified value on the egress will be rewritten.

**discard-unroutable**

When selected (enabled), messages that do not match any known route will be silently discarded. When disabled, unroutable messages are routed back to the connection where they came from. The default value is enabled.

**glob** Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

**handshake-timeout**

Specifies the number of seconds before the peer handshake times out. The default is 10 seconds.

**host-ip-address**

Specifies the value that will be used in the Host-IP-Address AVP sent in Capabilities-Exchange-Request and Capabilities-Exchange-Answer messages. When unset (default), the Diameter router will use the virtual server's IP address.

**max-message-size**

Specifies the maximum number of bytes acceptable in a Diameter message. The default value is 0 which indicates that there is no message size restriction for this session. Note: Messages exceeding this size are silently discarded.

**max-watchdog-failures**

Specifies the maximum number of device watchdog failures that the traffic management system can receive before it tears down the connection. After the system receives this number of device watchdog failures, it closes the connection. The default value is 1.

**origin-host**

Specifies the identifier of the originating server in the form `siteserver.f5.com`. Must specify the `origin-host`.

**origin-host-rewrite**

Specifies the value to rewrite to the Origin-Host AVP on egress.

**origin-realm**

Specifies the Origin-Realm AVP data. Must specify the `origin-realm`.

**origin-realm-rewrite**

Specifies the value to rewrite to the Origin-Realm AVP on egress.

**persist-avp**

Specifies the Diameter AVP that is used for persistence. The format is `avp[index]` for a single AVP or `a[x]:b[y]:c[z]:d[w]` for a grouped AVP. There may be at most 4 AVPs in a group. The AVP name is used as the session-key; it may be an ASCII string or numeric ID in the range 1 to 4294967295 (AVP code can be specified instead of AVP name). Note: The default value is `"SESSION-ID[0]"`. A grouped-avp can be specified with the following syntax: `grouped-avp-name[index]:nested-avp1[index1]:nested-avp2[index2]`, where `"nested-avp1"` and `"nested-avp2"` are the AVPs in the grouped AVP.

**persist-timeout**

Specifies the timeout value (in seconds) for persistence entries. The default value is 180. Note: Its recommended to have the `persist-timeout` to be greater than transaction timeout, specified in the Diameter router configuration, as the lesser of the two is used when creating the persist record on receiving of the first Diameter request message. Upon receiving of the response for the first Diameter request message the persistence record is updated with the `persist-timeout` value. For any subsequent responses received the `persist-timeout` is updated for the persist record.

**persist-type** Specifies the type of the persistence. The options are: `avp` Persist based on avp in the message.

**custom**

Persist based on a custom key set using `iRule`.

**none** Persistence is disabled.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

**reset-on-timeout**

When enabled, the system resets the connection when the number of watchdog failures exceeds the value of max-watchdog-failures. The default value is enabled.

#### route-unconfigured-peers

When enabled, all connections will be allowed. When disabled, connections from peers whose IP addresses cannot be found in a statically configured route will be rejected. The default value is enabled.

#### vendor-id

Specifies the vendor identification number assigned to your diameter server by the Internet Assigned Numbers Authority (IANA). The default value is 3375.

#### vendor-specific-vendor-id

Specifies the vendor ID number that will be sent in Vendor-Specific-Application-ID AVPs. A value of 0 disables the feature. If this value is set, exactly one of either vendor-specific-acct-app-id or vendor-specific-auth-app-id must also be specified. The default value is 0.

#### vendor-specific-acct-app-id

Specifies the accounting application ID number that will be sent in Vendor-Specific-Application-ID AVPs. A value of 0 disables the feature. If this value is set, vendor-specific-vendor-id must be set and vendor-specific-auth-app-id must be unset. The default value is 0.

#### vendor-specific-auth-app-id

Specifies the authentication/authorization application ID number that will be sent in Vendor-Specific-Application-ID AVPs. A value of 0 disables the feature. If this value is set, vendor-specific-vendor-id must be set and vendor-specific-acct-app-id must be unset. The default value is 0.

#### watchdog-timeout

Specifies the watchdog timeout in seconds. This setting specifies the number of seconds that a connection is idle before the device watchdog request is sent. A value of 0 means BIG-IP will not send a device watchdog request to either client or server side. The default value is 10 seconds.

## ltm message-routing diameter route

#### NAME

route - Configures a static route for use in Diameter protocol message routing.

#### MODULE

ltm message-routing diameter

#### SYNTAX

Configure the route component within the ltm message-routing diameter module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create route [name]
modify route [name]
options:
  app-service [[string] | none]
  application-id [integer]
  description [string]
  destination-realm [[string] | none]
  origin-realm [[string] | none]
  peer-selection-mode [ratio | sequential]
  peers { [none] | [peer_name ... ] }
  virtual-server [virtual-server_name]
```

```
edit route [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
```

##### DISPLAY

```
list route
list route [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config route
show running-config route [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  one-line

DELETE
delete route [name]
```

#### DESCRIPTION

You can use the route component to define origin and destination realms, virtual server, peers, and peer selection mode of a message routing Diameter static route.

#### EXAMPLES

```
create route my_route

Creates a route instance named my_route using the system defaults.

create route my_route peers { peer1 peer2 }

Creates a route instance named my_route that will use two peers for forwarding messages.
```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**application-id**  
Specifies the application-id to match in the Diameter message. Default value 0 matches every application-id.

**description**  
User defined description.

**destination-realm**  
When specified, match the Destination-Realm AVP value in the message. Default value of "" specifies all destination-realms may be routed.

**origin-realm**  
When specified, match the Origin-Realm AVP value in the message. Default value of "" specifies all origin-realms may be routed.

**peer-selection-mode**  
Specifies the mode of selecting a peer from a list of peers. The options are:

**ratio**  
Peers are selected based on their weights in comparison with other peers.

**sequential**  
Peers are selected in the order listed. All traffic will route the first peer unless all pool members in the peer are marked down.

**peers**  
Specifies an ordered list of peers to use for forwarding messages.

**virtual-server**  
Restricts routing for this route to connections originating on the specified virtual server. The default value is none which means the route is not restricted and messages originating on any connection may be routed to the route.

#### SEE ALSO

## ltm message-routing diameter transport-config

#### NAME

transport-config - Configures a Diameter transport-config instance for routing Diameter message protocol messages.

MODULE  
ltm message-routing diameter

SYNTAX  
Configure the transport-config component within the ltm message-routing diameter module using the syntax shown in the following sections.

```
CREATE/MODIFY
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  source-port [integer]
  profiles [add | delete | replace-all-with] {
    [profile_name ...] {
context [all | clientside | serverside]      read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] ] }
  source-address-translation {
    options:
  pool [ [pool_name] | none]
  type [ automap | snat | none ]
}
```

```
edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete transport-config [name]
```

DESCRIPTION  
You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

EXAMPLES

```
create transport-config my_transport-config
```

Creates a transport-config instance named my\_transport-config using the system defaults.

```
create transport-config my_transport-config { profiles add {
my_diameter my_tcp } }
```

Creates a transport-config instance named my\_transport-config that will use two profiles, my\_diameter and my\_tcp, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

OPTIONS

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description  
User defined description.

profiles  
Specifies a list of profiles that the outgoing connection uses to use to direct and manage traffic. The default value is none.

rules  
Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

source-address-translation  
Specifies the type of source address translation enabled for the transport configuration, as well as the pool that the source address translation uses.

pool Specifies the name of a SNAT pool used by the specified transport configuration.

type Specifies the type of source address translation associated with the specified transport configuration.

The options are:

automap  
Specifies the use of self IP addresses for transport configuration server source address translation.

none Specifies no source address translation is used by the transport configuration.

snat Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

source-port  
Specifies the source port to be used for the connection being created. If no value is specified an ephemeral port is chosen. The default value is 0.

SEE ALSO

BIG-IP ltm message-routing diameter transport-config(1)

---

## ltm message-routing generic peer

NAME

peer - Configures a peer for routing generic message protocol messages.

MODULE

ltm message-routing generic

SYNTAX

Configure the peer component within the ltm message-routing generic module using the syntax shown in the following sections.

CREATE/MODIFY

```
create peer [name]
modify peer [name]
options:
  app-service [[string] | none]
  auto-initialization [ enabled | disabled ]
  auto-initialization-interval [integer]
  connection-mode [ per-peer | per-blade | per-tmm | per-client ]
  description [string]
  number-connections [integer]
  pool [name]
  ratio [integer]
  transport-config [ transport-config ]
```

```
edit peer [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list peer
list peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete peer [name]
```

DESCRIPTION

You can use the peer component to manage a named generic message peer. A peer specifies the pool for the generic message parser to use as the destination for generic message routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

EXAMPLES

```
create peer my_peer { pool my_pool transport { type virtual name my_vip } }
```

Creates a generic message peer named my\_peer which uses the settings of my\_vip to establish a connection with a pool member from pool my\_pool.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auto-initialization

If enabled, the BIGIP will automatically create outbound connections to the active pool members in the specified pool using the configuration of the specified transport-config. For auto-initialization to attempt to create a connection, the peer must be

included in a route that is attached to a router instance. For each router instance that the peer is contained in, a connection will be initiated. The auto-initialization logic will verify at a configurable interval if the a connection exists between the BIG-IP and the pool members of the pool. If a connection does not exist, it will attempt to reestablish one. The default is disabled.

**auto-initialization-interval**  
Specifies the interval (in milliseconds) that attempts to initiate a connection occur. Valid ranges are from 500ms to 65535ms. The default is 5000ms.

**connection-mode**  
Specifies how the number of connections per host is limited. Note a host (specified in the referred pool) may exist more than one peer object, and those peer objects may have different settings for connection-mode and number connections. Thus, these settings specify how messages are routed through this peer are distributed between a set of connections, not the maximum number of connections to a specified host. The default value is per-peer.

**per-peer**  
Specifies the number of connections to a remote host.

**per-blade**  
Specifies the number of connections to a remote host per blade in the cluster.

**per-tmm**  
Specifies the number of connections to a remote host per TMM in the system.

**per-client**  
Specifies the number of connections to a remote host per client connection.

**description**  
User defined description.

**number-connections**  
Specifies the distribution of connections between the BIG-IP system and a remote host. The default value is 1.

**pool** Specifies the name of the pool to which the generic parser routes messages.

**ratio**  
Specifies the ratio the generic message parser uses to select a peer from a list of peers for the ltm message-routing generic route. The default value is 1.

**transport-config**  
Specifies the name of the transport configuration (ltm message-routing generic transport-config) the message router uses to create an outgoing connection.

## ltm message-routing generic protocol

**NAME**  
protocol - Configures a generic message protocol component for parsing generic messages.

**MODULE**  
ltm message-routing generic

**SYNTAX**  
Configure the protocol component within the ltm message-routing generic module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create protocol [name]  
modify protocol [name]  
options:  
  defaults-from [ [name] | none]  
  description [string]

```
disable-parser [ yes | no ]
max-egress-buffer [integer]
max-message-size [integer]
message-terminator [string]
no-response [ yes | no ]
```

```
edit protocol [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
reset-stats protocol
reset-stats protocol [ [ [name] | [glob] | [regex] ] ... ]
```

```
DISPLAY
list protocol
list protocol [ [ [name] | [glob] | [regex] ] ... ]
show running-config protocol
show running-config protocol [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show protocol
show protocol [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

```
DELETE
delete protocol [name]
```

#### DESCRIPTION

You can use the protocol component to implement a named generic message parser for use with the message routing framework. You can create a protocol component, and then add it to a virtual server. You do this when you want to separate a stream of bytes, from a connection to a peer, into messages for routing. This also enables a set of iRule commands to create, populate, and route messages.

#### EXAMPLES

```
create protocol my_protocol defaults-from genericmsg

Creates a message protocol component named my_protocol using the system
defaults.

create protocol my_protocol { welcome-message hello }

Creates a protocol instance named my_protocol that sends a welcome
message of "hello" to any new connection.
```

#### OPTIONS

**defaults-from**  
Specifies the protocol that you want to use as the parent protocol. The new protocol inherits all of the settings and values from the specified parent protocol. The default value is genericmsg.

**description**  
User defined description.

**disable-parser**  
When set to yes, the generic message parser is disabled. The parser ignores all incoming packets and does not directly send message data. This mode supports iRule script protocol implementations that generate messages from the incoming transport stream and send messages on the outgoing transport stream.

**max-egress-buffer**  
Specifies the maximum size of the send buffer in bytes. If the number of bytes in the send buffer for a connection exceeds this value, the generic message parser stops receiving outgoing messages from the router until the size of the buffer drops below this setting. The default value is 32768.

**max-message-size**  
Specifies the maximum size of a received message. If a message exceeds this size, the connection is reset. The default value is 32768.

**message-terminator**  
Specifies the string of characters used to terminate a message. If the message-terminator parameter is empty, the generic message parser does not separate the input stream into messages. The default value is \n.

**no-response**  
When set to yes, matching of responses to requests is disabled. The default value is no.

#### SEE ALSO

## ltm message-routing generic route

**NAME**  
route - Configures a static route the generic message parser uses to route generic message protocol messages.

**MODULE**  
ltm message-routing generic

**SYNTAX**  
Configure the route component within the ltm message-routing generic module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create route [name]
modify route [name]
  options:
    app-service [[string] | none]
    description [string]
    destination-address [string]
    peer-selection-mode [ sequential | ratio ]
    peers { [peer-name] }
    source-address [string]

edit route [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

reset-stats route
reset-stats route [ [name] | [glob] | [regex] ] ... ]
```

### DISPLAY

```
list route
list route [ [name] | [glob] | [regex] ] ... ]
show running-config route
show running-config route [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition

show route
show route [ [name] | [glob] | [regex] ] ... ]
  options:
    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
    field-fmt
```

### DELETE

```
delete route [name]
```

### DESCRIPTION

You can use the route component to manage a generic message static route.

### EXAMPLES

```
create route my_route
```

Creates a static route named `my_route` that uses a wildcard value for the `source-address` and `destination-address` parameters. This acts as a default route.

```
create route my_route { destination-address helpdesk peers add { peer1 peer2 } }
```

Creates a static route named `my_route` that contains two peers, `peer1` and `peer2`. Messages routed with a `destination-address` of `helpdesk` are routed to a pool member contained in `peer1` or `peer2`, based on the specified `peer-selection-mode`.

### OPTIONS

#### app-service

Specifies the name of the application service to which the object belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### destination-address

Specifies the destination address of the route. If this parameter is not present, the generic message parser considers the `destination-address` as a wildcard that matches all message destination addresses. The default value is `none`.

#### description

User defined description.

**peer-selection-mode**  
Specifies the method the generic message parser uses to select a peer from the specified list of peers. The default value is sequential.

**sequential**  
Specifies that the generic message parser selects the first peer in the list of peers. If the protocol retransmits the message, the generic message parser uses another pool member in the first peer. If all pool members in a peer are unavailable, the generic message parser uses the next peer in the list.

**ratio**  
Specifies that the generic message parser selects a peer from a list of peers based on the relative ratio values of each peer. For example if three peers have ratios of 1, 1, and 2, the first 2 peers have a 25% (1/4) probability of being selected and the third peer has a 50% (2/4) probability of being selected.

**peers**  
Specifies a list of peers.

**source-address**  
Specifies the source address of the route. If this parameter is not present, the generic message parser considers the source-address as a wildcard that matches all message sources addresses. The default value is none.

options:  
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)  
field-fmt

DELETE  
delete router [name]

#### DESCRIPTION

You can use the router component to manage a generic message router instance. All virtual servers containing the same router instance share the same route table and can route messages between peers.

#### EXAMPLES

```
create router my_router defaults-from messengerouter
```

Creates a message router instance named my\_router using the system defaults.

```
create router my_router { routes add { route1 route2 } }
```

Creates a router instance named my\_router that contains two static routes, route1 and route2.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the router belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the router. Only the application service can modify or delete the router.

##### defaults-from

Specifies the profile that you want to use as the parent profile. The new profile inherits all of the settings and values from the specified parent profile. The default value is messengerouter.

##### description

User defined description.

##### ignore-client-port

If set to yes, the system ignores the remote port on clientside connections (connections where the peer connected to the BIG IP system) when searching for an existing connection. The default value is no.

##### ha-message-sweeper-interval

Specifies the maximum time in milliseconds that a message will be held on the standby device as it waits for the active device to route the message. Messages on the standby device held for longer than the configurable sweeper interval, will be dropped. The default value is 1000 milliseconds.

##### inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

##### max-pending-bytes

Specifies the maximum number of bytes of pending messages that the router instance holds while waiting for a connection to a peer to be created. Once reached, any additional messages to the peer are flagged as undeliverable and returned to the originator. The default value is 32768.

##### max-pending-messages

Specifies the maximum number of pending messages that the router instance holds while waiting for a connection to a peer to be created. Once reached, any additional messages to the peer are flagged as undeliverable and returned to the originator. The default value is 64.

##### max-retries

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

##### mirrored

If enabled, connection created on the active device of the traffic-group specified, will be mirrored on the standby device. Messages processed on the active device will also be mirrored and perform equivalent processing on the standby device.

##### traffic-group

Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

##### inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

##### use-local-connection

If true, the router will route a message to an existing connection on the same TMM as the message was received on. If an existing connection is not found, it will route the message through an existing connection based on a deterministic algorithm that may be on another TMM. If a matching existing connection is not found, it will create a connection on the current TMM. Setting this flag may limit the number of connections that are created to a peer.

routes  
Specifies a list of static routes for the router instance to use.

## ltm message-routing generic transport-config

NAME

transport-config - Configures a message transport-config instance for routing generic message protocol messages.

MODULE

ltm message-routing generic

SYNTAX

Configure the transport-config component within the ltm message-routing generic module using the syntax shown in the following sections.

CREATE/MODIFY

```
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  source-port [integer]
  profiles [add | delete | replace-all-with] {
    [profile_name ...] {
context [all | clientside | serverside]    read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] }
  source-address-translation {
    options:
  pool [ [pool_name] | none]
  type [ automap | snat | none ]
}
```

```
edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete transport-config [name]
```

DESCRIPTION

You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

EXAMPLES

```
create transport-config my_transport-config
```

Creates a transport-config instance named my\_transport-config using the system defaults.

```
create transport-config my_transport-config { profiles add {
my_genericmsg my_tcp } }
```

Creates a transport-config instance named my\_transport-config that will use two profiles, my\_genericmsg and my\_tcp, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
User defined description.

**source-port**  
Specifies the source port to be used for the connection being created. If no value is specified an ephemeral port is chosen. The default value is 0.

**profiles**  
Specifies a list of profiles that the outgoing connection uses to direct and manage traffic. The default value is none.

**rules**  
Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

**source-address-translation**  
Specifies the type of source address translation enabled for the transport configuration, as well as the pool that the source address translation uses.

**pool** Specifies the name of a SNAT pool used by the specified transport configuration.

**type** Specifies the type of source address translation associated with the specified transport configuration.

The options are:

**automap**  
Specifies the use of self IP addresses for transport configuration server source address translation.

**none** Specifies no source address translation is used by the transport configuration.

**snat** Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

BIG-IP            ltm2message-routing generic transport-config(1)

---

## ltm message-routing sip peer

**NAME**  
peer - Configures a peer for routing SIP message protocol messages.

**MODULE**  
ltm message-routing sip

**SYNTAX**  
Configure the peer component within the ltm message-routing sip module using the syntax shown in the following sections.

```
CREATE/MODIFY
create peer [name]
modify peer [name]
options:
  connection-mode [ per-peer | per-blade | per-tmm | per-client ]
  app-service [[string] | none]
  auto-initialization [ enabled | disabled ]
  auto-initialization-interval [integer]
  connection-mode [ per-peer | per-blade | per-tmm | per-client ]
  description [string]
  number-connections [integer]
  pool [name]
  ratio [integer]
  transport-config [ transport-config ]

edit peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list peer
list peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete peer [name]
```

#### DESCRIPTION

You can use the peer component to manage a named SIP peer. A peer specifies the pool for the SIP router to use as the destination for SIP routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

#### EXAMPLES

```
create peer my_peer { pool my_pool transport { type virtual name my_vip
} }
```

Creates a SIP peer named `my_peer` which uses the settings of `my_vip` to establish a connection with a pool member from `my_pool`.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### auto-initialization

If enabled, the BIGIP will automatically create outbound connections to the active pool members in the specified pool using the configuration of the specified `transport-config`. For auto-initialization to attempt to create a connection, the peer must be included in a route that is attached to a router instance. For each router instance that the peer is contained in, a connection will be initiated. The auto-initialization logic will verify at a configurable interval if the a connection exists between the BIG-IP and the pool members of the pool. If a connection does not exist, it will attempt to reestablish one. The default is disabled.

##### auto-initialization-interval

Specifies the interval (in milliseconds) that attempts to initiate a connection occur. Valid ranges are from 500ms to 65535ms. The default is 5000ms.

##### connection-mode

Specifies how the number of connections per host is limited. Note a host (specified in the referred pool) may exist more than one peer object, and those peer objects may have different settings for `connection-mode` and `number-connections`. Thus, these settings specify how messages routed through this peer are distributed between a set of connections, not the maximum number of connections to a specified host. The default value is `per-peer`.

##### per-peer

Specifies the number of connections to a remote host.

##### per-blade

Specifies the number of connections to a remote host per blade in the cluster.

##### per-tmm

Specifies the number of connections to a remote host per TMM in the system.

##### per-client

Specifies the number of connections to a remote host per client connection.

##### description

User defined description.

##### number-connections

Specifies the distribution of connections between the BIG-IP system and a remote host. The default value is 1.

**pool** Specifies the name of the pool to which the SIP parser routes messages.

##### ratio

Specifies the ratio the SIP router uses to select a peer from a list of peers for the `ltm message-routing sip` route. The default value is 1.

##### transport-config

Specifies the name of the transport configuration (`ltm message-routing sip transport-config`) the message router uses to create an outgoing connection.

#### SEE ALSO

`create`, `delete`, `edit`, `glob`, `list`, `ltm virtual`, `modify`, `regex`, `tmsh`, `ltm message-routing sip route` `ltm message-routing sip profile session`

## ltm message-routing sip profile router

**NAME**  
router - Configures a Session Initiation Protocol (SIP) Router profile.

**MODULE**  
ltm message-routing sip profile

**SYNTAX**  
Configure the router component within the ltm message-routing sip profile module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create router [name]  
modify router [name]  
options:  
app-service [[string] | none]  
defaults-from [[name] | none]  
description [string]  
mirrored-message-sweeper-interval [integer]  
max-pending-bytes [integer]  
max-pending-messages [integer]  
max-retries [integer]  
media-proxy {  
max-media-sessions [integer]  
media-inactivity-timeout [integer]  
}  
mirrored [disabled | enabled]  
operation-mode [load-balancing]  
routes [add | default | delete | none | replace-all-with] {  
[route\_name] ...  
}  
session {  
transaction-timeout [integer]  
max-session-timeout [integer]  
}  
traffic-group [[string] | default | non-default | none]  
use-local-connection [disabled | enabled]  
  
edit router [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
  
reset-stats router  
reset-stats router [ [name] | [glob] | [regex] ] ... ]  
  
**DISPLAY**  
list router  
list router [ [name] | [glob] | [regex] ] ... ]  
show running-config router  
show running-config router [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition  
  
show router  
show router [ [name] | [glob] | [regex] ] ... ]  
options:  
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)  
field-fmt  
  
**DELETE**  
delete router [name]

**DESCRIPTION**  
You can use the router component to manage a SIP router profile.

**EXAMPLES**  
create router my\_router\_profile defaults-from router  
  
Creates a SIP router profile named my\_router\_profile using the system defaults.  
  
create router my\_router\_profile routes add { route1 route2 }  
  
Creates a SIP profile named my\_router\_profile with two static routes.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**defaults-from**

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is router.

**description**

User defined description.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**mirrored-message-sweeper-interval**

Specifies the maximum time in milliseconds that a message will be held on the standby device as it waits for the active device to route the message. Messages on the standby device held for longer than the configurable sweeper interval, will be dropped. The default value is 1000 milliseconds.

**max-pending-bytes**

Specifies the maximum number of bytes contained within pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator.

**max-pending-messages**

Specifies the maximum number of pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator.

**max-retries**

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

**mirrored**

If enabled, connection created on the active device of the traffic-group specified, will be mirrored on the standby device. Messages processed on the active device will also be mirrored and perform equivalent processing on the standby device.

**Important:** Changing traffic groups, with Connection Mirroring enabled, drops all mirrored connections and loses all persistence data. If you change traffic groups, mirroring must restart.

**operation-mode**

Specifies the behavior of the routing instance. The options are:

**load-balancing**

Messages will be load balanced.

**application-level-gateway**

The virtual will act as a forwarding virtual, forwarding messages to the server of peer identified as the destination address of the incoming connection. The messages will be inspected so that associated media flows can be created.

**partition**

Displays the administrative partition within which the component resides.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**routes**

Specifies a list of static routes. The ordering of the route entries is insignificant.

**session.transaction-timeout**

Specifies the maximum time (in seconds) between a request and its response. A provisional response restarts the timer. This may not affect all transactions. The scenarios where the system waits for response (eg. a final response for REGISTER request), are impacted by dropping any persistent data maintained for the request.

**session.max-session-timeout**

This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum duration (in seconds) the media for a call remains active. After this period call media is terminated.

**traffic-group**

Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

**inherited-traffic-group**

Read-only property that indicates if the traffic-group is inherited from the parent folder.

**media-proxy.max-media-sessions**

This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum number of media sessions that are allowed per call.

**media-proxy.media-inactivity-timeout**

This attribute is valid when the operation-mode is application-

level-gateway.Specifies the maximum duration (in seconds) that a media flow is active with no RTP packets. After this period the media flow is removed. This attribute is applicable only to RTP packets. Inactivity time applicable to RTCP packets is max-session-timeout.

#### use-local-connection

Enables or disables a preference for local connections established by the ingress TMM over connections established by other TMM's when selecting the egress connection to destination peer.

#### SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, tmsh

## ltm message-routing sip profile session

#### NAME

session - Configures a Session Initiation Protocol (SIP) Session profile.

#### MODULE

ltm message-routing sip profile

#### SYNTAX

Configure the session component within the ltm message-routing sip profile module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create session [name]
modify session [name]
options:
  app-service [[string] | none]
  custom-via [[via-header] | none]
  defaults-from [[name] | none]
  description [string]
  do-not-connect-back [disabled | enabled]
  generate-response-on-failure [disabled | enabled]
  honor-via [disabled | enabled]
  insert-record-route-header [disabled | enabled]
  insert-via-header [disabled | enabled]
  maintenance-mode [disabled | enabled]
  loop-detection [disabled | enabled]
  max-forwards-check [disabled | enabled]
  max-msg-header-count [integer]
  max-msg-header-size [integer]
  max-msg-size [integer]
  persistence {
    persist-key [Call-ID | Custom | Src-Addr]
    persist-timeout [integer]
    persist-type [session | none]
  }
  enable-sip-firewall [no | yes]

edit session [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

reset-stats session
reset-stats session [ [name] | [glob] | [regex] ] ... ]
```

#### DISPLAY

```
list session
list session [ [name] | [glob] | [regex] ] ... ]
show running-config session
show running-config session [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show session
show session [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

DELETE  
delete session [name]

#### DESCRIPTION

You can use the session component to manage a SIP session profile.

#### EXAMPLES

```
create session my_session_profile defaults-from session
```

Creates a SIP session profile named my\_session\_profile using the system defaults.

```
create session my_session_profile { insert-record-route-header enabled  
}
```

Creates a SIP profile named my\_session\_profile with insertion of record-route header in requests which establish a dialog.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**custom-via** Specifies the value the system uses for the Sent-by field of the Via header when the Insert Via Header setting is enabled. Note: The value that you enter must include a format of SIP/SIP-version/protocol, followed by a Sent-By value. For example, SIP/2.0/TCP www.siterequest.com:4343 or SIP/2.0/SCTP 10.10.4.32.  
**defaults-from**

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is session.

##### description

User defined description.

##### do-not-connect-back

Enables or disables whether a connection to a request originator is re-established (if it no longer exists) in order to deliver a response. When disabled, responses that cannot be forwarded using an existing connection are dropped.

##### generate-response-on-failure

Enables or disables sending failure response messages such as 4xx, 5xx and 6xx, when a SIP request is being dropped. Note: Where it is specified "silently" discarded/dropped, no error response is generated. In any case, a dropped message (request/response) is tracked by the Messages Dropped Statistic.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### honor-via

Enables or disables honoring any via which is not inserted by the system for routing the response. This attribute has no effect if the associated siprouter profileaXXs operation mode attribute is set to "application level gateway".

##### insert-record-route-header

Enables or disables the insertion of a record-route header in requests that establish dialog. When enabled, along with the URI, the custom parameters may be added to facilitate the routing of subsequent requests within this call to avoid route lookup. The record route URI is the local-IP and port of flows that are used for forwarding the message. This attribute has no effect if the associated siprouter profileaXXs operation mode attribute is set to "application level gateway".

##### insert-via-header

Enables or disables insertion of top via. When enabled, custom parameters to help route the response back are inserted, along with sent-by field of via. The source address:port of the flow forwarding the request is filled as value for sent-by field of the via unless a custom via value is specified. The custom parameters inserted to help routing, helps improve performance as it facilitates routing without any lookup. The via is inserted at egress side of the flow, after the SIP\_REQUEST\_SEND event. This attribute has no effect if the associated siprouter profileaXXs operation mode attribute is set to "application level gateway".

##### maintenance-mode

Enables or disables maintenance mode. When enabled, SIP response "503 Service Unavailable" will be sent for incoming SIP request. SIP response will be dropped.

##### loop-detection

Enables or disables loop-detection checking. When a loop is detected, the request is discarded. An error response is sent, if configured. A request is detected as seen before (forwarded/spiraled/looped) only if self inserted via is found in the message and the value of its branch param plays a key role in detecting loop versus spiral. Hence enabling via insertion becomes a requirement to do loop detection check. This attribute has no effect if the associated siprouter profileaXXs operation mode attribute is set to "application level gateway".

##### max-forwards-check

Enables or disables checking on max-forwards. The max-forwards header field serves to limit the number of hops a request can transit on the way to its destination. If 0, the request is discarded. An error response is sent, if configured. This

attribute has no effect if the associated siprouter profileaXXs operation mode attribute is set to \"application level gateway\".

**max-msg-header-count**

Indicates the maximum count of expected SIP message header fields. A message that exceeds this limit is silently discarded.

**max-msg-header-size**

Indicates the maximum SIP message header size (in bytes). A message which exceeds this size is silently discarded.

**max-msg-size**

Indicates the maximum number acceptable SIP message size (in bytes). A message which exceeds this size is silently discarded.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**

Displays the administrative partition within which the component resides.

**persistence**

Configure the persistence settings.

**persistence.persist-key**

Specifies the method which should be used to extract the key value that is used to persist on. The options are:

**Call-ID**

Persist based on the "Call-ID" header field value in the message.

**Custom**

Persist based on the custom key specified using an iRule.

**Src-Addr**

Persist based on originating IP address in the message.

The default option is Call-ID.

**persistence.persist-timeout**

Specifies the timeout value of persistence entries in seconds. Upon receiving of the response for the initial SIP Request message, the persistence record is updated with the persist-timeout value.

**persistence.persist-type**

Specifies the type of the persistence to be used for the specified "persist-key" attribute value. The options are:

**session**

Persistence is enabled guaranteeing that messages containing a given persistence key will be delivered to the same peer.

**none** Persistence is disabled.

The default option is session.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**enable-sip-firewall**

Indicates whether to enable the Application Firewall Security policy. When enabled, the configured AFM security features will apply to the virtual server(s) using this SIP session profile.

**SEE ALSO**

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, tmsh

### DELETE

delete route [name]

## DESCRIPTION

You can use the route component to define the URI's, virtual server, peers and peer selection mode of a message routing SIP static route.

## EXAMPLES

```
create route my_route
```

Creates a route instance named my\_route using the system defaults.

```
create route my_route peers { peer1 peer2 }
```

Creates a route instance named my\_route that will use two peers for forwarding messages.

## OPTIONS

### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

### description

User defined description.

### from-uri

Specifies the patterns to be matched against the From field of a SIP message. This URI will be matched as a case insignificant method. It should be in the form of user@domain. The "sip:" prefix should not be present. Any additional modifiers (for example port or transport) should also not be present. It may begin with a wildcard, "\*". If empty, it will be treated as if the entire URI was a wildcard (matching all From-URIs).

### peer-selection-mode

Specifies the mode of selecting a peer from a list of peers. The options are:

#### ratio

Peers are selected based on their weights in comparison with other peers.

#### sequential

Peers are selected in the order listed. All traffic will route the first peer unless all pool members in the peer are marked down.

### peers

Specifies an ordered list of peers to use for forwarding messages.

### request-uri

Specifies the patterns to be matched against the request-uri field of a SIP message. This URI will be matched as a case insensitive method. It should be in the form of user@domain. The "sip:" prefix should not be present. Any additional modifiers (for example port or transport) should also not be present. It may begin with a wildcard, "\*". If empty, it will be treated as if the entire URI was a \* wildcard (matching all Request-URIs).

#### to-uri

Specifies the patterns to be matched against the To field of a SIP message. This URI will be matched as a case insensitive method. It should be in the form of user@domain. The "sip:" prefix should not be present. Any additional modifiers (for example port or transport) should also not be present. It may begin with a wildcard, "\*". If empty, it will be treated as if the entire URI was a wildcard (matching all To-URIs).

#### virtual-server

Specifies the virtual server on which connections will be routed to this route. If the virtual server is unset, messages originating on any connection may be routed to the route.

#### SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, show, tmsh, ltm message-routing sip route

## ltm message-routing sip transport-config

#### NAME

transport-config - Configures a sip transport-config instance for routing sip message protocol messages.

#### MODULE

ltm message-routing sip

#### SYNTAX

Configure the transport-config component within the ltm message-routing sip module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  source-port [integer]
  profiles [add | delete | replace-all-with] {
    [profile_name ...] {
context [all | clientside | serverside]      read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] }
  source-address-translation {
    options:
  pool [ [pool_name] | none]
  type [ automap | snat | none ]
}
```

```
edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete transport-config [name]
```

#### DESCRIPTION

You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

#### EXAMPLES

```
create transport-config my_transport-config
```

Creates a transport-config instance named my\_transport-config using the system defaults.

```
create transport-config my_transport-config { profiles add { my_sipmsg
```

```
my_tcp } }
```

Creates a transport-config instance named my\_transport-config that will use two profiles, my\_sipmsg and my\_tcp, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### description

User defined description.

##### source-port

Specifies the source port to be used for the connection being created. If no value is specified an ephemeral port is chosen. The default value is 0.

##### profiles

Specifies a list of profiles that the outgoing connection uses to use to direct and manage traffic. The default value is none.

##### rules

Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

##### source-address-translation

Specifies the type of source address translation enabled for the transport configuration, as well as the pool that the source address translation uses.

**pool** Specifies the name of a SNAT pool used by the specified transport configuration.

**type** Specifies the type of source address translation associated with the specified transport configuration.

The options are:

##### automap

Specifies the use of self IP addresses for transport configuration server source address translation.

**none** Specifies no source address translation is used by the transport configuration.

**snat** Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

#### SEE ALSO

show running-config diameter [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete diameter [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the diameter component to configure a custom monitor, or you can use the default Diameter monitor that the Local Traffic Manager provides. This type of monitor checks the health of Diameter protocol resources.

#### EXAMPLES

```
create diameter my_diameter defaults-from diameter
```

Creates a monitor named `my_diameter` that inherits properties from the default Diameter monitor.

```
list diameter
```

Displays the properties of all of the Diameter monitors.

#### OPTIONS

**acct-application-id**  
Specifies the ID of the accounting portion of a Diameter application. If you specify this option, you must also specify a value for the `auth-application-id` option. The default value is `none`.

Note that the `acct-application-id` and `auth-application-id` attribute-value-pair (AVP), and the `vendor-specific-auth-application-id` and `vendor-specific-acct-application-id` AVP are mutually exclusive. You can only specify one of these AVPs.

**app-service**  
Specifies the name of the application service to which the monitor belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

**auth-application-id**  
Specifies the ID of the authentication and authorization portion of a Diameter application. If you specify this option, you must also specify a value for the `acct-application-id` option. The default value is `none`.

Note that the `acct-application-id` and `auth-application-id` attribute-value-pair (AVP), and the `vendor-specific-auth-application-id` and `vendor-specific-acct-application-id` AVP are mutually exclusive. You can only specify one set of these AVPs.

**defaults-from**  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `firepass`.

**description**  
User defined description.

**glob** Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

**host-ip-address**  
Specifies the IP address of the sender of the Diameter message for the Diameter protocol peer discovery feature. The default value is `none`.

**interval**  
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the `up-interval` option, whichever value is greater be a

multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### origin-host

Specifies the IP address from which the Diameter message originates. The default value is the fully-qualified domain name of the BIG-IP system.

#### origin-realm

Specifies the realm in which the host from which the Diameter message originates resides. The default value is f5.com.

#### partition

Displays the administrative partition within which the component resides.

#### product-name

Specifies the vendor-assigned name of the Diameter application. The value of this option must remain constant across firmware revisions for the same product. The default value is F5 BIGIP Diameter Health Monitoring.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### vendor-id

Specifies the IANA SMI Network Management Private Enterprise Code assigned to the vendor of the Diameter application. The default value is 3375.

#### vendor-specific-acct-application-id

Specifies the ID of the vendor-specific accounting portion of a Diameter application. If you specify this option, you must also specify a value for the vendor-specific-auth-application-id option. The default value is none.

Note that the acct-application-id and auth-application-id attribute-value-pair (AVP), and the vendor-specific-auth-application-id and vendor-specific-acct-application-id AVP are mutually exclusive. You can only specify one of these AVPs.

#### vendor-specific-auth-application-id

Specifies the ID of the vendor-specific authentication and authorization portion of a Diameter application. If you specify this option, you must also specify a value for the vendor-specific-acct-application-id option. The default value is none.

Note that the acct-application-id and auth-application-id attribute-value-pair (AVP), and the vendor-specific-auth-application-id and vendor-specific-acct-application-id AVP are mutually exclusive. You can only specify one of these AVPs.

#### vendor-specific-vendor-id

Specifies the ID of a vendor-specific Diameter application. The system uses this ID to advertise support for the application. The default value is none.

## ltm monitor dns

**NAME**  
dns - Configures a Domain Name System (DNS) monitor.

**MODULE**  
ltm monitor

**SYNTAX**  
Configure the dns component within the ltm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create dns [name]  
modify dns [name]  
options:  
accept-rcode [no-error | anything]  
adaptive [enabled | disabled]  
adaptive-divergence-type [relative | absolute]  
adaptive-divergence-value [integer]  
adaptive-limit [integer]  
adaptive-sampling-timespan [integer]  
answer-contains [query-type | any-type | anything]  
app-service [[string] | none]  
defaults-from [name]  
description [string]  
destination [ip address][port]  
interval [integer]  
manual-resume [enabled | disabled]  
qname [string]  
qtype [a | aaaa]  
recv [none | [string] ]  
reverse [enabled | disabled]  
time-until-up [integer]  
timeout [integer]  
transparent [disabled | enabled]  
up-interval [integer]

edit dns [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list dns  
list dns [ [ [name] | [glob] | [regex] ] ... ]  
show dns [ [ [name] | [glob] | [regex] ] ... ]  
show running-config dns  
show running-config dns [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DELETE**  
delete dns [name]

Note: You cannot delete default monitors.

**DESCRIPTION**  
You can use the dns component to configure a custom monitor. This type of monitor verifies the DNS service by attempting to send DNS requests generated using the parameters provided to a pool, pool member, or virtual server and validating the DNS response.

**EXAMPLES**  
create dns my\_dns defaults-from dns qname www.test.com  
  
Creates a monitor named my\_dns that inherits properties other than qname from the default DNS monitor.  
  
list dns  
  
Displays the properties of all of the DNS monitors.

**OPTIONS**  
accept\_rcode  
Specifies the RCODE required in the response for an 'up' status. The default value is no-error.

The options are:

no-error

Specifies that the status of the node will be marked up if the received dns message has RCODE = NOERROR.

anything

Specifies that the status of the node will be marked up irrespective of the RCODE in the dns message received.

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%). If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

answer\_contains

Specifies the record types required in the answer section of the response in order to mark the status of a node up. The default value is query-type.

The options are:

query-type

Specifies that the response should contain at least one answer of which the resource record type matches the qtype.

any-type

Specifies that the dns message should contain at least one answer.

anything

Specifies that an empty answer section is enough to mark the status of the node up.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is dns.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

qname

Specifies the query name that the monitor send a DNS query for. The default value is Enter a query name.

qtype

Specifies the query type of that the monitor sends a query. The default value is a.

The options are:

a Specifies that the monitor will send a DNS query of type A.

aaaa Specifies that the monitor will send a DNS query of type AAAA.

recv Specifies the ip address that the monitor looks for in the dns response's resource record sections. The ip address should be specified in the dotted-decimal notation or ipv6 notation. The default value is none. If no recv value is specified, then the dns message will be checked against accept\_rcode and answer\_contains monitor parameters respectively.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful receive string match marks the monitored object down instead of up. You can use the this mode only if you configure recv option.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

## ltm monitor external

**NAME**  
external - Configures an external monitor.

**MODULE**  
ltm monitor

**SYNTAX**  
Configure the external component within the ltm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create external [name]  
modify external [name]  
options:  
args [ [arguments] | none]  
app-service [[string] | none]  
defaults-from [name]  
description [string]  
destination [ip address][port]  
interval [integer]  
manual-resume [enabled | disabled]  
run [none | [path] ]  
time-until-up [integer]  
timeout [integer]  
user-defined [ [name] [value] | [name] none ]  
up-interval [integer]

edit external [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list external  
list external [ [ [name] | [glob] | [regex] ] ... ]  
show external [ [ [name] | [glob] | [regex] ] ... ]  
show running-config external  
show running-config external [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DELETE**  
delete external [name]

Note: You cannot delete default monitors.

**DESCRIPTION**  
You can use the external component to configure a custom monitor, or you can use the default external monitor that the Local Traffic Manager provides. Using this type of monitor, you can use your own programs to monitor services.

**EXAMPLES**  
create external my\_external defaults-from external  
  
Creates a monitor named my\_external that inherits properties from the default external monitor.  
  
list external  
  
Displays the properties of all of the external monitors.

**OPTIONS**  
args Specifies any command-line arguments that the external program requires. The default value is none.  
  
app-service  
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.  
  
defaults-from  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is external.  
  
description  
User defined description.  
  
destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the address and port supplied by a pool member.

\*:port  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval  
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume  
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

run Specifies the path and file name of a program to run as the external monitor, for example /config/monitors/myMonitor. The default value is none.

time-until-up  
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval  
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 zero, which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

user-defined  
Specifies any user-defined command-line arguments and variables that the external program requires. Use the following syntax to specify a user defined parameter.

```
modify external my_external user-defined my_param_name  
my_param_value
```

Use the following syntax to remove a user defined parameter.

```
modify external my_external user-defined my_param_name none
```

## ltm monitor firepass

**NAME**  
firepass - Configures a FirePass(r) monitor.

**MODULE**  
ltm monitor

**SYNTAX**  
Configure the firepass component within the ltm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create firepass [name]  
modify firepass [name]  
options:  
app-service [[string] | none]  
cipherlist [list]  
concurrency-limit [integer]  
defaults-from [name]  
description [string]  
destination [ip address][port]  
interval [integer]  
max-load-average [integer]  
password [password]  
time-until-up [integer]  
timeout [integer]  
up-interval [integer]  
username [ [name] | none]

edit firepass [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list firepass  
list firepass [ [ [name] | [glob] | [regex] ] ... ]  
show firepass [ [ [name] | [glob] | [regex] ] ... ]  
show running-config firepass  
show running-config firepass [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DELETE**  
delete firepass [name]

Note: You cannot delete default monitors.

**DESCRIPTION**  
You can use the firepass component to configure a custom monitor, or you can use the default Firepass monitor that the Local Traffic Manager provides. This type of monitor checks the health of FirePass systems.

**EXAMPLES**  
create firepass my\_firepass defaults-from firepass  
  
Creates a monitor named my\_firepass that inherits properties from the default Firepass monitor.  
  
list firepass  
  
Displays the properties of all of the Firepass monitors.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.  
  
cipherlist  
Specifies the list of ciphers for this monitor. The default value is HIGH:!ADH.  
  
concurrency-limit  
Specifies the maximum percentage of licensed connections currently in use under which the monitor marks the FirePass system up. The default value is 95.  
  
For example, a value of 95 percent means that the monitor marks

the FirePass system up until 95 percent of licensed connections are in use. When the number of in-use licensed connections exceeds 95 percent, the monitor marks the FirePass system down.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is firepass.

**description**

User defined description.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**interval**

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**max-load-average**

Specifies the number that the monitor uses to mark the FirePass system up or down. The system compares the value of this option to a one-minute average of the FirePass system load. When the FirePass system-load average falls within the specified value, the monitor marks the FirePass system up. When the average exceeds the value, the monitor marks the system down.

The default value is 12.0.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**

Displays the administrative partition within which the component resides.

**password**

Specifies the password, if the monitored target requires authentication. The default value is none.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**time-until-up**

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**up-interval**

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

**username**

Specifies the username, if the monitored target requires authentication. The default value is gtmuser.

## ltm monitor ftp

#### NAME

ftp - Configures a File Transfer Protocol (FTP) monitor.

#### MODULE

ltm monitor

#### SYNTAX

Configure the ftp component within the ltm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create ftp [name]
modify ftp [name]
options:
  app-service [[string] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  filename [ [filename] | none]
  interval [integer]
  manual-resume [enabled | disabled]
  mode [passive | port]
  password [none | [password] ]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [name]
```

```
edit ftp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list ftp
list ftp [ [ [name] | [glob] | [regex] ] ... ]
show ftp [ [ [name] | [glob] | [regex] ] ... ]
show running-config ftp
show running-config ftp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete ftp [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the ftp component to configure a custom monitor, or you can use the default FTP monitor that the Local Traffic Manager provides. This type of monitor verifies the FTP service by attempting to download a specific file to the /var/tmp directory on the system. Once downloaded successfully, the file is not saved.

#### EXAMPLES

```
create ftp my_ftp defaults-from ftp
```

Creates a monitor named my\_ftp that inherits properties from the default FTP monitor.

```
list ftp
```

Displays the properties of all of the FTP monitors.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

**debug**

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is ftp.

**description**

User defined description.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*.\*** Specifies to perform a health check on the address and port supplied by a pool member.

**\*:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**filename**

Specifies the full path and file name of the file that the system attempts to download. The health check is successful if the system can download the file. The default value is none.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**interval**

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

**Important:** F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

**manual-resume**

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

**mode** Specifies the data transfer process (DTP) mode. The default value is passive.

The options are:

**passive**

Specifies that the monitor sends a data transfer request to the FTP server. When the FTP server receives the request, the FTP server then starts and establishes the data connection.

**port** Specifies that the monitor starts and establishes the data connection with the FTP server.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**password**

Specifies the password, if the monitored target requires authentication. The default value is none.

**partition**

Displays the administrative partition within which the component resides.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**time-until-up**

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 zero, which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### username

Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

## ltm monitor gateway-icmp

#### NAME

gateway-icmp - Configures a Gateway Internet Control Message Protocol (ICMP) monitor.

#### MODULE

ltm monitor

#### SYNTAX

Configure the gateway-icmp component within the ltm monitor module using the syntax in the following sections.

#### CREATE/MODIFY

```
create gateway-icmp [name]
```

```
modify gateway-icmp [name]
```

#### options:

```
adaptive [enabled | disabled]
adaptive-divergence-type [relative | absolute]
adaptive-divergence-value [integer]
adaptive-limit [integer]
adaptive-sampling-timespan [integer]
app-service [[string] | none]
defaults-from [name]
description [string]
destination [ip address][port]
interval [integer]
manual-resume [enabled | disabled]
time-until-up [integer]
timeout [integer]
transparent [enabled | disabled]
up-interval [integer]
```

```
edit gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
```

#### DISPLAY

```
list gateway-icmp
```

```
list gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
```

```
show gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config gateway-icmp
```

```
show running-config gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
one-line
partition
```

#### DELETE

delete gateway-icmp [name]

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the gateway-icmp component to configure a custom monitor, or you can use the default Gateway ICMP monitor that the Local Traffic Manager provides. This type of monitor monitors a pool that implements gateway fail-safe for high availability.

#### EXAMPLES

```
create gateway-icmp my_icmp defaults-from gateway_icmp
```

Creates a monitor named `my_icmp` that inherits properties from the default Gateway ICMP monitor.

```
list gateway-icmp
```

Displays the properties of all of the Gateway ICMP monitors.

#### OPTIONS

`adaptive`

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

`adaptive-divergence-type`

Specifies whether the `adaptive-divergence-value` is relative or absolute.

`adaptive-divergence-value`

Specifies how far from mean latency each monitor probe is allowed to be. If `adaptive-divergence-type` is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%). If `adaptive-divergence-type` is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

`adaptive-limit`

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

`adaptive-sampling-timespan`

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

`app-service`

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

`defaults-from`

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `gateway_icmp`.

`description`

User defined description.

`destination`

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

`*:port`

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

`IP address:port (with the transparent option enabled)`

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`interval`

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this

option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### partition

Displays the administrative partition within which the component resides.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

#### up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

**Important:** F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### SEE ALSO

## ltm monitor http

#### NAME

http - Configures a Hypertext Transfer Protocol (HTTP) monitor.

#### MODULE

ltm monitor

#### SYNTAX

Configure the http component within the ltm monitor module using the syntax in the following sections.

#### CREATE/MODIFY

```
create http [name]
modify http [name]
options:
  adaptive [enabled | disabled]
  adaptive-divergence-type [relative | absolute]
```

```

adaptive-divergence-value [integer]
adaptive-limit [integer]
adaptive-sampling-timespan [integer]
app-service [[string] | none]
defaults-from [name]
description [string]
destination [ip address][port]
interval [integer]
ip-tos [integer]
manual-resume [enabled | disabled]
password [none | [password] ]
recv [none | [string] ]
recv-disable [none | [string] ]
reverse [enabled | disabled]
ip-dscp [integer]
send [none | [string] ]
time-until-up [integer]
timeout [integer]
transparent [enabled | disabled]
up-interval [integer]
username [ [name] | none]

edit http [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list http
list http [ [ [name] | [glob] | [regex] ] ... ]
show http [ [ [name] | [glob] | [regex] ] ... ]
show running-config http
show running-config http [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete http [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the http component to configure a custom monitor, or you can use the default HTTP monitor that the Local Traffic Manager provides. This type of monitor verifies the HTTP service by attempting to receive specific content from a Web page.

#### EXAMPLES

```
create http my_http defaults-from http
```

Creates a monitor named my\_http that inherits properties from the default HTTP monitor.

```
list http
```

Displays the properties of all of the HTTP monitors.

#### OPTIONS

**adaptive**  
Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

**adaptive-divergence-type**  
Specifies whether the adaptive-divergence-value is relative or absolute.

**adaptive-divergence-value**  
Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

**adaptive-limit**  
Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

**adaptive-sampling-timespan**  
Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

**app-service**  
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is http.

**description**  
User defined description.

**destination**  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)  
Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval  
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

ip-dscp  
Specifies the differentiated services code point (DSCP). DSCP is a 6-bit value in the Differentiated Services (DS) field of the IP header. It can be used to specify the quality of service desired for the packet. The valid range for this value is 0 to 63 (hex 0x0 to 0x3f). The default value is zero.

manual-resume  
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

password  
Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-disable  
Specifies a text string that the monitor looks for in the returned resource. If the text string is matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

You specify a recv-disable string in the same way that you specify a recv string.

If you specify a recv-disable string, you must also specify a recv string. You cannot specify a recv-disable string, if the reverse option is enabled.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse  
Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you

configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object.

The default setting is GET /, which retrieves a default HTML file for a web site. To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html.

Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

time-until-up  
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent  
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval  
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username  
Specifies the username, if the monitored target requires authentication. The default value is none.

## ltm monitor https

NAME  
https - Configures a Hypertext Transfer Protocol over Secure Socket Layer (HTTPS) monitor.

MODULE  
ltm monitor

SYNTAX  
Configure the https component within the ltm monitor module using the syntax in the following sections.

```
CREATE/MODIFY
create https [name]
modify https [name]
options:
  adaptive [enabled | disabled]
  adaptive-divergence-type [relative | absolute]
```

```

adaptive-divergence-value [integer]
adaptive-limit [integer]
adaptive-sampling-timespan [integer]
app-service [[string] | none]
cert [ [cert list] | none]
cipherlist [string]
compatibility [enabled | disabled]
defaults-from [name]
description [string]
destination [ip address][port]
interval [integer]
ip-dscp [integer]
key [ [key] | none]
manual-resume [enabled | disabled]
password [none | [password] ]
recv [none | [string] ]
recv-disable [none | [string] ]
reverse [enabled | disabled]
send [none | [string] ]
time-until-up [integer]
timeout [integer]
transparent [enabled | disabled]
up-interval [integer]
username [ [name] | none]

edit https [ [ [name] | [glob] | [regex] ] ... ]
options:

options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete https [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the https component to configure a custom monitor, or you can use the default HTTPS monitor that the Local Traffic Manager provides. This type of monitor verifies the HTTPS service by attempting to receive specific content from a Web page protected by Secure Socket Layer (SSL) security.

Note that one of the pre-configured HTTPS monitors is named https\_443, which performs a health check on a server using the IP address supplied by the pool member and port 443.

#### EXAMPLES

```
create https my_https defaults-from https
```

Creates a monitor named my\_https that inherits properties from the default HTTPS monitor.

```
list https
```

Displays the properties of all of the HTTPS monitors.

#### OPTIONS

##### adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

##### adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

##### adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

##### adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

##### adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

#### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

cert Specifies a file object for a client certificate that the monitor sends to the target SSL server. The default value is none.

#### cipherlist

Specifies the list of ciphers for this monitor. The default list DEFAULT:+SHA:+3DES:+kEDH is located in the file base\_monitors.conf.

#### compatibility

Specifies, when enabled, that the SSL options setting (in OpenSSL) is set to ALL. The default value is enabled.

#### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is https.

#### description

User defined description.

#### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

#### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

#### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

#### IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### ip-dscp

Specifies the differentiated services code point (DSCP). DSCP is a 6-bit value in the Differentiated Services (DS) field of the IP header. It can be used to specify the quality of service desired for the packet. The valid range for this value is 0 to 63 (hex 0x0 to 0x3f). The default value is zero.

key Specifies the RSA private key if the monitored target requires authentication. The key must be surrounded by quotation marks, for example, key "client.key". Note that if you specify a key, you must also specify a value for the cert option. The default value is none.

#### manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### partition

Displays the administrative partition within which the component resides.

#### password

Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for

both the send and recv options, the monitor performs a simple service check and connect only.

#### recv-disable

Specifies a text string that the monitor looks for in the returned resource. If the text string is matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

You specify a recv-disable string in the same way that you specify a recv string.

If you specify a recv-disable string, you must also specify a recv string. You cannot specify a recv-disable string, if the reverse option is enabled.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object.

The default setting is GET /, which retrieves a default HTML file for a web site. To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html.

Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

#### time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

#### up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### username

Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## ltm monitor icmp

**NAME**  
icmp - Configures an Internet Control Message Protocol (ICMP) monitor.

**MODULE**  
ltm monitor

**SYNTAX**  
Configure the icmp component within the ltm monitor module using the syntax shown in the following sections.

```
CREATE/MODIFY
create icmp [name]
modify icmp [name]
options:
  adaptive [enabled | disabled]
  adaptive-divergence-type [relative | absolute]
  adaptive-divergence-value [integer]
  adaptive-limit [integer]
  adaptive-sampling-timespan [integer]
  app-service [[string] | none]
  defaults-from {name}
  description [string]
  destination [ip address]
  interval [integer]
  manual-resume [enabled | disabled]
  time-until-up [integer]
  timeout [integer]
  transparent [enabled | disabled]
  up-interval [integer]

edit icmp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list icmp
list icmp [ [ [name] | [glob] | [regex] ] ... ]
show icmp [ [ [name] | [glob] | [regex] ] ... ]
show running-config icmp
show running-config icmp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete icmp [name]
```

Note: You cannot delete default monitors.

**DESCRIPTION**  
You can use the icmp component to configure a custom monitor, or you can use the default ICMP monitor that the Local Traffic Manager provides.

**EXAMPLES**  
create icmp my\_icmp defaults-from icmp  
  
Creates a monitor named my\_icmp that inherits properties from the default ICMP monitor.  
  
list icmp  
  
Displays the properties of all of the ICMP monitors.

**OPTIONS**

**adaptive**  
Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

**adaptive-divergence-type**  
Specifies whether the adaptive-divergence-value is relative or absolute.

**adaptive-divergence-value**  
Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%). If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

**adaptive-limit**  
Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

#### adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

#### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

#### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is icmp.

#### description

User defined description.

#### destination

Specifies the IP address of the resource that is the destination of this monitor. The default value is \*.

Possible values are:

\* Specifies to perform a health check on the IP address of the node.

#### IP address

Specifies to perform a health check on the IP address that you specify, and mark the associated node up or down accordingly.

#### IP address (with the transparent option enabled)

Specifies to perform a health check on the IP address that you specify, route the check through the IP address of the associated node, and mark the IP address of the associated node up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### partition

Displays the administrative partition within which the component resides.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

#### up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this

option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

SEE ALSO

## ltm monitor imap

NAME

imap - Configures an Internet Message Access Protocol (IMAP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the imap component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create imap [name]

modify imap [name]

options:

app-service [[string] | none]  
debug [no | yes]  
defaults-from [name]  
description [string]  
destination [ip address][port]  
folder [ [name] | none]  
interval [integer]  
manual-resume [enabled | disabled]  
password [none | [password] ]  
time-until-up [integer]  
timeout [integer]  
up-interval [integer]  
username [ [name] | none]

edit imap [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties  
non-default-properties

DISPLAY

list imap

list imap [ [ [name] | [glob] | [regex] ] ... ]

show imap [ [ [name] | [glob] | [regex] ] ... ]

show running-config imap

show running-config imap [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties  
non-default-properties  
one-line  
partition

DELETE

delete imap [name]

Note: You cannot delete default monitors.

DESCRIPTION

You can use the imap component to configure a custom monitor, or you can use the default IMAP monitor that the Local Traffic Manager provides. This type of monitor verifies IMAP by attempting to open a specified mail folder on a server. This monitor is similar to the POP3 monitor.

EXAMPLES

create imap my\_imap defaults-from imap

Creates a monitor named my\_imap that inherits properties from the default IMAP monitor.

list imap

Displays the properties of all of the IMAP monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor

belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

#### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

#### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is imap.

#### description

User defined description.

#### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*.\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

#### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

#### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

#### folder

Specifies the name of the folder on the IMAP server that the monitor tries to open. The default value is INBOX.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

**Important:** F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### partition

Displays the administrative partition within which the component resides.

#### password

Specifies the password if the monitored target requires authentication. The default value is none.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**up-interval**  
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

**Important:** F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

**SEE ALSO**

create, delete, edit, glob, list, modify, regex, show, tmsh

**COPYRIGHT**

## ltm monitor inband

**NAME**  
inband - Configures an Inband (passive) monitor.

**MODULE**  
ltm monitor

**SYNTAX**  
Configure the inband component within the ltm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create inband [name]  
modify inband [name]  
options:  
app-service [[string] | none]  
defaults-from [name]  
description [string]  
failure-interval [integer]  
failures [integer]  
response-time [integer]  
retry-time [integer]

edit inband [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list inband  
list inband [ [name] | [glob] | [regex] ] ... ]  
show inband [ [name] | [glob] | [regex] ] ... ]  
show running-config inband  
show running-config inband [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DELETE**  
delete inband [name]

Note: You cannot delete default monitors.

**DESCRIPTION**

You can use the inband component to configure a custom monitor, or you can use the default Inband monitor that the Local Traffic Manager provides. With this type of monitor the BIG-IP(r) system can perform passive monitoring as part of client requests.

**EXAMPLES**

create inband my\_inband defaults-from inband

Creates a monitor named my\_inband that inherits properties from the default Inband monitor.

list inband

Displays the properties of all of the Inband monitors.

## OPTIONS

### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is inband.

### description

User defined description.

### failure-interval

Specifies an interval, in seconds. If the number of failures specified in the failures option occurs within this interval, the system marks the pool member as being unavailable. The default value is 30.

### failures

Specifies the number of failures that the system allows to occur, within the time period specified in the failure-interval option, before marking a pool member unavailable. The default value is 3, which means that the system marks the pool member unavailable at the fourth failure. The multiple tmm processes use a per-process number to calculate failures, depending on the specified load. For example, for the Round Robin load balancing method, if there are N tmm processes and M pool members, and the Failures setting is set to L, then up to  $N*M*L+1$  failures can occur before the system marks the node as down.

Specifying a value of 0 (zero) disables this option.

A failure can be either a failure to connect or a failure of the pool member to respond within the time specified in the response-time option.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

### partition

Displays the administrative partition within which the component resides.

### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

### response-time

Specifies an amount of time, in seconds. If the pool member does not respond with data after the specified amount of time has passed, the number of failures in this interval increments by 1. Specifying a value of 0 (zero) disables this option.

### retry-time

Specifies the amount of time in seconds after the pool member has been marked unavailable before the system retries to connect to the pool member. Specifying a value of 0 (zero) disables this option.

## SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

## ltm monitor ldap

### NAME

ldap - Configures a Lightweight Directory Access Protocol (LDAP) monitor.

### MODULE

ltm monitor

## SYNTAX

Configure the ldap component within the ltm monitor module using the syntax in the following sections.

### CREATE/MODIFY

```
create ldap [name]
modify ldap [name]
options:
  app-service [[string] | none]
  base [none | [string] ]
  chase-referrals [no | yes]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  filter [ [LDAP key] | none]
  interval [integer]
  mandatory-attributes [no | yes]
  manual-resume [enabled | disabled]
  password [none | [password] ]
  security [none | ssl | tls]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [ [name] | none]

edit ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

### DISPLAY

```
list ldap
list ldap [ [ [name] | [glob] | [regex] ] ... ]
show ldap [ [ [name] | [glob] | [regex] ] ... ]
show running-config ldap
show running-config ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete ldap [name]
```

Note: You cannot delete default monitors.

## DESCRIPTION

You can use the ldap component to configure a custom monitor, or you can use the default LDAP monitor that the Local Traffic Manager provides. This type of monitor verifies the LDAP service by attempting to authenticate the specified user.

## EXAMPLES

```
create ldap my_ldap defaults-from ldap
```

Creates a monitor named my\_ldap that inherits properties from the default LDAP monitor.

```
list ldap
```

Displays the properties of all of the LDAP monitors.

## OPTIONS

**app-service**  
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

**base** Specifies the location in the LDAP tree from which the monitor starts the health check. A sample value is dc=bigip-test,dc=net. The default value is none.

**chase-referrals**  
Specifies whether the monitor upon receipt of an LDAP referral entry chases that referral. The default value is yes.

The options are:

**no** Specifies that the system will treat a referral entry as a normal entry and refrain from querying the remote LDAP server(s) pointed to by the referral entry.

**yes** Specifies that the system upon receiving any referral entry from the monitored LDAP server query, the system will then query the corresponding LDAP server(s) pointed to by the LDAP query. If the query for the referral is unsuccessful the system will mark the monitored LDAP server down.

**debug**

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

**defaults-from**  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is ldap.

**description**  
User defined description.

**destination**  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*:\*** Specifies to perform a health check on the address and port supplied by a pool member.

**\*:port**  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**filter**  
Specifies an LDAP key for which the monitor searches. A sample value is objectclass=\*. The default value is none.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**interval**  
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

**Important:** F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

**mandatory-attributes**  
Specifies whether the target must include attributes in its response to be considered up. The default value is no.

The options are:

**no** Specifies that the system performs only a one-level search (based on the value of the filter option), and does not require that the target returns any attributes.

**yes** Specifies that the system performs a sub-tree search, and if the target returns no attributes, the target is considered down.

**manual-resume**  
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

**Note** that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**password**  
Specifies the password if the monitored target requires authentication. The default value is none.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**security**  
Specifies the secure communications protocol that the monitor uses to communicate with the target. The default value is none. The options are:

**none** Specifies that the system does not use a security protocol for communications with the target.

**ssl** Specifies that the system uses the SSL protocol for communications with the target.

**tls** Specifies that the system uses the TLS protocol for communications with the target.

**time-until-up**  
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid

response is received from the node. The default value is 0 (zero).

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### username

Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## ltm monitor module-score

#### NAME

module-score - Configures a Module Score monitor that monitors the performance of a pool or node, rather than the health of the pool or node.

#### MODULE

ltm monitor

#### SYNTAX

Configure the module-score component within the ltm monitor module using the syntax in the following sections.

#### CREATE/MODIFY

create module-score [name]

modify module-score [name]

#### options:

app-service [[string] | none]  
debug [no | yes]  
defaults-from [name]  
description [string]  
interval [integer]  
pool [name]  
snmp-community [none | [string] ]  
snmp-ip-address [ [ip address] | none]  
snmp-port [port]  
snmp-version [string]  
time-until-up [integer]  
timeout [integer]  
up-interval [integer]

edit module-score [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties  
non-default-properties

#### DISPLAY

list module-score

list module-score [ [ [name] | [glob] | [regex] ] ... ]

show module-score [ [ [name] | [glob] | [regex] ] ... ]

show running-config module-score

show running-config module-score [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties  
non-default-properties  
one-line  
partition

DELETE  
delete module-score [name]

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the module-score component to configure a custom monitor, or you can use the default Module Score monitor that the Local Traffic Manager provides. This type of monitor enables global and local traffic management systems to load balance in a proportional manner to local traffic management virtual servers associated with the Web Accelerator(tm) and Application Security Manager modules. When you configure a Module Score type of monitor, the local traffic management system uses SNMP to pull the gtm\_score values from the downstream virtual servers and set the dynamic ratios on the associated upstream local traffic management pool members or nodes.

More specifically, the Module Score monitor retrieves the gtm\_score values from the virtual server and the gtm\_vs\_score values associated with the virtual server. Then, if a pool name is not specified, this monitor sets the dynamic ratio on the node that is associated with the virtual server.

The BIG-IP(r) system uses the lowest non-zero value of the gtm\_vs\_score values to set the dynamic ratio. If all gtm\_vs\_score values are zero, then the gtm\_score value is used to set the dynamic ratios. If you specify a pool name in the monitor definition, then the dynamic ratio is set on the pool member.

Note: If you want to distribute traffic to a cluster of WebAccelerator or Application Security Manager virtual servers, you must create a separate custom Module Score monitor for each back-end Local Traffic Manager system.

#### EXAMPLES

```
create module-score my_module-score defaults-from module_score
```

Creates a monitor named my\_module-score that inherits properties from the default Module Score monitor.

```
list module-score
```

Displays the properties of all of the Module Score monitors.

#### OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is module\_score.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

pool Specifies a Local Traffic Manager pool name. Use this option if you want the system to set dynamic ratios on a pool member instead of on the associated node for the pool member. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

snmp-community  
Specifies the identifier for the SNMP community. The default value is public.

snmp-ip-address  
Specifies the IP address of the SNMP server. The default value is none.

snmp-port  
Specifies the port associated with the SNMP server. The default value is 161.

snmp-version  
Specifies the SNMP version in use by the system. The default value is v2c.

time-until-up  
Specifies the amount of time in seconds after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval  
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

## ltm monitor mssql

NAME  
mssql - Configures a Microsoft(r) Windows(r) Structured Query Language (MSSQL) monitor.

MODULE  
ltm monitor

SYNTAX  
Configure the mssql component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY  
create mssql [name]  
modify mssql [name]  
options:  
app-service [[string] | none]  
count [integer]  
database [ [name] | none]  
debug [no | yes]  
defaults-from {name}  
description [string]  
destination [ip address][port]  
interval [integer]  
manual-resume [enabled | disabled]  
password [none | [password] ]  
recv [none | [string] ]  
recv-column [none | [string] ]  
recv-row [none | [string] ]  
send [none | [string] ]  
time-until-up [integer]

```

timeout [integer]
up-interval [integer]
username [(name) | none]

edit mssql [ [ (name) | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list mssql
list mssql [ [ (name) | [glob] | [regex] ] ... ]
show mssql [ [ (name) | [glob] | [regex] ] ... ]
show running-config mssql
show running-config mssql [ [ (name) | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete mssql (name)

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the mssql component to configure a custom monitor, or you can use the default Microsoft Windows SQL monitor that the Local Traffic Manager provides. This type of monitor verifies Microsoft Windows SQL-based services.

#### EXAMPLES

```
create mssql my_mssql defaults-from mssql
```

Creates a monitor named my\_mssql that inherits properties from the default MSSQL monitor.

```
list mssql
```

Displays the properties of all of the MSSQL monitors.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

##### count

Specifies the number of monitor probes after which the connection to the database will be terminated. Count value of zero indicates that the connection will never be terminated. The default value is zero.

##### database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

##### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mssql.

##### description

User defined description.

##### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

##### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

##### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### partition

Displays the administrative partition within which the component resides.

#### password

Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

#### recv-column

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

#### recv-row

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(\*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

#### time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### username

Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

#### COPYRIGHT

show running-config mysql [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition  
  
**DELETE**  
delete mysql [name]

Note: You cannot delete default monitors.

**DESCRIPTION**  
You can use the mysql component to configure a custom monitor, or you can use the default MySQL monitor that the Local Traffic Manager provides. This type of monitor verifies MySQL-based services.

**EXAMPLES**  
create mysql my\_mysql defaults-from mysql  
  
Creates a monitor named my\_mysql that inherits properties from the default MySQL monitor.  
  
list mysql  
  
Displays the properties of all of the MySQL monitors.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.  
  
count  
Specifies the number of monitor probes after which the connection to the database will be terminated. Count value of zero indicates that the connection will never be terminated. The default value is zero.  
  
database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

#### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

#### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mysql.

#### description

User defined description.

#### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

#### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

#### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

**Important:** F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### partition

Displays the administrative partition within which the component resides.

#### password

Specifies the password if the monitored target requires authentication. The default value is none.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

#### recv-column

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

#### recv-row

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**send** Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(\*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the `recv` option and ignores the option even if not null.

#### time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

#### username

Specifies the username, if the monitored target requires authentication. The default value is none.

## ltm monitor nntp

#### NAME

`nntp` - Configures a Network News Transfer Protocol (NNTP) monitor.

#### MODULE

`ltm monitor`

#### SYNTAX

Configure the `nntp` component within the `ltm monitor` module using the syntax in the following sections.

#### CREATE/MODIFY

```
create nntp [name]
```

```
modify nntp [name]
```

#### options:

```
app-service [[string] | none]
```

```
debug [no | yes]
```

```
defaults-from [name]
```

```
description [string]
```

```
destination [ip address][port]
```

```
interval [integer]
```

```
manual-resume [enabled | disabled]
```

```
newsgroup [ [name] | none]
```

```
password [none | [password] ]
```

```
time-until-up [integer]
```

```
timeout [integer]
```

```
up-interval [integer]
```

```
username [[name] | none]
```

```
edit nntp [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
```

```
non-default-properties
```

#### DISPLAY

```
list nntp
```

```
list nntp [ [ [name] | [glob] | [regex] ] ... ]
```

```
show nntp [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config nntp
```

```
show running-config nntp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete nntp [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the nntp component to configure a custom monitor, or you can use the default NNTP monitor that the Local Traffic Manager provides. This type of monitor verifies the Usenet News protocol service by attempting to retrieve a newsgroup identification string from the server.

#### EXAMPLES

```
create nntp my_nntp defaults-from nntp
```

Creates a monitor named my\_nntp that inherits properties from the default NNTP monitor.

```
list nntp
```

Displays the properties of all of the NNTP monitors.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

##### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is nntp.

##### description

User defined description.

##### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

##### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

##### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

**Important:** F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

##### manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

##### newsgroup

Specifies the name of the newsgroup that you are monitoring, for

example alt.car.mercedes. The default value is none.

**partition**  
Displays the administrative partition within which the component resides.

**password**  
Specifies the password if the monitored target requires authentication. The default value is none.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**time-until-up**  
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**up-interval**  
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

#### COPYRIGHT

## ltm monitor none

**NAME**  
none - Disables monitoring for a node or pool member.

**MODULE**  
ltm monitor

**SYNTAX**  
Apply the none monitor using the syntax in the following sections. The "none" attribute is indicated when viewing the listed node.

**MODIFY**  
modify ltm node [ [ [name] | [glob] | [regex] ] ... ] monitor none

**DISPLAY**  
list ltm node monitor

**DESCRIPTION**  
To disable monitoring on the node or pool member, set the monitor to none.

**EXAMPLES**  
modify ltm pool [name] monitor none

Apply a none monitor on a pool.

modify ltm pool members modify { [name] { monitor none } }

Apply a none monitor on a pool member.

```
modify ltm node [name] monitor none
```

Apply a none monitor on a node.

```
list ltm node monitor
```

Displays the monitor applied to all nodes.

```
list ltm node [name] monitor
```

Displays the monitor applied to a specific node.

```
list ltm pool p1 members { all { monitor } }
```

Displays the monitor applied to all pools' members.

```
list ltm pool [name] members { monitor }
```

Displays the monitor applied to a pool's members.

#### SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

## ltm monitor oracle

#### NAME

oracle - Configures an Oracle(r) monitor.

#### MODULE

ltm monitor

#### SYNTAX

Configure the oracle component within the ltm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create oracle [name]
```

```
modify oracle [name]
```

##### options:

```
app-service [[string] | none]
count [integer]
database [ [name] | none]
debug [no | yes]
defaults-from [name]
description [string]
destination [ip address][port]
interval [integer]
manual-resume [enabled | disabled]
password [none | [password] ]
recv [none | [string] ]
recv-column [none | [string] ]
recv-row [none | [string] ]
send [none | [string] ]
time-until-up [integer]
timeout [integer]
up-interval [integer]
username [ [name] | none]
```

```
edit oracle [ [ [name] | [glob] | [regex] ] ... ]
```

##### options:

```
all-properties
non-default-properties
```

##### DISPLAY

```
list oracle
```

```
list oracle [ [ [name] | [glob] | [regex] ] ... ]
```

```
show oracle [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config oracle
```

```
show running-config oracle [ [ [name] | [glob] | [regex] ] ... ]
```

##### options:

```
all-properties
non-default-properties
one-line
partition
```

##### DELETE

```
delete oracle [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the oracle component to configure a custom monitor, or you can use the default Oracle monitor that the Local Traffic Manager provides. This type of monitor verifies Oracle database services.

#### EXAMPLES

```
create oracle my_oracle defaults-from oracle
```

Creates a monitor named my\_oracle that inherits properties from the default Oracle monitor.

```
list oracle
```

Displays the properties of all of the Oracle monitors.

#### OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

count

Specifies the number of monitor probes after which the connection to the database will be terminated. Count value of zero indicates that the connection will never be terminated. The default value is zero.

database

Specifies the name of the database with which the monitor attempts to communicate. The proper format for database name is ::. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is oracle.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component

resides.

**password**

Specifies the password if the monitored target requires authentication. The default value is none.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

**recv-column**

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**recv-row**

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**send** Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(\*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

**time-until-up**

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**up-interval**

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

**username**

Specifies the username, if the monitored target requires authentication. The default value is none.

## ltm monitor pop3

NAME

pop3 - Configures a Post Office Protocol (POP3) monitor.

MODULE

ltm monitor

#### SYNTAX

Configure the pop3 component within the ltm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create pop3 [name]
modify pop3 [name]
options:
  app-service [(string) | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  interval [integer]
  manual-resume [enabled | disabled]
  password [none | [password] ]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [ [name] | none]
```

```
edit pop3 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list pop3
list pop3 [ [ [name] | [glob] | [regex] ] ... ]
show pop3 [ [ [name] | [glob] | [regex] ] ... ]
show running-config pop3
show running-config pop3 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete pop3 [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the pop3 component to configure a custom monitor, or you can use the default POP3 monitor that the Local Traffic Manager provides. This type of monitor verifies the POP3 service by attempting to connect to a pool, pool member, or virtual server, log on as the specified user, and log off.

#### EXAMPLES

```
create pop3 my_pop3 defaults-from pop3
```

Creates a monitor named my\_pop3 that inherits properties from the default POP3 monitor.

```
list pop3
```

Displays the properties of all of the POP3 monitors.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

##### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is pop3.

##### description

User defined description.

##### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

##### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**interval**  
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

**Important:** F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

**manual-resume**  
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**password**  
Specifies the password if the monitored target requires authentication. The default value is none.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**time-until-up**  
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**up-interval**  
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

**Important:** F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

**NAME**  
 postgresql - Configures a PostgreSQL(r) monitor.

**MODULE**  
 ltm monitor

**SYNTAX**  
 Configure the postgresql component within the ltm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
 create postgresql [name]  
 modify postgresql [name]  
 options:  
   app-service [[string] | none]  
   count [integer]  
   database [ [name] | none]  
   debug [no | yes]  
   defaults-from [name]  
   description [string]  
   destination [ip address][port]  
   interval [integer]  
   manual-resume [enabled | disabled]  
   password [none | [password] ]  
   recv [none | [string] ]  
   recv-column [none | [string] ]  
   recv-row [none | [string] ]  
   send [none | [string] ]  
   time-until-up [integer]  
   timeout [integer]  
   up-interval [integer]  
   username [[name] | none]

edit postgresql [ [ [name] | [glob] | [regex] ] ... ]  
 options:  
   all-properties  
   non-default-properties

**DISPLAY**  
 list postgresql  
 list postgresql [ [ [name] | [glob] | [regex] ] ... ]
