

# F5 TMSH Reference - 15.x

F5 TMSH references are collections of the available BIG-IP TMSH man pages.

## General

### grep

#### NAME

grep - Display lines matching a pattern

#### SYNTAX

```
list [component] " | " grep [ [option] | pattern] ... ]
show [component] " | " grep [ [option] | pattern] ... ]
```

##### options:

- A [integer]
- B [integer]
- C [integer]
- E
- G
- P
- c
- e [pattern]
- i
- m [integer]
- n
- o
- v
- w
- x Note: Each option must be followed by a space.

Note: tmsh treats any argument that is not preceded by a supported option, and does not begin with a hyphen, as a search pattern preceded by -e.

#### DESCRIPTION

You can use grep to filter the output generated by the commands list (configuration settings) and show (statistics and runtime status). You must type the character | before the grep specification. You can use multiple filters chained together.

#### EXAMPLES

The following examples show how to use the grep utility in tmsh.

```
list ltm node | grep "^10\.2"
list ltm virtual | grep -i seattle
list ltm virtual | grep -i abc | grep -i ab | grep -i a
```

#### OPTIONS

- A Display the specified number of lines of context after matching lines.
- B Display the specified number of lines of context before matching lines.
- C Display the specified number of lines of context before and after matching lines.
- E Interpret patterns as extended regular expressions.
- G Interpret patterns as basic regular expressions.
- P Interpret patterns as Perl regular expressions.
- c Display a count of the lines that match. If -v is specified the number of non-matching lines is displayed.
- e Specify a pattern. This is useful to protect against patterns beginning with a hyphen.
- i Case insensitive search.
- m Stop reading input after the specified number of matching lines. If -c is specified the count will not exceed the value specified for -m. If -v is specified grep will stop after finding the specified number of non-matching lines.
- n Prefix each line of output with the line number relative to the input.
- o Show only the part of a matching line that matches the pattern.
- v Invert the sense of matching, to select non-matching lines.
- w Select only those lines containing matches that form whole words. The test is that the matching substring must either be at

the beginning of the line, or preceded by a non-word constituent character. Similarly, it must be either at the end of the line or followed by a non-word constituent character. Word-constituent characters are letters, digits, and the underscore.

-x Select only those matches that exactly match the whole line.

## time

NAME

Time - Date and Time formats.

MODULE

All tmsh modules.

SYNTAX

Date/Time Syntax  
now[ [ + | - ] [ d | h | w | m ] ]  
yyyy-mm-dd[ : | T ]hh:mm[:ss]  
mm-dd[-yyyy][ : | T ]hh:mm[:ss]  
mm/dd[/yyyy][ : | T ]hh:mm[:ss]  
  
Date Range Syntax  
now[ [ + | - ] [ d | h | w | m ] ]--now[ [ + | - ] [ d | h | w | m ] ]  
yyyy-mm-dd[ : | T ]hh:mm[:ss]--yyyy-mm-dd[ : | T ]hh:mm[:ss]  
mm-dd[-yyyy][ : | T ]hh:mm[:ss]--indefinite  
epoch--mm/dd[/yyyy][ : | T ]hh:mm[:ss]  
now[ [ + | - ] [ d | h | w | m ] ]

DESCRIPTION

The date or time format is found in tmsh as an attribute or parameter for many configuration items. Below are the various formats supported for both Date/Time and Date Range. Please see the examples for further assistance in using the required formats.

DATE:TIME FORMATS

nowX This date format starts with now (the current time) and is optionally followed by + or - some time span. The format will look like the following: now[ [ + | - ] integer [ d | h | w | m ] ], where the user picks either before (-) or after (+) the current time and then specifies integer number of minutes(m), hours(h), days(d) or weeks(w). This format is case-insensitive.

Examples:

Input	Date	Description
-------	------	-------------

now-3d		3 days ago.
now+3h		3 hours from now.
now-3m		3 minutes ago.
now+3w		3 weeks from now.

yyyy-mm-dd:hh:mm:ss

This format requires a year, month, day separated by - characters. A time is also required, which is specified as hour:minute:second, where the seconds are optional. The date and time must be separated by a : colon. Note: This is the default time format for output from tmsh.

Examples:

Input	Date	Description
-------	------	-------------

2013-05-29:13:30		May 29th, 2013 at 1:30pm.
2000-01-04:12:22:30		January 4th, 2000 at 12:22pm and 30 seconds.

mm-dd-yyyy:hh:mm:ss

This format requires at least a month(m) and day(d) specified and optionally a year (y). If no year is specified, tmsh will auto-fill the year with the current year. A time is also required in the format of hour:minute:second, where the seconds are optional.

Examples:

Input	Date	Description
-------	------	-------------

3-12-2015:12:01:00		March 12th, 2015 at 12:01 pm.
4-15:22:10:30		April 15th of this year at 10:10 pm and 30 seconds.

mm/dd/yyyy:hh:mm:ss

This format requires at least a month(m) and day(d) specified and optionally a year (y). If no year is specified, tmsh will auto-fill the year with the current year. A time is also required in the format of hour:minute:second, where the seconds are optional.

#### Examples:

Input Date	Description
------------	-------------

3/12/2015:12:01:00	March 12th, 2015 at 12:01 pm.
4/15:22:10:30	April 15th of this year at 10:10 pm and 30 seconds.

#### T Delimiter

Any of the above time formats may optionally use a capital letter T (as in the word Time) to separate the date from the time, instead of using a colon (:).

#### Examples:

Input Date	Description
------------	-------------

9/16/2005T12:01:01	September 16th, 2005 at 12:01pm and 1 second.
2011-11-12T00:03:30	November 12th, 2011 at 12:03am and 30 seconds.

#### Special Dates

There are two special dates that may be used in tmsh. They are indefinite and epoch. Below is an explanation of those dates.

#### indefinite

The date will be marked as being infinitely in the future (end of time).

#### epoch

The date will be marked as being infinitely in the past (beginning of time).

### DATE RANGES

#### DateX--DateZ

A Date Range is 2 dates in a valid Date Format separated by a -- (double hyphen). The dates may be any of the Date Formats specified above. See examples below on how to use this notation.

#### Examples:

Input Date	Description
------------	-------------

now-2d--now-4d	2 to 4 days ago.
now--now-3m	From 3 minutes ago to now.
epoch--3/12/2011:12:00:00	Everything older than March 12th, 2011 at noon.
2008-03-12--indefinite	Everything after midnight on March 12th, 2008.

#### DateX

When specifying a date range, the second date may be left out. This will cause the system to assume the second date in the range to be now. Using this format for a date range may make it confusing when using the NowX date format listed above. The following examples will help clarify how to use this format with any supported Date Format.

#### Examples:

Input Date	Description
------------	-------------

now-3d	From 3 days ago to now.
now+3w	From now to 3 weeks from now.
epoch	Everything before the current date and time.
indefinite	Everything after the current date and time.

## tmsh

### NAME

tmsh - Traffic Management Shell - A command line interface for managing the BIG-IP(r) system.

### DESCRIPTION

You can use tmsh to configure and manage the BIG-IP system in conjunction with the Configuration utility, which is the browser-based BIG-IP system and network management tool.

### MODULES

The structure of tmsh is hierarchical and modular. The highest level is the root module, which contains subordinate modules: auth, cli, gtm, ltm, net, sys and wom. Use the command help with no arguments to display the module hierarchy relative to the current module.

The gtm, ltm, net, sys, and wom modules also contain subordinate modules. All modules and subordinate modules contain components. To display the list of modules and components that are available in the current module type Tab or ? at the tmsh prompt.

Commands operate on components. To display the list of available commands type Tab or ? at the beginning of the command line. To display a list of components on which a command can operate type the command followed by a space followed by Tab or ?.

The following examples illustrate how to navigate the tmsh hierarchy.

To enter a module, type the name of the module at the tmsh prompt.

```
(tmsh)# ltm
```

The prompt displays the current module location.

```
(tmsh.ltm)#
```

You can display the components in a module using the commands list (configuration) and show (statistics and runtime status). The following command sequence displays the virtual server configuration of the BIG-IP system.

```
(tmsh.ltm)# list virtual
```

In the following examples, the commands list and show display information about only ltm components.

```
(tmsh.ltm)# list
(tmsh.ltm)# show
```

You can access any component in any module from any other module by specifying a complete path to the component. For example, from the ltm module, the following command displays all of the properties of the VLANs on the system. The forward slash / specifies that what follows is relative to the root module.

```
(tmsh.ltm)# list /net vlan all-properties
```

The forward slash is optional if the root module is the current module. For example, the following command sequences display profiles.

```
(tmsh)# list ltm profile
(tmsh)# list /ltm profile
(tmsh)# list / ltm profile
```

Most components also support component mode. You can navigate to a single component and run commands to manage that component. For example, from the ltm module, to navigate to the node component, use the following command.

```
(tmsh.ltm)# node
```

To display the properties of all nodes, use the following command.

```
(tmsh.ltm.node)# list
```

You can also navigate to a specific object (object mode). For example, from the node component, to enter object mode for a specific node, enter the command modify followed by the IP address of the node.

```
(tmsh.ltm.node)# modify 10.1.1.10
```

In object mode, you can configure property settings directly. For example, to set the connection limit for 10.1.1.10 to 10000, use the following command.

```
(tmsh.ltm.node.10.1.1.10)# connection-limit 10000
```

To exit a module enter the command exit at the tmsh prompt, as shown below.

```
(tmsh.ltm)# exit
(tmsh)#
```

## PRODUCT PROVISIONING

You must provision a BIG-IP system module before you can use tmsh to configure that product, for example, the Global Traffic Manager. The command sequence list sys provision displays the BIG-IP system modules that can be provisioned. For more information about provisioning, see the TMOS(r) Management Guide for BIG-IP Systems and help sys provision.

## LOADING/SAVING THE SYSTEM CONFIGURATION

The system applies all configuration changes that you make from within tmsh to the running configuration of the system.

You can save a portion of the running configuration known as the base configuration. You can also load the base configuration from the stored configuration files.

To save the base configuration to the stored configuration files, use the command sequence: save sys base-config.  
To replace the running base configuration with the configuration in the stored configuration files, use the command sequence: load /sys base-config.

Additionally, you can save the entire running configuration or load all

of the stored configuration files.

To save the entire running configuration to the stored configuration files, use the command sequence: `save /sys config`.  
To replace the entire running configuration with the configuration in the stored configuration files using the command sequence: `load /sys config`.

#### HELP

tmsh includes man pages for each of the commands and components that are available within tmsh. You access the man pages using the following command syntax: `help [ [command] | [full path to component] ]`.

For example, to access the man page for the vlan component from the root module, use this command sequence: `help / net vlan`.

You can also search the man pages for information on a specific topic. To do this you use the command syntax: `help search [topic]`. You can perform a help search from within any module in the tmsh hierarchy. For example, to find the man pages that contain a reference to VLANs, use this command sequence: `help search vlan`

To display a list of topics that are available in a module use this command sequence: `help [full path to module]`.

For example, to display the topics that are available in the current module use this command: `help`. To display the topics that are available in the net module use this command sequence: `help / net`.

#### CONTEXT-SENSITIVE HELP

tmsh includes a context-sensitive help feature that provides help as you type commands. At any time, you can type a question mark (?) on the command line, and tmsh returns information to assist you in completing the command. Based on when you type the question mark, you get the following results.

When you type a question mark immediately following any portion of a command, tmsh returns possible completions for the command, but does not complete the command as the command completion feature does. When you type a space before the question mark, tmsh returns descriptive text that explains the commands, components, or properties that you can configure. When you type a question mark in the middle of a command, tmsh returns help on the command to the left of the cursor.

Note: To use a question mark in a Glob or regular expression, you must escape the question mark using quotation marks, apostrophes, or a backslash.

Additionally, you can request context-sensitive help for the last command in a series of commands. For more information, see ENTERING MULTIPLE COMMANDS, following.

#### COMMAND COMPLETION

At any point while typing or editing a command in tmsh, you can press the Tab key. tmsh either completes the current or next word, or displays possible completions for the current or next word. If tmsh displays nothing after you press the Tab key, no options exist to complete the word. If you move the cursor anywhere on the command line and press the Tab key, tmsh completes what is to the left of the cursor.

Command completion also reduces the amount of typing that is required to run commands. When you press the Tab key, the system automatically completes the current command-line element to as many unique characters as possible. If there is more than one possible completion the list of possible completions displays. Command completion also completes configuration object identifiers.

#### ENTERING MULTIPLE COMMANDS

You can enter multiple commands on the command line by separating the commands with semi-colons (;). For example, to display the properties of the self IP addresses and VLANs of the system, use this command sequence:

```
list / net self ; list / net vlan
```

When you enter multiple commands in this way, all of the commands are added to the command history in a single line item, regardless of whether any of the commands were successful. However, if one of the commands that you enter fails to parse, tmsh does not run the remaining commands you entered. tmsh audits commands as the commands run; therefore, if a command fails to parse, tmsh does not audit the remaining commands. For more information about the command history, see COMMAND HISTORY, following.

You can also specify multiple commands in a command alias by separating the commands with semi-colons. For example, to create an alias that displays the properties of the VLANs and VLAN groups on the system, use this command sequence:

```
create / cli alias vlans command "list / net vlan ; list / net vlan-group"
```

You can request context-sensitive help and utilize the command completion feature on the last command in a series of commands. For example, the following command sequence displays help for the vlan-group component.

```
list / net vlan ; list / net vlan-group ?
```

#### COMMAND HISTORY

tmsh saves in the command history file each command that you enter. The command history persists when you log off of the system. The next time

you log on to the system, you can search for, display, and then edit, the tmsh commands that you entered in previous sessions. The command history persists even through a restart of the BIG-IP system. For more information about the command history feature, see help history.

The following examples show how to use the command history feature.

To display the commands in the history list, enter either the command sequence show history or an exclamation point (!). tmsh displays a list of commands each preceded by a numeric ID.

To run a command from the history list, enter an exclamation point followed by the numeric ID of the command.

To run the previous command, enter !!.

#### FILTERING OUTPUT

You can filter the output generated by the commands list (configuration settings) and show (statistics and runtime status) using the UNIX grep utility. You must type the character | before the grep specification. You can use multiple filters chained together. For a list of supported grep options, see the Traffic Management Shell (tmsh) Reference Guide.

The following examples show how to use the grep utility in tmsh.

```
list ltm node | grep "^10\.2"
list ltm virtual | grep -i seattle
list ltm virtual | grep -i abc | grep -i ab | grep -i a
```

#### KEYBOARD BINDINGS

tmsh supports vi, emacs and default keyboard bindings. You can set the binding using the keymap preference. For more information, see help cli preference. For a detailed description of the default mapping, see the Traffic Management Shell (tmsh) Reference Guide.

Note that all mappings provide command-line editing and the capability to search the command history.

#### WILDCARD OBJECT IDENTIFIERS

You can specify configuration object identifiers using glob and regular expression syntax.

For glob and regular expression syntax rules, see help glob and help regex. Note that you can escape the glob and regular expression special characters using a back slash.

The following examples show how to use glob and regular expressions in tmsh.

Uses a glob expression to display the configuration of all nodes that begin with 10.1..

```
list ltm node 10.1.*
```

Uses a regular expression to display the configuration of all nodes that begin with 10. and contain .44.. Note that a regular expression must begin with an @ symbol. This identifies to tmsh that the identifier should be treated as a regular expression and not a glob or standard object identifier. The leading @ is not part of the regular expression.

```
list ltm node @^10\..*\44\.
```

#### PREFERENCES

You can customize the behavior of tmsh. For more information, see help cli preference.

#### FILES

tmsh manages several files in a user's home directory.

\$HOME/.tmsh-history- contains command history.

#### STATISTICS

You can use tmsh to display statistics, including historical performance statistics. You can select the format in which the statistics display, as well as reset the statistics for some of the tmsh components. To determine if statistics are available for a component, see the man page for the specific component.

The following examples show how to display and reset statistics for the net interface component from the root module.

```
show net interface
reset-stats net interface
```

The following examples show how to display and reset statistics for the net interface component from the net module.

```
show interface
reset-stats interface
```

#### AUTOMATING TMSH

You can use tmsh to build TCL scripts to automate management of the BIG-IP. See the cli script help page.

#### COMMAND LINE OPTIONS

The following options can be specified when tmsh is started from the system shell.

-a tmsh does not write commands to the command history file.

Note that if auditing is enabled, tmsh continues to write commands to the audit log. This option is useful when writing scripts from the system shell, because it stops the scripts from filling up the

command history file. This option applies to the non-interactive mode only.

-c Run the specified command. A command that contains multiple arguments must be in quotes. No other options may be specified after -c

-d [ip address | host name]  
Connects to the specified blade in a clustered system.

-e Disables video highlighting in tmsh.

-h Displays options you can use when accessing tmsh from the system shell.

-m Generates a tmsh debug log named tmsh.out in the current directory.

Note that when you run a tmsh script, the shell generates a debug log file for the script named tmsh.out.[script name].

Using this option causes tmsh to run significantly slower.

-q Prevents tmsh from responding to user actions with questions. This option is useful when writing non-interactive shell scripts from the system shell.

-r  
This option allows the user to run TMSH the specified version. This is used to provide backwards compatibility for older TMSH syntax only. The version must be specified in the format maj.min.pt, for example 11.5.0

#### SEE ALSO

Detailed information on the following topics is available through the help command: cli preference, cli script, glob, help, regex, and sys provision.

For complete information about tmsh, see the Traffic Management Shell (tmsh) Reference Guide. This guide is available on the AskF5(sm) Knowledge Base ().

# Commands

## cd

NAME  
cd command - Change the current working folder.

MODULE  
All tmsh modules.

SYNTAX  
Use the command cd to change the current working folder.

```
cd [folder name]
cd /[folder name]
```

DESCRIPTION  
The command cd [folder name] changes the current working folder to allow the user navigation around the folder system (see sys folder). The command pwd displays the current working directory.

The current working folder may be listed in the tmos command prompt while in tmsh interactive mode (see cli preference).

Folder names are separated by a forward slash /.

There are two built-in folders:

/ is the root folder

/Common is the default folder for creating new configurations objects.

Additionally, the following directory entries:

. is the current folder  
.. is the parent folder

#### EXAMPLES

cd /Common

Change the current working folder to /Common.

cd resources

Change the current working folder to resources. In this example the resources folder is relative to the current working folder. As an example, if the current working folder was /Common, the new working folder will be /Common/resources.

cd resources/profiles/udp

Multiple folders may be specified. Tab complete assists filling the command line with folder names.

cd /

Make the current working folder the root folder.

cd ../Alpha

Change the working directory by first going to the parent, and then switch to the sub-folder Alpha.

## cp

#### NAME

cp command - Creates a copy of a TMOS(tm) configuration object.

#### MODULE

All tmsh modules.

#### SYNTAX

Use the command cp within a tmsh module to create a copy of the component that resides in that module. To create a copy component that resides in another module, use the full path to the component.

```
cp [component] [source] [destination]
cp / [module...module] [component] [source] [destination]
```

#### DESCRIPTION

You must provide a unique name for each component destination of the copy operation.

#### EXAMPLES

cp template mytemplate newtemplate

From within the sys application module, creates a new Application Template named newtemplate with the same properties as mytemplate .

cp / cli script my\_script1 my\_script2

From within the sys application module, copies the my\_script1 script to my\_script2 within the cli module.

#### OPTIONS

component

Specifies the type of the component that you want to copy.

module

Specifies the module within which the component that you want to copy resides.

source

Specifies the component to be copied.

destination

Specifies a unique name for the component that will be created as part of the copy.

SEE ALSO  
tmsh

COPYRIGHT

## create

NAME  
create command - Creates a TMOS(tm) configuration component.

MODULE  
All tmsh modules.

SYNTAX  
Use the command create within a tmsh module to create a component that resides in that module. To create a component that resides in another module, use the full path to the component.

```
create [component] [name] [property [value]...]
create / [module...module] [component] [name] [property [value]...]
```

DESCRIPTION  
You must provide a unique name for each component that you create.

EXAMPLES  
create pool pool1  
  
From within the gtm module, creates a Global Traffic Manager pool named pool1.  
  
create / ltm pool my\_pool  
  
From within the gtm module, creates a Local Traffic Manager pool named my\_pool.

OPTIONS  
component  
Specifies the type of the component that you want to create.  
  
module  
Specifies the module within which the component that you want to create resides.  
  
name Specifies a unique name for the component.  
  
property [value]...  
Specifies properties for the component and their values.

SEE ALSO

BIG-IP 2016-03-14 create(1)

---

## delete

NAME  
delete command - Deletes a tmsh component.

MODULE

All tmsh modules.

#### SYNTAX

Use the command delete within a tmsh module to delete a component that resides in that module. To delete a component that resides in another module, use the full path to the component.

```
delete [component] [name]
delete / [module...module] [component] [name]
```

#### DESCRIPTION

You must provide the name of the component that you want to delete.

#### EXAMPLES

```
delete pool pool1
```

From within the gtm module, deletes the Global Traffic Manager pool named pool1.

```
delete / ltm pool my_pool
```

From within the gtm module, deletes the Local Traffic Manager pool named my\_pool.

#### OPTIONS

component

Specifies the type of the component that you want to delete.

module

Specifies the module within which the component that you want to delete resides.

name Specifies the name of the component that you want to delete. All may be used as an identifier for most component types.

recursive

Deletes all items in the current folder and all sub-folders that match the module, component and the name specified. all may be used as the name identifier with this command.

Note: When using recursive and all together, you will be prompted to verify this action. If you wish to disable this prompt, you may run tmsh using the -q command-line option. This is very useful when writing scripts that use this command.

#### SEE ALSO

F5 Networks and BIG-IP (c) Copyright 2008-2010, 2013, 2016. All rights reserved.

BIG-IP          2016-03-14          delete(1)

---

## edit

#### NAME

edit command - Opens the specified components in an editor.

#### MODULES

All tmsh modules.

#### SYNTAX

Use the command edit to create components or modify the configuration of components using a text editor. To edit a component that resides in another module, use the full path to the component.

```
edit [component] [name ... name | all]
edit / [module...module] [component] [name ... name | all]
```

#### DESCRIPTION

You can use the command edit to create or modify components in the auth, cli, gtm, ltm, net, sys and wom modules, and iRules(r).

If you are assigned the role of Administrator, when you use the command edit, the system starts the vi editor. If you are assigned any other role, the system starts the pico/nano editor.

The system saves, in a temporary directory, the text file, named data, that you are editing. When you save the file and close the editor, the system checks for errors, and then prompts you with an opportunity to continue editing and resolve any errors.

When you edit an existing component that can have associations, such as a Global Traffic Manager wide IP that can have pool member

associations. but the component does not currently have associations, to create the new associations, you must use the full command syntax in the text file. For the full command syntax for each component, see the associated man page.

When you edit a component that has associations with components that are children of the component you are editing, the text file contains a line for the configuration of the child components that begins with the command modify, for example: pools modify { [existing pool members configurations] }. In this case, if you want to add or delete pool members, you must add additional lines to the text file, for example: pools delete { [pool members to delete] }.

If you want the text file that opens to contain all of the editable properties of the component that you want to edit, you must use the all-properties option at the end of the edit command sequence; otherwise, only the non-default properties display in the text file.

#### EXAMPLES

```
edit / gtm pool a*
```

From the root module, opens a file in an editor in which you can modify the configuration of all Global Traffic Manager pools with names that start with the letter a using the template that displays in the editor.

```
edit datacenter new_dc
```

From the gtm module, opens a file in an editor in which you can create the Data Center named new\_dc using the template that displays in the editor.

```
edit datacenter a*
```

From the gtm module, opens a file in an editor in which you can edit all existing datacenters with names that begin with the letter a.

```
edit datacenter new_datacenter existing_datacenter
```

From the gtm module, opens a file in an editor in which you can create a new datacenter and edit an existing datacenter. Note that when the file opens, a template displays that you can use to create a new datacenter followed by the configuration of the existing datacenter.

```
edit rule rule_1
```

From the gtm module, opens a file in an editor in which you can create an iRule named rule\_1 using the template that displays in the editor.

When the editor opens, and you are creating or editing an iRule, you must enclose the iRule syntax in brackets, for example, [ ...iRule... ]. Note that the template includes the brackets.

#### OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

component

Specifies the type of component that you want to create or modify.

module

Specifies the module within which the component resides.

name Specifies a unique name of each component that you want to create or modify.

## exit

#### NAME

exit command - Exits a tmsh module or component.

#### MODULE

All tmsh modules.

#### SYNTAX

Use the command exit within a tmsh module or component to leave that module or component and return to the higher level of the shell

structure.

exit

Note that to exit tmsh and return to the BIG-IP(r) system prompt, use the command quit.

#### DESCRIPTION

For more information about the structure of tmsh, see the Traffic Management Shell (tmsh) Reference Guide.

#### SEE ALSO

tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP            2012-04-05            exit(1)

---

## generate

#### NAME

generate - Generate signed scripts using different algorithms for components (for example, iRules).

#### MODULE

All tmsh modules.

#### DESCRIPTION

Use the generate command to generate signed scripts for components. Currently two algorithms are supported: checksum and signature.

generate checksum  
generate signature signing-key

#### SEE ALSO

ltm rule, sys application template

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP            2014-04-08            generate(1)

---

## help

#### NAME

help command - Displays context-sensitive help text.

#### MODULE

All tmsh modules.

#### SYNTAX

Use the command help within a tmsh module to display information about the components that reside within that module, or at the component level to display help about the component. To display help for a component that resides in one module from within another module, use the full path to the component.

Type the question mark (?) character anywhere in tmsh to display a list of modules, components, and commands that are available within the module in which you are currently working.

?  
help  
help [module...module]  
help [component]

```
help / [module...module] [component]
help search [text]
```

#### DESCRIPTION

You can display tmsh man pages using the command help.

#### EXAMPLES

?

From within the gtm module, displays a list of modules, components, and commands that are available.

```
help pool
```

From within the gtm module, displays help about Global Traffic Manager pools.

```
help / ltm pool
```

From within the gtm module, displays help about Local Traffic Manager pools.

#### OPTIONS

component

Specifies the type of the component for which you want to display help.

search

Use the search option to find help topics that contain the specified text. The search is case insensitive. Text that contains a space or special tmsh characters must be quoted. Note that the search will not always find text that spans multiple lines.

module

Specifies the module within which the component for which you want to display help resides.

#### SEE ALSO

tmsh

#### COPYRIGHT

## install

#### NAME

install - Install and update components.

#### MODULE

All tmsh modules.

#### DESCRIPTION

Use the command install to install or update the following components. For the description and syntax see the help page for each component.

sys license

sys software block-device-hotfix

sys software block-device-image

sys software hotfix

sys software image

#### SEE ALSO

sys license, sys software block-device-hotfix, sys software block-device-image, sys software hotfix, sys software image, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP      2014-04-20      install(1)

---

## list

### NAME

list command - Displays components that you have permission to view.

### MODULE

All tmsh modules.

### SYNTAX

Use the list command within a tmsh module to display the properties of the components in that module. To display the properties of the components in one module from within another module, use the full path to the component.

```
list [component]
list [component] [name]
list [component] [name] [property]
list / [module...module] [component] [name] [property]
options:
  all-properties
  current-module
  non-default-properties
  one-line
  partition
  recursive
```

### DESCRIPTION

When the default Read partition is All, use the list command to display all of the components that you have permission to view within a tmsh module. When you specify a Read partition, the list command displays:

- o Only the components that you have permission to view in the current partition
- o All of the components that are not in partitions
- o All of the components in partition Common

### EXAMPLES

```
list / ltm
```

From within the gtm module, displays the properties of all of the components in the ltm module, including the components in the ltm monitor, ltm persistence, and ltm profile modules.

```
list / ltm current-module
```

From within the gtm module, displays the properties of all of the components in the ltm module, not including the components in the ltm monitor, ltm persistence, and ltm profile modules.

```
list pool
```

From within the gtm module, displays the properties of all of the Global Traffic Manager pools.

```
list pool all-properties
```

From within the gtm module, displays all of the properties of all of the Global Traffic Manager pools.

```
list pool monitor
```

From within the gtm module, displays the monitor associated with each Global Traffic Manager pool.

```
list / ltm pool
```

From within the gtm module, displays the properties of all of the Local Traffic Manager pools.

### OPTIONS

all-properties

Displays the values of all of the properties of the specified component.

component

Specifies the component that you want to display.

current-module

Specifies to display only the components that reside in the specified module, not the components that reside in the sub-modules of that module.

For example, from within the ltm module to display only the components in the gtm module, and not the components in the gtm monitor and gtm settings sub-modules, use the following command sequence: list / gtm current-module.

module

Specifies the module within which the component that you want to display resides.

Note: When you use the command list at the module level, by default, the system does not display all of the components that reside in the specified module. To display the properties of some components you must explicitly specify the component. For example, from the ltm module, to display the virtual addresses for the

Local Traffic Manager, use this command sequence:

list virtual-address

For more information about displaying the properties of a component, see the man page for the component.

name Specifies the unique name of the component.

non-default-properties

Displays the values of all of the properties for which a user changed the value from the default value for the specified component.

one-line

Displays the configuration for each object on one line. Configuration that consists of scripts will not be formatted on to a single line. This include ltm and gtm iRules and tmsh scripts.

partition

Displays the administrative partition within which the specified component exists.

property

Specifies the property of the component that you want to display.

recursive

Specifies to display the components not only from the current folder but also from all sub-folders recursively.

SEE ALSO

tmsh

## load

NAME

load command - Replaces the running configuration of the BIG-IP(r) system with the configuration in the specified files. You can also use this command to import an ASM policy from a file / standard input, and to install the Anti-fraud engine / signatures update.

MODULE

All tmsh modules.

SEE ALSO

save, tmsh, asm policy, ltm dns dns-express db, sys config, sys geoip, sys ucs

COPYRIGHT

---

## modify

NAME

modify command - Modifies a tmsh component.

MODULE

All tmsh modules.

**SYNTAX**

Use the command `modify` within a `tmsh` module to modify a component that resides in that module. To modify a component in one module from within another module, use the full path to the component.

```
modify [component] [name] [property [value] ]...
modify / [module...module] [component] [name] [property [value] ]...
```

**DESCRIPTION**

You must provide the name of the component that you want to modify.

You can apply one or more property settings to multiple components using a single command sequence. For example, to associate the Local Traffic Manager pool named `pool-1` with the virtual servers named `virtual-1` and `virtual-2`, use this command sequence: `modify ltm virtual virtual-1 virtual-2 pool pool-1`

**EXAMPLES**

```
modify pool pool1 disabled
```

From within the `gtm` module, disables the Global Traffic Manager pool named `pool1`.

```
modify / ltm pool my_pool disabled
```

From within the `gtm` module, disables the Local Traffic Manager pool named `my_pool`.

**OPTIONS**

**component**  
Specifies the type of the component that you want to modify.

**module**  
Specifies the module within which the component that you want to modify resides.

**name** Specifies the unique name of the component that you want to modify.

**property [value]...**  
Specifies the properties of the component that you want to modify and their new values.

**SEE ALSO**

`tmsh`

**COPYRIGHT**

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2010, 2013, 2016. All rights reserved.

BIG-IP      2016-03-14      `modify(1)`

---

## mv

**NAME**

`mv` command - Renames or moves a TMOS(tm) configuration object.

**MODULE**

All `tmsh` modules.

**SYNTAX**

Use the `mv` command within a `tmsh` module to move or rename the component that resides in that module. To move a component that resides in another module, use the full path to the component.

```
mv [component] [source] [destination]
mv / [module...module] [component] [source] [destination]
```

**DESCRIPTION**

You must provide a unique name for the source and destination of the move operation.

**WARNING** Currently `MV` is an experimental feature. By using this feature, you may be subject to loss of statistics and disruption in GTM service. If you plan to move or rename a Virtual Server, please contact your GTM administrator before doing so. You may enable this feature by setting the appropriate db variable. This can be done by issuing the command:

```
modify /sys db mcpd.mvenabled value true
```

This will turn on the feature and allow moving and rename of select objects through TMSH only. Once you have finished using the feature, we recommend disabling it once again. You may do this by issuing the following command:

```
modify /sys db mcpd.mvenabled value false
```

Please use responsibly.

#### EXAMPLES

```
mv cm device bigip seattle32
```

Renames the device named bigip to seattle32.

```
mv ltm pool mypool myotherpool
```

Renames the LTM Pool named mypool to myotherpool.

```
mv ltm pool /Common/by/mypool /Common/myotherpool  
/Common/sub/mythirdpool to-folder /Partition2/sub1
```

Moves the 3 pools in 3 different locations named mypool, myotherpool and mythirdpool into a single folder in another partition.

#### OPTIONS

to-folder

Specifies the folder to move the item or items into.

component

Specifies the type of the component that you want to move.

destination

Specifies a unique name for the component.

module

Specifies the module within which the component that you want to move resides.

source

Specifies the component to be moved.

## publish

#### NAME

publish - Finalizes changes in the policy by creating a read-only copy of it.

#### MODULE

All tmsh modules.

#### DESCRIPTION

Use the command publish to make wam policies available for usage in wam applications. You can also use this command to apply asm policies. For the description and syntax see the help page for wam policy or asm policy.

#### SEE ALSO

asm policy, wam policy, tmsh

#### COPYRIGHT

# pwd

NAME  
pwd command - Display the current working folder.

MODULE  
All tmsh modules.

SYNTAX  
Use the command pwd to display the current working folder.

pwd

DESCRIPTION  
Display the current working folder

EXAMPLES  
pwd

SEE ALSO  
cd, help, sys folder, tmsh

COPYRIGHT  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2012. All rights reserved.

BIG-IP 2012-04-05 pwd(1)

---

# quit

NAME  
quit command - Exits tmsh.

MODULE  
All tmsh modules.

SYNTAX  
Use the following command at the tmsh prompt to close tmsh and return to the BIG-IP(r) system prompt.

quit

Note that to exit a tmsh module or component, you use the command exit.

SEE ALSO  
tmsh

COPYRIGHT  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2010. All rights reserved.

BIG-IP 2010-12-06 quit(1)

---

# reboot

NAME  
reboot command - Reboots the system or boots the system into a different volume.

MODULE  
All tmsh modules.

SYNTAX  
reboot  
options:

```
slot [ [slot number] | all ]
volume [name]
```

#### DESCRIPTION

You can use the command `reboot` to reboot the system or cluster. If you do not specify an option, the local system reboots.

You can use the volume option to reboot a system into a specific volume. For a cluster, you can use the volume option to reboot all slots into the specified volume.

Additionally, for a cluster, you can use the slot option to reboot either a specific slot or all slots. Note that the slot option does not modify the active volume.

#### EXAMPLES

```
reboot
```

Immediately reboots the running image.

```
reboot volume HD1.2
```

If the volume HD1.2 has a complete image on it, the system (or cluster) reboots into that image immediately. However, if a software installation is in progress on the volume the system reboots as soon as the installation is complete.

#### OPTIONS

```
slot [ [slot number] | all ]
```

Reboots either a specific slot or all slots in a cluster, without changing the active volume of the slot(s).

This option is only available in a clustered environment.

Note: The slot and volume options are mutually exclusive.

```
volume
```

Specifies the volume that you want to boot. The volume you specify becomes the default boot volume. You cannot specify the active volume. In a clustered environment all slots reboot into the same volume.

Note: The slot and volume options are mutually exclusive.

#### SEE ALSO

`install`, `sys software hotfix`, `sys software image`, `sys software status`, `sys software volume`, `tmsh`

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2012. All rights reserved.

BIG-IP          2012-09-04          reboot(1)

---

## reset-stats

#### NAME

`reset-stats` - Resets statistics for the specified components.

#### MODULE

All `tmsh` modules.

#### SYNTAX

Use the command `reset-stats` within a `tmsh` module to reset the statistics for the specified component to zero. To reset the statistics for the specified component in one module from within another module, use the full path to the component.

```
reset-stats [component]
reset-stats [component] [name]
reset-stats / [module...module] [component]
reset-stats / [module...module] [component] [name]
```

#### DESCRIPTION

You can reset statistics for a group of components, or you can reset statistics for a specific component.

After you reset statistics, when you run the command `show`, you may see a value of `nan`. This stands for not a number, which indicates that no data is currently available. Wait a few moments and run the command `show` again, and in most cases the `nan` value will be replaced by an integer value.

It is important to note the following when you reset statistics:

- o For a data center, the system also resets the statistics for the

servers in that data center.

- o For a Global Traffic Manager server, the system also resets the statistics for the virtual servers on that server.
- o For a Global Traffic Manager pool, the system also resets the statistics for the pool members.
- o For a Local Traffic Manager pool, the system also resets the statistics for the pool members.
- o For a VLAN, you must reset the statistics for the trunks and interfaces associated with the VLAN.
- o You cannot reset statistics for system-supplied profiles.

#### EXAMPLES

reset-stats pool

From within the gtm module, resets the statistics for all of the Global Traffic Manager pools.

reset-stats pool pool1

From within the ltm module, resets the statistics for the Local Traffic Manager pool named pool1.

reset-stats / ltm pool my\_pool

From within the gtm module, resets the statistics for the Local Traffic Manager pool named my\_pool.

reset-stats all-stats

From within the sys performance module, resets all performance statistics for the system.

#### OPTIONS

component

Specifies the type of the component for which you want to reset statistics.

module

Specifies the module within which the component for which you want to reset statistics resides.

name Specifies the unique name of the component for which you want to reset statistics.

#### SEE ALSO

tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2012. All rights reserved.

BIG-IP 2012-04-05 reset-stats(1)

---

## restart

#### NAME

restart command - Restarts a service on the BIG-IP(r) system.

#### MODULE

All tmsh modules.

#### SYNTAX

Use the command restart within tmsh to restart a specified service.

```
restart
options:
/sys service [service name]
```

#### DESCRIPTION

You can use the command restart to restart a specified service.

#### EXAMPLES

restart /sys service mcpd

Restarts the mcpd daemon.

restart /sys service snmpd

Restarts the snmpd daemon.

#### OPTIONS

Tip: Use the tab completion feature to see a list of available services.

#### SEE ALSO

start, stop, sys service, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2010, 2013, 2016. All rights reserved.

BIG-IP        2016-03-14        restart(1)

---

## run

#### NAME

run command - Runs the specified program.

#### MODULE

All tmsh modules.

#### SYNTAX

Use the run command within tmsh to run a specified utility.

#### run

##### options:

```
/cli script [arguments]
/cm add-to-trust
/cm config-sync
/cm remove-from-trust
/cm sniff-updates
/cm watch-devicegroup-device
/cm watch-sys-device
/cm watch-trafficgroup-device
/gtm big3d_install [arguments]
/gtm bigip_add [arguments]
/gtm gtm_add [arguments]
/ltn monitor [arguments]
/security anti-fraud engine-update
/security anti-fraud signatures-update [arguments]
/sys air-filter-reset
/util bash [arguments]
/util diadb [arguments]
/util dig [arguments]
/util dnat [arguments]
/util get-ccn-dossier
/util get-dossier [arguments]
/util ihealth [arguments]
/util qkcloud [arguments]
/util ipsecalgdb [arguments]
/util lsndb [arguments]
/util netstat [arguments]
/util ping [arguments]
/util ping6 [arguments]
/util qkview [arguments]
/util racoonctl [arguments]
/util sipdb [arguments]
/util ssh-keyswap [arguments]
/util sys-icheck [arguments]
/util tcpdump [arguments]
/util tracepath [arguments]
/util tracepath6 [arguments]
/util traceroute [arguments]
/util traceroute6 [arguments]
/wom diagnose-conn
/wom verify-config
```

#### DESCRIPTION

You can use the run command to run the specified program, utility or process.

You can read about the arguments that are available for the utilities in the cm module using the following command sequence:

```
help /cm [utility name]
```

You can read about the arguments that are available for the utilities in the gtm module using the following command sequence:

```
help /gtm [big3d_install | bigip_add | gtm_add]
```

You can read about the arguments that are available for the utilities in the ltm module using the following command sequence:

```
help /ltn monitor [type]
```

You can read about the arguments that are available for the utilities in the util module using the following command sequence:

```
help /util [utility name]
```

Note: Some tmsh features, such as tab completion, context-sensitive help, paging, and grep, are not available for utilities.

When you are building a batch mode transaction in tmsh, if you type the run command, the system runs the specified program immediately. It does not add the run command to the transaction that you are building.

#### EXAMPLES

```
help /util ping
```

Displays the help page for the ping utility.

#### OPTIONS

```
/cli script
```

Run the specified script, with provided arguments.

```
/cm add-to-trust
```

Add a device to a trust domain.

```
/cm config-sync
```

Synchronize the configuration between devices.

```
/cm remove-from-trust
```

Remove a device from a trust domain.

```
/cm sniff-updates
```

Display the commit ID updates that occur over the CMI communications channel. When you troubleshoot a ConfigSync issue, it is helpful to determine which device group member has the latest commit ID update and contains the most recent configuration. You can then decide whether to replicate the newer configuration to the group, or perform a ConfigSync operation that replicates an older configuration to the group, thus overwriting a newer configuration.

```
/cm watch-devicegroup-device
```

Display information about the devices in the device group to which the local device belongs.

```
/cm watch-sys-device
```

Display information about the local device.

```
/cm watch-trafficgroup-device
```

Display information about the traffic groups associated with devices in a device group.

```
/gtm big3d_install
```

Specifies to install the big3d daemon.

```
/gtm bigip_add
```

Specifies the BIG-IP systems that you want to add to the Global Traffic Manager configuration.

```
/gtm gtm add
```

Specifies the Global Traffic Manager systems that you want to add to the Global Traffic Manager configuration.

```
/ltm monitor
```

Performs a one-shot test of a custom LTM health monitor against a specified target node.

```
/security anti-fraud engine-update
```

For the description and syntax see the help page for security anti-fraud engine-update.

```
/security anti-fraud signatures-update
```

For the description and syntax see the help page for security anti-fraud signatures-update.

```
/sys air-filter-reset
```

Runs the command to reset the timer and the retry counter for air filter notifications.

```
/util bash
```

Accesses the system shell.

```
/util diadb
```

Displays Diameter persistence entries. The diadb utility displays diameter persistence entries or delete a particular persistence entry.

```
/util dig
```

Runs the specified dig command. The dig utility queries DNS name servers.

```
/util dnat
```

Runs the specified dnat command for the purpose of doing forward/reverse mapping of addresses for DNAT.

```
/util get-ccn-dossier
```

Runs the get\_ccn\_dossier utility for the purpose of displaying system information for dossier creation.

```
/util get-dossier
```

Runs the get\_dossier utility for the purpose of displaying system license dossier information.

```
/util ihealth
```

Runs the ihealth utility for the purpose of uploading a new or

existent qkview file to ihealth.

/util qkcloud  
Runs the qkcloud utility for the purpose of displaying cloud meta-data.

/util ipsecalgdb  
Runs the ipsecalgdb utility to view IPsecALG translation, and pending IKE connection count entries.

/util lsndb  
Runs the lsndb utility to view Large Scale NAT persistence entries, inbound mappings, client connection counts, and PCP mappings.

/util netstat  
Displays network connections, routing tables, interface statistics, masquerade connections, and multicast memberships.

/util ping  
Runs the specified ping command. The ping utility sends ICMP echo requests to network hosts.

/util ping6  
Runs the specified ping6 command. The ping6 utility sends ICMPv6 echo requests to network hosts.

/util qkview  
Runs the specified qkview command. The qkview utility gathers diagnostic information from a BIG-IP system.

/util racoonctl  
Runs the specified racoonctl command. The racoonctl utility is used to control operation of the racoon daemon.

/util sipdb  
Displays SIP persistence entries. The sipdb utility displays specific persistence entries and deletes a particular persistence record.

/util ssh-keyswap  
Runs the keyswap.sh script for managing SSH keys on the BIG-IP.

/util sys-icheck  
Runs the specified sys-icheck command. The sys-icheck utility verifies all RPM packages and files.

/util tcpdump  
Runs the specified tcpdump command. The tcpdump utility prints headers and content of network traffic.

/util tracepath  
Displays the route packets take to a network host.

/util tracepath6  
Displays the route packets take to an IPv6 network host.

/util traceroute  
Displays the route packets take to a network host.

/util traceroute6  
Displays the route packets take to an IPv6 network host.

/wom diagnose-conn  
Runs the specified diagnose-conn script, which detects the sources of network connection and performance problems in a WAN optimization configuration.

/wom verify-config  
Runs the specified verify-config script, which detects errors in the configuration of the WAN Optimization Manager.

## save

**NAME**  
save - Writes the running configuration of the BIG-IP(r) system to the specified file.

**MODULE**  
All tmsh modules.

**DESCRIPTION**  
You can use the save command to write changes that you make to the running configuration of the BIG-IP system to the specified file. You can also use this command to save an analytics report to a file on the BIG-IP(r) system or to export an ASM policy to a file / standard output.

**SEE ALSO**  
analytics report, asm policy, load, sys config, sys ucs, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP          2012-10-16          save(1)

---

## send-mail

**NAME**  
send-mail - Send an e-mail to a list of recipients containing configuration or statistical information about the BIG-IP(r) system.

**MODULE**  
All tmsh modules.

**DESCRIPTION**  
You can use the send-mail command to send an analytics report from the BIG-IP system to a list of e-mail recipients.

**SEE ALSO**  
analytics report, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## show

**NAME**  
show command - Displays statistics for and the status of specified components.

**MODULE**  
All tmsh modules.

**SYNTAX**  
Use the show command within a tmsh module to display statistics for and the status of components in that module. To display statistics for and the status of components in another module, use the full path to the component.

show  
show [component]

```

show [component] [name]
show / [module] [component] [name]
options:
  all-stats
  current-module
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  (detail | global | historical)
  field-fmt
  running-config
  recursive

```

#### DESCRIPTION

You can use the show command to specify the unit value in which the system displays statistics and the type of statistics that you want the system to display.

After you reset statistics, when you run the command show, you may see a value of nan. This stands for not a number, which indicates that no data is currently available. Wait a few moments and run the show command again, and in most cases the nan value is replaced by an integer value. For more information, see help reset-stats.

#### EXAMPLES

```
show / ltm current-module
```

From within the gtm module, displays statistics and status for all the components within the ltm module, but not the components in the ltm monitor, ltm persistence, and ltm profile modules.

```
show pool
```

From within the gtm module, displays statistics and status for all Global Traffic Manager pools.

```
show pool pool1
```

From within the gtm module, displays statistics and status for the Global Traffic Manager pool named pool1.

```
show / ltm pool
```

From within the gtm module, displays statistics and status for all Local Traffic Manager pools.

```
show / ltm profile tcp global
```

From within the gtm module, displays global statistics and status for all Local Traffic Manager TCP profiles in the system default unit.

#### OPTIONS

all-stats

Displays all of the available system performance statistics.

component

Specifies the type of the component for which you want to show statistics and status.

current-module

Specifies to display only the components that reside in the specified module, not the components that reside in the sub-modules of that module.

For example, from within the ltm module to display only the components in the gtm module, and not the components in the gtm monitor and gtm settings sub-modules, use this command sequence:  
show / gtm current-module.

default

Displays data in the simplest units. For example, if the value of the data is 1,200,001, the system displays 1.20M; however, if the value of the data is 1,200, the system displays 1.2K.

detail

Displays detailed data for the specified component and associated components. Note that this option is available for only a partial set of tmsh components.

You can use the tab completion and context-sensitive help features to determine if this option is available. For more information about these features, see help.

field-fmt

Displays data as a list of options and their values. The option names can be used to retrieve statistics and status values in a shell script, see cli script.

gig Displays data in parts per billion.

global

Displays global statistics for the specified component that includes statistics for all components of the specified type. Note that this option is available for only a partial set of tmsh components. You can use the tab completion and context-sensitive help features to determine if this option is available.

historical

Displays historical statistics for the specified component. Note that this option is available only for a partial set of tmsh components. You can use the tab completion and context-sensitive help features to determine if this option is available.

kil Displays data in parts per thousand.

lines

Specifies how many lines of the log that you want the system to display.

meg Displays data in parts per million.

module

Specifies the module within which the component for which you want to show statistics and status resides.

Note: When you use the command show at the module level, by default, the system does not display all of the components that reside in the module. To display some components you must explicitly specify the component. For example, from the ltm module, to display the statistics for and status of the virtual addresses of the Local Traffic Manager, use the following command sequence:

show virtual-address

For more information about displaying statistics for and status of a component, see the man page for the component.

name Specifies the unique name of the component for which you want to show statistics and status.

range

Specifies a date range for the logs that you want the system to display, for example:

2d-4d

Specifies 2 - 4 days ago.

3d Specifies 3 days ago to now.

epoch--7/25:12:00:00

Specifies everything older than July 25th at noon.

2008-07-25--2008-07-28:13:30

Specifies between July 25th and 28th at 1:30 p.m.

raw Displays raw data.

recursive

Specifies to display the components not only from the current folder, but also from all sub-folders recursively.

running-config

Displays the running configuration of the components that you have permission to view within a tmsh module, if the default Read partition is All. If you specify a Read partition, this option displays only the components that you have permission to view in the current partition, all of the components that are not in partitions, and all of the components in partition Common. Note that this option is valid only for tmsh components you can configure.

The running-config option must be specified immediately after the show command, for example:

show running-config ltm pool

## shutdown

NAME

shutdown command - Shuts down the system.

MODULE

All tmsh modules.

SYNTAX

shutdown

options:

slot [ [slot number] | all ]

DESCRIPTION

You can use the command shutdown to power down the system or cluster.

If you do not specify an option, the local system shuts down.

For a cluster, you can use the slot option to shut down either a specific slot or all slots.

#### EXAMPLES

shutdown

Immediately shuts down the running system.

#### OPTIONS

slot [ [slot number] | all ]

Shuts down either a specific slot or all slots in the cluster.  
This option is only available in a clustered environment.

#### SEE ALSO

reboot, install

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2013. All rights reserved.

BIG-IP      2013-03-21      shutdown(1)

---

## start

#### NAME

start command - Starts a service on the BIG-IP(r) system.

#### MODULE

All tmsh modules.

#### SYNTAX

Use the start command within tmsh to restart a specified service.

```
start
options:
/sys service [service name]
```

#### DESCRIPTION

You can use the start command to start a specified service.

#### EXAMPLES

start /sys service mcpd

Starts the mcpd daemon.

start /sys service snmpd

Starts the snmpd daemon.

#### OPTIONS

**Tip:** Use the tab completion feature to see a list of available services.

#### SEE ALSO

restart, stop, sys service, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2013, 2016. All rights reserved.

BIG-IP      2016-03-14      start(1)

---

## stop

#### NAME

stop command - Stops a service or test operation that is running on the BIG-IP(r) system.

MODULE  
All tmsh modules.

SYNTAX  
Use the command stop within tmsh to stop a running service or test operation.

```
stop
options:
  /sys service [service name]
  /ltm monitor [arguments]
```

DESCRIPTION  
You can use the command stop to stop a running service or test operation.

EXAMPLES

```
stop /sys service mcpd

Stops the mcpd daemon.

stop /sys service snmpd

Stops the snmpd daemon.

stop /ltm monitor http my_http

Cancels a pending health monitor test for the custom ltm http monitor my_http.
```

OPTIONS  
Tip: Use the tab completion feature to see a list of available services.

SEE ALSO  
ltm monitor, restart, start, sys service, tmsh

COPYRIGHT  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2010, 2013, 2016-2017. All rights reserved.

BIG-IP          2017-03-24          stop(1)

---

## submit

NAME  
submit - Runs the transaction that you are creating.

MODULE  
All tmsh modules.

SYNTAX  
Use the submit command to run a transaction that you are creating.

```
submit transaction
```

DESCRIPTION  
You can use the submit command to run a transaction, which is a series of commands that you enter in transaction mode.

For more information about creating transactions, see cli transaction.

SEE ALSO  
cli transaction, tmsh

COPYRIGHT  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

# Modules

## analytics

### analytics afm-sweeper report

**NAME**  
report - Displays an afm-sweeper analytics report.

**MODULE**  
analytics afm-sweeper

**SYNTAX**  
Show, save or send an analytics afm-sweeper report using the syntax shown in the following sections.

**DISPLAY**  
show report view-by [ policy-name | context-type | context-name | eviction-reason | client-ip ]  
options:  
 drilldown {  
 {  
entity [ policy-name | context-type | context-name | eviction-reason | client-ip ]  
values  
 {  
 [value ...]  
 }  
 } ...  
 }  
 field-fmt  
 include-total  
 include-others  
 limit [number of rows]  
 measures {  
 [measure name ...]  
 }  
 order-by {  
 {  
 measure [ measure name ]  
 sort-type [ asc / desc ]  
 } ...  
 }  
 range [date range]

**SAVE**  
save report view-by [ policy-name | context-type | context-name | eviction-reason | client-ip ]  
options:  
 drilldown {  
 {  
entity [ policy-name | context-type | context-name | eviction-reason | client-ip ]  
values  
 {  
 [value ...]  
 }  
 } ...  
 }  
 file [ file name ]  
 format [ csv-aggregated | csv-time-series | pdf ]  
 include-total  
 include-others  
 limit [number of rows]  
 measures {  
 [measure name ...]  
 }  
 order-by {  
 {  
 measure [ measure name ]  
 sort-type [ asc / desc ]  
 } ...  
 }  
 range [date range]

**SEND**  
send-mail report view-by [ policy-name | context-type | context-name | eviction-reason | client-ip ]  
options:  
 drilldown {  
 {  
entity [ policy-name | context-type | context-name | eviction-reason | client-ip ]  
values  
 {  
 [value ...]  
 }  
 } ...  
 }  
 email-addresses {  
 [email address ...]  
 }  
 format [ csv-aggregated | csv-time-series | pdf ]  
 include-total  
 include-others  
 limit [number of rows]  
 measures {  
 [measure name ...]  
 }  
 order-by {

```

{
  measure [ measure name ]
  sort-type [ asc / desc ]
} ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate afm-sweeper analytics reports. You can generate an afm-sweeper analytics report for the following entities:

- o policy-name - Name of the sweeper policy.
- o context-type - The context type of the eviction. Can be one of three possible values: "Virtual Server", "Route Domain", "Global".
- o context-name - The name of the context. Depends on the context-type this value can be either a virtual server name (e.g. "my\_vs1"), route domain id (e.g. 317) or "Global".
- o eviction-reason - The algorithm used by sweeper that caused the eviction of a connection.
- o client-ip - The source IP of the evicted connection.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics afm-sweeper report view-by client-ip

show analytics afm-sweeper report view-by client-ip drilldown { {
entity context-type values { Global } } }

send-mail analytics afm-sweeper report view-by client-ip measures {
avg-connections-age } limit 15 order-by { { measure avg-connections-age
sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }

For more syntactical examples, see the tmsh help manual for analytics
report.

```

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**avg-connections-age**  
The average time that the connections lasted before evicted for the selected filter (entity).

**evicted-connections**  
The total number of evicted connections for the selected filter (entity).

**total-bytes-in**  
The total number of bytes received for the selected filter (entity).

**total-bytes-out**  
The total number of bytes sent for the selected filter (entity).

**order-by**  
Specifies the measures and sort type (ascending or descending)

that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics afm-sweeper scheduled-report

#### NAME

scheduled-report - Configure scheduled reports for AFM sweeper.

#### MODULE

analytics afm-sweeper

#### SYNTAX

Configure the scheduled-report component within the analytics afm-sweeper module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

##### DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

##### DELETE

```
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the AFM sweeper module.

#### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
```

```
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the AFM sweeper scheduled reports.

#### OPTIONS

email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics afm-sweeper report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics afm-sweeper report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

#### SEE ALSO

  } ...
  }
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]
```

DESCRIPTION  
Use this command to generate application-security-anomalies analytics reports. You can generate an application-security-network analytics report for the following entities:

- o anomaly-type - Anomaly type (Brute Force/Web Scraping)
- o application - Application services.

- o policy - Security policy.
- o virtual - Virtual servers.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics application-security-network report view-by application

show analytics application-security-network report view-by application
drilldown { { entity virtual values { my_vip } } }
```

```
send-mail analytics application-security-anomalies report view-by
virtual measures { rejected-requests } limit 20 order-by { { measure
rejected-requests sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### rejected-requests

The total number of rejected requests for the selected filter (entity).

##### total-attacks

The total number of attacks for the selected filter (entity).

##### total-violations

The total number of violations for the selected filter (entity).

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### SEE ALSO

## analytics application-security-anomalies scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for application security anomalies (ASM anomalies).

**MODULE**  
analytics application-security-anomalies

**SYNTAX**  
Configure the scheduled-report component within the analytics application-security-anomalies module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create scheduled-report [name]  
modify scheduled-report [name]  
options:  
email-addresses [none | add | delete | modify |  
replace-all-with] { email-address [string] }  
first-time [date]  
frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]  
include-total [enabled | disabled]  
multi-leveled-report {  
chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }  
limit [number of rows]  
time-diff [last-hour | last-day | last-week | last-month | last-year]  
view-by { entity name [string] }  
measures [none | add | delete | modify | replace-all-with] { measure name [string] }  
}  
predefined-report-name [name]  
smtp-config [name]  
device-group [name]

**DISPLAY**  
list scheduled-report  
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]  
show running-config scheduled-report  
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

**DELETE**  
delete scheduled-report [name]

**DESCRIPTION**  
Use the scheduled-report component to create, modify or delete scheduled reports for the application security anomalies (ASM anomalies) module.

**EXAMPLES**  
create scheduled-report myScheduledReport first-time now predefined-report-name "Top blocked URLs" frequency every-6-hours email-addresses add { person@domain.com } smtp-config asm\_smtp\_conf  
  
Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.  
  
modify scheduled-report myScheduledReport smtp-config none  
  
Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.  
  
create scheduled-report myCustomScheduledReport first-time now email-addresses add { person@domain.com } frequency every-6-hours smtp-config asm\_smtp\_conf multi-leveled-report { view-by url time-diff last-hour limit 5 chart-path add { policy violation } }  
  
Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.  
  
list scheduled-report  
  
Displays all of the application security anomalies (ASM anomalies) scheduled reports.

**OPTIONS**  
email-addresses  
A list of the email addresses of the recipients that receive the scheduled report.  
  
first-time  
First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total  
Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics application-security-anomalies report.

limit  
The number of view-by entities displayed in the scheduled report.

time-diff  
The time range for the report.

view-by  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics application-security-anomalies report.

measures  
The measures which are available for the selected entities.

predefined-report-name  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

        } ...
    }
    range [date range]
    smtp-config-override [ smtp configuration object name ]

DESCRIPTION
    Use this command to generate application-security-anomalies analytics
    reports. You can generate an application-security-network analytics
    report for the following entities:

    o    anomaly-type - Anomaly type (Brute Force/Web Scraping)
    o    application - Application services.
    o    policy - Security policy.
    o    virtual - Virtual servers.

    Different measures are collected for each of these entities and can be
    a part of the report request.

EXAMPLES
    show analytics application-security-network report view-by application

    show analytics application-security-network report view-by application
    drilldown { { entity virtual values { my_vip } } }

    send-mail analytics application-security-anomalies report view-by
    virtual measures { rejected-requests } limit 20 order-by { { measure
    rejected-requests sort-type desc } } format pdf email-addresses {
    some.one@someaddress.com }

    For more syntactical examples, see the tmsh help manual for analytics
    report.

```

## OPTIONS

### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

### drilldown

Specifies specific entities that are used as a filter.

### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

### rejected-requests

The total number of rejected requests for the selected filter (entity).

### total-attacks

The total number of attacks for the selected filter (entity).

### total-violations

The total number of violations for the selected filter (entity).

### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

    [email address ...]
  }
  format [ csv-aggregated | csv-time-series | pdf ]
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]
```

### DESCRIPTION

Use this command to generate application-security-network analytics reports. You can generate an application-security-network analytics report for the following entities:

- o application - Application services.
- o virtual - Virtual servers.
- o request-type - Request types (Legal/Alarmed/Blocked).
- o policy - Security policy.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics application-security-network report view-by violation

show analytics application-security-network report view-by violation
drilldown { { entity severity values { Error } } }

send-mail analytics application-security-network report view-by virtual
measures {events} limit 20 order-by { { measure events sort-type desc
} } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples see manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### events

The total number of events (requests) for the selected filter (entity).

##### throughput

The average throughput (bits/s) for the selected filter (entity).

**tps** The average number of transactions per second for the selected filter (entity).

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics application-security-network scheduled-report

### NAME

scheduled-report - Configure scheduled reports for application security network (ASM network).

### MODULE

analytics application-security-network

### SYNTAX

Configure the scheduled-report component within the analytics application-security-network module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

#### DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

#### DELETE

```
delete scheduled-report [name]
```

### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the application security network (ASM network) module.

### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the application security network (ASM network) scheduled reports.

### OPTIONS

#### email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

#### first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

#### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

#### include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics application-security-network report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics application-security-network report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

SEE ALSO

list, modify, show, tmsh, analytics application-security-network report, sys smtp-server

#### DESCRIPTION

Use this command to generate application-security analytics reports.  
You can generate an application-security analytics report for the following entities:

- o application - Application services.
- o virtual - Virtual servers.
- o request-type - Request types (Legal/Alarmed/Blocked).
- o severity - Violation severities.
- o rating - Violation ratings.
- o username - User names.
- o attack-type - Attack type of the illegal request.
- o ip-address-intelligence - IP Address reputation categories.
- o policy - Security policy.
- o response-code - Response codes.
- o ip - Source IP addresses.
- o violation - Violation types.
- o country - Countries of the source IP address.

- o method - HTTP methods.
- o protocol - Protocols (HTTP/HTTPS).
- o session-id - IDs of sessions.
- o url - Requested URLs.
- o virus - Viruses that were detected by the system.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics application-security report view-by violation

show analytics application-security report view-by violation drilldown
{ { entity severity values { Error } } }

send-mail analytics application-security report view-by ip measures
{requests} limit 20 order-by { { measure requests sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples see manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**requests**  
The total number of requests for the selected filter (entity).

**occurrences**  
Number of occurrences for the selected filter (relevant for attack-type, violation and ip-address-intelligence entities)

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics application-security scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for application security (ASM).

**MODULE**  
analytics application-security

**SYNTAX**  
Configure the scheduled-report component within the analytics application-security module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create scheduled-report [name]  
modify scheduled-report [name]  
options:  
email-addresses [none | add | delete | modify |  
replace-all-with] { email-address [string] }  
first-time [date]  
frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]  
include-total [enabled | disabled]  
multi-leveled-report {  
chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }  
limit [number of rows]  
time-diff [last-hour | last-day | last-week | last-month | last-year]  
view-by { entity name [string] }  
measures [none | add | delete | modify | replace-all-with] { measure name [string] }  
}  
predefined-report-name [name]  
smtp-config [name]  
device-group [name]

**DISPLAY**  
list scheduled-report  
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]  
show running-config scheduled-report  
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

**DELETE**  
delete scheduled-report [name]

**DESCRIPTION**  
Use the scheduled-report component to create, modify or delete scheduled reports for the application security module.

**EXAMPLES**  
create scheduled-report myScheduledReport first-time now predefined-report-name "Top blocked URLs" frequency every-6-hours email-addresses add { person@domain.com } smtp-config asm\_smtp\_conf  
  
Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.  
  
modify scheduled-report myScheduledReport smtp-config none  
  
Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.  
  
create scheduled-report myCustomScheduledReport first-time now email-addresses add { person@domain.com } frequency every-6-hours smtp-config asm\_smtp\_conf multi-leveled-report { view-by url time-diff last-hour limit 5 chart-path add { policy violation } }  
  
Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.  
  
list scheduled-report  
  
Displays all of the application security scheduled reports.

**OPTIONS**  
email-addresses  
A list of the email addresses of the recipients that receive the scheduled report.  
  
first-time  
First scheduled report time. Must be after current time and rounded up to the next round hour.  
  
frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with **predefined-report-name**. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics application-security report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics application-security report.

**measures**  
The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with **multi-leveled-report**.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

        } ...
    }
    range [date range]
    smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate asm-bypass analytics reports. You can generate an asm-bypass analytics report for the following entities:

- o slot - Blade Number
- o memory - BD memory

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics asm-bypass report view-by slot
```

```
show analytics asm-bypass report view-by slot drilldown { { entity slot
values { slot_index } } }
```

```
end-mail analytics asm-bypass report view-by slot measures { backlog-
messages } limit 20 order-by { { measure backlog-messages sort-type
desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a

report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

backlog-messages

The sum of backlog messages for the selected filter (entity).

http-requests

The sum of HTTP requests for the selected filter (entity).

transactions-bypass

The sum of transactions bypass for the selected filter (entity).

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics asm-bypass scheduled-report

NAME

scheduled-report - Configure scheduled reports for ASM bypass.

MODULE

analytics asm-bypass

SYNTAX

Configure the scheduled-report component within the analytics asm-bypass module using the syntax shown in the following sections.

CREATE/MODIFY

create scheduled-report [name]  
modify scheduled-report [name]

```

options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]

DISPLAY
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

DELETE
delete scheduled-report [name]

```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the ASM bypass module.

#### EXAMPLES

```

create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf

```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```

modify scheduled-report myScheduledReport smtp-config none

```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```

create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }

```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```

list scheduled-report

```

Displays all of the ASM bypass scheduled reports.

#### OPTIONS

**email-addresses**  
A list of the email addresses of the recipients that receive the scheduled report.

**first-time**  
First scheduled report time. Must be after current time and rounded up to the next round hour.

**frequency**  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics asm-bypass report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics asm-bypass report.

**measures**

The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

#### DESCRIPTION

Use this command to generate asm-cpu analytics reports. You can generate an asm-cpu analytics report for the following entities:

- o virtual - Virtual servers.
- o slot - Blade Number

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

show analytics asm-cpu report view-by slot

show analytics asm-cpu report view-by slot drilldown { { entity slot values { slot\_index } } }

send-mail analytics asm-cpu report view-by slot measures { bd-cpu-utilization } limit 20 order-by { { measure bd-cpu-utilization sort-type desc } } format pdf email-addresses { some.one@someaddress.com }

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen

entity type. The options are:

bd-cpu-utilization

The BD CPU utilization for the selected filter (entity).

tmm-cpu-utilization

The TMM CPU utilization for the selected filter (entity).

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics asm-cpu scheduled-report

NAME

scheduled-report - Configure scheduled reports for ASM CPU.

MODULE

analytics asm-cpu

SYNTAX

Configure the scheduled-report component within the analytics asm-cpu module using the syntax shown in the following sections.

CREATE/MODIFY

create scheduled-report [name]

modify scheduled-report [name]

options:

email-addresses [none | add | delete | modify |  
replace-all-with] { email-address [string] }

first-time [date]

frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]

include-total [enabled | disabled]

multi-leveled-report {

chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }

limit [number of rows]

time-diff [last-hour | last-day | last-week | last-month | last-year]

view-by { entity name [string] }

measures [none | add | delete | modify | replace-all-with] { measure name [string] }

}

predefined-report-name [name]

smtp-config [name]

device-group [name]

DISPLAY

list scheduled-report

list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

show running-config scheduled-report

show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

DELETE

delete scheduled-report [name]

DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the ASM CPU module.

EXAMPLES

create scheduled-report myScheduledReport first-time now predefined-report-name "Top blocked URLs" frequency every-6-hours email-addresses add { person@domain.com } smtp-config asm\_smtp\_conf

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp

configuration defined in `asm_smtp_conf`.

`modify scheduled-report myScheduledReport smtp-config none`

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

`create scheduled-report myCustomScheduledReport first-time now email-addresses add { person@domain.com } frequency every-6-hours smtp-config asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour limit 5 chart-path add { policy violation } }`

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to `person@domain.co` using the smtp configuration defined in `asm_smtp_conf`.

`list scheduled-report`

Displays all of the ASM CPU scheduled reports.

#### OPTIONS

`email-addresses`

A list of the email addresses of the recipients that receive the scheduled report.

`first-time`

First scheduled report time. Must be after current time and rounded up to the next round hour.

`frequency`

The scheduled report frequency. Example: `every-6-hours` means that the report will be generated and sent every 6 hours.

`include-total`

Enables or disables including a summary (Overall result) entity in results.

`multi-leveled-report`

Defines a custom multi-leveled report. Mutually exclusive with `predefined-report-name`. The `multi-leveled-report` definition contains the following parameters:

`chart-path`

A list of entities that define the scope in which the report will be displayed. For example: a chart path `{ violation url }` means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics `asm-cpu` report.

`limit`

The number of view-by entities displayed in the scheduled report.

`time-diff`

The time range for the report.

`view-by`

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics `asm-cpu` report.

`measures`

The measures which are available for the selected entities.

`predefined-report-name`

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with `multi-leveled-report`.

`smtp-config`

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

`device-group`

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

## DESCRIPTION

Use this command to generate ASM Enforced Entities analytics reports. You can generate an ASM Enforced Entities analytics report for the following entities:

- o policy - Security Policy.

Different measures are collected for each of these entities and can be a part of the report request.

## EXAMPLES

```
show analytics asm-enforced-entities report view-by policy
```

```
show analytics asm-enforced-entities report view-by policy drilldown {  
{ entity policy values { policy_1 policy_2 } } }
```

```
send-mail analytics asm-enforced-entities report view-by policy  
measures { not-enforced-entities-count } limit 20 order-by { { measure  
not-enforced-entities-count sort-type desc } } format pdf email-  
addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

## OPTIONS

### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

### drilldown

Specifies specific entities that are used as a filter.

### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

#### enforced-entities-count

The total number of enforced entities in a specific security policy.

#### not-enforced-entities-count

The total number of entities that are not enforced in a specific security policy.

#### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

#### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

#### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

{
  measure [ measure name ]
  sort-type [ asc / desc ]
} ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate ASM Learning Suggestions analytics reports. You can generate an ASM Learning Suggestions analytics report for the following entities:

- o policy - Security Policy.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics asm-learning-suggestions report view-by policy
```

```
show analytics asm-learning-suggestions report view-by policy drilldown
{ { entity policy values { policy_1 policy_2 } } }
```

```
send-mail analytics asm-learning-suggestions report view-by policy
measures { pending-high-score-suggestions-count } limit 20 order-by { {
measure pending-high-score-suggestions-count sort-type desc } } format
pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### accepted-suggestions-count

The total number of accepted suggestions for a specific security policy.

##### ignored-suggestions-count

The total number of ignored suggestions for a specific security policy.

##### pending-high-score-suggestions-count

The total number of pending suggestions with a score of at least 50 for a specific security policy.

##### pending-low-score-suggestions-count

The total number of pending suggestions with a score less than 50 for a specific security policy.

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by

email. This overrides the default SMTP settings.

  } ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate asm-memory analytics reports. You can generate a ASM memory analytics report for the following entities:

- o slot - Slot ID

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics asm-memory report view-by slot
```

```
show analytics asm-memory report view-by slot drilldown { { entity slot
values { slot_index } } }
```

```
send-mail analytics asm-memory report view-by slot measures { total-
swap-size } limit 20 order-by { { measure total-swap-size sort-type
desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### bd-memory-utilization

The BD memory utilization out of total assigned to BD (in percents) for the selected filter (entity).

##### tmm-memory-util

The TMM memory utilization out of total assigned to TMM (in percents) for the selected filter (entity).

##### bd-swap-size

The swap used by BD in MBs for the selected filter (entity).

##### total-swap-size

The total swap used in MBs for the selected filter (entity).

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics asm-memory scheduled-report

NAME

scheduled-report - Configure scheduled reports for ASM memory.

MODULE

analytics asm-memory

SYNTAX

Configure the scheduled-report component within the analytics asm-memory module using the syntax shown in the following sections.

CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete scheduled-report [name]
```

DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the ASM memory module.

EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
```

```
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the ASM memory scheduled reports.

#### OPTIONS

email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics asm-memory report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics asm-memory report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

DESCRIPTION  
Use this command to generate ASM Policy Changes analytics reports. You can generate an ASM Policy Changes analytics report for the following entities:

- o policy - Security Policy.
- o user - User.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics asm-policy-changes report view-by policy
```

```
show analytics asm-policy-changes report view-by policy drilldown { {  
entity user values { user_1 user_2 } } }
```

```
send-mail analytics asm-policy-changes report view-by policy measures {  
policy-changes-count } limit 20 order-by { { measure policy-changes-  
count sort-type desc } } format pdf email-addresses {  
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

policy-changes-count

The total number of changes made to the policy by a specific user.

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### SEE ALSO

show, save, send-mail, tmsh, ltm profile analytics, analytics, analytics report

#### COPYRIGHT

## analytics asm-violation report

**NAME** report - Displays an Application Security Violation analytics report.

**MODULE** analytics asm-violation

**SYNTAX** Show, save or send an analytics asm-violation report using the syntax shown in the following sections.

**DISPLAY**

```
show report view-by [ application | attack-type | microservice | policy | protocol | request-type | severity | violation-rating | virtual | virus ]
options:
  drilldown {
  {
  entity [ application | attack-type | microservice | policy | protocol | request-type | severity | violation | violation-rating | virtual | virus ]
  values
  {
    [value ...]
  }
  } ...
  }
  field-fmt
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
```

**SAVE**

```
save report view-by [ application | attack-type | microservice | policy | protocol | request-type | severity | violation-rating | virtual | virus ]
options:
  drilldown {
  {
  entity [ application | attack-type | microservice | policy | protocol | request-type | severity | violation | violation-rating | virtual | virus ]
  values
  {
    [value ...]
  }
  } ...
  }
  file [ file name ]
  format [ csv-aggregated | csv-time-series | pdf ]
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
```

**SEND**

```
send-mail report view-by [ application | attack-type | microservice | policy | protocol | request-type | severity | violation-rating | virtual | virus ]
options:
  drilldown {
  {
  entity [ application | attack-type | microservice | policy | protocol | request-type | severity | violation | violation-rating | virtual | virus ]
  values
  {
    [value ...]
  }
  } ...
  }
  email-addresses {
    [email address ...]
  }
  format [ csv-aggregated | csv-time-series | pdf ]
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  }
```

```
range [date range]
smtp-config-override [ smtp configuration object name ]
```

#### DESCRIPTION

Use this command to generate Application Security Violation analytics reports. You can generate an Application Security Violation analytics report for the following entities:

- o application - Application services.
- o attack-type - Attack type of the illegal request.
- o microservice - Microservice.
- o policy - Security policy.
- o protocol - Protocols of requests (HTTP/HTTPS).
- o request-type - Enforcement action on request(Legal or Alarmed/Blocked/Dropped).
- o severity - Violation severities.
- o violation - Violation types.
- o violation-rating - Violation ratings.
- o virtual - Virtual servers.
- o virus - Viruses that were detected by the system.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics asm-violation report view-by application
```

```
show analytics asm-violation report view-by application drilldown { {
entity attack-type values { attack-type_Value } } }
```

```
send-mail analytics asm-violation report view-by application measures {
requests } limit 20 order-by { { measure requests sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### occurrences

Occurrence count.

##### requests

Request count.

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that

you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics asm-violation scheduled-report

NAME

scheduled-report - Configure scheduled reports for ASM violation.

MODULE

analytics asm-violation

SYNTAX

Configure the scheduled-report component within the analytics asm-violation module using the syntax shown in the following sections.

CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete scheduled-report [name]
```

DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the ASM violation module.

EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the

top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the ASM violation scheduled reports.

#### OPTIONS

email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics asm-violation report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics asm-violation report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

  } ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]
```

## DESCRIPTION

Use this command to generate Bot Defense Event analytics reports. You

can generate a Bot Defense Event analytics report for the following entities:

- o bot-category - Bot Defense Category.
- o bot-classification - Bot Classification.
- o implied-mitigation-action - Implied Mitigation Action.
- o micro-service-name - Bot Defense Micro Service Name.
- o micro-service-type - Bot Defense Micro Service Type.
- o mobile-app-emulation-mode - Mobile App Emulation Mode.
- o mobile-app-jailbroken - Mobile App Jail Broken Rooted.
- o mobile-app-name - Mobile App Display Name.
- o mobile-app-version - Mobile App Version.
- o mobile-is-human-behavior - Mobile Is Human Behavior.
- o profile - Bot Defense Profile.
- o virtual - Virtual servers.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics bot-defense-event report view-by bot-category
```

```
show analytics bot-defense-event report view-by bot-category drilldown  
{ { entity bot-classification values { some_value } } }
```

```
send-mail analytics bot-defense-event report view-by bot-category  
measures { occurrences } limit 20 order-by { { measure occurrences  
sort-type desc } } format pdf email-addresses {  
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### occurrences

Occurrence count.

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

#### DESCRIPTION

Use this command to generate CPU Per Virtual analytics reports. You can generate a CPU Per Virtual analytics report for the following entities:

- o slot - Slot ID.
- o virtual - Virtual server.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics cpu-per-vip report view-by slot
```

```
show analytics cpu-per-vip report view-by slot drilldown { { entity
virtual values { virtual_1 virtual_2 } } }
```

```
send-mail analytics cpu-per-vip report view-by slot measures { avg-lmin
} limit 20 order-by { { measure avg-lmin sort-type desc } } format pdf
email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

avg-lmin

Average one minute.

avg-5min

Average five minute.

avg-5sec

Average five seconds.

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate cpu analytics reports. You can generate a IP-layer analytics report for the following entities:

- o slot - Slot ID
- o cpu - CPU number ID

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics cpu report view-by cpu
```

```
show analytics cpu report view-by cpu drilldown { { entity cpu values {
1 } } }
```

```
send-mail analytics cpu report view-by slot measures { cpu-usage }
limit 20 order-by { { measure cpu-usage sort-type desc } } format pdf
email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### cpu-usage

The average time percentage of real CPU usage (user + system + nice) usage for the selected filter (entity).

**io** The average time percentage of (iowait + irq + softirq) for

the selected filter (entity).

**stolen**  
The average time percentage of virtual CPU waits for a real CPU while the hypervisor is servicing another virtual processor.

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics cpu scheduled-report

#### NAME

scheduled-report - Configure scheduled reports for CPU.

#### MODULE

analytics cpu

#### SYNTAX

Configure the scheduled-report component within the analytics cpu module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

##### DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

##### DELETE

```
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the CPU module.

#### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

modify scheduled-report myScheduledReport smtp-config none

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

create scheduled-report myCustomScheduledReport first-time now email-addresses add { person@domain.com } frequency every-6-hours smtp-config asm smtp\_conf multi-leveled-report { view-by url time-diff last-hour limit 5 chart-path add { policy violation } }

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the CPU scheduled reports.

#### OPTIONS

email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics cpu report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics cpu report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]
```

**DESCRIPTION**

Use this command to generate Device Traffic Stats analytics reports. You can generate a Device Traffic Stats analytics report for the

following entities:

- o cpu-num - CPU num.
- o slot-id - Slot id.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

show analytics device-traffic report view-by cpu-num

show analytics device-traffic report view-by cpu-num drilldown { { entity slot-id values { 0 } } }

send-mail analytics device-traffic report view-by cpu-num measures { client-bits-out } limit 20 order-by { { measure client-bits-out sort-type desc } } format pdf email-addresses { some.one@someaddress.com }

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

avg-client-concurrent-connections

Avg Client Concurrent connections.

avg-server-concurrent-connections

Avg Server Concurrent connections.

client-bits-in

Client Incoming bits.

client-bits-out

Client Outgoing bits.

client-connections

Client Connections.

client-packets-in

Client Incoming packets.

client-packets-out

Client Outgoing packets.

max-client-concurrent-connections

Maximum Client Concurrent connections at peak.

max-server-concurrent-connections

Maximum Server Concurrent connections at peak.

requests

Requests.

server-bits-in

Server Incoming bits.

server-bits-out

Server Outgoing bits.

server-connections

Server Connections.

server-packets-in  
Server Incoming packets.

server-packets-out  
Server Outgoing packets.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics device-traffic scheduled-report

#### NAME

scheduled-report - Configure scheduled reports for device traffic.

#### MODULE

analytics device-traffic

#### SYNTAX

Configure the scheduled-report component within the analytics device-traffic module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

##### DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

##### DELETE

```
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the device traffic module.

#### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

modify scheduled-report myScheduledReport smtp-config none

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

create scheduled-report myCustomScheduledReport first-time now email-addresses add { person@domain.com } frequency every-6-hours smtp-config asm\_smtp\_conf multi-leveled-report { view-by url time-diff last-hour limit 5 chart-path add { policy violation } }

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the device traffic scheduled reports.

#### OPTIONS

email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics device-traffic report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics device-traffic report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

```

## DESCRIPTION

Use this command to generate disk-info analytics reports. You can generate a disk-info analytics report for the following entities:

- o slot - Slot ID

Different measures are collected for each of these entities and can be a part of the report request.

## EXAMPLES

show analytics disk-info report view-by slot

show analytics disk-info report view-by slot drilldown { { entity slot values { 7 } } }

send-mail analytics disk-info report view-by slot measures { total-ios } limit 20 order-by { { measure total-ios sort-type desc } } format pdf email-addresses { some.one@someaddress.com }

For more syntactical examples, see the tmsh help manual for analytics report.

## OPTIONS

### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

### drilldown

Specifies specific entities that are used as a filter.

### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

### total-ios

The total number of I/O for the selected filter (entity).

### read-operations

The total number of read operations for the selected filter (entity).

### read-merged

The total number of merged reads for the selected filter (entity).

### write-operations

The total number of write operations for the selected filter (entity).

### write-merged

The total number of merged writes for the selected filter (entity).

### read-bytes

The total number of read bytes for the selected filter (entity).

### write-bytes

The total number of write bytes for the selected filter (entity).

### max-read-latency

The max value of read latency for the selected filter (entity).

### average-read-latency

The average number of average read latency for the selected filter (entity).

### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort

type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics disk-info scheduled-report

NAME

scheduled-report - Configure scheduled reports for disk information.

MODULE

analytics disk-info

SYNTAX

Configure the scheduled-report component within the analytics disk-info module using the syntax shown in the following sections.

CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete scheduled-report [name]
```

DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the disk information module.

EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the disk information scheduled reports.

#### OPTIONS

email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics disk-info report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics disk-info report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

```

DESCRIPTION  
Use this command to generate DNS Cache Resolver analytics reports. You can generate a DNS Cache Resolver analytics report for the following entities:

- o name - DNS cache resolver name.

Different measures are collected for each of these entities and can be a part of the report request.

EXAMPLES

```
show analytics dns-cache-resolver report view-by name

show analytics dns-cache-resolver report view-by name drilldown { {
entity name values { name_1 } } }

send-mail analytics dns-cache-resolver report view-by name measures {
rpz-rewrite } limit 20 order-by { { measure rpz-rewrite sort-type desc
} } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**hit-ratio**  
DNS cache resolver hit ratio.

**rpz-rewrite**  
DNS cache resolver rpz rewrites.

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

BIG-IP 2018-0analytics dns-cache-resolver report(1)

NAME           report - Displays a DNS Profiles analytics report.

MODULE         analytics dns-profile

SYNTAX         Show, save or send a analytics dns-profile report using the syntax shown in the following sections.

```
DISPLAY
show report view-by [ name | vs-name ]
options:
  drilldown {
    {
  entity [ name | vs-name ]
  values
  {
    [value ...]
  }
  } ...
  }
  field-fmt
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]

SAVE
save report view-by [ name | vs-name ]
options:
  drilldown {
    {
  entity [ name | vs-name ]
  values
  {
    [value ...]
  }
  } ...
  }
  file [ file name ]
  format [ csv-aggregated | csv-time-series | pdf ]
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]

SEND
send-mail report view-by [ name | vs-name ]
options:
  drilldown {
    {
  entity [ name | vs-name ]
  values
  {
    [value ...]
  }
  } ...
  }
  email-addresses {
    [email address ...]
  }

  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]
```

DESCRIPTION     Use this command to generate DNS Profiles analytics reports. You can generate a DNS Profiles analytics report for the following entities:

- o   name - name.

o vs-name - vs names.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics dns-profile report view-by name
```

```
show analytics dns-profile report view-by name drilldown { { entity vs-  
name values { vs_1 vs_2 } } }
```

```
send-mail analytics dns-profile report view-by name measures { average-  
responses } limit 20 order-by { { measure average-responses sort-type  
desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

average-a-reqs

IPv4 address requests per seconds.

average-aaaa-reqs

IPv6 address requests per seconds.

average-any-reqs

Retrieves all the available type for given name per seconds.

average-cname-reqs

Alias of one name to another: the DNS lookup will continue by retrying the lookup with the new name per seconds.

average-dns64fails

IPv6 To IPv4 Requests per seconds.

average-dns64reqs

IPv6 To IPv4 Requests per seconds.

average-dns64trans

IPv6 To IPv4 Transfers per seconds.

average-drops

DNS drops per seconds.

average-fast-dns-allowed

Last action allowed per seconds.

average-fast-dns-drops

Last action drops per seconds.

average-fast-dns-queries

Rapid Responses fast queries per seconds.

average-fast-dns-resp-ne

Last Action no error per seconds.

average-fast-dns-resp-nx

Last action NX domain per seconds.

average-fast-dns-resp-rf

Last action refused per seconds.

average-fast-dns-resp-tc  
last action truncated per seconds.

average-fast-dns-responses  
Rapid responses per seconds.

average-hdr-aa  
Authoritative Answers per seconds.

average-hdr-ad  
Authenticated data per seconds.

average-hdr-ra  
Recursion available per seconds.

average-hdr-tc  
Truncated per seconds.

average-hints  
Cache of the DNS servers list per seconds.

average-hit-ratio  
DNS Hit Ratio - Responses / (Responses + Requests) per seconds.

average-hw-inspected  
Inspected per seconds.

average-improperly-formatted  
Hardware handled packets improperly formatted per seconds.

average-invalid-authority  
Invalid Authority per seconds.

average-malformed  
Protocol violations improperly formatted per seconds.

average-mx-reqs  
Maps a domain name to a list of message transfer agents for that domain per seconds.

average-naptr-reqs  
NAPTR is a type of resource record in the DNS per seconds.

average-ns-reqs  
Delegates a DNS zone to use the given authoritative name servers per seconds.

average-other-reqs  
Other Requests per seconds.

average-ptr-reqs  
Pointer records are used to map a network interface (IP) to a host name per seconds.

average-queries  
DNS queries per seconds.

average-r-noerror  
No Error per seconds.

average-r-nxdomain  
Domain per seconds.

average-r-refused  
Query refused per seconds.

average-r-servfail  
Server Failure per seconds.

average-rejects  
rejects per seconds.

average-responses  
DNS responses per seconds.

average-soa-reqs  
Specifies authoritative information about a DNS zone per seconds.

average-srv-reqs  
A Service record is a specification of data in the Domain Name System defining the location per seconds.

average-success-queries  
Query completed successfully per seconds.

average-todns  
DNS todns per seconds.

average-txt-reqs  
Originally for arbitrary human-readable text in a DNS record per seconds.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics dns-protocol scheduled-report

NAME

scheduled-report - Configure scheduled reports for DNS protocol.

MODULE

analytics dns-protocol

SYNTAX

Configure the scheduled-report component within the analytics dns-protocol module using the syntax shown in the following sections.

CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete scheduled-report [name]
```

DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the DNS protocol module.

EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the DNS protocol scheduled reports.

#### OPTIONS

email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics dns-protocol report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics dns-protocol report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

## analytics dns-rpz report

#### NAME

report - Displays a DNS Response Policy Zones analytics report.

#### MODULE

analytics dns-rpz

#### SYNTAX

Show, save or send a analytics dns-rpz report using the syntax shown in

the following sections.

```
DISPLAY
show report view-by [ rpz ]
options:
  drilldown {
  {
  entity [ rpz ]
  values
  {
    [value ...]
  }
  } ...
  }
  field-fmt
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]

SAVE
save report view-by [ rpz ]
options:
  drilldown {
  {
  entity [ rpz ]
  values
  {
    [value ...]
  }
  } ...
  }
  file [ file name ]
  format [ csv-aggregated | csv-time-series | pdf ]
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]

SEND
send-mail report view-by [ rpz ]
options:
  drilldown {
  {
  entity [ rpz ]
  values
  {
    [value ...]
  }
  } ...
  }
  email-addresses {
    [email address ...]
  }
  format [ csv-aggregated | csv-time-series | pdf ]
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]
```

#### DESCRIPTION

Use this command to generate DNS Response Policy Zones analytics reports. You can generate a DNS Response Policy Zones analytics report for the following entities:

- o rpz - Response policy zone.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics dns-rpz report view-by rpz
```

```
show analytics dns-rpz report view-by rpz drilldown { { entity rpz
values { rpz_name } } }
```

```
send-mail analytics dns-rpz report view-by rpz measures { rpz-queries }
limit 20 order-by { { measure rpz-queries sort-type desc } } format pdf
email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### queries

Queries.

##### rpz-queries

Response policy zone queries.

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### SEE ALSO

## analytics dns report

#### NAME

report - Displays a DNS analytics report.

MODULE  
analytics dns

SYNTAX  
Show, save or send an analytics dns report using the syntax shown in the following sections.

```
DISPLAY
show report view-by [ activity-type | application | attack-id | client-ip | country | country-code | dns-transaction-o
options:
  drilldown {
    {
entity [ activity-type | application | attack-id | client-ip | country | country-code | dns-transaction-outcome | dom
values
{
  [value ...]
}
} ...
}
field-fmt
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc | desc ]
  } ...
}
range [date range]
```

```
SAVE
save report view-by [ activity-type | application | attack-id | client-ip | country | country-code | dns-transaction-o
options:
  drilldown {
    {
entity [ activity-type | application | attack-id | client-ip | country | country-code | dns-transaction-outcome | dom
values
{
  [value ...]
}
} ...
}
file [ file name ]
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc | desc ]
  } ...
}
range [date range]
```

```
SEND
send-mail report view-by [ activity-type | application | attack-id | client-ip | country | country-code | dns-transact
options:
  drilldown {
    {
entity [ activity-type | application | attack-id | client-ip | country | country-code | dns-transaction-outcome | dom
values
{
  [value ...]
}
} ...
}
email-addresses {
  [email address ...]
}
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc | desc ]
  } ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]
```

DESCRIPTION  
Use this command to generate DNS analytics reports. You can generate a DNS analytics report for the following entities:

- o activity-type - Activity type.
- o application - Application services (iApps(tm)).
- o attack-id - (Only available with AFM is provisioned) DoS Attack ID.

- o client-ip - DNS query source/client IP address.
- o country - Country.
- o country-code - Country code.
- o dns-transaction-outcome - Request outcome.
- o domain-name - Queried domain name.
- o dos-profile - DoS profile.
- o mitigation - Mitigation.
- o query-type - DNS query type.
- o suspected-ip - Suspected address IP.
- o trigger - Trigger.
- o vector - Attack vector.
- o virtual - Virtual server.

#### EXAMPLES

show analytics dns report view-by virtual

show analytics dns report view-by query-type drilldown { { entity  
virtual values { /Common/v1 } } }

send-mail analytics dns report view-by client-ip limit 20 format pdf  
email-addresses { some.one@someaddress.com }

For more syntactical examples see manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a  
report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is  
sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save  
command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This  
option must be specified when using the save or send-mail  
commands.

##### include-others

Specifies that the grand total for the measure is displayed for  
all entities, except for those shown in the result. It can be used  
along with include-total.

##### include-total

Specifies that a total summary row should be added to the  
analytics report. For average measures, the total value is also an  
average.

##### limit

Specifies the maximum number of rows/entities in the output result  
set/file. The default value is 10, not including the total  
row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen  
entity type. The options are:

##### attacks-count

The total number of DNS attacks for the specified view-by  
entity.

##### packets

The total number of DNS packets for the specified view-by  
entity.

##### packets-per-second

The average number of DNS packets for the specified view-by  
entity.

##### order-by

Specifies the measures and sort type (ascending or descending)  
that will be used to sort the final report. The value for each  
measure is a previously chosen measure. The default value for sort  
type is desc (descending).

##### range

Specifies the time/date range of the analytics information that  
you want to display. The given results will reflect the time range  
chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by  
email. This overrides the default SMTP settings.

## analytics dns scheduled-report

NAME

scheduled-report - Configure scheduled reports for DNS.

MODULE

analytics dns

SYNTAX

Configure the scheduled-report component within the analytics dns module using the syntax shown in the following sections.

CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete scheduled-report [name]
```

DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the DNS module.

EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the DNS scheduled reports.

## OPTIONS

### email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

### first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

### include-total

Enables or disables including a summary (Overall result) entity in results.

### multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

#### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics dns report.

#### limit

The number of view-by entities displayed in the scheduled report.

#### time-diff

The time range for the report.

#### view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics dns report.

#### measures

The measures which are available for the selected entities.

#### predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

#### smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

#### device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

## analytics dos-l3 report

### NAME

report - Displays a DoS (Layers 3-4) prevention analytics report.

### MODULE

analytics dos-l3

### SYNTAX

Show, save or send an analytics dos-l3 report using the syntax shown in the following sections.

#### DISPLAY

show report view-by [ action | activity-type | application | attack-id | category | client-ip | country | country-code | dos-profile | mitigation | server-ip | suspected-ip | trigger | vector | virtual | vlan | vlan-group ] options:

```

drilldown {
{
entity [ action | activity-type | application | attack-id | category | client-ip | country | country-code | dest-coun
dos-profile | mitigation | server-ip | suspected-ip | trigger | vector | virtual | vlan | vlan-group ]
values
{
[value ...]
}
} ...
}
field-fmt
include-total
include-others
limit [number of rows]
measures {
[measure name ...]
}
order-by {
{
measure [ measure name ]
sort-type [ asc | desc ]
} ...
}
range [date range]

SAVE
save report view-by [ action | activity-type | application | attack-id | category | client-ip | country | country-code
dos-profile | mitigation | server-ip | suspected-ip | trigger | vector | virtual | vlan | vlan-group ]
options:
drilldown {
{
entity [ action | activity-type | application | attack-id | category | client-ip | country | country-code | dest-coun

smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate DoS (Layers 3-4) prevention analytics reports. You can generate a DoS prevention analytics report for the following entities:

- o action - Action taken (allowed/dropped).
- o activity-type - Activity type.
- o application - Application services (iApps(tm)).
- o attack-id - DoS attack ID.
- o category - Attack category.
- o client-ip - Source/client IP address.

- o country - Country.
- o country-code - Country code.
- o dest-country - Destination country.
- o dest-country-code - Destination country code.
- o dos-profile - DoS profile.
- o mitigation - Mitigation.
- o server-ip - Server address IP.
- o suspected-ip - Suspect address IP.
- o trigger - Trigger.
- o vector - Attack vector.
- o virtual - Virtual server.
- o vlan - VLAN.
- o vlan-group - VLAN Group.

#### EXAMPLES

```
show analytics dos-l3 report view-by virtual
```

```
show analytics dos-l3 report view-by attack-type drilldown { { entity
virtual values { /Common/v1 } } }
```

```
send-mail analytics dos-l3 report view-by source-ip limit 20 format pdf
email-addresses { some.one@someaddress.com }
```

For more syntactical examples see manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### allowed-requests

The total number of packets that were received by the virtual server(/s)s

##### allowed-requests-per-second

The average number of packets that were received by the virtual server(/s)s

##### attacks-count

The total number of attacks for the selected view-by entity.

##### dropped-requests

The total number of packets that were dropped by the virtual server(/s)s

##### dropped-requests-per-second

The average number of packets that were dropped by the virtual server(/s)s

##### total-requests

The total number of packets that were received or dropped by the virtual server(/s)s

total-requests-per-second  
The average number of packets that were received or dropped  
by the virtual server(/s)s

order-by  
Specifies the measures and sort type (ascending or descending)  
that will be used to sort the final report. The value for each  
measure is a previously chosen measure. The default value for sort  
type is desc (descending).

range  
Specifies the time/date range of the analytics information that  
you want to display. The given results will reflect the time range  
chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by  
email. This overrides the default SMTP settings.

## analytics dos-l3 scheduled-report

NAME

scheduled-report - Configure scheduled reports for DoS L3.

MODULE

analytics dos-l3

SYNTAX

Configure the scheduled-report component within the analytics dos-l3  
module using the syntax shown in the following sections.

CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete scheduled-report [name]
```

DESCRIPTION

Use the scheduled-report component to create, modify or delete  
scheduled reports for the DoS L3 module.

EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing  
every 6 hours. The report contains a PDF showing statistics for the top  
blocked URLs and is sent to person@domain.com using the smtp  
configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the DoS L3 scheduled reports.

#### OPTIONS

##### email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

##### first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

##### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

##### include-total

Enables or disables including a summary (Overall result) entity in results.

##### multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

##### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics dos-l3 report.

##### limit

The number of view-by entities displayed in the scheduled report.

##### time-diff

The time range for the report.

##### view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics dos-l3 report.

##### measures

The measures which are available for the selected entities.

##### predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

##### smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

##### device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

#### SEE ALSO

order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate HTTP analytics reports. You can generate an HTTP analytics report for the following entities:

- o activity-type - Activity type.
- o application - Application services.
- o attack-id - Application/L7 DoS Attack ID.
- o behavioral-signature - Behavioral signature.
- o browser - Browser.
- o client-ip - A single client identified by an IP address.
- o client-subnet - Client subnet.
- o country - A country from which HTTP/HTTPS traffic was sent to each of the virtual servers.
- o country-code - Country code from which HTTP/HTTPS traffic was sent to each of the virtual servers.
- o device-id - Device ID.
- o dos-profile - DoS Profile.
- o http-method - Method.
- o http-transaction-outcome - HTTP Transaction outcomes (Blocked/Dropped/Passthrough/etc.)
- o mitigation - Mitigation.
- o os - OS name.
- o pool-member - Pool members.
- o response-code - An HTTP response code that was sent back to the client.
- o suspected-ip - Suspected address IP.
- o trigger - Trigger.
- o url - A URL accessed by HTTP or HTTPS.
- o user-agent - A browser identifier sent by the client's browser as part of the request for URL.
- o vector - Attack vector.
- o virtual - Virtual servers.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics dos-l7 report view-by virtual measures {average-tps}
limit 20

```

Gets the average tps of 20 virtual servers (unordered).

```

show analytics dos-l7 report view-by virtual measures {average-tps}
limit 20 order-by { { measure average-tps sort-type desc } }

```

Gets the average tps of the top 20 virtual servers.

```

show analytics dos-l7 report view-by virtual measures {average-tps}
limit 20 order-by { { measure average-tps sort-type desc } } range
now-3d--now

```

Gets the average tps of the top 20 virtual servers from the last three days.

```

show analytics dos-l7 report view-by virtual drilldown { { entity
application values { app } } { entity pool-member values { p1 p2 } } }
range now-4d--now-2d measures {average-tps} limit 10 order-by { {
measure average-tps sort-type DESC } }

```

Gets the average tps of the top 10 virtual servers (ordered by average tps) on app iApp (out of several monitored) on pool members p1 and p2 (out of five monitored p1-p5) in the interval ranging from two to four days ago.

```

show analytics dos-l7 report view-by response-code drilldown { { entity
virtual values { v1 } } } measures { transactions }

```

Gets a distribution of requests per response code on virtual v1.

```

show analytics dos-l7 report view-by country drilldown { { entity
application values { app } } } measures { average-concurrent-sessions
average-sessions } order-by { { measure average-sessions sort-type DESC
} } limit 5

```

Gets the new sessions and average concurrent sessions of the top five countries, ordered by the average concurrent sessions on the application app.

```
show analytics dos-17 report view-by client-ip drilldown { { entity  
virtual values { v1 } } } measures { max-page-load-time } limit 1
```

Gets the client IP address with the worst page load time.

```
show analytics dos-17 report view-by application drilldown { { entity  
pool-member values { p1 p2 } } } measures { transactions } order-by { {  
measure transactions } } range now-7d--now
```

Gets the distribution of requests per application on pool members p1 and p2 ordered by the number of requests during the last week.

```
save analytics dos-17 report view-by virtual measures {average-tps}  
limit 20 order-by { { measure average-tps sort-type desc } } format pdf  
file report.pdf
```

Gets the average tps of the top 20 virtual servers and exports to a PDF file on the BIG-IP system.

```
save analytics dos-17 report view-by virtual measures {average-tps}  
limit 20 order-by { { measure average-tps sort-type desc } } format  
csv-aggregated file report.csv
```

Gets the average tps of the top 20 virtual servers and exports to a CSV file on the BIG-IP system.

```
save analytics dos-17 report view-by virtual measures {average-tps}  
limit 20 order-by { { measure average-tps sort-type desc } } format  
csv-time-series file report.csv
```

Gets the average tps over time of the top 10 virtual servers and exports to a CSV file on the BIG-IP system.

```
send-mail analytics dos-17 report view-by virtual measures  
{average-tps} limit 20 order-by { { measure average-tps sort-type desc  
} } format pdf email-addresses { some.one@someaddress.com }
```

Gets the average tps over time of the top 10 virtual servers and sends out an email containing the report as a PDF.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The default value is transactions. The options are:

##### average-concurrent-sessions

The average number of concurrent sessions for each entity.

##### average-new-sessions

The average number of new sessions for each entity.

##### average-page-load-time

The average client page load time for each entity.

##### average-request-throughput

The average request throughput for each entity.

##### average-response-throughput

The average response throughput for each entity.

##### average-server-latency

The average server latency for each entity.

average-tps  
The average number of transactions per second for each entity.

client-side-sampled-transactions  
The number of transactions sampled for client side page load time.

max-page-load-time  
The maximum client page load time for each entity.

max-request-throughput  
The maximum request throughput for each entity.

max-response-throughput  
The maximum response throughput for each entity.

max-server-latency  
The maximum server latency for each entity.

max-tps  
The maximum number of transactions per second for each entity.

transactions  
The absolute number of transactions for each entity.

min-server-latency  
The minimum server latency for each entity.

average-request-size  
The average request size for each entity.

average-response-size  
The average response size for each entity.

average-application-response-time  
The average application response time for each entity.

min-application-response-time  
The minimum application response time for each entity.

max-application-response-time  
The maximum application response time for each entity.

average-client-ttfb  
The average client TTFB for each entity.

min-client-ttfb  
The minimum client TTFB for each entity.

max-client-ttfb  
The maximum client TTFB for each entity.

average-clientside-network-latency  
The average client-side network latency for each entity.

min-clientside-network-latency  
The minimum client-side network latency for each entity.

max-clientside-network-latency  
The maximum client-side network latency for each entity.

average-serverside-network-latency  
The average server-side network latency for each entity.

min-serverside-network-latency  
The minimum server-side network latency for each entity.

max-serverside-network-latency  
The maximum server-side network latency for each entity.

average-request-duration  
The average request duration for each entity.

min-request-duration  
The minimum request duration for each entity.

max-request-duration  
The maximum request duration for each entity.

average-response-duration  
The average response duration for each entity.

min-response-duration  
The minimum response duration for each entity.

max-response-duration  
The maximum response duration for each entity.

attacks-count  
The total number of attack for each entity.

valid  
The total number of valid transactions for each entity.

average-valid-tps  
The average number of valid transactions for each entity.

mitigated  
The total number of mitigated transaction for each entity.

average-mitigated-tps  
The average number of mitigated transaction for each entity.

blocked  
The total number of blocked transactions for each entity.

average-blocked-tps  
The average number of blocked transactions for each entity.

incomplete  
The total number of incomplete transactions for each entity.

average-incomplete-tps  
The average number of incomplete transactions for each entity.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The default value for measures is previously chosen measures. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

      measure [ measure name ]
      sort-type [ asc | desc ]
    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate DoS Attacks analytics reports. You can generate a DoS Attacks analytics report for the following entities:

- o attack-id - Unique attack ID.
- o event-idx - Index of an event in an attack.
- o protocol - Attacked protocol (HTTP, DNS, SIP, Network).
- o virtual - Name of the attacked Virtual Server.
- o dos-profile - DoS profile that detects and mitigates the attack.
- o trigger - Threshold that was hit to indicate the attack.
- o vector - Attack vector (used by AFM, ASM has only 1 vector).
- o mitigation - Mitigation to the attack.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics dos-vis-attacks report view-by virtual

show analytics dos-vis-attacks report view-by virtual drilldown { {
entity protocol values { DNS } } }

send-mail analytics dos-vis-attacks report view-by virtual measures {
attack-severity } limit 15 order-by { { measure attack-severity sort-
type desc } } format pdf email-addresses { some.one@someaddress.com }

For more syntactical examples, see the tmsh help manual for analytics
report.

```

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is

sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures Specifies a list of measures that can be used with the chosen entity type. The options are:

event-start  
The start moment of the event.

event-end  
The end moment of the event.

total-blocked  
Total number of blocked transactions.

concurrent-ips  
Maximum number of simultaneous attacking IPs per 10 second interval.

severity  
Calculated severity of the attack.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate DoS Common analytics reports. You can generate a DoS Common analytics report for the following entities:

- o activity-type - Tells whether a transaction was created by client regular activity or due to BIG-IP internal activity/injected JavaScripts.
- o application - Application services.
- o attack-id - Attack's unique ID.
- o client-ip - A single client identified by an IP address.
- o country - The name of the country from which the traffic arrived.

- o country-code - An ISO 3166-1 Alpha-2 country code from which the traffic arrived.
- o dos-profile - Name of the DoS Profile involved in classifying relevant traffic as attack.
- o mitigation - The mitigation of the attack.
- o protocol - The protocol that was attacked (HTTP/SIP/DNS/L3).
- o suspected-ip - Is this IP suspected by dos module as "attacking".
- o trigger - The trigger of the attack.
- o vector - The vector of the attack.
- o virtual - Name of the virtual server.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics dos-vis-common report view-by activity-type
```

```
show analytics dos-vis-common report view-by activity-type drilldown {
{ entity virtual values { virtual_1 virtual_2 } } }
```

```
send-mail analytics dos-vis-common report view-by activity-type
measures { network-dropped-requests-per-second } limit 20 order-by { {
measure network-dropped-requests-per-second sort-type desc } } format
pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### attacks-count

Number of distinct attacks.

##### average-tps

Average number of transactions per second (tps).

##### dns-hits-count

The total number of DNS packets.

##### http-transactions

The absolute number of transactions for each entity.

##### network-allowed-requests

Total number of attacking network requests that were allowed by AFM.

##### network-allowed-requests-per-second

Average number of network-attacking requests allowed per second.

##### network-dropped-requests

Total number of dropped network requests.

##### network-dropped-requests-per-second

Average number of network-attacking requests dropped per

second.

network-total-requests  
Total number of attacking requests.

network-total-requests-per-second  
Average number of attacking requests per second (allowed and dropped).

packets-per-second  
Average DNS packets per second.

sip-hits-count  
The total number of SIP requests.

sip-requests-per-sec  
Average number of SIP requests per second.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### DESCRIPTION

Use this command to generate DoS Virtual Servers analytics reports. You can generate a DoS Virtual Servers analytics report for the following entities:

- o virtual - Name of the virtual server.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics dos-vis-vips report view-by virtual
```

```
show analytics dos-vis-vips report view-by virtual drilldown { { entity
virtual values { virtual_1 virtual_2 } } }
```

```
send-mail analytics dos-vis-vips report view-by virtual measures { avg-
client-side-concurrent-conns } limit 20 order-by { { measure avg-
client-side-concurrent-conns sort-type desc } } format pdf email-
addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

avg-abandoned-conns

Average number of abandoned connections per second.

avg-client-in-pps

Average packets rate in from clients per second.

avg-client-in-throughput

Average bits rate in from clients per second.

avg-client-out-pps

Average packets rate out to clients per second.

avg-client-out-throughput

Average bits rate outs to clients per second.

avg-client-side-concurrent-conns

Average client side concurrent connections.

avg-expired-conns

Average number of expired connections per second.

avg-failed-conns

Average number of failed connections per second.

avg-new-client-conns

Average number of new client side connections per second.

avg-new-server-conns

Average number of new server side connections per second.

avg-server-in-pps

Average packets rate in from servers per second.

avg-server-in-throughput

Average bits rate in from servers per second.

avg-server-latency

Average server latency (in ms).

avg-server-latency-health

Health score of the Latency parameter.

avg-server-out-pps

Average packets rate out to servers per second.

avg-server-out-throughput

Average bits rate out to servers per second.

avg-server-side-concurrent-conns

Average server side concurrent connections.

avg-throughput-health

Health score of the Throughput parameter.

concurrent-attacking-ips

The number of monitored simultaneous IPs participating in attacks per 10 second interval.

concurrent-blocked-ips

The number of monitored simultaneous blocked IPs per 10 second interval.

concurrent-conns-health

Health score of the Connections parameter.

concurrent-ips

The number of monitored simultaneous IP connections per 10 second interval.

max-concurrent-attacks

The number of monitored simultaneous attacks per 10 second interval.

max-concurrent-attacks-overtime

The at least number of simultaneous attacks per 10 second interval.

max-concurrent-client-conns

Highest number of simultaneous client side connections observed.

max-concurrent-server-conns

Highest number of simultaneous server side connections observed.

special-concurrent-ips-for-all-vips

The least number of simultaneous IPs connections per 10 second interval for all VIPs.

total-abandoned-conns  
Total number of abandoned connections.

total-client-in-bytes  
Total bytes in from clients.

total-client-out-bytes  
The total client out bytes.

total-expired-conns  
Total number of expired connections.

total-failed-conns  
Total number of failed connections.

total-health  
Overall health score of the virtual server (in %).

total-new-client-conns  
Total number of new client side connections.

total-new-server-conns  
Total number of new server side connections.

total-server-in-bytes  
Total bytes in from servers.

total-server-out-bytes  
Total bytes out to servers.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate firewall NAT analytics reports. You can generate a firewall NAT analytics report for the following entities:

- o name - Name.

#### EXAMPLES

```

show analytics fw-nat report view-by name

show analytics fw-nat report view-by name drilldown { { entity name
values { my_name } } }

send-mail analytics fw-nat report view-by name limit 20 format pdf
email-addresses { some.one@someaddress.com }

```

For more syntactical examples see manual for analytics report.

#### OPTIONS

- device  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)
- device-list  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)
- drilldown  
Specifies specific entities that are used as a filter.
- email-addresses  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.
- file  
Specifies the exported file path to be saved when using the save

command. The file name should be simple (not a full path).

#### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

#### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. This option must be used with the drilldown option. You can also use it along with include-others.

#### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

#### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

#### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

#### avg-source-translation-requests

The average number of FW NAT source translation requests for the selected filter (entity).

#### avg-source-translation-request-failures

The average number of FW NAT source translation request failures for the selected filter (entity).

#### avg-destination-translation-requests

The average number of FW NAT destination translation requests for the selected filter (entity).

#### avg-destination-translation-request-failures

The average number of FW NAT destination translation request failures for the selected filter (entity).

#### avg-active-translations

The average number of FW NAT active translations for the selected filter (entity).

#### avg-backup-pool-translations

The average number of FW NAT backup-pool translations for the selected filter (entity).

#### avg-log-attempts

The average number of FW NAT log attempts for the selected filter (entity). Only applies to FW NATs in logging mode.

#### avg-log-failures

The average number of FW NAT log failures for the selected filter (entity). Only applies to FW NATs in logging mode.

#### avg-active-port-blocks

The average number of FW NAT active port-blocks for the selected filter (entity). Only applies to FW NATs in PBA mode.

#### avg-port-block-allocations

The average number of FW NAT port-block allocations for the selected filter (entity). Only applies to FW NATs in PBA mode.

#### avg-port-block-deallocations

The average number of FW NAT port-block de-allocations for the selected filter (entity). Only applies to FW NATs in PBA mode.

#### avg-zombie-port-blocks-created

The average number of FW NAT zombie port-blocks which have been created for the selected filter (entity). Only applies to FW NATs in PBA mode.

#### avg-zombie-port-blocks-deleted

The average number of FW NAT zombie port-blocks which have been deleted for the selected filter (entity). Only applies to FW NATs in PBA mode.

#### avg-active-clients-reached-limit

The average number of FW NAT active-clients limit reached for the selected filter (entity). Only applies to FW NATs in PBA mode.

#### avg-clients-reached-limit

The average number of FW NAT total-clients limit reached for the selected filter (entity). Only applies to FW NATs in PBA mode.

#### avg-pcp-request

The average number of FW NAT PCP-requests for the selected filter (entity). Only applies to FW NATs in PCP mode.

#### avg-pcp-response

The average number of FW NAT PCP-responses for the selected filter (entity). Only applies to FW NATs in PCP mode.

#### avg-pcp-error

The average number of FW NAT PCP-errors for the selected

filter (entity). Only applies to FW NATs in PCP mode.

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics fw-nat scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for firewall NAT.

**MODULE**  
analytics fw-nat

**SYNTAX**  
Configure the scheduled-report component within the analytics fw-nat module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create scheduled-report [name]  
modify scheduled-report [name]  
options:  
  email-addresses [none | add | delete | modify |  
    replace-all-with] { email-address [string] }  
  first-time [date]  
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]  
  include-total [enabled | disabled]  
  multi-leveled-report {  
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }  
  limit [number of rows]  
  time-diff [last-hour | last-day | last-week | last-month | last-year]  
  view-by { entity name [string] }  
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }  
  }  
  predefined-report-name [name]  
  smtp-config [name]  
  device-group [name]

**DISPLAY**  
list scheduled-report  
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]  
show running-config scheduled-report  
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

**DELETE**  
delete scheduled-report [name]

**DESCRIPTION**  
Use the scheduled-report component to create, modify or delete scheduled reports for the firewall NAT module.

**EXAMPLES**  
create scheduled-report myScheduledReport first-time now predefined-report-name "Top blocked URLs" frequency every-6-hours email-addresses add { person@domain.com } smtp-config asm\_smtp\_conf  
  
Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.  
  
modify scheduled-report myScheduledReport smtp-config none  
  
Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin

generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the firewall NAT scheduled reports.

#### OPTIONS

email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics fw-nat report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics fw-nat report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

BIG-IP 2018-10-analytics fw-nat scheduled-report(1)

NAME  
global-settings - set up global analytics parameters.

MODULE  
analytics global-settings

SYNTAX  
List or set up parameters related to analytics data publishing using the syntax shown in the following sections.

LIST GLOBAL SETTINGS  
list analytics global-settings [ all-properties | non-default-properties | one-line | recursive ]

GLOBAL PUBLISHING SETTINGS  
modify avrd-interval [ value ]  
modify avrd-debug-mode [ disabled | enabled ]  
modify disable-all-internal-logging [ disabled | enabled ]

HSL PUBLISHER  
modify external-logging-publisher [ publisher name | none ]

OFFBOX SETTINGS  
modify offbox-protocol [ ecm-tm | hsl | none | tcp ]  
modify offbox-tcp-addresses  
[ add | delete | none | replace-all-with ] { list of IP addresses... }  
modify offbox-tcp-port [ value ]  
modify use-offbox [ disabled | enabled ]

DESCRIPTION  
Use the analytics global-settings command to list or modify the following global analytics settings:

- o avrd-interval - analytics data collection interval in seconds. If this interval is different from the default value (300 seconds), internal statistics are not collected unless avrd-debug-mode is set to enabled. Minimal interval is 20 seconds, maximum interval is 300 seconds.
- o avrd-debug-mode - enable or disable debug mode. If debug mode is disabled (by default), internal statistics are collected only if avrd-interval is set to the default value (300 seconds).
- o disable-all-internal-logging - when it is enabled, internal statistics are never collected, regardless of avrd-interval and avrd-debug-mode settings.
- o external-logging-publisher - choose which logging publisher will be used for the external HSL protocol. Relevant when offbox-protocol is set to 'hsl'.
- o offbox-protocol - protocol for communication with offbox analytics application. The protocol can be defined as one of the following four options: 'hsl' - (High Speed Logging) a protocol based on UDP or TCP; 'tcp' - the proprietary TCP-based protocol; 'ecm-tm' - a protocol based on Google RPC (grpc); and 'none'. Note: 'ecm-tm' is the recommended option. Note: If 'none' is chosen, the analytics module does not try to connect to the offbox analytics application.
- o offbox-tcp-addresses - server IP addresses used only if the 'tcp' protocol is chosen. Multiple IP addresses are supported. If more than one IP address is configured, the analytics module first tries to connect to the first IP address in the list. If the connection can't be established, it tries the next IP address, and so on.
- o offbox-tcp-port - server TCP port for the server IP addresses used only if 'tcp' protocol is chosen. If multiple tcp addresses are configured they all use the same port.
- o use-offbox - enables and disables all communication with the offbox application on global level.

EXAMPLES  
Display all current analytics global settings:

```
list analytics global-settings all-properties
```

Enable the analytics module to communicate with an offbox application using the 'tcp' protocol. In this example, the offbox application IP addresses are 192.168.1.1 and 192.168.1.2, TCP port is - 3344 :

```
modify analytics global-settings offbox-tcp-addresses  
add { 192.168.1.1 192.168.1.2 }  
modify analytics global-settings offbox-tcp-port 3344  
modify analytics global-settings offbox-protocol tcp  
modify analytics global-settings use-offbox enabled
```

Create an analytics report every 20 seconds. Note: Since it has a big performance impact, this should be configured for debugging purposes only.

```
modify analytics global-setting avrd-debug-mode enabled  
modify analytics global-setting avrd-interval 20
```

```

#### DESCRIPTION

Use this command to generate GTM WideIp analytics reports. You can generate a GTM WideIp analytics report for the following entities:

- o name - GTM wideip name.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics gtm-wideip report view-by name
```

```
show analytics gtm-wideip report view-by name drilldown { { entity name
values { some_name } } }
```

```
send-mail analytics gtm-wideip report view-by name measures { dropped }
limit 20 order-by { { measure dropped sort-type desc } } format pdf
email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

alternate

GTM wideip alternate.

cname-resolutions

GTM wideip cname.

dropped

GTM wideip dropped.

fallback

GTM wideip fallback.

preferred

GTM wideip preferred.

requests

GTM wideip request.

resolutions

GTM wideip resolutions.

return-from-dns

GTM wideip return from DNS.

return-to-dns

GTM wideip return to DNS.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

#### DESCRIPTION

Use this command to generate HTTP analytics reports. You can generate an HTTP analytics report for the following entities:

- o activity-type - Activity type.
- o application - Application services.
- o attack-id - Application/L7 DoS Attack ID.
- o behavioral-signature - Behavioral signature.
- o browser - Browser.
- o client-ip - A single client identified by an IP address.
- o client-subnet - Client subnet.
- o country - A country from which HTTP/HTTPS traffic was sent to each of the virtual servers.
- o country-code - Country code from which HTTP/HTTPS traffic was sent to each of the virtual servers.
- o device-id - Device ID.
- o dos-profile - DoS Profile.
- o http-method - Method.
- o http-transaction-outcome - HTTP Transaction outcomes (Blocked/Dropped/Passthrough/etc.)
- o mitigation - Mitigation.
- o os - OS name.
- o pool-member - Pool members.
- o response-code - An HTTP response code that was sent back to the client.
- o suspected-ip - Suspected address IP.
- o trigger - Trigger.
- o url - A URL accessed by HTTP or HTTPS.
- o user-agent - A browser identifier sent by the client's browser as part of the request for URL.
- o vector - Attack vector.
- o virtual - Virtual servers.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics http report view-by virtual measures {average-tps} limit 20
```

Gets the average tps of 20 virtual servers (unordered).

```
show analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } }
```

Gets the average tps of the top 20 virtual servers.

```
show analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } range now-3d--now
```

Gets the average tps of the top 20 virtual servers from the last three days.

```
show analytics http report view-by virtual drilldown { { entity application values { app } } { entity pool-member values { p1 p2 } } } range now-4d--now-2d measures {average-tps} limit 10 order-by { { measure average-tps sort-type DESC } }
```

Gets the average tps of the top 10 virtual servers (ordered by average tps) on app iApp (out of several monitored) on pool members p1 and p2 (out of five monitored p1-p5) in the interval ranging from two to four days ago.

```
show analytics http report view-by response-code drilldown { { entity virtual values { v1 } } } measures { transactions }
```

Gets a distribution of requests per response code on virtual v1.

```
show analytics http report view-by country drilldown { { entity application values { app } } } measures { average-concurrent-sessions average-sessions } order-by { { measure average-sessions sort-type DESC } } limit 5
```

Gets the new sessions and average concurrent sessions of the top five countries, ordered by the average concurrent sessions on the application app.

```
show analytics http report view-by client-ip drilldown { { entity virtual values { v1 } } } measures { max-page-load-time } limit 1
```

Gets the client IP address with the worst page load time.

```
show analytics http report view-by application drilldown { { entity pool-member values { p1 p2 } } } measures { transactions } order-by { { measure transactions } } range now-7d--now
```

Gets the distribution of requests per application on pool members p1 and p2 ordered by the number of requests during the last week.

```
save analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format pdf file report.pdf
```

Gets the average tps of the top 20 virtual servers and exports to a PDF file on the BIG-IP system.

```
save analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format csv-aggregated file report.csv
```

Gets the average tps of the top 20 virtual servers and exports to a CSV file on the BIG-IP system.

```
save analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format csv-time-series file report.csv
```

Gets the average tps over time of the top 10 virtual servers and exports to a CSV file on the BIG-IP system.

```
send-mail analytics http report view-by virtual measures {average-tps} limit 20 order-by { { measure average-tps sort-type desc } } format pdf email-addresses { some.one@someaddress.com }
```

Gets the average tps over time of the top 10 virtual servers and sends out an email containing the report as a PDF.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

#### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

#### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

#### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

#### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

#### measures

Specifies a list of measures that can be used with the chosen entity type. The default value is transactions. The options are:

#### average-concurrent-sessions

The average number of concurrent sessions for each entity.

#### average-new-sessions

The average number of new sessions for each entity.

#### average-page-load-time

The average client page load time for each entity.

#### average-request-throughput

The average request throughput for each entity.

#### average-response-throughput

The average response throughput for each entity.

#### average-server-latency

The average server latency for each entity.

#### average-tps

The average number of transactions per second for each entity.

#### client-side-sampled-transactions

The number of transactions sampled for client side page load time.

#### max-page-load-time

The maximum client page load time for each entity.

#### max-request-throughput

The maximum request throughput for each entity.

#### max-response-throughput

The maximum response throughput for each entity.

#### max-server-latency

The maximum server latency for each entity.

#### max-tps

The maximum number of transactions per second for each entity.

#### transactions

The absolute number of transactions for each entity.

#### min-server-latency

The minimum server latency for each entity.

#### average-request-size

The average request size for each entity.

#### average-response-size

The average response size for each entity.

#### average-application-response-time

The average application response time for each entity.

#### min-application-response-time

The minimum application response time for each entity.

#### max-application-response-time

The maximum application response time for each entity.

#### average-client-ttfb

The average client TTFB for each entity.

#### min-client-ttfb

The minimum client TTFB for each entity.

#### max-client-ttfb

The maximum client TTFB for each entity.

#### average-clientside-network-latency

The average client-side network latency for each entity.

#### min-clientside-network-latency

The minimum client-side network latency for each entity.

#### max-clientside-network-latency

The maximum client-side network latency for each entity.

average-serverside-network-latency  
The average server-side network latency for each entity.

min-serverside-network-latency  
The minimum server-side network latency for each entity.

max-serverside-network-latency  
The maximum server-side network latency for each entity.

average-request-duration  
The average request duration for each entity.

min-request-duration  
The minimum request duration for each entity.

max-request-duration  
The maximum request duration for each entity.

average-response-duration  
The average response duration for each entity.

min-response-duration  
The minimum response duration for each entity.

max-response-duration  
The maximum response duration for each entity.

attacks-count  
The total number of attack for each entity.

valid  
The total number of valid transactions for each entity.

average-valid-tps  
The average number of valid transactions for each entity.

mitigated  
The total number of mitigated transaction for each entity.

average-mitigated-tps  
The average number of mitigated transaction for each entity.

blocked  
The total number of blocked transactions for each entity.

average-blocked-tps  
The average number of blocked transactions for each entity.

incomplete  
The total number of incomplete transactions for each entity.

average-incomplete-tps  
The average number of incomplete transactions for each entity.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The default value for measures is previously chosen measures. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics http scheduled-report

#### NAME

scheduled-report - Configure scheduled reports for HTTP.

MODULE  
analytics http

SYNTAX  
Configure the scheduled-report component within the analytics http module using the syntax shown in the following sections.

```
CREATE/MODIFY
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
limit [number of rows]
time-diff [last-hour | last-day | last-week | last-month | last-year]
view-by { entity name [string] }
measures [none | add | delete | modify | replace-all-with] { measure name [string] }
}
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]

DISPLAY
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

DELETE
delete scheduled-report [name]
```

DESCRIPTION  
Use the scheduled-report component to create, modify or delete scheduled reports for the HTTP module.

EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the HTTP scheduled reports.

OPTIONS

email-addresses  
A list of the email addresses of the recipients that receive the scheduled report.

first-time  
First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total  
Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics http report.

limit  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics http report.

**measures**  
The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

SEE ALSO  
list, modify, show, tmsh, analytics http report, sys smtp-server

**COPYRIGHT**

## analytics ip-intelligence report

**NAME**  
report - Displays an IP Intelligence analytics report.

**MODULE**  
analytics ip-intelligence

**SYNTAX**  
Show, save or send an analytics ip-intelligence report using the syntax shown in the following sections.

**DISPLAY**  
show report view-by [ actions | class-name | context-name | context-type | hit-type | policy | protocol | source-ip | options:  
drilldown {  
{  
entity [ actions | class-name | context-name | context-type | hit-type | policy | protocol | source-ip | vlan ]  
values  
{  
[value ...]  
}  
} ...  
}  
field-fmt  
include-total  
include-others  
limit [number of rows]  
measures {  
[measure name ...]  
}  
order-by {  
{  
measure [ measure name ]  
sort-type [ asc / desc ]  
} ...  
}  
range [date range]

**SAVE**  
save report view-by [ actions | class-name | context-name | context-type | hit-type | policy | protocol | source-ip | options:  
drilldown {  
{  
entity [ actions | class-name | context-name | context-type | hit-type | policy | protocol | source-ip | vlan ]  
values  
{  
[value ...]  
}  
} ...  
}

```

}
file [ file name ]
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]

    [measure name ...]
}
order-by {
    {
        measure [ measure name ]
        sort-type [ asc / desc ]
    } ...
}
range [date range]

SEND
send-mail report view-by [ actions | class-name | context-name | context-type | hit-type | policy | protocol | source-
options:
    drilldown {
        {
entity [ actions | class-name | context-name | context-type | hit-type | policy | protocol | source-ip | vlan ]
values
{
    [value ...]
}
} ...
}
email-addresses {
    [email address ...]
}
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
    [measure name ...]
}
order-by {
    {
        measure [ measure name ]
        sort-type [ asc / desc ]
    } ...
}
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate IP Intelligence analytics reports. You can generate an IP Intelligence analytics report for the following entities:

- o actions - Actions (dropped / allowed).
- o class-name - Class-Name for the hit.
- o context-name - Context Name (VS name, RouteDomain name etc...).
- o context-type - Context Type (Virtual, RouteDomain or Global).
- o hit-type - Hit Type (BlackList Hit or BlackList+WhiteList Hit).
- o policy - Policy Name (Name of the DWBL policy which was hit).
- o protocol - Standard IP protocol (tcp, udp, etc...).
- o source-ip - Source IPs of hits.
- o vlan - Vlan.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics ip-intelligence report view-by actions
```

```
show analytics ip-intelligence report view-by actions drilldown { {
entity vlan values { vlan_1 vlan_2 } } }
```

```
send-mail analytics ip-intelligence report view-by actions measures {
request-count } limit 20 order-by { { measure request-count sort-type
desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save

command. The file name should be simple (not a full path).

#### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

#### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

#### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

#### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

#### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

#### count-class

The total number of events for Dynamic White/Black List with respect to the Class-Names.

#### request-count

The total number of events for Dynamic White/Black List.

#### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

#### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

#### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### SEE ALSO

show, save, send-mail, tmsh, ltm profile analytics, analytics, analytics report

## analytics ip-intelligence scheduled-report

#### NAME

scheduled-report - Configure scheduled reports for IP intelligence (DWBL).

#### MODULE

analytics ip-intelligence

#### SYNTAX

Configure the scheduled-report component within the analytics ip-intelligence module using the syntax shown in the following sections.

#### CREATE/MODIFY

create scheduled-report [name]  
modify scheduled-report [name]

#### options:

email-addresses [none | add | delete | modify |  
replace-all-with] { email-address [string] }  
first-time [date]  
frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]  
include-total [enabled | disabled]  
multi-leveled-report {  
chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }  
limit [number of rows]  
time-diff [last-hour | last-day | last-week | last-month | last-year]  
view-by { entity name [string] }  
measures [none | add | delete | modify | replace-all-with] { measure name [string] }

```

    }
    predefined-report-name [name]
    smtp-config [name]
    device-group [name]

DISPLAY
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

DELETE
delete scheduled-report [name]

DESCRIPTION
    Use the scheduled-report component to create, modify or delete
    scheduled reports for the IP intelligence (DWBL) module.

EXAMPLES
    create scheduled-report myScheduledReport first-time now predefined-
    report-name "Top blocked URLs" frequency every-6-hours email-addresses
    add { person@domain.com } smtp-config asm_smtp_conf

    Creates a scheduled report, starting from the next hour and executing
    every 6 hours. The report contains a PDF showing statistics for the top
    blocked URLs and is sent to person@domain.com using the smtp
    configuration defined in asm_smtp_conf.

    modify scheduled-report myScheduledReport smtp-config none

    Set smtp configuration of the scheduled report "myScheduledReport" to
    none, thus effectively disabling the scheduled report from begin
    generated and sent over eMail.

    create scheduled-report myCustomScheduledReport first-time now email-
    addresses add { person@domain.com } frequency every-6-hours smtp-config
    asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
    limit 5 chart-path add { policy violation } }

    Creates a scheduled report, starting from the next hour and executing
    every 6 hours. The report contains a PDF showing statistics for the top
    5 violated URLs after drilling-down to the top policy followed by the
    top violation. The report is sent to person@domain.co using the smtp
    configuration defined in asm_smtp_conf.

    list scheduled-report

    Displays all of the IP intelligence (DWBL) scheduled reports.

OPTIONS
    email-addresses
    A list of the email addresses of the recipients that receive the
    scheduled report.

    first-time
    First scheduled report time. Must be after current time and
    rounded up to the next round hour.

    frequency
    The scheduled report frequency. Example: every-6-hours means that
    the report will be generated and sent every 6 hours.

    include-total
    Enables or disables including a summary (Overall result) entity in
    results.

    multi-leveled-report
    Defines a custom multi-leveled report. Mutually exclusive with
    predefined-report-name. The multi-leveled-report definition
    contains the following parameters:

    chart-path
    A list of entities that define the scope in which the report
    will be displayed. For example: a chart path { violation url
    } means: Use the top violation list and generate a top URL
    list from it. These top URLs will be then used to display the
    view-by entity. For a list of valid entities see the help
    manual for analytics ip-intelligence report.

    limit
    The number of view-by entities displayed in the scheduled
    report.

    time-diff
    The time range for the report.

    view-by
    The main entity that the report is viewed by. For a list of
    valid entities see the help manual for analytics ip-
    intelligence report.

    measures
    The measures which are available for the selected entities.

    predefined-report-name
    Defines which predefined report (AKA predefined filter) will
    be used to generate the report. This keyword is mutually
    exclusive with multi-leveled-report.

    smtp-config
    Defines which SMTP configuration will be used to send the
    scheduled report. If set to none, the scheduled report will
    be disabled.

```

device-group  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

## analytics ip-layer report

NAME

report - Displays an ip-layer analytics report.

MODULE

analytics ip-layer

SYNTAX

Show, save or send an analytics ip-layer report using the syntax shown in the following sections.

DISPLAY

```
show report view-by [ ip ]
options:
  drilldown {
  {
    entity [ ip ]
    values
    {
      [value ...]
    }
  } ...
  }
  field-fmt
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
```

SAVE

```
save report view-by [ ip ]
options:

}
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
[measure name ...]
}
order-by {
{
measure [ measure name ]
sort-type [ asc / desc ]
} ...
}
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate ip-layer analytics reports. You can generate a IP-layer analytics report for the following entities:

- o ip - IP version (IPV4 / IPV6)

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics ip-layer report view-by ip
```

```
show analytics ip-layer report view-by ip drilldown { { entity ip
values { IP-V4 } } }
```

```
send-mail analytics ip-layer report view-by ip measures { dropped-pkts
} limit 20 order-by { { measure dropped-pkts sort-type desc } } format
pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### transmitted-pkts

The total number of transmitted packets for the selected filter (entity).

##### received-pkts

The total number of received packets for the selected filter (entity).

##### dropped-pkts

The total number of dropped packets for the selected filter (entity).

**err-invalid-len**  
The total number of error invalid length for the selected filter (entity).

**err-memory**  
The total number of error memory for the selected filter (entity).

**err-retransmitted**  
The total number of error retransmitted for the selected filter (entity).

**err-protocol**  
The total number of error protocol for the selected filter (entity).

**err-options**  
The total number of error options for the selected filter (entity).

**err-checksum**  
The total number of error checksum for the selected filter (entity).

**received-frags**  
The total number of received fragments for the selected filter (entity).

**received\_dropped\_frags**  
The total number of received dropped fragments for the selected filter (entity).

**transmitted-frags**  
The total number of transmitted fragments for the selected filter (entity).

**transmitted-dropped-frags**  
The total number of transmitted dropped fragment for the selected filter (entity).

**reassembled-frags**  
The total number of reassembled fragment for the selected filter (entity).

**reassembled-dropped-frags**  
The total number of 'too long' reassembled dropped fragment for the selected filter (entity).

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

BIG-IP 2015-07-22 analytics ip-layer report(1)

## analytics ip-layer scheduled-report

#### NAME

scheduled-report - Configure scheduled reports for IP layer.

#### MODULE

analytics ip-layer

#### SYNTAX

Configure the scheduled-report component within the analytics ip-layer module using the syntax shown in the following sections.

```

CREATE/MODIFY
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]

```

```

DISPLAY
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

```

```

DELETE
delete scheduled-report [name]

```

**DESCRIPTION**  
Use the scheduled-report component to create, modify or delete scheduled reports for the IP layer module.

**EXAMPLES**

```

create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf

Creates a scheduled report, starting from the next hour and executing
every 6 hours. The report contains a PDF showing statistics for the top
blocked URLs and is sent to person@domain.com using the smtp
configuration defined in asm_smtp_conf.

modify scheduled-report myScheduledReport smtp-config none

Set smtp configuration of the scheduled report "myScheduledReport" to
none, thus effectively disabling the scheduled report from begin
generated and sent over eMail.

create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }

Creates a scheduled report, starting from the next hour and executing
every 6 hours. The report contains a PDF showing statistics for the top
5 violated URLs after drilling-down to the top policy followed by the
top violation. The report is sent to person@domain.co using the smtp
configuration defined in asm_smtp_conf.

list scheduled-report

Displays all of the IP layer scheduled reports.

```

**OPTIONS**

**email-addresses**  
A list of the email addresses of the recipients that receive the scheduled report.

**first-time**  
First scheduled report time. Must be after current time and rounded up to the next round hour.

**frequency**  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics ip-layer report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics ip-layer

report.

measures  
The measures which are available for the selected entities.

predefined-report-name  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

## analytics lsn-pool report

NAME  
report - Displays an LSN Pool analytics report.

MODULE  
analytics lsn-pool

SYNTAX  
Show, save or send an analytics lsn-pool report using the syntax shown in the following sections.

```
DISPLAY
show report view-by [ lsn-pool ]
options:
  drilldown {
  {
entity [ none ]
values
{
  [value ...]
}
} ...
}
field-fmt
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]

SAVE
save report view-by [ lsn-pool ]
options:
  drilldown {
  {
entity [ none ]
values
{
  [value ...]
}
} ...
}
file [ file name ]
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
```

```

measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]

SEND
send-mail report view-by [ lsn-pool ]
options:
  drilldown {
    {
      entity [ none ]
      values
      {
        [value ...]
      }
    } ...
  }
  email-addresses {
    [email address ...]
  }
  format [ csv-aggregated | csv-time-series | pdf ]
  include-total
  include-others
  limit [number of rows]
  measures {
    [measure name ...]
  }
  order-by {
    {
      measure [ measure name ]
      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate lsn-pool analytics reports. You can generate a LSN analytics report for the following entities:

- o lsn-pool - LSN Pool translation statistics

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics lsn-pool report view-by lsn-pool
```

```
send-mail analytics lsn-pool report view-by lsn-pool measures { active-
translations } limit 20 order-by { { measure active-translations sort-
type desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

active-translations  
The average number of active LSN translations for the selected filter (entity).

translation-request  
The total number of LSN translation requests for the selected filter (entity).

translation-failure  
The total number of failed LSN translations for the selected filter (entity).

translation-from-backup  
The total number of LSN translations using the backup pool for selected filter (entity). Only applies to LSN Pool in Deterministic NAT mode.

active-pb  
The average number of active port-blocks for the selected filter (entity). Only applies to LSN Pool in PBA mode.

pb-allocations  
The total number of port-block allocations for the selected filter (entity). Only applies to LSN Pool in PBA mode.

pb-freed  
The total number of port-block deallocations for the selected filter (entity). Only applies to LSN Pool in PBA mode.

zombie-block-created  
The total number of zombie blocks created for the selected filter (entity). Only applies to LSN Pool in PBA mode.

zombie-block-deleted  
The total number of zombie blocks deleted for the selected filter (entity). Only applies to LSN Pool in PBA mode.

active-pb-clients-reached-limit  
The average number of port-block clients that have reached the port-block limit for the selected filter (entity). Only applies to LSN Pool in PBA mode.

pb-client-reached-limit  
The total number of port-block clients that have reached the port-block limit for the selected filter (entity). Only applies to LSN Pool in PBA mode.

pcp-requests  
The total number of PCP requests for the selected filter (entity). Only applies to LSN Pool with PCP profile.

pcp-responses  
The total number of PCP responses for the selected filter (entity). Only applies to LSN Pool with PCP profile.

pcp-errors  
The total number of PCP errors for the selected filter (entity). Only applies to LSN Pool with PCP profile.

log-attempts  
The total number of logging attempts for the selected filter (entity). Only applies to LSN Pool with Log publisher attached.

log-failures  
The total number of logging failures for the selected filter (entity). Only applies to LSN Pool with Log publisher attached.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics lsn-pool scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for LSN pool.

**MODULE**  
analytics lsn-pool

**SYNTAX**  
Configure the scheduled-report component within the analytics lsn-pool module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create scheduled-report [name]  
modify scheduled-report [name]  
options:  
    email-addresses [none | add | delete | modify |  
        replace-all-with] { email-address [string] }  
    first-time [date]  
    frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]  
    include-total [enabled | disabled]  
    multi-leveled-report {  
chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }  
limit [number of rows]  
time-diff [last-hour | last-day | last-week | last-month | last-year]  
view-by { entity name [string] }  
measures [none | add | delete | modify | replace-all-with] { measure name [string] }  
    }  
    predefined-report-name [name]  
    smtp-config [name]  
    device-group [name]

**DISPLAY**  
list scheduled-report  
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]  
show running-config scheduled-report  
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

**DELETE**  
delete scheduled-report [name]

**DESCRIPTION**  
Use the scheduled-report component to create, modify or delete scheduled reports for the LSN pool module.

**EXAMPLES**  
create scheduled-report myScheduledReport first-time now predefined-report-name "Top blocked URLs" frequency every-6-hours email-addresses add { person@domain.com } smtp-config asm\_smtp\_conf  
  
Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.  
  
modify scheduled-report myScheduledReport smtp-config none  
  
Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.  
  
create scheduled-report myCustomScheduledReport first-time now email-addresses add { person@domain.com } frequency every-6-hours smtp-config asm\_smtp\_conf multi-leveled-report { view-by url time-diff last-hour limit 5 chart-path add { policy violation } }  
  
Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.  
  
list scheduled-report  
  
Displays all of the LSN pool scheduled reports.

**OPTIONS**  
email-addresses  
A list of the email addresses of the recipients that receive the scheduled report.  
  
first-time  
First scheduled report time. Must be after current time and rounded up to the next round hour.  
  
frequency  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.  
  
include-total  
Enables or disables including a summary (Overall result) entity in results.  
  
multi-leveled-report  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition

contains the following parameters:

**chart-path**

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics lsn-pool report.

**limit**

The number of view-by entities displayed in the scheduled report.

**time-diff**

The time range for the report.

**view-by**

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics lsn-pool report.

**measures**

The measures which are available for the selected entities.

**predefined-report-name**

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

**SEE ALSO**

list, modify, show, tmsh, analytics lsn-pool report, sys smtp-server

            entity [ pid | proc-name | slot ]
            values
            {
            [value ...]
            }
            } ...
        }
        file [ file name ]
        format [ csv-aggregated | csv-time-series | pdf ]
        include-total
        include-others
        limit [number of rows]
        measures {
            [measure name ...]
        }
        order-by {
            {
            measure [ measure name ]
            sort-type [ asc / desc ]
            } ...
        }
        range [date range]

    SEND
    send-mail report view-by [ pid | proc-name | slot ]
    options:
        drilldown {
            {
            entity [ pid | proc-name | slot ]
            values
            {
            [value ...]
            }
            } ...
        }
        email-addresses {
            [email address ...]
        }
        format [ csv-aggregated | csv-time-series | pdf ]
        include-total
        include-others
        limit [number of rows]
        measures {
            [measure name ...]
        }
        order-by {
            {
            measure [ measure name ]
            sort-type [ asc / desc ]
            } ...
        }
        range [date range]
        smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate Memory Per Process analytics reports. You can generate a Memory Per Process analytics report for the following entities:

- o pid - Process ID.
- o proc-name - Process name.
- o slot - Slot ID.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics memory-per-process report view-by pid

show analytics memory-per-process report view-by pid drilldown { {
entity slot values { 0 1 } } }

send-mail analytics memory-per-process report view-by pid measures {
vsz } limit 20 order-by { { measure vsz sort-type desc } } format pdf
email-addresses { some.one@someaddress.com }

For more syntactical examples, see the tmsh help manual for analytics
report.

```

#### OPTIONS

```

device
Specifies a BIG-IP device on which to generate a report.
(Enterprise Manager only)

device-list
Specifies a custom list of BIG-IP devices on which to generate a
report. (Enterprise Manager only)

drilldown
Specifies specific entities that are used as a filter.

email-addresses
Specifies the list of email addresses to which the report file is
sent when using the send-mail command.

```

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**rss** Resident set size.

**vsz** Virtual memory size.

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

#### DESCRIPTION

Use this command to generate memory analytics reports. You can generate a memory analytics report for the following entities:

- o slot - Slot ID

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics memory report view-by slot
```

```
show analytics memory report view-by slot drilldown { { entity slot
values { IP-V4 } } }
```

```
send-mail analytics memory report view-by slot measures { dropped-pkts
} limit 20 order-by { { measure host-usage sort-type desc } } format
pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures  
Specifies a list of measures that can be used with the chosen entity type. The options are:

tmm-total-ram The average of total TMM memory for the selected filter (entity).  
tmm-used-ram The average of used TMM memory for the selected filter (entity).  
tmm-free-ram The average of free TMM memory for the selected filter (entity).  
other-total-ram The average of total other (daemons and kernel) memory for the selected filter (entity).  
other-used-ram The average of used other (daemons and kernel) memory for the selected filter (entity).  
other-free-ram The average of free other (daemons and kernel) memory for the selected filter (entity).  
system-total-ram The average of total system memory for the selected filter (entity).  
system-used-ram The average of used system memory for the selected filter (entity).  
system-free-ram The average of free system memory for the selected filter (entity).  
swap-total-ram The average of total swap memory for the selected filter (entity).  
swap-used-ram The average of used swap memory for the selected filter (entity).  
swap-free-ram The average of free swap memory for the selected filter (entity).

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics memory scheduled-report

NAME  
scheduled-report - Configure scheduled reports for memory.

MODULE  
analytics memory

## SYNTAX

Configure the scheduled-report component within the analytics memory module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

### DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

### DELETE

```
delete scheduled-report [name]
```

## DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the memory module.

## EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the memory scheduled reports.

## OPTIONS

### email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

### first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

### include-total

Enables or disables including a summary (Overall result) entity in results.

### multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics memory report.

### limit

The number of view-by entities displayed in the scheduled report.

### time-diff

```

DESCRIPTION
Use this command to generate network firewall analytics reports. You can generate a network firewall analytics report for the following entities:

o action - Action taken (allowed/dropped).

o acl-enforced-application - Application services (ACL - Enforced).
```

- o acl-enforced-destination-ip - Destination IP Address (ACL - Enforced).
- o acl-enforced-destination-port - Destination IP Port (ACL - Enforced).
- o acl-enforced-policy - Policy (ACL - Enforced).
- o acl-enforced-rule-action - Rule Action (ACL - Enforced).
- o acl-enforced-rule-context - Rule Context (ACL - Enforced).
- o acl-enforced-rule-context-type - Rule Context Type (ACL - Enforced).
- o acl-enforced-rule - Rule (ACL - Enforced).
- o acl-enforced-self-ip - Self IP Address (ACL - Enforced).
- o acl-enforced-server-ip - Server IP Address (ACL - Enforced).
- o acl-enforced-source-ip - Source IP Address (ACL - Enforced).
- o acl-enforced-source-port - Source IP Port (ACL - Enforced).
- o acl-enforced-translation-pool - Translation Pool (ACL - Enforced).
- o acl-enforced-translation-type - Translation Type (ACL - Enforced).
- o acl-enforced-vlan - VLAN (ACL - Enforced).
- o acl-mgmt-application - Application services (ACL - Management).
- o acl-mgmt-destination-ip - Destination IP Address (ACL - Management).
- o acl-mgmt-destination-port - Destination IP Port (ACL - Management).
- o acl-mgmt-rule-action - Rule Action (ACL - Management).
- o acl-mgmt-rule-context - Rule Context (ACL - Management).
- o acl-mgmt-rule - Rule (ACL - Management).
- o acl-mgmt-source-ip - Source IP Address (ACL - Management).
- o acl-mgmt-source-port - Source IP Port (ACL - Management).
- o acl-staged-application - Application services (ACL - Staged).
- o acl-staged-destination-ip - Destination IP Address (ACL - Staged).
- o acl-staged-destination-port - Destination IP Port (ACL - Staged).
- o acl-staged-policy - Policy (ACL - Staged).
- o acl-staged-rule-action - Rule Action (ACL - Staged).
- o acl-staged-rule-context - Rule Context (ACL - Staged).
- o acl-staged-rule-context-type - Rule Context Type (ACL - Staged).
- o acl-staged-rule - Rule (ACL - Staged).
- o acl-staged-self-ip - Self IP Address (ACL - Staged).
- o acl-staged-server-ip - Server IP Address (ACL - Staged).
- o acl-staged-source-ip - Source IP Address (ACL - Staged).
- o acl-staged-source-port - Source IP Port (ACL - Staged).
- o acl-staged-translation-pool - Translation Reason (ACL - Staged).
- o acl-staged-translation-type - Translation Type (ACL - Staged).
- o acl-staged-vlan - VLAN (ACL - Staged).
- o 1314-errors-action - Network firewall errors action.
- o 1314-errors-destination-ip - Destination IP address (Network firewall errors).
- o 1314-errors-error-reason - Network firewall error reason.
- o 1314-errors-network-protocol - Destination port (Network protocol).
- o 1314-errors-source-ip - Source IP address (Network firewall errors).
- o 1314-errors-vlan - VLAN (Network firewall errors).

#### EXAMPLES

```
show analytics network report view-by acl-enforced-rule
```

```
show analytics network report view-by acl-staged-vlan drilldown { {
entity acl-staged-destination-port values { 80 } } }
```

```
send-mail analytics network report view-by acl-mgmt-source-ip limit 20
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples see manual for analytics report.

## OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**acl-matches**  
The total number of ACL rule matches. Applicable only to view-by entities starting with "acl-".

**errors**  
The total number of firewall errors. Applicable only to view-by entities starting with "l3l3-errors-".

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics network scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for network.

**MODULE**  
analytics network

**SYNTAX**  
Configure the scheduled-report component within the analytics network

module using the syntax shown in the following sections.

```
CREATE/MODIFY
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]

DISPLAY
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

DELETE
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the network module.

#### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the network scheduled reports.

#### OPTIONS

**email-addresses**  
A list of the email addresses of the recipients that receive the scheduled report.

**first-time**  
First scheduled report time. Must be after current time and rounded up to the next round hour.

**frequency**  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics network report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics network report.

**measures**  
The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

## analytics network stale-rules

**NAME**  
stale-rules - Displays a network firewall stale rules report.

**MODULE**  
analytics network

**SYNTAX**  
Show an analytics network stale-rules report using the syntax shown in the following sections.

**DISPLAY**  
show stale-rules type [ enforced | staged ]

options:

drilldown {  
{  
entity [ context | policy | rule-name ]  
values  
{  
[value ...]  
}  
} ...  
}

field-fmt  
first-rule-number [ value ]  
number-of-rules [ value ]  
range [ date range ]

**DESCRIPTION**

Use this command to generate network firewall stale rules reports. A stale rule is one that has had not hits, or very few hits, over a specified time period. The report is displayed in order from the least-hit rules (including rules with no hits) to the most hit rules. You can generate a stale rules report for either enforced or staged rules.

**EXAMPLES**

show analytics network stale-rules type enforced

Shows a stale rules report for enforced rules (either inline or not).

show analytics network stale-rules type staged drilldown { { entity context values { /Common/virtual\_server\_1 } } }

Shows a stale rules report for staged rules in the context of the virtual server /Common/virtual\_server\_1

show analytics network stale-rules type enforced number-of-rules 100 range now-1w

Shows a stale rules report for enforced rules. 100 rules are shown in the report. This report is shown for the last week (including the last day).

```
show analytics network stale-rules type enforced first-rule-number 10
number-of-rules 100 range now-1w
```

Shows a stale rules report for enforced rules. The first least hit 9 rules are skipped, and 100 rules are shown in the report. This report is shown for the last week (including the last day).

```
show analytics network stale-rules type enforced first-rule-number 10
number-of-rules 100 range now-1d--now-1w
```

Shows a stale rules report for enforced rules. The first least hit 9 rules are skipped, and 100 rules are shown in the report. This report is shown for the last week, excluding the last day.

#### OPTIONS

**drilldown**  
Specifies specific entities that are used as a filter.

**field-fmt**  
Shows statistics in field format for the specified items.

**first-rule-number**  
Specifies the first rule number being displayed (rules are ordered by hit count in an ascending order).

**number-of-rules**  
Specifies the maximum number of firewall rules being displayed in the output result set. The default value is 10.

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate pem analytics reports. You can generate a PEM analytics report for the following entities:

- o application - Classification application
- o category - Classification category
- o url-category - URL category
- o policy - Classification application policy
- o service - Forwarding service (endpoint)
- o action - PEM action (Gate, Forward, ICAP, Modify HTTP header, etc...)
- o tower - Tower the subscriber communicates from
- o subscribers - Subscriber summary statistics
- o subscriber-name - Subscriber name
- o ip-list - IP address list
- o device-name - Device name
- o device-os - Device operating system
- o called-station - Called station
- o calling-station - Calling station
- o subscriber-type - Subscriber type
- o user-name - User Name

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics pem report view-by category

```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### hitcount

The total number of classified flows for the selected filter (entity).

##### total-bytes-in

The total number of bytes received for the selected filter (entity).

##### total-bytes-out

The total number of bytes sent for the selected filter (entity).

##### total-flows-opened

The total number of flows (classified and non-classified) for the selected filter (entity).

##### total-flows-closed

The total number of closed flows for the selected filter (entity).

##### total-subscribers-login

The total number of login events for the selected filter (entity).

##### total-subscribers-logout

The total number of logout events for the selected filter (entity).

##### avg-distinct-apps

The average number of distinct applications for the selected filter (entity).

##### avg-distinct-categories

The average number of distinct categories for the selected filter (entity).

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics pem scheduled-report

#### NAME

scheduled-report - Configure scheduled reports for PEM.

#### MODULE

analytics pem

#### SYNTAX

Configure the scheduled-report component within the analytics pem module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

##### DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

##### DELETE

```
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the PEM module.

#### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the PEM scheduled reports.

#### OPTIONS

**email-addresses**  
A list of the email addresses of the recipients that receive the scheduled report.

**first-time**  
First scheduled report time. Must be after current time and rounded up to the next round hour.

**frequency**  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics pem report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics pem report.

**measures**  
The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate Pool Traffic Stats analytics reports. You can generate a Pool Traffic Stats analytics report for the following entities:

- o pool-address - Pool Address.
- o pool-name - Pool Name.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics pool-traffic report view-by pool-address
```

```
show analytics pool-traffic report view-by pool-address drilldown { {
entity pool-name values { pool_name } } }
```

```
send-mail analytics pool-traffic report view-by pool-address measures {
server-bits-out } limit 20 order-by { { measure server-bits-out sort-
type desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

## OPTIONS

### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

### drilldown

Specifies specific entities that are used as a filter.

### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

max-server-concurrent-connections  
Maximum Concurrent connections at peak.

server-bits-in  
Incoming bits.

server-bits-out  
Outgoing bits.

server-concurrent-connections  
Server Concurrent connections.

server-connections  
Server Connections.

server-packets-in  
Incoming packets.

server-packets-out  
Outgoing packets.

### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

# analytics pool-traffic scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for pool traffic.

**MODULE**  
analytics pool-traffic

**SYNTAX**  
Configure the scheduled-report component within the analytics pool-traffic module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create scheduled-report [name]  
modify scheduled-report [name]  
options:  
    email-addresses [none | add | delete | modify |  
        replace-all-with] { email-address [string] }  
    first-time [date]  
    frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]  
    include-total [enabled | disabled]  
    multi-leveled-report {  
chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }  
limit [number of rows]  
time-diff [last-hour | last-day | last-week | last-month | last-year]  
view-by { entity name [string] }  
measures [none | add | delete | modify | replace-all-with] { measure name [string] }  
    }  
    predefined-report-name [name]  
    smtp-config [name]  
    device-group [name]

**DISPLAY**  
list scheduled-report  
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]  
show running-config scheduled-report  
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

**DELETE**  
delete scheduled-report [name]

**DESCRIPTION**  
Use the scheduled-report component to create, modify or delete scheduled reports for the pool traffic module.

**EXAMPLES**  
create scheduled-report myScheduledReport first-time now predefined-report-name "Top blocked URLs" frequency every-6-hours email-addresses add { person@domain.com } smtp-config asm\_smtp\_conf

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

modify scheduled-report myScheduledReport smtp-config none

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

create scheduled-report myCustomScheduledReport first-time now email-addresses add { person@domain.com } frequency every-6-hours smtp-config asm\_smtp\_conf multi-leveled-report { view-by url time-diff last-hour limit 5 chart-path add { policy violation } }

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

list scheduled-report

Displays all of the pool traffic scheduled reports.

**OPTIONS**  
email-addresses  
A list of the email addresses of the recipients that receive the scheduled report.

first-time  
First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total  
Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url

} means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics pool-traffic report.

limit  
The number of view-by entities displayed in the scheduled report.

time-diff  
The time range for the report.

view-by  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics pool-traffic report.

measures  
The measures which are available for the selected entities.

predefined-report-name  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate Process CPU Utilization analytics reports. You can generate a Process CPU Utilization analytics report for the following entities:

- o blade-num - Blade Number.
- o process-id - Process ID.
- o process-name - Process Name.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics proc-cpu report view-by blade-num

show analytics proc-cpu report view-by process-name drilldown { {
entity blade-num values { 0 } } }

send-mail analytics proc-cpu report view-by blade-num measures { cpu-
usage } limit 20 order-by { { measure cpu-usage sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }

```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**cpu-usage**  
CPU Usage.

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

```
DELETE
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the process CPU module.

#### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the process CPU scheduled reports.

#### OPTIONS

email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics proc-cpu report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics proc-cpu report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

```

#### DESCRIPTION

Use this command to generate IPS analytics reports. You can generate an IPS analytics report for the following entities:

- o accuracy - Accuracy.
- o action - Action.
- o attack-type - Attack type of the illegal request.
- o dest-ip - Destination IP addresses of requests.
- o dest-port - Destination port.
- o inspection-id - Inspection Id.
- o inspection-name - Inspection name.
- o perfimpact - Performance Impact.
- o profile - Profile.
- o protocol - Protocol.
- o reference - Industry Reference.
- o risk - Risk.
- o service - Service.
- o source-country - Country from which the traffic originated.
- o src-ip - Source IP addresses of requests.
- o subscriber - Subscriber names.
- o support-id - Support Id.
- o virtual - Virtual servers.
- o vlan - Vlan.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics protocol-inspection report view-by accuracy

show analytics protocol-inspection report view-by accuracy drilldown {
{ entity virtual values { virtual_1 } } }

send-mail analytics protocol-inspection report view-by accuracy
measures { last-updated } limit 20 order-by { { measure last-updated
sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }

```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures  
Specifies a list of measures that can be used with the chosen entity type. The options are:

dest-ip-count  
Destination IP count.

last-updated  
Last Updated.

occurrences  
Occurrence count.

source-ip-count  
Source IP count.

virtual-count  
Virtual count.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

}
order-by {
{
measure [ measure name ]
sort-type [ asc / desc ]
} ...
}
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate HTTP Protocol Security analytics reports. You can generate a HTTP Protocol Security analytics report for the following entities:

- o action - Enforcement action on request(Legal or alarmed/Blocked/Dropped).
- o application - Application services.
- o client-ip - A single client identified by an IP address.
- o url - A URL accessed by HTTP or HTTPS.
- o violation - Violation types.
- o virtual - Virtual servers.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics protocol-security-http report view-by action

show analytics protocol-security-http report view-by action drilldown {
{ entity application values { application_name } } }

send-mail analytics protocol-security-http report view-by action
measures { requests } limit 20 order-by { { measure requests sort-type
desc } } format pdf email-addresses { some.one@someaddress.com }

For more syntactical examples, see the tmsh help manual for analytics
report.
```

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**occurrences**  
Occurrence count.

**requests**  
Requests count.

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

BIG-IP      20analytics protocol-security-http report(1)

**NAME**

scheduled-report - Configure scheduled reports for protocol security HTTP (PSM HTTP).

**MODULE**

analytics protocol-security-http

**SYNTAX**

Configure the scheduled-report component within the analytics protocol-security-http module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

**DISPLAY**

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

**DELETE**

```
delete scheduled-report [name]
```

**DESCRIPTION**

Use the scheduled-report component to create, modify or delete scheduled reports for the protocol security HTTP (PSM HTTP) module.

**EXAMPLES**

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the protocol security HTTP (PSM HTTP) scheduled reports.

**OPTIONS**

**email-addresses**  
A list of the email addresses of the recipients that receive the scheduled report.

**first-time**  
First scheduled report time. Must be after current time and rounded up to the next round hour.

**frequency**  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL

list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics protocol-security-http report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics protocol-security-http report.

**measures**  
The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

```

#### DESCRIPTION

Use this command to generate protocol-security analytics reports. You can generate a protocol-security analytics report for the following entities:

- o application - Application services.
- o virtual-server - Virtual servers.
- o ip - Source IP addresses.
- o violation - Violation types.
- o protocol-type - Protocol type (HTTP/FTP/SMTP)
- o request-type - PRequest type (Legal or Alarmed/Blocked/Dropped)

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```

show analytics protocol-security report view-by protocol-type

show analytics protocol-security report view-by request-type drilldown
{ { entity protocol-type values { HTTP } } }

send-mail analytics protocol-security report view-by protocol-type
measures {transactions} limit 20 order-by { { measure transactions
sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }

```

For more syntactical examples, see the manpage for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is

sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**requests**  
Request count.

**occurrences**  
Number of occurrences for the selected filter (relevant for violation entity only)

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics protocol-security scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for protocol security (PSM).

**MODULE**  
analytics protocol-security

**SYNTAX**  
Configure the scheduled-report component within the analytics protocol-security module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create scheduled-report [name]  
modify scheduled-report [name]  
options:  
email-addresses [none | add | delete | modify |  
replace-all-with] { email-address [string] }  
first-time [date]  
frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]  
include-total [enabled | disabled]  
multi-leveled-report {  
chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }

```
limit [number of rows]
time-diff [last-hour | last-day | last-week | last-month | last-year]
view-by { entity name [string] }
measures [none | add | delete | modify | replace-all-with] { measure name [string] }
}
predefined-report-name [name]
smtp-config [name]
device-group [name]
```

#### DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

#### DELETE

```
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the protocol security (PSM) module.

#### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the protocol security (PSM) scheduled reports.

#### OPTIONS

##### email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

##### first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

##### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

##### include-total

Enables or disables including a summary (Overall result) entity in results.

##### multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

##### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics protocol-security report.

##### limit

The number of view-by entities displayed in the scheduled report.

##### time-diff

The time range for the report.

##### view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics protocol-security report.

##### measures

The measures which are available for the selected entities.

##### predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

##### smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

```

#### DESCRIPTION

Use this command to generate HTTP analytics reports. You can generate an HTTP analytics report for the following entities:

- o activity-type - Activity type.
- o application - Application services.
- o attack-id - Application/L7 DoS Attack ID.
- o behavioral-signature - Behavioral signature.
- o browser - Browser.
- o client-ip - A single client identified by an IP address.
- o client-subnet - Client subnet.
- o country - A country from which HTTP/HTTPS traffic was sent to each of the virtual servers.
- o country-code - Country code from which HTTP/HTTPS traffic was sent to each of the virtual servers.
- o device-id - Device ID.
- o dos-profile - DoS Profile.
- o http-method - Method.
- o http-transaction-outcome - HTTP Transaction outcomes (Blocked/Dropped/Passthrough/etc.)
- o mitigation - Mitigation.
- o os - OS name.
- o pool-member - Pool members.
- o response-code - An HTTP response code that was sent back to the client.
- o suspected-ip - Suspected address IP.
- o trigger - Trigger.
- o url - A URL accessed by HTTP or HTTPS.
- o user-agent - A browser identifier sent by the client's browser as part of the request for URL.
- o vector - Attack vector.
- o virtual - Virtual servers.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics report view-by virtual measures {average-tps} limit 20
```

Gets the average tps of 20 virtual servers (unordered).

```
show analytics report view-by virtual measures {average-tps} limit 20
order-by { { measure average-tps sort-type desc } }
```

Gets the average tps of the top 20 virtual servers.

```
show analytics report view-by virtual measures {average-tps} limit 20
order-by { { measure average-tps sort-type desc } } range now-3d--now
```

Gets the average tps of the top 20 virtual servers from the last three days.

```
show analytics report view-by virtual drilldown { { entity application
values { app } } { entity pool-member values { p1 p2 } } } range
now-4d--now-2d measures {average-tps} limit 10 order-by { { measure
average-tps sort-type DESC } }
```

Gets the average tps of the top 10 virtual servers (ordered by average tps) on app iApp (out of several monitored) on pool members p1 and p2 (out of five monitored p1-p5) in the interval ranging from two to four days ago.

```
show analytics report view-by response-code drilldown { { entity
virtual values { v1 } } } measures { transactions }
```

Gets a distribution of requests per response code on virtual v1.

```
show analytics report view-by country drilldown { { entity application
values { app } } } measures { average-concurrent-sessions average-
sessions } order-by { { measure average-sessions sort-type DESC } }
limit 5
```

Gets the new sessions and average concurrent sessions of the top five countries, ordered by the average concurrent sessions on the application app.

```
show analytics report view-by client-ip drilldown { { entity virtual
values { v1 } } } measures { max-page-load-time } limit 1
```

Gets the client IP address with the worst page load time.

```
show analytics report view-by application drilldown { { entity pool-
member values { p1 p2 } } } measures { transactions } order-by { {
measure transactions } } range now-7d--now
```

Gets the distribution of requests per application on pool members p1 and p2 ordered by the number of requests during the last week.

```
save analytics report view-by virtual measures {average-tps} limit 20
order-by { { measure average-tps sort-type desc } } format pdf file
report.pdf
```

Gets the average tps of the top 20 virtual servers and exports to a PDF file on the BIG-IP system.

```
save analytics report view-by virtual measures {average-tps} limit 20
order-by { { measure average-tps sort-type desc } } format csv-
aggregated file report.csv
```

Gets the average tps of the top 20 virtual servers and exports to a CSV file on the BIG-IP system.

```
save analytics report view-by virtual measures {average-tps} limit 20
order-by { { measure average-tps sort-type desc } } format csv-time-
series file report.csv
```

Gets the average tps over time of the top 10 virtual servers and exports to a CSV file on the BIG-IP system.

```
send-mail analytics report view-by virtual measures {average-tps} limit
20 order-by { { measure average-tps sort-type desc } } format pdf
email-addresses { some.one@someaddress.com }
```

Gets the average tps over time of the top 10 virtual servers and sends out an email containing the report as a PDF.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for

all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The default value is transactions. The options are:

average-concurrent-sessions

The average number of concurrent sessions for each entity.

average-new-sessions

The average number of new sessions for each entity.

average-page-load-time

The average client page load time for each entity.

average-request-throughput

The average request throughput for each entity.

average-response-throughput

The average response throughput for each entity.

average-server-latency

The average server latency for each entity.

average-tps

The average number of transactions per second for each entity.

client-side-sampled-transactions

The number of transactions sampled for client side page load time.

max-page-load-time

The maximum client page load time for each entity.

max-request-throughput

The maximum request throughput for each entity.

max-response-throughput

The maximum response throughput for each entity.

max-server-latency

The maximum server latency for each entity.

max-tps

The maximum number of transactions per second for each entity.

transactions

The absolute number of transactions for each entity.

min-server-latency

The minimum server latency for each entity.

average-request-size

The average request size for each entity.

average-response-size

The average response size for each entity.

average-application-response-time

The average application response time for each entity.

min-application-response-time

The minimum application response time for each entity.

max-application-response-time

The maximum application response time for each entity.

average-client-ttfb

The average client TTFB for each entity.

min-client-ttfb

The minimum client TTFB for each entity.

max-client-ttfb

The maximum client TTFB for each entity.

average-clientside-network-latency

The average client-side network latency for each entity.

min-clientside-network-latency

The minimum client-side network latency for each entity.

max-clientside-network-latency

The maximum client-side network latency for each entity.

average-serverside-network-latency

The average server-side network latency for each entity.

min-serverside-network-latency

The minimum server-side network latency for each entity.

max-serverside-network-latency  
The maximum server-side network latency for each entity.

average-request-duration  
The average request duration for each entity.

min-request-duration  
The minimum request duration for each entity.

max-request-duration  
The maximum request duration for each entity.

average-response-duration  
The average response duration for each entity.

min-response-duration  
The minimum response duration for each entity.

max-response-duration  
The maximum response duration for each entity.

attacks-count  
The total number of attack for each entity.

valid  
The total number of valid transactions for each entity.

average-valid-tps  
The average number of valid transactions for each entity.

mitigated  
The total number of mitigated transaction for each entity.

average-mitigated-tps  
The average number of mitigated transaction for each entity.

blocked  
The total number of blocked transactions for each entity.

average-blocked-tps  
The average number of blocked transactions for each entity.

incomplete  
The total number of incomplete transactions for each entity.

average-incomplete-tps  
The average number of incomplete transactions for each entity.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The default value for measures is previously chosen measures. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

```

#### DESCRIPTION

Use this command to generate SIP DoS analytics reports. You can generate a SIP DoS prevention analytics report for the following entities:

- o activity-type - Activity type.
- o application - Application services (iApp).
- o attack-id - DoS attack ID.
- o callee - Callee.
- o caller - Caller.
- o client-ip - Source IP Address.
- o country - Country.

- o country-code - Country code.
- o dos-profile - DoS profile.
- o mitigation - Mitigation.
- o sip-method - Method.
- o sip-transaction-outcome - Transaction outcome.
- o suspected-ip - Suspected IP Address.
- o trigger - Trigger.
- o vector - Attack vector.
- o virtual - Virtual server.
- o vlan - VLAN.

#### EXAMPLES

```
show analytics sip-dos report view-by attack-id

show analytics sip-dos report view-by vector drilldown { { entity
method values { ACK } } }

send-mail analytics sip-dos report view-by callee limit 20 format pdf
email-addresses { some.one@someaddress.com }
```

For more syntactical examples see manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. This option must be used with the drilldown option. You can also use it along with include-others.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### attacks-count

The total number of attacks for the selected view-by entity.

##### requests-count

The total number of requests that were received by the virtual server(/s)s

##### requests-per-sec

The average number of requests that were received by the virtual server(/s)s

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics sip-dos scheduled-report

#### NAME

scheduled-report - Configure scheduled reports for SIP DoS.

#### MODULE

analytics sip-dos

#### SYNTAX

Configure the scheduled-report component within the analytics sip-dos module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

##### DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

##### DELETE

```
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the SIP DoS module.

#### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the SIP DoS scheduled reports.

#### OPTIONS

email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

include-total

Enables or disables including a summary (Overall result) entity in results.

multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics sip-dos report.

limit

The number of view-by entities displayed in the scheduled report.

time-diff

The time range for the report.

view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics sip-dos report.

measures

The measures which are available for the selected entities.

predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

SEE ALSO

#### DESCRIPTION

Use this command to generate SIP DoS analytics reports. You can generate a SIP DoS prevention analytics report for the following entities:

- o activity-type - Activity type.
- o application - Application services (iApp).
- o attack-id - DoS attack ID.
- o callee - Callee.
- o caller - Caller.
- o client-ip - Source IP Address.
- o country - Country.
- o country-code - Country code.
- o dos-profile - DoS profile.
- o mitigation - Mitigation.

- o sip-method - Method.
- o sip-transaction-outcome - Transaction outcome.
- o suspected-ip - Suspected IP Address.
- o trigger - Trigger.
- o vector - Attack vector.
- o virtual - Virtual server.
- o vlan - VLAN.

#### EXAMPLES

```
show analytics sip report view-by attack-id

show analytics sip report view-by vector drilldown { { entity method
values { ACK } } }

send-mail analytics sip report view-by callee limit 20 format pdf
email-addresses { some.one@someaddress.com }
```

For more syntactical examples see manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. This option must be used with the drilldown option. You can also use it along with include-others.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### attacks-count

The total number of attacks for the selected view-by entity.

##### requests-count

The total number of requests that were received by the virtual server(/s)s

##### requests-per-sec

The average number of requests that were received by the virtual server(/s)s

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics sip scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for SIP.

**MODULE**  
analytics sip

**SYNTAX**  
Configure the scheduled-report component within the analytics sip module using the syntax shown in the following sections.

```
CREATE/MODIFY
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]

DISPLAY
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

DELETE
delete scheduled-report [name]
```

**DESCRIPTION**  
Use the scheduled-report component to create, modify or delete scheduled reports for the SIP module.

**EXAMPLES**

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the SIP scheduled reports.

**OPTIONS**

**email-addresses**  
A list of the email addresses of the recipients that receive the scheduled report.

**first-time**  
First scheduled report time. Must be after current time and rounded up to the next round hour.

#### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

#### include-total

Enables or disables including a summary (Overall result) entity in results.

#### multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

#### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics sip report.

#### limit

The number of view-by entities displayed in the scheduled report.

#### time-diff

The time range for the report.

#### view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics sip report.

#### measures

The measures which are available for the selected entities.

#### predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

#### smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

#### device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

#### SEE ALSO

    }
    range [date range]
    smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate SSL Orchestrator Service Virtual Server Stats analytics reports. You can generate a SSL Orchestrator Service Virtual Server Stats analytics report for the following entities:

- o virtual - SSLO Service Virtual Servers.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics ssl-orchestrator-service-virtual report view-by virtual
```

```
show analytics ssl-orchestrator-service-virtual report view-by virtual
drilldown { { entity virtual values { virtual_1 virtual_2 } } }
```

```
send-mail analytics ssl-orchestrator-service-virtual report view-by
virtual measures { server-side-bits-out } limit 20 order-by { { measure
server-side-bits-out sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown

Specifies specific entities that are used as a filter.

email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

avg-server-side-concurrent-conns

Avg server side concurrent connections.

max-server-side-concurrent-conns

Max server side concurrent connections.

server-side-bits-in

Server side incoming bits.

server-side-bits-out

Server side outgoing bits.

server-side-conns

Server side connections.

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics ssl-orchestrator-service-virtual scheduled-report

NAME

scheduled-report - Configure scheduled reports for SSL Orchestrator Service Virtual Server Stats.

MODULE

analytics ssl-orchestrator-service-virtual

## SYNTAX

Configure the scheduled-report component within the analytics ssl-orchestrator-service-virtual module using the syntax shown in the following sections.

```
CREATE/MODIFY
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]

DISPLAY
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

DELETE
delete scheduled-report [name]
```

## DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the SSL Orchestrator Service Virtual Server Stats module.

## EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the SSL Orchestrator Service Virtual Server Stats scheduled reports.

## OPTIONS

**email-addresses**  
A list of the email addresses of the recipients that receive the scheduled report.

**first-time**  
First scheduled report time. Must be after current time and rounded up to the next round hour.

**frequency**  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics ssl-orchestrator-service-virtual report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics ssl-orchestrator-service-virtual report.

**measures**  
The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate SSL Orchestrator analytics reports. You can generate a SSL Orchestrator analytics report for the following entities:

- o application - Application Name.
- o application-family - Application Family.
- o client-cipher-name - Client Cipher Name.
- o client-cipher-version - Client Cipher Version.
- o decryption-status - Decryption status.
- o dest-country - Destination Country.
- o ip-reputation - IP reputation.
- o policy-action - Policy action.
- o server-cipher-name - Server Cipher Name.
- o server-cipher-version - Server Cipher Version.
- o service-path - Service Path.
- o site-ip - Site IP.
- o traffic-type - Traffic type.
- o url-category - URL category.
- o virtual - Virtual servers.

Different measures are collected for each of these entities and can be a part of the report request.

## EXAMPLES

```
show analytics ssl-orchestrator report view-by application

show analytics ssl-orchestrator report view-by application drilldown {
{ entity virtual values { virtual_1 virtual_2 } } }

send-mail analytics ssl-orchestrator report view-by application
measures { hits-count-per-sec } limit 20 order-by { { measure hits-
count-per-sec sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

## OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file**  
Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**client-bytes-in**  
Client Bytes In.

**client-bytes-in-per-sec**  
Client Bytes In Per Sec.

**client-bytes-out**  
Client Bytes Out.

**client-bytes-per-sec**  
Client Bytes Out Per Second.

**duration**  
Duration.

**hits-count**  
Hits Count.

**hits-count-per-sec**  
Hits Count Per Second.

**server-bytes-in**  
Server Bytes In.

**server-bytes-in-per-sec**  
Server Bytes In Per Sec.

**server-bytes-out**  
Server Bytes Out.

**server-bytes-out-per-sec**  
Server Bytes Out Per Second.

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by

email. This overrides the default SMTP settings.

## analytics ssl-orchestrator scheduled-report

NAME

scheduled-report - Configure scheduled reports for SSL orchestrator.

MODULE

analytics ssl-orchestrator

SYNTAX

Configure the scheduled-report component within the analytics ssl-orchestrator module using the syntax shown in the following sections.

CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete scheduled-report [name]
```

DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the SSL orchestrator module.

EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the SSL orchestrator scheduled reports.

#### OPTIONS

##### email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

##### first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

##### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

##### include-total

Enables or disables including a summary (Overall result) entity in results.

##### multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

##### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics ssl-orchestrator report.

##### limit

The number of view-by entities displayed in the scheduled report.

##### time-diff

The time range for the report.

##### view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics ssl-orchestrator report.

##### measures

The measures which are available for the selected entities.

##### predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

##### smtp-config

Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

##### device-group

Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

values
{
  [value ...]
}
} ...
}
file [ file name ]
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]

```

```

SEND
send-mail report view-by [ ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | security-
options:
  drilldown {
    {
entity [ ssl_bypass | username | client_ip | url | category | url_filter | filter_policy | security-category | host-n
values
{
  [value ...]
}
} ...
}
email-addresses {
  [email address ...]
}
format [ csv-aggregated | csv-time-series | pdf ]
include-total
include-others
limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate swg-blocked analytics reports. You can generate an application-security-network analytics report for the following entities:

- o ssl\_bypass - Is HTTP/HTTPS inspection bypassed
- o username - User name
- o client-ip - Client IP
- o host-name - Host name
- o url - URL
- o category - URL category
- o security-category - Categories which their parent is 'Security' category

- o url-filter - URL filter
- o scheme - Scheme

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics swg-blocked report view-by client-ip

show analytics swg-blocked report view-by client-ip drilldown { {
entity scheme values { my_scheme } } }

send-mail analytics swg-blocked report view-by category measures {
blocked-count } limit 20 order-by { { measure blocked-count sort-type
desc } } format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### blocked-count

The total number of blocked requests for the selected filter (entity).

##### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

##### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

##### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

#### SEE ALSO

## analytics swg-blocked scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for SWG (blocked).

**MODULE**  
analytics swg-blocked

**SYNTAX**  
Configure the scheduled-report component within the analytics swg-blocked module using the syntax shown in the following sections.

```
CREATE/MODIFY
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]

DISPLAY
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

DELETE
delete scheduled-report [name]
```

**DESCRIPTION**  
Use the scheduled-report component to create, modify or delete scheduled reports for the SWG (blocked) module.

**EXAMPLES**

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the SWG (blocked) scheduled reports.

**OPTIONS**

**email-addresses**  
A list of the email addresses of the recipients that receive the scheduled report.

**first-time**  
First scheduled report time. Must be after current time and rounded up to the next round hour.

**frequency**  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics swg-blocked report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics swg-blocked report.

**measures**  
The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

}
order-by {
  {
    measure [ measure name ]
    sort-type [ asc / desc ]
  } ...
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate swg analytics reports. You can generate an application-security-network analytics report for the following entities:

- o action - Transaction's action (Blocked / Allowed / Allowed with log)
- o ssl\_bypass - Is HTTP/HTTPS inspection bypassed
- o username - User name
- o client-ip - Client IP
- o host-name - Host name
- o url - URL
- o category - URL category
- o url-filter - URL filter
- o scheme - Scheme

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics swg report view-by client-ip
```

```
show analytics swg report view-by client-ip drilldown { { entity scheme
values { my_scheme } } }
```

```
send-mail analytics swg report view-by category measures { blocked-
count } limit 20 order-by { { measure blocked-count sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

```
device
Specifies a BIG-IP device on which to generate a report.
(Enterprise Manager only)
```

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**request-count**  
The total number of requests for the selected filter (entity).

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

```

#### DELETE

```
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the SWG module.

#### EXAMPLES

```

create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf

```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```

create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }

```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the SWG scheduled reports.

#### OPTIONS

##### email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

##### first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

##### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

##### include-total

Enables or disables including a summary (Overall result) entity in results.

##### multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

##### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics swg report.

##### limit

The number of view-by entities displayed in the scheduled report.

##### time-diff

The time range for the report.

##### view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics swg report.

##### measures

The measures which are available for the selected entities.

##### predefined-report-name

Defines which predefined report (AKA predefined filter) will

be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

      } ...
    }
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate System Monitor analytics reports. You can generate a System Monitor analytics report for the following entities:

- o slot - Slot ID.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics system-monitor report view-by slot
```

```
show analytics system-monitor report view-by slot drilldown { { entity
slot values { 0 1 } } }
```

```
send-mail analytics system-monitor report view-by slot measures { avg-
cpu } limit 20 order-by { { measure avg-cpu sort-type desc } } format
pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### avg-concurrent-connections

An average number of concurrent connections at any given time.

avg-cpu  
Average TMM CPU usage over the selected time period.

avg-memory  
Average RAM usage over the selected time period.

avg-throughput  
Average bidirectional client throughput.

concurrent-connections-health  
Concurrent connections health percent.

cpu-health  
CPU health percent.

max-concurrent-connections  
Concurrent Connections Max value.

max-cpu  
TMM CPU Max value.

max-memory  
Memory Max value.

max-throughput  
Throughput Max value.

memory-health  
Memory health percent.

throughput-health  
Throughput health percent.

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics tcp-analytics report

NAME  
report - Displays the TCP analytics report.

MODULE  
analytics tcp analytics

SYNTAX  
Show, save or send an analytics tcp-analytics report using the syntax shown in the following sections.

DISPLAY  
show report view-by [ application | city-postcode | continent-code | country-region | nexthop | remote-address | request-side | subnet | user-key | virtual ]  
options:  
drilldown {  
{  
entity [ application | city-postcode | continent-code | country-region | nexthop | remote-address | request-side | s  
values  
{  
[value ...]  
}  
} ...  
}  
field-fmt  
include-total  
include-others

```

limit [number of rows]
measures {
  [measure name ...]
}
order-by {
  {

      sort-type [ asc / desc ]
    } ...
  }
  range [date range]
  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate tcp analytics reports. You can generate a TCP analytics report for the following entities:

- o application - Application services
- o city-postcode - City and postcode of remote host
- o continent-code - Continent of remote host
- o country-region - Country and region of remote host
- o nexthop - MAC address of next routing hop
- o remote-address - IP address of remote host
- o request-side - Client-side or server-side connection
- o subnet - /24 subnet of remote host
- o user-key - Key user-defined by TCP::analytics iRule.
- o virtual - Virtual Server

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics tcp-analytics report view-by virtual
```

```
show analytics tcp-analytics report view-by virtual drilldown { {
```

```
entity remote-address values { 10.10.2.2 } } }
```

```
send-mail analytics tcp-analytics report view-by remote-address  
measures { goodput-rcv } limit 20 order-by { { measure goodput-rcv  
sort-type desc } } format pdf email-addresses {  
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

##### avg-connection-goodput-received

The mean incoming goodput (in bits per second) of all TCP connections for the selected filter (entity).

##### avg-connection-goodput-sent

The mean outgoing goodput (in bits per second) of all TCP connections for the selected filter (entity).

##### connections-closed

The total number of connections ended for the selected filter (entity).

##### connections-length-mean

The mean connection length (in ms) for the selected filter (entity).

##### connections-opened

The total number connections started for the selected filter (entity).

##### delaystate-3whs

Time (in ms) spent by the connection in delay state three-way handshake (3WHS) for the selected filter (entity).

##### delaystate-app

Time (in ms) spent by the connection in delay state limited by lack of application data for the selected filter (entity).

##### delaystate-closing

Time (in ms) spent by the connection in delay state waiting for ack of FIN for the selected filter (entity).

##### delaystate-cwnd

Time (in ms) spent by the connection in delay state limited by the congestion window for the selected filter (entity).

##### delaystate-nagle

Time (in ms) spent by the connection in delay state where the app is limited, last packet held due to Nagle algorithm for the selected filter (entity).

##### delaystate-ratepace

Time (in ms) spent by the connection in delay state where the app is limited, transmission delayed by rate pacing for the selected filter (entity).

##### delaystate-retx

Time (in ms) spent by the connection in delay state retransmitting lost packets for the selected filter (entity).

##### delaystate-rwnd

Time (in ms) spent by the connection in delay state where the client receive window is limited for the selected filter (entity).

delaystate-sndbuf  
Time (in ms) spent by the connection in delay state limited by send buffer configuration for the selected filter (entity).

delaystate-waitforack  
Time (in ms) spent by the connection in delay state waiting for acknowledgement for the selected filter (entity).

goodput-received  
The aggregate data rate (in bits per second) received over all connections for the selected filter (entity).

goodput-sent  
The aggregate data rate (in bits per second) sent over all connections for the selected filter (entity).

max-connection-goodput-received  
The maximum incoming goodput (in bits per second) on any TCP connection for the selected filter (entity).

max-connection-goodput-sent  
The maximum outgoing goodput (in bits per second) on any TCP connection for the selected filter (entity).

min-connection-goodput-received  
The minimum incoming goodput (in bits per second) on any TCP connection for the selected filter (entity).

min-connection-goodput-sent  
The minimum outgoing goodput (in bits per second) on any TCP connection for the selected filter (entity).

packet-loss-rate  
The fraction of sent packets that are lost for the selected filter (entity).

packets-lost  
The total number of sent packets lost for the selected filter (entity).

packets-received  
The total number of packets received for the selected filter (entity).

packets-sent  
The total number of packets sent for the selected filter (entity).

rtt-avg  
The mean round trip time (in ms) for the selected filter (entity).

rtt-max  
The maximum round trip time in ms for the selected filter (entity).

rtt-min  
The minimum round trip time (in ms) for the selected filter (entity).

rttvar-mean  
The mean variance of the round trip time (in ms) for the selected filter (entity).

## analytics tcp-analytics scheduled-report

NAME  
scheduled-report - Configure scheduled reports for TCP analytics.

MODULE  
analytics tcp-analytics

## SYNTAX

Configure the scheduled-report component within the analytics tcp-analytics module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

### DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

### DELETE

```
delete scheduled-report [name]
```

## DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the TCP analytics module.

## EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the TCP analytics scheduled reports.

## OPTIONS

### email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

### first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

### include-total

Enables or disables including a summary (Overall result) entity in results.

### multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics tcp-analytics report.

### limit

The number of view-by entities displayed in the scheduled report.

### time-diff

The time range for the report.

view-by  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics tcp-analytics report.

measures  
The measures which are available for the selected entities.

predefined-report-name  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

        } ...
    }
    range [date range]
    smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate tcp analytics reports. You can generate a TCP analytics report for the following entities:

- o virtual - Virtual Server
- o tcp - TCP Profile

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics tcp report view-by virtual
```

```
show analytics tcp report view-by virtual drilldown { { entity virtual
values { 172.12.34.56 } } }
```

```
send-mail analytics tcp report view-by tcp measures { max-active-conns
} limit 20 order-by { { measure max-active-conns sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an

average.

limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

avg-active-conns

The average number of active connections for the selected filter (entity).

max-active-conns

The max number of active connections for the selected filter (entity).

total-accepts

The total number of accepted connections for the selected filter (entity).

total-accept\_fails

The total number of denied accept connections for the selected filter (entity).

total-new-conns

The total number of new connections for the selected filter (entity).

total-failed-conns

The total number of failed connections for the selected filter (entity).

total-expired-conns

The total number of expired connections for the selected filter (entity).

total-abandoned-connections

The total number of abandoned connections for the selected filter (entity).

total-rst-packets

The total number of RST connections for the selected filter (entity).

total-malformed-segments

The total number of malformed connections for the selected filter (entity).

total-oo-segs

The total number of out of ordered segments for the selected filter (entity).

total-rx-cookie

The total number of received SYN cookies for the selected filter (entity).

total-rxbadcookies

The total number of received bad SYN cookies for the selected filter (entity).

total-hw-cookies

The total number of received HW SYN cookies for the selected filter (entity).

total-syncacheover

The total number of SYN cache overflow for the selected filter (entity).

total-txrexmits

The total number of retransmitted segments for the selected filter (entity).

total-sndpack

The total number of sent packets for the selected filter (entity).

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics tcp scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for TCP.

**MODULE**  
analytics tcp

**SYNTAX**  
Configure the scheduled-report component within the analytics tcp module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create scheduled-report [name]  
modify scheduled-report [name]  
options:  
email-addresses [none | add | delete | modify |  
replace-all-with] { email-address [string] }  
first-time [date]  
frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]  
include-total [enabled | disabled]  
multi-leveled-report {  
chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }  
limit [number of rows]  
time-diff [last-hour | last-day | last-week | last-month | last-year]  
view-by { entity name [string] }  
measures [none | add | delete | modify | replace-all-with] { measure name [string] }  
}  
predefined-report-name [name]  
smtp-config [name]  
device-group [name]

**DISPLAY**  
list scheduled-report  
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]  
show running-config scheduled-report  
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

**DELETE**  
delete scheduled-report [name]

**DESCRIPTION**  
Use the scheduled-report component to create, modify or delete scheduled reports for the TCP module.

**EXAMPLES**  
create scheduled-report myScheduledReport first-time now predefined-report-name "Top blocked URLs" frequency every-6-hours email-addresses add { person@domain.com } smtp-config asm\_smtp\_conf  
  
Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.  
  
modify scheduled-report myScheduledReport smtp-config none  
  
Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.  
  
create scheduled-report myCustomScheduledReport first-time now email-addresses add { person@domain.com } frequency every-6-hours smtp-config asm\_smtp\_conf multi-leveled-report { view-by url time-diff last-hour limit 5 chart-path add { policy violation } }  
  
Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.  
  
list scheduled-report  
  
Displays all of the TCP scheduled reports.

**OPTIONS**  
email-addresses  
A list of the email addresses of the recipients that receive the scheduled report.  
  
first-time  
First scheduled report time. Must be after current time and rounded up to the next round hour.  
  
frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with **predefined-report-name**. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics tcp report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics tcp report.

**measures**  
The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate TMM DNS Zone analytics reports. You can generate a TMM DNS Zone analytics report for the following entities:

- o zone - TMM DNS zone.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics tmm-dns-zone report view-by zone
```

```
show analytics tmm-dns-zone report view-by zone drilldown { { entity
zone values { value } } }
```

```
send-mail analytics tmm-dns-zone report view-by zone measures {
responses } limit 20 order-by { { measure responses sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

#### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

#### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

#### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

#### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

#### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

#### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

#### a-queries

Dnsx qtype IPV4 address.

#### aaaa-queries

Dnsx qtype IPV6 address.

#### any-queries

Dnsx qType any.

#### axfr-queries

Dnsx qtype axfr.

#### cname-queries

Dnsx qtype cname.

#### ixfr-queries

Dnsx qtype ixfr.

#### mx-queries

Dnsx qtype mx.

#### ns-queries

Dnsx qtype ns.

#### other-queries

Dnsx qtype other.

#### queries

Dnsx queries.

#### responses

Dnsx response.

#### soa-queries

Dnsx qtype soa.

#### srv-queries

Dnsx qtype srv.

#### tsig-bad-key

Transaction signature bad key.

#### tsig-bad-sig

Transaction signature bad sig.

#### tsig-bad-time

Transaction signature bad time.

#### tsig-missing

Transaction signature missing.

#### tsig-not-required

Transaction signature not required.

#### tsig-verified

Transaction signature verified.

#### txt-queries

Dnsx qtype txt.

#### order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

#### range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

#### smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics traffic-classification report

NAME

report - Displays a Traffic Classification analytics report.

MODULE

analytics traffic-classification

SYNTAX

Show, save or send a analytics traffic-classification report using the syntax shown in the following sections.

DISPLAY

```
show report view-by [ action-name | application | application-category | destination-country | destination-ip | destination-port |
                    profiles | risk | source-country | source-ip | url-category | user-name |
                    virtual ]
options:
  drilldown {
  {
entity [ action-name | application | application-category | destination-country | destination-ip | destination-port |
        profiles | risk | source-country | source-ip | url-category | user-name |
        virtual ]
values
{

        } ...
    }
}
range [date range]
smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate Traffic Classification analytics reports. You can generate a Traffic Classification analytics report for the following entities:

- o action-name - Actions Name.
- o application - Classification application Name.
- o application-category - Application classification category.
- o destination-country - Destination countries.
- o destination-ip - A single destination identified by an IP address.
- o destination-port - Destination ports.
- o profiles - Classification profile.
- o risk - Risk.
- o source-country - Country from which the traffic originated.
- o source-ip - A single source identified by an IP address.
- o url-category - URL category.
- o user-name - Users name.
- o virtual - Virtual servers.

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics traffic-classification report view-by action-name
```

```
show analytics traffic-classification report view-by action-name
drilldown { { entity application values { application_name } } }
```

```
send-mail analytics traffic-classification report view-by action-name
measures { total-bytes-in } limit 20 order-by { { measure total-bytes-
in sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**average-throughput**  
Total average throughput.

**average-throughput-in**  
Average incoming throughput.

**average-throughput-out**  
Average outgoing throughput.

**flows**  
Total number of classified flows.

**total-bytes**  
Total bytes in both incoming and outgoing traffic.

**total-bytes-in**  
Byte counter of incoming (uplink) traffic.

**total-bytes-out**  
Byte counter of outgoing (downlink) traffic.

**order-by**  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

**range**  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

**smtp-config-override**  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics traffic-classification scheduled-report

**NAME**  
scheduled-report - Configure scheduled reports for traffic classification.

**MODULE**  
analytics traffic-classification

**SYNTAX**  
Configure the scheduled-report component within the analytics traffic-classification module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create scheduled-report [name]  
modify scheduled-report [name]

```

options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]

DISPLAY
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

DELETE
delete scheduled-report [name]

```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the traffic classification module.

#### EXAMPLES

```

create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf

```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```

modify scheduled-report myScheduledReport smtp-config none

```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```

create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }

```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```

list scheduled-report

```

Displays all of the traffic classification scheduled reports.

#### OPTIONS

**email-addresses**  
A list of the email addresses of the recipients that receive the scheduled report.

**first-time**  
First scheduled report time. Must be after current time and rounded up to the next round hour.

**frequency**  
The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**  
Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics traffic-classification report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics traffic-classification report.

**measures**

The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

## analytics udp report

**NAME**  
report - Displays an udp analytics report.

**MODULE**  
analytics udp

**SYNTAX**  
Show, save or send an analytics udp report using the syntax shown in the following sections.

**DISPLAY**  
show report view-by [ virtual | udp ]  
options:  
  drilldown {  
    {  
  entity [ virtual | udp ]  
  values  
  {  
    [value ...]  
  }  
  } ...  
  }  
  field-fmt  
  include-total  
  include-others  
  limit [number of rows]  
  measures {  
    [measure name ...]  
  }  
  order-by {  
    {  
      measure [ measure name ]  
      sort-type [ asc / desc ]  
    } ...  
  }  
  range [date range]

**SAVE**  
save report view-by [ virtual | udp ]  
options:  
  drilldown {  
    {  
  entity [ virtual | udp ]  
  values  
  {  
    [value ...]  
  }  
  } ...  
  }  
  file [ file name ]  
  format [ csv-aggregated | csv-time-series | pdf ]  
  include-total  
  include-others  
  limit [number of rows]  
  measures {  
    [measure name ...]

```

    }
    order-by {
        {
            measure [ measure name ]
            sort-type [ asc / desc ]
        } ...
    }
    range [date range]

    SEND
send-mail report view-by [ virtual | udp ]
options:
    drilldown {
        {
            entity [ virtual | udp ]
            values
            {
                [value ...]
            }
        } ...
    }
    email-addresses {
        [email address ...]
    }
    format [ csv-aggregated | csv-time-series | pdf ]
    include-total
    include-others
    limit [number of rows]
    measures {
        [measure name ...]
    }
    order-by {
        {
            measure [ measure name ]
            sort-type [ asc / desc ]
        } ...
    }
    range [date range]
    smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate udp analytics reports. You can generate a UDP analytics report for the following entities:

- o virtual - Virtual Server
- o udp - UDP Profile

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics udp report view-by virtual
```

```
show analytics udp report view-by virtual drilldown { { entity virtual
values { 172.12.34.56 } } }
```

```
send-mail analytics udp report view-by udp measures { max-active-conns
} limit 20 order-by { { measure max-active-conns sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

##### device

Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

##### device-list

Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

##### drilldown

Specifies specific entities that are used as a filter.

##### email-addresses

Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

##### format

Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

##### include-others

Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

##### include-total

Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

##### limit

Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

##### measures

Specifies a list of measures that can be used with the chosen entity type. The options are:

avg-active-conns

The average number of active connections for the selected filter (entity).

max-active-conns

The max number of active connections for the selected filter (entity).

total-accepts

The total number of accepted connections for the selected filter (entity).

total-accept\_fails

The total number of denied accept connections for the selected filter (entity).

total-new-conns

The total number of new connections for the selected filter (entity).

total-failed-conns

The total number of failed connections for the selected filter (entity).

total-expired-conns

The total number of expired connections for the selected filter (entity).

total-received-datagrams

The total number of received datagrams for the selected filter (entity).

total-malformed-datagrams

The total number of malformed datagrams for the selected filter (entity).

total-icmp-unreachable

The total number of ICMP unreachable for the selected filter (entity).

total-bad-sum-datagrams

The total number of bad checksum datagrams for the selected filter (entity).

total-no-sum-datagrams

The total number of 'no checksum' datagrams for the selected filter (entity).

total-transmitted-datagrams

The total number of transmitted datagrams for the selected filter (entity).

order-by

Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range

Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override

Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics udp scheduled-report

NAME

scheduled-report - Configure scheduled reports for UDP.

MODULE

analytics udp

#### SYNTAX

Configure the scheduled-report component within the analytics udp module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

##### DISPLAY

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

##### DELETE

```
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the UDP module.

#### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the UDP scheduled reports.

#### OPTIONS

##### email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

##### first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

##### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

##### include-total

Enables or disables including a summary (Overall result) entity in results.

##### multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

##### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics udp report.

##### limit

The number of view-by entities displayed in the scheduled report.

time-diff  
The time range for the report.

view-by  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics udp report.

measures  
The measures which are available for the selected entities.

predefined-report-name  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

smtp-config  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

## analytics uri-type

NAME  
uri-type - Configure uri-type

MODULE  
analytics uri-type

SYNTAX  
Configure the uri-types components within the analytics module using the syntax shown in the following sections.

```
CREATE/MODIFY
create uri-type [name]
modify uri-type [name]
  properties:
    file-extensions
      [add | delete | replace-all-with] {
name [string]
  options:
    name - file extension name
  }

DISPLAY
list uri-type
list uri-type [ [ [name] | [glob] | [regex] ] ...]
  options:
    all
    all-properties
    one-line

  properties:
    file-extensions

DELETE
delete uri-type [ [name] | all ]
```

DESCRIPTION  
Use the analytics uri-type command to create / list / modify uri-types.

uri-type is a definitions for URIs that should be collected and reported under predefined name value.

Each uri-type has a name value and a file-extensions list associated with it.

Once uri-type(s) created it will be associated with all AVR profiles (see below), any URI that has a match, will be reported as uri-type name value under view-by url analytics report. For example: create /analytics uri-type Images file-extensions add { png jpg gif ico } /images/logo.png is a URI match png and will be reported as "Image"

file extension. /favicon.ico is a URI match ico and will be reported as "Image" file extension. /images/pic.jpg is a URI match jpg and will be reported as "Image" file extension.

Limitations may apply on total number of uri-types object and total number of file extensions associated with them, cross the whole system.

uri-type can only be defined under partition /Common.

Notes:

uri-type name is unique - there can't be two uri-types with the same name value.

uri-type file-extensions list is unique - any file extension can be defined only once. Means, it is not possible to share same file extensions across multiple uri-type configuration objects.

uri-type is a global analytics configuration. All AVR profiles will be affected by every configured uri-type object.

name The identifier of the uri-type and the actual URL replace value. This value will be seen in analytics reports instead of the original URI. Eg: In create uri-type Image file-extensions add { jpg png gif } example, the name is Image and file-extensions are: jpg, png, gif.

file-extensions List of at least one or more file extensions (aka file types / file suffixes) that belongs to this uri-type. The value is provided in lower case characters but it represents case insensitive match. Eg: 'jpg' will match all of the following file extensions: JPG, jPg, jpG, JPg etc...

#### EXAMPLES

```
Display all current uri-types:

list uri-types

Create new uri-type to associate and report certain images files as
"Image" URL:

create uri-type Images file-extensions add { jpg png gif ico
icon jjpg }

Modify uri-type, associate more file extensions with it:

modify uri-type Images file-extensions add { jpeg }

Modify uri-type, remove and disassociate file extension:

modify uri-type Images file-extensions delete { jjpg }

Delete uri-type:

delete uri-type Images
```

## analytics vcmp report

NAME report - Displays an vcmp analytics report.

MODULE analytics vcmp

SYNTAX Show, save or send an analytics vcmp report using the syntax shown in the following sections.

```
DISPLAY
show report view-by [ guest | slot | interface | process-name ]
options:
  drilldown {
  {
entity [ guest | slot | interface | process-name ]
values
{
  [value ...]
}
} ...
```

```

    }
    field-fmt
    include-total
    include-others
    limit [number of rows]
    measures {
        [measure name ...]
    }
    order-by {
        {
            measure [ measure name ]
            sort-type [ asc / desc ]
        } ...
    }
    range [date range]

SAVE
save report view-by [ guest | slot | interface | process-name ]
options:
    drilldown {
        {
            entity [ guest | slot | interface | process-name ]
            values
            {
                [value ...]
            } ...
        }
        file [ file name ]
        format [ csv-aggregated | csv-time-series | pdf ]
        include-total
        include-others
        limit [number of rows]
        measures {
            [measure name ...]
        }
        order-by {
            {
                measure [ measure name ]
                sort-type [ asc / desc ]
            } ...
        }
        range [date range]

SEND
send-mail report view-by [ guest | slot | interface | process-name ]
options:
    drilldown {
        {
            entity [ guest | slot | interface | process-name ]
            values
            {
                [value ...]
            } ...
        }
        email-addresses {
            [email address ...]
        }
        format [ csv-aggregated | csv-time-series | pdf ]
        include-total
        include-others
        limit [number of rows]
        measures {
            [measure name ...]
        }
        order-by {
            {
                measure [ measure name ]
                sort-type [ asc / desc ]
            } ...
        }
        range [date range]
        smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate vcmp analytics reports. You can generate a vCMP analytics report for the following entities:

- o slot - Slot ID
- o guest - vCMP Guest name
- o interface - vCMP Interface
- o process-name - Process name

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics vcmp report view-by slot
```

```
show analytics vcmp report view-by slot drilldown { { entity slot
values { 5 } } }
```

```
send-mail analytics vcmp report view-by guest measures { network-bytes-
in } limit 20 order-by { { measure network-bytes-in sort-type desc } }
format pdf email-addresses { some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

device  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

device-list  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

drilldown  
Specifies specific entities that are used as a filter.

email-addresses  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

file  
Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

format  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

include-others  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

include-total  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

limit  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

measures  
Specifies a list of measures that can be used with the chosen entity type. The options are:

network-bytes-in  
The total number of external and internal bytes received for the selected filter (entity).

network-bytes-out  
The total number of external and internal bytes sent for the selected filter (entity).

network-average-in-throughput  
The average internal and external received throughput for the selected filter (entity).

network-average-out-throughput  
The average internal and external throughput sent for the selected filter (entity).

average-guest-cpu-usage  
The average number of CPU usage for the selected filter (entity) relative to host CPU.

diskio-bytes-read  
The average number of bytes read from disk for the selected filter (entity).

diskio-bytes-written  
The average number of bytes written to disk for the selected filter (entity).

diskio-requests-read  
The average number of read requests from disk for the selected filter (entity).

diskio-requests-written  
The average number of write requests from disk for the selected filter (entity).

average-process-cpu-usage  
The average number of CPU usage for the selected filter (entity) normalized relatively to guest CPU.

traffic-client-new-connections  
The total number of client-side new connections for the selected filter (entity).

traffic-client-avg-connections  
The average number of client-side connections opened for a selected filter (entity).

traffic-client-packets-in  
The total number of client-side received packets for a selected filter (entity).

traffic-client-packets-out  
The total number of client-side sent packets for a selected filter (entity).

traffic-client-bytes-in  
The total number of client-side received bytes for a selected filter (entity).

traffic-client-bytes-out  
The total number of client-side sent bytes for a selected

filter (entity).

traffic-server-new-connections

The total number of server-side new connections for the selected filter (entity).

traffic-server-avg-connections

The average number of server-side connections opened for a selected filter (entity).

traffic-server-packets-in

The total number of server-side received packets for a selected filter (entity).

traffic-server-packets-out

The total number of server-side sent packets for a selected filter (entity).

traffic-server-bytes-in

The total number of server-side received bytes for a selected filter (entity).

traffic-server-bytes-out

The total number of server-side sent bytes for a selected filter (entity).

total-assisted-connections

The total number of all hardware accelerated assisted connections for a selected filter (entity).

current-assisted-connections

The average number of all hardware accelerated assisted connections for a selected filter (entity).

hardware-syncookies-generated

The total number of SYN cookies generated for a selected filter (entity).

hardware-syncookies-detected

The total number of SYN cookies detected for a selected filter (entity).

hw-accel-client-packets-in

The total number of hardware accelerated client-side received packets for a selected filter (entity).

hw-accel-client-packets-out

The total number of hardware accelerated client-side received sent for a selected filter (entity).

hw-accel-client-bytes-in

The total number of hardware accelerated client-side received bytes for a selected filter (entity).

hw-accel-client-bytes-out

The total number of hardware accelerated client-side sent bytes for a selected filter (entity).

hw-accel-client-max-connections

The max number of hardware accelerated client-side connections for a selected filter (entity).

hw-accel-client-new-connections

The total number of hardware accelerated client-side new connections for a selected filter (entity).

hw-accel-client-current-connections

The average number of hardware accelerated client-side opened connections for a selected filter (entity).

hw-accel-server-packets-in

The total number of hardware accelerated server-side received packets for a selected filter (entity).

hw-accel-server-packets-out

The total number of hardware accelerated server-side received sent for a selected filter (entity).

hw-accel-server-bytes-in

The total number of hardware accelerated server-side received bytes for a selected filter (entity).

hw-accel-server-bytes-out

The total number of hardware accelerated server-side sent bytes for a selected filter (entity).

hw-accel-server-max-connections

The max number of hardware accelerated server-side connections for a selected filter (entity).

hw-accel-server-new-connections

The total number of hardware accelerated server-side new connections for a selected filter (entity).

hw-accel-server-current-connections

The average number of hardware accelerated server-side opened connections for a selected filter (entity).

tmm-total-ram

The average of total TMM memory for the selected filter (entity).

tmm-used-ram

The average of used TMM memory for the selected filter

(entity).

tmm-free-ram  
The average of free TMM memory for the selected filter (entity).

other-total-ram  
The average of total other (daemons and kernel) memory for the selected filter (entity).

other-used-ram  
The average of used other (daemons and kernel) memory for the selected filter (entity).

other-free-ram  
The average of free other (daemons and kernel) memory for the selected filter (entity).

system-total-ram  
The average of total system memory for the selected filter (entity).

system-used-ram  
The average of used system memory for the selected filter (entity).

system-free-ram  
The average of free system memory for the selected filter (entity).

swap-total-ram  
The average of total swap memory for the selected filter (entity).

swap-used-ram  
The average of used swap memory for the selected filter (entity).

swap-free-ram  
The average of free swap memory for the selected filter (entity).

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

BIG-IP 2015-07-22 analytics vcmp report(1)

## analytics vcmp scheduled-report

NAME  
scheduled-report - Configure scheduled reports for vCMP.

MODULE  
analytics vcmp

SYNTAX  
Configure the scheduled-report component within the analytics vcmp module using the syntax shown in the following sections.

CREATE/MODIFY  
create scheduled-report [name]  
modify scheduled-report [name]  
options:  
email-addresses [none | add | delete | modify |  
replace-all-with] { email-address [string] }  
first-time [date]

```

frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
include-total [enabled | disabled]
multi-leveled-report {
chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
limit [number of rows]
time-diff [last-hour | last-day | last-week | last-month | last-year]
view-by { entity name [string] }
measures [none | add | delete | modify | replace-all-with] { measure name [string] }
}
predefined-report-name [name]
smtp-config [name]
device-group [name]

```

#### DISPLAY

```

list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]

```

#### DELETE

```
delete scheduled-report [name]
```

#### DESCRIPTION

Use the scheduled-report component to create, modify or delete scheduled reports for the vCMP module.

#### EXAMPLES

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the vCMP scheduled reports.

#### OPTIONS

##### email-addresses

A list of the email addresses of the recipients that receive the scheduled report.

##### first-time

First scheduled report time. Must be after current time and rounded up to the next round hour.

##### frequency

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

##### include-total

Enables or disables including a summary (Overall result) entity in results.

##### multi-leveled-report

Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

##### chart-path

A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics vcmp report.

##### limit

The number of view-by entities displayed in the scheduled report.

##### time-diff

The time range for the report.

##### view-by

The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics vcmp report.

##### measures

The measures which are available for the selected entities.

##### predefined-report-name

Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually

exclusive with multi-leveled-report.

smtp-config  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

device-group  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

  smtp-config-override [ smtp configuration object name ]

```

#### DESCRIPTION

Use this command to generate virtual analytics reports. You can generate a VIP analytics report for the following entities:

- o virtual - Virtual Server

Different measures are collected for each of these entities and can be a part of the report request.

#### EXAMPLES

```
show analytics virtual report view-by virtual
```

```
show analytics virtual report view-by virtual drilldown { { entity
virtual values { 172.12.34.67 } } }
```

```
send-mail analytics virtual report view-by virtual measures { total-
server-packets-in } limit 20 order-by { { measure total-server-packets-
in sort-type desc } } format pdf email-addresses {
some.one@someaddress.com }
```

For more syntactical examples, see the tmsh help manual for analytics report.

#### OPTIONS

**device**  
Specifies a BIG-IP device on which to generate a report.  
(Enterprise Manager only)

**device-list**  
Specifies a custom list of BIG-IP devices on which to generate a report. (Enterprise Manager only)

**drilldown**  
Specifies specific entities that are used as a filter.

**email-addresses**  
Specifies the list of email addresses to which the report file is sent when using the send-mail command.

**file** Specifies the exported file path to be saved when using the save command. The file name should be simple (not a full path).

**format**  
Specifies the exported file format to be saved or sent. This option must be specified when using the save or send-mail commands.

**include-others**  
Specifies that the grand total for the measure is displayed for all entities, except for those shown in the result. It can be used along with include-total.

**include-total**  
Specifies that a total summary row should be added to the analytics report. For average measures, the total value is also an average.

**limit**  
Specifies the maximum number of rows/entities in the output result set/file. The default value is 10, not including the total row/entity. The maximum value is 1000.

**measures**  
Specifies a list of measures that can be used with the chosen entity type. The options are:

**total-client-packets-in**  
The total number of client-side received packets for the selected filter (entity).

total-client-packets-out  
The total number of client-side sent packets for the selected filter (entity).

total-server-packets-in  
The total number of server-side received packets for the selected filter (entity).

total-server-packets-out  
The total number of server-side sent packets for the selected filter (entity).

total-client-bits-in  
The total number of client-side received bits for the selected filter (entity).

total-client-bits-out  
The total number of client-side sent bits for the selected filter (entity).

total-server-bits-in  
The total number of server-side received bits for the selected filter (entity).

total-server-bits-out  
The total number of server-side sent bits for the selected filter (entity).

total-client-conns  
The total number of client-side connections for the selected filter (entity).

avg-client-concurrent-conns  
The average number of client-side concurrent connections for the selected filter (entity).

max-client-concurrent-conns  
The max value of client-side concurrent connections for the selected filter (entity).

total-server-conns  
The total number of server-side connections for the selected filter (entity).

avg-server-concurrent-conns  
The average number of server-side concurrent connections for the selected filter (entity).

max-server-concurrent-conns  
The max value of server side concurrent connections for the selected filter (entity).

total-syncookies  
The total number of syncookies for the selected filter (entity).

total-syncookies-accepts  
The total number of accepted syncookies for the selected filter (entity).

total-syncookies-rejects  
The total number of rejected syncookies for the selected filter (entity).

total-hw-syncookies  
The total number of HW syncookies for the selected filter (entity).

total-hw-syncookies-accepts  
The total number of accepted HW syncookies for the selected filter (entity).

order-by  
Specifies the measures and sort type (ascending or descending) that will be used to sort the final report. The value for each measure is a previously chosen measure. The default value for sort type is desc (descending).

range  
Specifies the time/date range of the analytics information that you want to display. The given results will reflect the time range chosen here. The default value is the last hour (now--now-1h).

smtp-config-override  
Specifies the SMTP configuration to use when sending reports by email. This overrides the default SMTP settings.

## analytics virtual scheduled-report

**NAME**

scheduled-report - Configure scheduled reports for virtual.

**MODULE**

analytics virtual

**SYNTAX**

Configure the scheduled-report component within the analytics virtual module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create scheduled-report [name]
modify scheduled-report [name]
options:
  email-addresses [none | add | delete | modify |
    replace-all-with] { email-address [string] }
  first-time [date]
  frequency [every-6-hours | every-12-hours | every-24-hours | every-week | every-month]
  include-total [enabled | disabled]
  multi-leveled-report {
  chart-path [none | add | delete | modify | replace-all-with] { entity name [string] }
  limit [number of rows]
  time-diff [last-hour | last-day | last-week | last-month | last-year]
  view-by { entity name [string] }
  measures [none | add | delete | modify | replace-all-with] { measure name [string] }
  }
  predefined-report-name [name]
  smtp-config [name]
  device-group [name]
```

**DISPLAY**

```
list scheduled-report
list scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
show running-config scheduled-report
show running-config scheduled-report [ [ [name] | [glob] | [regex] ] ... ]
```

**DELETE**

```
delete scheduled-report [name]
```

**DESCRIPTION**

Use the scheduled-report component to create, modify or delete scheduled reports for the virtual module.

**EXAMPLES**

```
create scheduled-report myScheduledReport first-time now predefined-
report-name "Top blocked URLs" frequency every-6-hours email-addresses
add { person@domain.com } smtp-config asm_smtp_conf
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top blocked URLs and is sent to person@domain.com using the smtp configuration defined in asm\_smtp\_conf.

```
modify scheduled-report myScheduledReport smtp-config none
```

Set smtp configuration of the scheduled report "myScheduledReport" to none, thus effectively disabling the scheduled report from begin generated and sent over eMail.

```
create scheduled-report myCustomScheduledReport first-time now email-
addresses add { person@domain.com } frequency every-6-hours smtp-config
asm_smtp_conf multi-leveled-report { view-by url time-diff last-hour
limit 5 chart-path add { policy violation } }
```

Creates a scheduled report, starting from the next hour and executing every 6 hours. The report contains a PDF showing statistics for the top 5 violated URLs after drilling-down to the top policy followed by the top violation. The report is sent to person@domain.co using the smtp configuration defined in asm\_smtp\_conf.

```
list scheduled-report
```

Displays all of the virtual scheduled reports.

**OPTIONS**

**email-addresses**

A list of the email addresses of the recipients that receive the scheduled report.

**first-time**

First scheduled report time. Must be after current time and rounded up to the next round hour.

**frequency**

The scheduled report frequency. Example: every-6-hours means that the report will be generated and sent every 6 hours.

**include-total**

Enables or disables including a summary (Overall result) entity in results.

**multi-leveled-report**  
Defines a custom multi-leveled report. Mutually exclusive with predefined-report-name. The multi-leveled-report definition contains the following parameters:

**chart-path**  
A list of entities that define the scope in which the report will be displayed. For example: a chart path { violation url } means: Use the top violation list and generate a top URL list from it. These top URLs will be then used to display the view-by entity. For a list of valid entities see the help manual for analytics virtual report.

**limit**  
The number of view-by entities displayed in the scheduled report.

**time-diff**  
The time range for the report.

**view-by**  
The main entity that the report is viewed by. For a list of valid entities see the help manual for analytics virtual report.

**measures**  
The measures which are available for the selected entities.

**predefined-report-name**  
Defines which predefined report (AKA predefined filter) will be used to generate the report. This keyword is mutually exclusive with multi-leveled-report.

**smtp-config**  
Defines which SMTP configuration will be used to send the scheduled report. If set to none, the scheduled report will be disabled.

**device-group**  
Defines the device-group which the report should generate the report for. If 'none' is set to this field, then the report will be generate for the 'self' device.

    peta
    raw
    tera
    yotta
    zetta

DELETE
delete apiprotection [name]
options:
    all
    recursive

```

#### DESCRIPTION

You use the apiprotection component to configure an apiprotection profile. An API protection profile specified a group of settings that you can use to configure an API protection server.

NOTE: For the API protection profile to take effect, it must be associated with a virtual server that also specifies an HTTP profile.

#### EXAMPLES

```

create apiprotection myAPIProtectionProfile {
    access-profile myAPIProtectionProfile_ap
    default-response myAPIProtectionProfile_response1
    default-server myAPIProtectionProfile_server1
    defaults-from apiprotection
    description "My API protection Profile"
    dns-mode ipv4-only
    dns-resolver default-dns-resolver
    last-generated-path-id 1
    max-concurrent-subsessions 1
    openapi-version "2.0"
    partition Common
    paths {
        myAPIProtectionProfile_path1 {
active true
method GET
path-id 1
uri /somepath
        }
    }
    per-request-policy myAPIProtectionProfile_prp
    responses {
        myAPIProtectionProfile_response1
    }
    servers {
        myAPIProtectionProfile_server1
    }
    use-pool false
}

```

Creates an API protection profile named myAPIProtectionProfile based on the default profile named apiprotection. The profile provides protection to API requests handled by the server myAPIProtectionProfile\_server1. Based on the Per-request-Policy configured in myAPIProtectionProfile\_prp, a default response configured as myAPIProtectionProfile\_response1 is provided for invalid requests. This profile serves GET requests to URI /somepath on the virtual server to which this profile is attached. The connection to the API server myAPIProtectionProfile\_server1 is determined using the DNS resolver configuration default-dns-resolver resolving only IPv4 requests.

list apiprotection all all-properties

Displays a list of API protection profiles, including parameter values.

delete apiprotection myAPIProtectionProfile

Deletes the API protection profile named myAPIProtectionProfile.

#### OPTIONS

##### access-profile

Specifies the name of the associated access profile. If the API protection profile is created using REST API or GUI, the default access profile is automatically created and associated. The default is none if created using TMSH.

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### default-response

Specifies the response name available under api-protection response. This value is mandatory. If the API protection profile is created using REST API or GUI, the default response is automatically created and associated using OpenAPI spec configuration. Create a response under api-protection response and associate here when using TMSH.

##### default-server

Specifies the server name available under api-protection server. If the API protection profile is created using REST API or GUI, default server is automatically created and associated.

##### defaults-from

Specifies the default API protection profile from which this profile is created. The default is apiprotection.

##### description

Specifies the description of the profile.

##### dns-mode

Specifies the DNS mode to use when resolving API server FQDN. Allowed values are ipv4-only, ipv6-only, and ipv6-prefer. The default is ipv4-only.

##### dns-resolver

Specifies the DNS resolver name configured under net dns-resolver. This cannot be empty when API Server is configured.

##### last-generated-path-id

Specifies the maximum path-id value configured for a path under paths. This value is used and set internally and requires no manual configuration.

##### max-concurrent-subsessions

Specifies the maximum number of concurrent subsessions. The default is 0, which sets the maximum number of concurrent subsessions to 5 times the licensed access session limit.

##### openapi-version

Specifies version information of the OpenAPI spec file used when creating the profile using REST API or GUI. This is set automatically when you use the spec file.

##### paths

Specifies the list of path configurations.

##### path-name

Specifies the name of the path configuration.

##### active

Specifies if the path-name is active. If path is inactive, Request-Classification-Agent under per-request policy will ignore the branch. The default is true.

##### description

Specifies description of path-name.

##### method

Specifies the HTTP method associated with the specific path path-name. This is mandatory input.

##### path-id

Specifies the path-id associated with the specific path path-name. This value is used in the Request Classification Agent under per-request policy to create a path specific branch.

##### server

Specifies the API server associated with the specific path path-name.

uri Specifies the URI associated with the specific path path-name. This is mandatory input.

##### per-request-policy

Specifies the per-request access policy attached to the API protection profile.

##### responses

Specifies the API response(s) associated with the profile. The configuration is defined under api-protection response.

**servers**  
Specifies the API server name(s) associated with the profile. The configuration is defined under api-protection server.

**use-pool**  
Specifies that the API protection profile is used to protect pool members.

## api-protection response

NAME

response - Manages responses for API Protection Profile.

MODULE

api-protection response

SYNTAX

Configure the response component within the api-protection module using the following syntax.

```
CREATE/MODIFY
create response [name]
modify response [name]
options
  app-service [[string] | none]
  body [[string] | none]
  description [[string] | none]
  headers [add | delete | modify | none | replace-all-with] {
    [name] {
      app-service [[string] | none]
      header-name [[string] | none]
      header-value [[string] | none]
    }
  }
  status-code [string]
  status-string [string]

edit response [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

DISPLAY
list response
list response [ [ [name] | [glob] | [regex] ] ... ]
show running-config response
show running-config response [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

DELETE
delete response [name]
```

DESCRIPTION

You can use the response component to create and manage responses that can be used by the API Protection profile.

EXAMPLES

```
create response response401 {
  description "Unauthorized Request"
  status-code 401
  status-string "Unauthorized"
}
```

Creates a response named response401 with status-code set to 401 and corresponding status-string set to Unauthorized.

```
list response
```

Displays a list of responses.

```
delete response response401
```

Deletes the response named response401.

## OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**[name]**  
Specifies the name of the Response object. This setting is required.

**body** Specifies the body of the response. This value can be any string or session variable.

**description**  
Specifies the description of the response.

**partition**  
Displays the partition within which the component resides.

**headers**  
Adds, deletes, modifies or replaces a set of headers, by specifying a header name and value for each entry. Header name and header value can be any string or session variable.

**status-code**  
Specifies the response code that must be issued. This value can be any string or session variable. This setting is required.

**status-string**  
Specifies the status string that must be issued. This value can be any string or session variable. This setting is required.

## api-protection server

### NAME

server - Manages servers for API Protection Profile.

### MODULE

api-protection server

### SYNTAX

Configure the server component within the api-protection module using the following syntax.

```
CREATE/MODIFY
create server [name]
modify server [name]
options
  app-service [[string] | none]
  description [[string] | none]
  serverssl-profile [[string] | none]
  url [string]

edit server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

DISPLAY
list server
list server [ [ [name] | [glob] | [regex] ] ... ]
show running-config server
show running-config server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

DELETE
delete server [name]
```

### DESCRIPTION

You can use the server component to create and manage servers that can

be used by the API Protection profile.

#### EXAMPLES

```
create server serverA {
  description "Server A"
  serverssl-profile apm-default-serverssl
  url "https://abc.com"
}
```

Creates a server named serverA with url https://abc.com and references a serverssl-profile.

```
list server
```

Displays a list of servers.

```
delete server serverA
```

Deletes the server named serverA.

#### OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

[name]

Specifies the name of the server object. This setting is required.

description

Specifies the description of the server.

partition

Displays the partition within which the component resides.

serverssl-profile

References a serverssl-profile. This setting is required when url is of https scheme.

url Specifies the URL of the server.

#### SEE ALSO

## apm

### apm aaa active-directory-trusted-domains

#### NAME

active-directory-trusted-domains - Manages authentication access policy (AAA) Active Directory(r) Trusted Domains.

#### MODULE

apm aaa

#### SYNTAX

Configure the active-directory-trusted-domains component within the aaa module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create active-directory-trusted-domains [name]
modify active-directory-trusted-domains [name]
options:
  app-service [[string] | none]
  description [[string] | none]
  root-domain [string]
  trusted-domains [add | delete | modify | replace-all-with] {
    {
      active-directory [name]
    }
  }
}
```

```
edit active-directory-trusted-domains [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```

DISPLAY
list active-directory-trusted-domains
list active-directory-trusted-domains [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

DELETE
delete active-directory-trusted-domains [name]

DESCRIPTION
  You can use the active-directory-trusted-domains component to manage
  AAA Active Directory Trusted Domains. You can use this object to
  configure cross-domain authentication across a forest. It also allows
  to configure Active Directory(r) agents to work in a Route Domains
  environment.

EXAMPLES
  create active-directory-trusted-domains MyTRD { trusted-domains {
    myDomain1 myDomain2 myDomain3 } root-domain /Common/myDomain2 }
  Creates an object named MyTRD, sets domains myDomain1, myDomain2,
  myDomain3 as trusted and the root-domain is set to myDomain2. To
  use this example you need to have Active Directory servers
  myDomain1, myDomain2 and myDomain3 pre-configured.

  delete active-directory MyTRD
  Deletes the AAA Active Directory Trusted Domains named MyTRD from
  the system.

OPTIONS
  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  description
  Specifies a user-defined description for the Active Directory
  Trusted Domains.

  root-domain
  Specifies an entry point to an Active Directory forest. An
  initial authentication request will always to be sent to root
  domain first. This setting is required.

  trusted-domains
  Specifies a list of AAA Active Directory server components. Trust
  relationships should be defined for domains you add into this
  list. This setting is required.

SEE ALSO
  active-directory

COPYRIGHT
  No part of this program may be reproduced or transmitted in any form or
  by any means, electronic or mechanical, including photocopying,
  recording, or information storage and retrieval systems, for any
  purpose other than the purchaser's personal use, without the express
  written permission of F5 Networks, Inc.

```

    domain [[string] | none]
    domain-controller [[string] | none]
    domain-controllers [add | delete | modify | replace-all-with] {
        [name] {
    ip [ip address]
        }
    }
    group-cache-ttl [integer]
    domain-controllers none
    location-specific [true | false]
    pool [name]
    pso-cache-ttl [integer]
    padata [encryption type]
    timeout [integer]

edit active-directory [ [ [name] | [glob] | [regex] ] ... ]
    options:
        all-properties
        non-default-properties

DISPLAY
list active-directory
list active-directory [ [ [name] | [glob] | [regex] ] ... ]
    options:
        all-properties
        app-service
        non-default-properties
        one-line
        partition

DELETE
delete active-directory [name]

DESCRIPTION
    You can use the active-directory component to manage an AAA Active
    Directory server. The Active Directory is a network structure
    supported by Windows(r) 2000, or later, that provides support for
    tracking and locating any object on a network.

EXAMPLES
    create active-directory MyADserver { domain-controller
    "server01.company.com domain "company.com " admin-name "administrator"
    admin-encrypted-password "!My123Password" }
    Creates the AAA Active Directory server named MyADserver in the
    company.dom domain, sets the administrator logon name to
    administrator and the administrator password to !My123Password,
    and sets the Key Distribution Center to company.com.

    delete active-directory MyActiveDirectoryServer
    Deletes the AAA Active Directory server named
    MyActiveDirectoryServer from the system.

OPTIONS
    admin-encrypted-password
    Specifies the password associated with admin name. This option is
    required only when you are using an Active Directory Query agent
    with this Active Directory server object.

    admin-name
    Specifies the user name that has administrative permissions on an
    AAA Active Directory server. This option is required only when you
    are using an Active Directory Query agent with this Active
    Directory server object.

    app-service
    Specifies the name of the application service to which the object
    belongs. The default value is none. Note: If the strict-updates
    option is enabled on the application service that owns the object,
    you cannot modify or delete the object. Only the application
    service can modify or delete the object.

    cleanup-cache
    Specifies whether this is a cache cleanup request. You can clean
    up the group, PSO or Kerberos cache. The default value is none.

    description
    Specifies a description for the component. The default is none.

    domain
    Specifies the Active Directory domain name. This setting is
    required.

    [name]
    Specifies the name of an AAA Active Directory server. This setting
    is required.

    domain-controller
    Specifies the fully qualified domain name (FQDN) of the domain
    controller for the domain specified in the domain option. The
    default is none.

    domain-controllers
    Adds, deletes, or replaces a set of domain controllers, by
    specifying an FQDN for each entry. You can configure the following
    options for each domain controller:

    ip An IP address for specified domain controller entry.

    group-cache-ttl
    Specifies group cache lifetime in days [0..1825]. The default
    value is 30. If you specify group cache lifetime 0, that means
    cache will be updated on every request.

    pso-cache-ttl

```

Specifies password security objects (PSO) Cache lifetime in days [0..1825]. The default value is 30. If you specify PSO cache lifetime 0, that means cache will be updated on every request.

#### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

pool Specifies the name of the pool with which the server is associated. The default is none.

#### partition

Displays the partition within which the component resides. The default is Common.

#### padata

Specifies a Kerberos preauthentication encryption type. If it is specified, the BIG-IP system includes Kerberos preauthentication data within the first AS-REQ. If you do not need to include preauthentication data, set this option to "none". Supported encryption types: none, des-cbc-crc, des-cbc-md5, aes128-cts-hmac-shal-96, aes256-cts-hmac-shal-96, rc4-hmac. The default is rc4-hmac.

#### timeout

Specifies a timeout interval (in seconds) after which an AAA Active Directory server closes a connection. The default is 15.

## apm aaa crldp

### NAME

crldp - Configure a Certificate Revocation List Distribution Point (CRDLP) server object for implementing a CRLDP authentication module.

### MODULE

apm aaa

### SYNTAX

Configure the crldp component within the aaa module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create crldp [name]
modify crldp [name]
options:
  address [ip addr]
  allow-nullcrl [true | false]
  app-service [[string] | none]
  base-dn [[string> | none]
  cache-expire [[integer] | none]
  connection-timeout [[integer] | none]
  description [[string> | none]
  location-specific [true | false]
  pool [name]
  port [[integer] | none]
  reverse-dn [true | false]
  use-issuer [true | false]
  use-pool [enabled | disabled]
  verify-sig [true | false]
```

```
edit crldp [ [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list crldp
list crldp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
```

partition

DELETE  
delete crldp [name]

#### DESCRIPTION

Configure a CRLDP authentication server, and then assign the server to the CRLDP auth agent in your access policy.

#### EXAMPLES

```
create crldp aaa-ldap-2027 { address 172.27.32.60 allow-nullcrl false
base-dn DC=net,DC=aina,DC=test cache-expire 1000 connection-timeout 15
description none partition Common pool aaa-ldap-2027-pool port ldap
reverse-dn true use-issuer false use-pool disabled verify-sig true }
Creates a CRLDP server named aaa-ldap-2027.
```

```
delete crldp server my_crldp_server
Deletes the CRLDP server named my_crldp_server.
```

#### OPTIONS

address

Specifies the IP address of the server. This option is required.

allow-nullcrl

Specifies whether to consider a null CRL from the CRLDP server a successful authentication. The default is false.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

base-dn

Specifies the LDAP base directory name for certificates that specify the CRL distribution point in directory name (dirName) format. Used when the value of the X509v3 attribute crlDistributionPoints is of type dirName. In this case, the BIG-IP system attempts to match the value of the crlDistributionPoints attribute to the Base DN value. An example of a Base DN value is cn=xxxx,dc=f5,dc=com.

cache-expire

Specifies (in seconds) an update interval for CRL distribution points. The update interval for distribution points ensures that CRL status is checked at regular intervals, regardless of the CRL timeout value. This helps prevent CRL information from becoming outdated before the Access Policy Manager checks the status of a certificate.

connection-timeout

Specifies the number of seconds of inactivity the system allows before the connection times out. The default is 15.

description

Specifies a unique description for the server. The default is none.

partition

Displays the partition within which the component resides.

location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

pool Specifies the name of the pool with which the server is associated.

port Specifies the CRLDP service port. The default is 389.

reverse-dn

Specifies in which order the system is to attempt to match the Base DN value to the value of the X509v3 attribute crlDistributionPoints. Possible values are enabled and disabled. When set to enabled, the system matches the base DN from left to right, or from the beginning of the DN string, to accommodate dirName strings in certificates such as C=US,ST=WA,L=SEA,OU=F5,CN=xxx. The default value is false.

use-issuer

Specifies whether the CRL distribution point is extracted from the certificate of the client certificate issuer. The default is false.

use-pool

Enables or disables high availability between CRLDP servers. When enabled, Access Policy Manager sends CRLDP authentication requests for the associated CRLDP auth agent to the virtual server, and standard pool behavior is used to implement high availability for CRLDP.

verify-sig

Specifies whether the signature on the received CRL is verified. The default is true.

## apm aaa endpoint-management-system

### NAME

endpoint-management-system - Manages an integration with a remote Mobile Device Management (MDM) server.

### MODULE

apm aaa

### SYNTAX

Configure the endpoint-management-system component within the aaa module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create endpoint-management-system [name]
options:
  type [airwatch | maas360 | ms-intune]
  fqdn [string]
  port [port]
  serverssl-profile [name]
  description [[string] | none]
  username [string]
  password [string]
  mdm-token [[string] | none]
  billing-id [[string] | none]
  application-id [[string] | none]
  access-key [[string] | none]
  platform [[string] | none]
  tenant-id [[string] | none]
  client-id [[string] | none]
  client-secret [[string] | none]
  dns-resolver [[name] | none]
  app-version [[string] | none]
  sync-interval [[integer] | none]
  location-specific [true | false]
modify endpoint-management-system [name]
options:
  fqdn [string]
  port [port]
  serverssl-profile [name]
  description [[string] | none]
  username [string]
  password [string]
  mdm-token [[string] | none]
  billing-id [[string] | none]
  application-id [[string] | none]
  access-key [[string] | none]
  platform [[string] | none]
  tenant-id [[string] | none]
  client-id [[string] | none]
  client-secret [[string] | none]
  dns-resolver [[name] | none]
  app-version [[string] | none]
  sync-interval [[integer] | none]
  location-specific [true | false]
```

```
edit endpoint-management-system [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list endpoint-management-system
list endpoint-management-system [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

#### DELETE

```
delete endpoint-management-system [name]
```

### DESCRIPTION

You can use the endpoint-management-system component to manage an integration with remote Mobile Device Management (MDM) server.

### EXAMPLES

```
create endpoint-management-system MyEndpointManagementSystem { type
airwatch fqdn "server01.company.com" port 443 serverssl-profile
```

```

serverssl username "administrator" password "!My123Password" mdm-token
"token" }
Creates the endpoint management system named
MyEndpointManagementSystem with MDM API URL
server01.company.com:port, sets serverssl-profile to serverssl,
sets the MDM administrator user name to administrator and the
password to !My123Password, and sets the API token to token.

delete endpoint-management-system MyEndpointManagementSystem
Deletes the endpoint management system named
MyEndpointManagementSystem from the system.

```

#### OPTIONS

**name** Specifies the name for the endpoint management system. This setting is required.

**type** Specifies the type of endpoint management system: airwatch, maas360 or ms-intune. This setting is required.

**fqdn** Specifies the fully qualified domain name. This setting is required.

**port** Specifies the port number. Default is 443

**serverssl-profile**  
Specifies the server SSL profile. This setting is required.

**description**  
Specifies a description for the component. The default is none.

**username**  
Specifies the user name of the MDM administrator. This setting is required.

**password**  
Specifies the password the MDM administrator uses to log in. This setting is required.

**mdm-token**  
Specifies the API token.

**billing-id**  
Specifies the billing ID for the user's IBM Maas360 account. Valid only for maas360 type.

**application-id**  
Specifies the application ID provided by IBM Maas360. Valid only for maas360 type.

**access-key**  
Specifies the access key provided by IBM Maas360. Valid only for maas360 type.

**platform**  
Specifies the platform version of the IBM Maas360 console. Valid only for maas360 type.

**tenant-id**  
Specifies the Microsoft Intune Tenant Id. Valid only for ms-intune type.

**client-id**  
Specifies the Client Id of the Web App created on Microsoft Azure for the Microsoft Intune Integration. Valid only for ms-intune type.

**client-secret**  
Specifies the Client Secret of Web App created on Microsoft Azure for the Microsoft Intune Integration. Valid only for ms-intune type.

**dns-resolver**  
Specifies the Dns Resolver. Valid only for ms-intune type.

**app-version**  
Specifies the current version number of the application that corresponds to the account.

**sync-interval**  
Specifies the length of time it takes for the synchronization to complete. The default is 240 minutes.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

## apm aaa f5-mfa-configuration

**NAME**

f5-mfa-configuration - defines F5 multi-factor authentication configuration.

**MODULE**

apm aaa

**SYNTAX**

Configure the f5-mfa-configuration component within the aaa module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create f5-mfa-configuration [name]
modify f5-mfa-configuration [name]
options:
  app-service [[string] | none]
  f5-service-connector [name]
  permitted-devices-types [add | delete | modify | replace-all-with] {
    [mobile | totp]
  }
  max-mobile-devices-per-user [[integer] | none]
  registration-sms-template [[string] | none]
  require-biometric [[true | false] | none]
```

**edit f5-mfa-configuration** [ [ [name] | [glob] | [regex] ] ... ]

options:

- all-properties
- non-default-properties

**DISPLAY**

**list f5-mfa-configuration**

**list f5-mfa-configuration** [ [ [name] | [glob] | [regex] ] ... ]

options:

- all-properties
- app-service
- non-default-properties
- one-line
- partition

**DELETE**

```
delete f5-mfa-configuration [name]
```

**DESCRIPTION**

You can use the f5-mfa-configuration component to define F5 multi-factor authentication configuration.

**EXAMPLES**

```
create f5-mfa-configuration MyF5MFAConfiguration { f5-service-connector
MyF5ServiceConnector permitted-devices-types { mobile } max-mobile-
devices-per-user 2 registration-sms-template "Hello, Please follow the
link below to register your device for second factor authentication:
%{session.f5_mfa.device_registration.registration_url}" require-
biometric true }
```

Creates the f5 mfa configuration named MyF5MFAConfiguration with f5-service-connector MyF5ServiceConnector, adds mobile to permitted-devices-types, sets max-mobile-devices-per-user to 2, sets registration-sms-template to Hello, Please follow the link below to register your device for second factor authentication: %{session.f5\_mfa.device\_registration.registration\_url} and sets require-biometric to true

```
delete f5-mfa-configuration MyF5MFAConfiguration
```

Deletes the f5 mfa configuration named MyF5MFAConfiguration from the system.

**OPTIONS**

[name]

Specifies the name for the f5 mfa configuration. This setting is required.

f5-service-connector

Specifies the f5-service-connector. This setting is required.

permitted-devices-types

Specifies permission of the use of mobile devices or hardware tokens (TOTP) or both for multi-factor authentication. This setting is required.

max-mobile-devices-per-user

Specifies the number of devices that one user can register for multi-factor authentication.

registration-sms-template

Specifies the message to send to a user to register their mobile devices.

require-biometric

Set this item to true to require that the user present a physical characteristic, such as a fingerprint, on the mobile device for an additional authentication factor.

## apm aaa f5-service-connector

### NAME

f5-service-connector - Specifies properties for establishing a connection to an F5 multi-factor authentication service that is external to and separate from BIG-IP Access Policy Manager and the BIG-IP system.

### MODULE

apm aaa

### SYNTAX

Configure the f5-service-connector component within the aaa module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create f5-service-connector [name]
modify f5-service-connector [name]
options:
  app-service [[string] | none]
  service-url [string]
  customer-id [string]
  customer-key [string]
  dns-resolver [name]
  serverssl-profile [name]
```

```
edit f5-service-connector [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list f5-service-connector
list f5-service-connector [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

#### DELETE

```
delete f5-service-connector [name]
```

### DESCRIPTION

You can use the f5-service-connector component to create F5 MFA Configuration component.

### EXAMPLES

```
create f5-service-connector MyF5ServiceConnector { service-url
"https://service01.company.com" customer-id "id01" customer-key "key01"
dns-resolver new-dns-resolver serverssl-profile serverssl }
Creates the F5 service connector named MyF5ServiceConnector with
service URL https://service01.company.com, sets the customer id to
id01, sets the customer-key to key01, sets dns-resolver to new-
dns-resolver and sets serverssl-profile to serverssl
```

```
delete f5-service-connector MyF5ServiceConnector
Deletes the F5 service connector named MyF5ServiceConnector from
the system.
```

### OPTIONS

[name]  
Specifies the name for the F5 service connector. This setting is required.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

service-url  
Specifies the URL for connecting to the service. This setting is required.

customer-id  
Specifies the customer id for the service. This setting is

required.

**customer-key**  
Specifies the customer key for the service. This setting is required.

**dns-resolver**  
Specifies the DNS resolver for the connector to use. This setting is required.

**serverssl-profile**  
Specifies the server SSL profile. This setting is required.

SEE ALSO  
COPYRIGHT

## apm aaa http

**NAME**  
http - Specify an http server configuration used for authentication.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the http component within the aaa module using the syntax shown in the following sections.

```
CREATE/MODIFY
create http [name]
modify http [name]
options:
  app-service [[string] | none]
  auth-type [form-based | basic-ntlm | custom-post]
  content-type [xml-utf8 | url-encoded-utf8 | none]
  custom-body [[string] | none]
  description [[string] | none]
  follow-redirect [integer]
  form-action [[string] | none]
  form-fields [[string] | none]
  form-method [get | post]
  form-params [[string] | none]
  form-password [[string] | none]
  form-username [[string] | none]
  headers [add | delete | modify | replace-all-with | none] {
[name] {
  app-service [[string] | none]
  hname [[string] | none]
  hvalue [[string] | none]
}
}
  location-specific [true | false]
  start-uri [[string] | none]
  success-match-type [url | cookie | string | exact-cookie]
  success-match-value [[string] | none]

edit http [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list http
list http [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

DELETE
delete http [name]
```

**DESCRIPTION**  
You can use the http component to create and manage AAA HTTP servers.

**EXAMPLES**  
create http myHttpServer { start-uri "http://mycompany.com/" auth-type basic-ntlm }  
Creates an HTTP authentication server named "myHttpServer" with a starting URI of http://mycompany.com.

delete http myHttpServer  
Deletes the myHttpServer AAA HTTP server.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### auth-type

Specifies the type of authentication you want to use.

##### form-based

Specifies the authentication type to be form-based.

##### basic-ntlm

Specifies the authentication type to be basic-ntlm.

##### custom-post

Specifies the authentication type to be custom-post.

##### content-type

Specifies the encoding (xml-utf8, url-encoded-utf8, or none) for an HTTP custom post. If you specify 'none', you must use the headers option to add a custom header. In addition to specifying a custom header, you must apply your own encoding through an iRule.

##### custom-body

Specifies the body for a HTTP Custom Post.

##### description

Specifies a unique description for the server. The default is none.

##### follow-redirect

Specifies the number of pages away from the landing page the request should travel before failing.

##### form-action

Specifies the complete destination URL to process the form using HTTP form-based authentication. This is optional. If you do not specify a form action, then Access Policy Manager will use the URI from the request to perform HTTP form-based authentication.

##### form-fields

Specifies the hidden form parameters that are required by the authentication server logon form at your location. The default is none. Specify a parameter name, a space, and the parameter value, if any. Multiple parameters can be configured with each "name value" pair in one line. Use edit to add multiple parameters. Please note that create and modify do not allow using new line on the terminal.

##### form-method

Specifies the form method you want to use for the form-based HTTP authentication. The value is either Get or POST. The default is POST. However, if you specify GET, the Access Policy Manager will force the authentication using HTTP GET rather than perform authentication using form-based POST.

##### form-password

Specifies the parameter names used by the form you are sending the POST request to.

##### form-username

Specifies the parameter names used by the form you are sending the POST request to.

##### headers

Specifies the name and value of the header content to be inserted in an HTTP Post. The options are:

##### app-service

Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

##### hname

The name of the HTTP header.

##### hvalue

The value of the HTTP header.

##### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

##### [name]

Specifies the name of the aaa http server. This option is required.

##### partition

Displays the partition within which the component resides. The

default is Common.

**start-uri**  
Specifies a URL resource, for example, `http://plum.tree.lab2.sp.companynet.com/`. This resource must respond with a challenge to a non-authenticated request.

**success-match-type**  
Specifies the method your authentication server uses and determines the option definition used for this field. The field toggles according to your selection.

**cookie**  
Specifies any string in cookie is required.

**exact-cookie**  
Specifies key fields in cookie is required.

**string**  
Specifies a specific string is required.

**url** Specifies a URL is required.

**success-match-value**  
Specifies the URL, any string in cookie, exact cookie or specific string used for the specific success match type you see.

#### SEE ALSO COPYRIGHT

## apm aaa kerberos-keytab-file

**NAME**  
kerberos-keytab-file - Manages a Kerberos keytab file.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the kerberos-keytab-file component within the aaa module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create kerberos-keytab-file [name]  
modify kerberos-keytab-file [name]  
options:  
app-service [[string] | none]  
source-path [string]

edit kerberos-keytab-file [ [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list kerberos-keytab-file  
list kerberos-keytab-file [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
app-service  
non-default-properties  
one-line  
partition

**DELETE**  
delete kerberos-keytab-file [name]

**DESCRIPTION**  
You can use the kerberos-keytab-file component to create and manage a Kerberos Keytab file.

**EXAMPLES**  
create kerberos-keytab-file my\_keytab { source-path  
file:/root/apmkeytab }  
Creates a Kerberos Keytab file name my\_keytab located at root/apmkeytab.

delete kerberos-keytab-file my\_keytab  
Deletes the Kerberos Keytab file name my\_keytab.

**OPTIONS**

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**source-path**  
Specifies the location of the Kerberos Keytab file.

**partition**  
Displays the partition within which the component resides.

## apm aaa kerberos

**NAME**  
kerberos - Configures a Kerberos server.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the kerberos component within the aaa module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create kerberos [name]  
modify kerberos [name]  
options  
auth-realm [[string] | none]  
app-service [[string] | none]  
keytab-file-obj [[string] | none]  
location-specific [true | false]  
service-name [[string] | none]  
  
edit kerberos | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
  
**DISPLAY**  
list kerberos  
list kerberos [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
app-service  
non-default-properties  
one-line  
partition  
  
**DELETE**  
delete kerberos [name]

**DESCRIPTION**  
You can use the kerberos component to create and manage AAA Kerberos servers. Use the Kerberos authentication server to configure authentication for the Access Policy Manager. A client retrieves credentials from the domain controller and passes those credentials to the Access Policy Manager. Then Access Policy Manager uses the value in the keytab-file-obj option of the Kerberos AAA server object to verify the credentials. Access Policy Manager system does not have to reside in the domain.

**EXAMPLES**  
delete kerberos my\_kerberos  
Deletes the server named my\_kerberos.

**OPTIONS**  
**auth-realm**  
Specifies a Kerberos auth realm name (administrative name), such as user@realm.com to establish the boundaries within which an authentication server has the authority to authenticate a user, host, or service. Kerberos clients manually map DNS domain names to Kerberos realm names. This option is required.  
  
**app-service**  
Specifies the name of the application service to which the object

belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**keytab-file-obj**

Specifies a keytab file that contains the keys (derived from the Kerberos password) that the server uses to authenticate the client. This option is required.

**location-specific**

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**

Specifies the name of an AAA Kerberos server. This option is required.

**partition**

Displays the partition within which the component resides.

**service-name**

Specifies the Kerberos service name defined inside KDC in the format service name/hostname@kerberosrealm. This option is required, for example, HTTP.

**SEE ALSO**  
**COPYRIGHT**

## apm aaa ldap

**NAME**

ldap - Manages an AAA LDAP server.

**MODULE**

apm aaa

**SYNTAX**

Configure the ldap component within the aaa module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create ldap [name]
modify ldap [name]
options:
  address [[ip addr] | none]
  admin-dn [[string] | none]
  admin-encrypted-password [[string] | none]
  app-service [[string] | none]
  base-dn [string]
  description [[string] | none]
  is-ldaps [false | true]
  location-specific [true | false]
  pool [name]
  port [[service] | none]
  schema-attr {
    group-member [[string] | none]
    group-member-value [[string] | none]
    group-memberof [[string] | none]
    group-object-class [[string]]
    user-memberof [[string] | none]
    user-object-class [string]
  }
  serverssl-profile [none | serverssl | serverssl-insecure-compatible | wom-default-serverssl]
  timeout [integer]
  use-pool [enabled | disabled]

edit ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list ldap
list ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
```

app-service  
non-default-properties  
one-line  
partition

DELETE  
delete ldap [name]

#### DESCRIPTION

You can use the ldap component to create and manage an AAA LDAP server.

#### EXAMPLES

```
create ldap MyLDAPserver { address 172.30.6.144 admin-dn
  "cn=administrator,cn=users,dc=company,dc=companynet,dc=com" admin-
  encrypted-password "!MyPassword" }
Creates the AAA LDAP server named MyLDAPserver that is assigned
the IP address 172.30.6.144 and the
cn=administrator,cn=users,dc=company,dc=companynet,dc=com admin dn
with a password of !MyPassword.
```

```
delete ldap MyLDAPServer
Deletes the AAA LDAP server named MyLDAPServer from the system.
```

#### OPTIONS

address  
Specifies the IP address of an AAA LDAP server. This option is required.

admin-dn  
Specifies the Container Distinguished Name (DN) to use for authentication. This option is required.

admin-encrypted-password  
Specifies the password for admin name. This option is required.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

base-dn  
Specifies the base DN from which to search. This search DN is used to search groups across a whole directory.

group-cache-ttl  
Specifies a lifetime for the group cache (days).

cleanup-cache  
Specifies whether cache invalidation is required. The default is none. The options are:

none  
group  
description  
Specifies a unique description for the server. The default is none.

is-ldaps  
Specifies whether to use the LDAPS protocol during authentication. If true, you must also specify the option serverssl-profile.

location-specific  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]  
Specifies the name of the AAA server. This option is required.

partition  
Displays the partition within which the component resides.

pool Specifies the name of the pool with which the server is associated. The default is none.

port Specifies the port number of the AAA LDAP server. The default is ldap. This option is required.

schema-attr  
Specifies LDAP schema-specific attribute names.

user-object-class The value of the objectClass attribute for a user object. The default is "user".  
user-memberof If the user object maintains a group membership, you should specify the membership attribute name here. The default is "memberOf".  
group-object-class The value of the objectClass attribute for a group object. The default is "group".  
group-memberof If the group object maintains a group membership in other groups, you should specify a membership attribute name here. The default is "memberOf".  
group-member If the group object maintains a list of users that belong to the group, you should specify the attribute here. The default is "member".  
group-member-value If the "group-member" attribute is specified, you should specify the attribute that is used to add users into a group. The default is "dn".  
serverssl-profile

Specifies the server side SSL profile. LDAPS is achieved by directing LDAP traffic over a virtual server that uses a server side SSL to communicate with the LDAP server.

The options are:

serverssl  
serverssl-insecure-compatible  
wom-default-serverssl  
timeout

Specifies a timeout interval (in seconds) for the AAA server after which the server closes a connection. The default is 15.

use-pool  
Enables or disables high availability between pool members. When enabled, the Access Policy Manager sends AAA requests for the associated policy item to the virtual server, and standard pool behavior is used to implement high availability for CRDLP.

## apm aaa oam

NAME  
oam - Manages an AAA Oracle Access Manager server.

MODULE  
apm aaa

SYNTAX  
Configure the oam component within the aaa module using the syntax shown in the following sections.

CREATE/MODIFY  
create oam [name]  
modify oam [name]  
options:  
access-server-hostname [[string] | none]  
access-server-name [[string] | none]  
access-server-port [[integer] | none]  
access-server-retries [integer]  
accessgate-encrypted-password [[string] | none]  
accessgates [add | delete | modify | replace-all-with] {  
[name]  
}  
action [config-accessgate | noop]  
admin-id [[string] | none]  
admin-password [[string] | none]  
app-service [[string] | none]  
description [[string] | none]  
enable [false | true]  
global-access-protocol-passphrase [[string] | none]  
location-specific [true | false]  
transport-security-mode [cert | open | simple]

edit oam | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

DISPLAY  
list oam  
list oam [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
app-service  
non-default-properties  
one-line  
partition

DELETE  
delete oam [name]

DESCRIPTION  
You can use the oam component to create and manage an AAA Oracle Access Manager server.

EXAMPLES  
create oam oam10g { access-server-hostname www.localcorp.biz access-server-name accessSrv1 access-server-port 6021 access-server-retries 0 accessgates { oam10gwebgate1 { encrypted-password [string] } } admin-id

```
    firstname.lastname admin-password "[string]" global-access-protocol-
    passphrase "[string]" transport-security-mode simple }
Creates the AAA OAM server named oam10g accessing the web gate
oam10gwebgate1 on the Access Server accessSrv1 at host name
www.localcorp.biz on port 6021. The server retries connections
zero times.
```

```
    delete aaa oam MyOAMServer
Deletes the AAA Oracle Access Manager server named MyOAMServer
from the system.
```

#### OPTIONS

**access-server-hostname**  
Specifies the IP address or FQDN of the Oracle Access Manager server. This option is required.

**access-server-name**  
Specifies the name of the Oracle Access Manager server. This option is required.

**access-server-port**  
Specifies the port of the Oracle Access Manager server. The default is 6021.

**access-server-retries**  
Specify the number of times you want the access gate to attempt to connect to the Oracle Access Manager server when the action option is set to config-accessgate. The default is 0 (zero).

**accessgates**  
Specifies the ID of the access gate or web gate on the OAM Server. The system supports the use of multiple access gates/web gates as long as they are from the same OAM server.

**action**  
Specifies the Oracle Access Manager action type. Actions allow you to pass user profile information or to redirect the user's browser to another site. For more information on Actions, refer to the Access Administration Guide provided by Oracle. The options are:

**config-accessgate**  
Specifies that you want the system to use the configureAccessGate tool.

**noop** Specifies "no operation performed." This is the default.

**admin-id**  
Specifies the administrator ID required by the Oracle Access Manager server. This option is required.

**admin-password**  
Specifies the administrator password required by the Oracle Access Manager server. The default is none.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
Specifies a unique description for the Oracle Access Manager server. The default is none.

**enable**  
Specifies whether you want to enable the server. The default is true.

**global-access-protocol-passphrase**  
Specifies a global passphrase for all Oracle components. The default is none.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies the name of an AAA Oracle Access Manager server. This setting is required.

**transport-security-mode**  
Specifies the transport security level for the communication between Oracle components and Access Policy Manager. The options are:

**open** Communication is not encrypted for protection. Use this mode when security is not an issue

**simple**  
Communication is encrypted with Oracle Access Manager's internal CA. Simple mode encrypts communications using Transport Layer Security, RFC 2246 (TLS v1). This mode is less secure than Cert mode. Use this mode if you have some security concerns but do not want to manage your own CA.

**cert** Communication is encrypted with an external CA. Use cert mode if you want different certificates on OAM servers and webgates and you have a trusted 3rd party CA. Oracle Access

Manager components use X.509 digital certificates in PEM format only.

## apm aaa oauth-provider

NAME  
oauth-provider - Manages an OAuth Provider.

MODULE  
apm aaa

SYNTAX  
Configure the oauth-provider component within the aaa module using the syntax shown in the following sections.

CREATE/MODIFY  
create oauth-provider [name]  
modify oauth-provider [name]  
options:  
allow-self-signed-jwk-cert [bool]  
app-service [[string] | none]  
authentication-uri [[string] | none]  
auto-jwt-config-name [[string] | none]  
description [[string] | none]  
ignore-expired-cert [bool]  
last-discovery-time [date/time]  
manual-jwt-config-name [[string] | none]  
max-json-nesting-layers [integer]  
max-response-size [integer]  
openid-cfg-uri [[string] | none]  
save-json-payload [enabled | disabled]  
token-uri [[string] | none]  
token-validation-scope-uri [[string] | none]  
trusted-ca-bundle [[string] | none]  
type [custom | f5 | facebook | google | ping]  
use-auto-jwt-config [bool]  
userinfo-request-uri [[string] | none]  
  
edit oauth-provider[ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
  
DISPLAY  
list oauth-provider  
list oauth-provider [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
app-service  
non-default-properties  
one-line  
partition  
  
DELETE  
delete oauth-provider [name]

DESCRIPTION  
You can use the oauth-provider component to manage an OAuth Provider. The OAuth Provider specifies endpoint URIs to retrieve token, refresh token, validate token, get a list of scopes associated with token and redirect user to obtain authorization\_code. It specifies URIs to retrieve userinfo and to perform OpenID discovery to retrieve JSON web tokens and JSON web keys.

EXAMPLES  
create oauth-provider f5Provider { authentication-uri  
https://local.f5.com/f5-oauth2/v1/authorize auto-jwt-config-name  
auto\_jwt\_f5Provider last-discovery-time 2017-06-09:07:48:57 openid-cfg-  
uri  
https://f5-oauth.local/f5-oauth2/v1/.well-known/openid-configuration  
description "OAuth provider defines F5 AS" token-uri  
https://local.f5.com/f5-oauth2/v1/token token-validation-scope-uri  
https://local.f5.com/f5-oauth2/v1/validate trusted-ca-bundle  
ca-bundle.crt type f5 }  
Creates the OAuth Provider named f5Provider of type f5, defines  
all endpoint URIs to the local Authorization Server.  
  
delete oauth-provider f5Provider  
Deletes the OAuth Provider named f5Provider from the system.

## OPTIONS

### allow-self-signed-jwk-cert

Specifies whether creating JWK config containing self-signed certificate is allowed. The default value is yes.

### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

### authentication-uri

The endpoint URI that is used to redirect user for authentication in order to get `authorization_code`. This endpoint is used by OAuth Client agent, when grant type is configured to Authorization Code.

### auto-jwt-config-name

Specifies the name of the auto-discovered JWT config.

### description

Specifies a description for the component. The default is none.

### ignore-expired-cert

Specifies whether the expired AS certificate enforcement is to be ignored. The default value is false.

### last-discovery-time

Specifies the last time JWT config and JWK config were auto-discovered.

### manual-jwt-config-name

Specifies the name of the manually created JWT config.

### max-json-nesting-layers

Specifies the maximum nesting layers of JSON responses that will be processed and stored. The default value is 8.

### max-response-size

Specifies the size limit for all responses from all endpoints of the provider. The default value is 128kb.

### openid-cfg-uri

The endpoint URI that is used to pull JSON web tokens and JSON web keys from Authorization server. This endpoint is used by OAuth Client agent.

### save-json-payload

Specifies whether the entire JSON text is to be saved in a session variable. The default value is false.

### partition

Displays the partition within which the component resides. The default is Common.

### token-uri

The endpoint URI that is used to retrieve an `access_token`. This endpoint is used by OAuth Client agent.

### token-validation-scope-uri

The endpoint URI that is used by OAuth Scope agent, in order to retrieve a list of scopes associated with an `access_token`. The same URI is used to validate an `access_token` by OAuth Client agent.

### trusted-ca-bundle

Specifies the trusted CA bundle for AS certificate that is used for autodiscovery of JSON web tokens and JSON web keys.

`type` The type of the provider.

### use-auto-jwt-config

Specifies whether the OAuth Provider uses auto-discovered JWT config specified in `auto-jwt-config-name` or manually created JWT config specified in `manual-jwt-config-name`. The default value is true.

### userinfo-request-uri

The endpoint URI that is used to request userinfo information. This endpoint is used by OAuth Scope agent.

`custom` The provider is using a custom Authorization Server.

`azure-ad` The provider is using an AzureAD Authorization Server.

`azure-ad-b2c` The provider is using an AzureAD-B2C Authorization Server.

`f5` The provider is using an F5 Authorization Server.

`facebook` The provider is Facebook Authorization Server.

`google` The provider is Google Authorization Server.

`okta` The provider is using an Okta Authorization Server.

`ping` The provider is Ping Identity Authorization Server.

Default value for provider type is f5.

## apm aaa oauth-request

**NAME**

oauth-request - Manages an OAuth Request.

**MODULE**

apm aaa

**SYNTAX**

Configure the oauth-request component within the aaa module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create oauth-request [name]
modify oauth-request [name]
options:
  app-service [[string] | none]
  description [[string] | none]
  headers [add | delete | modify | replace-all-with] {
    [name] {
      value [value]
    }
  }
  method [get | post]
  parameters [add | delete | modify | replace-all-with] {
    [name] {
      type [parameter type]
      value [[string] | none]
    }
  }
  type [request type]
  uri [[string] | none]
```

**edit oauth-request [ [ [name] | [glob] | [regex] ] ... ]**

**options:**

- all-properties
- non-default-properties

**DISPLAY**

```
list oauth-request
list oauth-request [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

**DELETE**

```
delete oauth-request [name]
```

**DESCRIPTION**

You can use the oauth-request component to manage an OAuth Request. The OAuth Request is an HTTP request that is used during communication between the BIG-IP system and an OAuth Authorization Server (AS). Different types of OAuth Requests can be configured for both OAuth Client and OAuth Scope agents.

**EXAMPLES**

```
create oauth-request F5AuthRedirectRequest { description "F5
Authentication Redirect request" method get parameters add { client_id
{ type client-id } redirect_uri { type redirect-uri } response_type {
value "code" } } type auth-redirect-request }
Creates the OAuth Request named F5AuthRedirectRequest of type
auth-redirect-request, sets HTTP method to get and specifies the
list of GET parameters to be sent: client-id, redirect_uri,
response_type.
```

```
delete oauth-request F5AuthRedirectRequest
Deletes the OAuth Request named F5AuthRedirectRequest from the
system.
```

**OPTIONS**

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**

Specifies a description for the component. The default is none.

**headers**

Adds, deletes, or replaces a set of headers, by specifying a header name and value for each entry.

**value**

The value of the header.

method

Specifies the HTTP method for the OAuth Request. The options are:

get Configures the system to make HTTP request using GET method.

post Configures the system to make HTTP request using POST method.

parameters

Adds, deletes, or replaces a set of parameters, by specifying a parameter name for each entry. You can configure the following options for each parameter:

type The type of the parameter. For a custom type of parameter, you must provide a value. For other parameter types, the value is taken from other configurations. The options for the type of a parameter are:

access-token The value for the parameter is access\_token.

Value assigned from session variable

session.oauth.client.access\_token

client-id The value for this\_parameter type is the Client Id that is configured in the OAuth Server object.

client-secret The value for this parameter type is the Client Secret that is configured in the OAuth Server object.

grant-type The value for this parameter type is the Grant Type that is configured in the OAuth Client agent.

redirect-uri The value for this parameter type is the

Redirect URI that is configured in the OAuth Client agent.

resource-server-id The value for this parameter is the Resource Server Id that is configured in the OAuth Server object.

resource-server-secret The value for this parameter is the Resource Server Secret that is configured in the OAuth Server object.

scope The value for this parameter is the Scope that is configured in the OAuth Client agent.

custom Custom parameter value; you can specify any custom value for the parameter.

Default value for parameter type is custom.

value

The value of the parameter. A value is required for parameters of type custom only.

partition

Displays the partition within which the component resides. The default is Common.

type Type of the request. The options for the type of a request are:

auth-redirect-request The Authentication Redirect request. This type of request is used to redirect user to an Authorization Server, when OAuth Client agent is configured to use "Authorization Code" grant type.

token-request The Token request. This type of request is used to access an Authorization Server in order to obtain an access\_token or exchange an authorization\_code for an access\_token.

token-refresh-request The Refresh Token request. This type of request is used to refresh an expired access\_token.

token-revocation-request The Revocation request. This type of request is used to revoke an access\_token.

validation-scopes-request The Validation and Scopes request. This type of request is used in OAuth Client agent to validate an existing token. The same type of request is used to get a list of scopes associated with an existing token.

scope-data-request The Scope Data request. This type of request is used to obtain additional information from an Authorization Server.

Default value for request type is scope-data-request.

uri Request URI. This option is required for request of type scope-data-request only. All other types of requests use endpoint URIs configured at OAuth Provider component.

SEE ALSO

## apm aaa oauth-server

NAME

oauth-server - Manages an OAuth Server.

## MODULE

apm aaa

## SYNTAX

Configure the oauth-server component within the aaa module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create oauth-server [name]
modify oauth-server [name]
options:
  app-service [[string] | none]
  client-id [string]
  client-secret [[string] | none]
  client-serverssl-profile-name [name]
  dns-resolver-name [name]
  mode [client | rs | client-rs]
  provider-name [name]
  resource-server-id [string]
  resource-server-secret [[string] | none]
  resource-serverssl-profile-name [name]
  rules [[string] | none]
  token-validation-interval [[integer] | none]
```

```
edit oauth-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

### DISPLAY

```
list oauth-server
list oauth-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete oauth-server [name]
```

## DESCRIPTION

You can use the oauth-server component to manage an OAuth Server. The OAuth Server specifies the configuration of an OAuth Authorization server for use by the OAuth Client or OAuth Scope agents.

## EXAMPLES

```
create oauth-server f5Server { provider-name Google mode client client-
id myClientApplicationId client-secret
e939e2lead60c0406341c9be587a005056890213d480f456 client-serverssl-
profile-name serverssl dns-resolver-name myResolver}
Creates the OAuth Server named f5Server and defines all required
options. In this example, the BIG-IP system is supposed to only
acquire an access_token from Google. The server mode is set to
client and resource server credentials are not needed.
```

```
delete oauth-server f5Server
Deletes the OAuth Server named f5Server from the system.
```

## OPTIONS

### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

### client-id

Specifies the client application ID. The client application must be configured before configuring the OAuth Server on the BIG-IP system.

### client-secret

Specifies the client application secret. The client application must be configured at the authorization server before configuring the OAuth Server on the BIG-IP system.

### client-serverssl-profile-name

SSL profile to be used by the BIG-IP system when connecting to authorization server.

### dns-resolver-name

DNS resolver object to be used by OAuth Server to resolve DNS names for endpoint URIs.

**mode** The mode of operation for the OAuth Server. The options for the mode of operation are:

**client** The OAuth Server can be used by OAuth Client agent only. In this mode, you do not need to specify Resource Server credentials.  
**rs** The OAuth Server can be used by OAuth Scope agent only. In this mode, you do not need to specify Client Application credentials.  
**client-rs** The OAuth Server can be used by either OAuth Client or OAuth Scope agent. Client Application credentials and Resource Server credentials are required.

### partition

Displays the partition within which the component resides. The default is Common.

### resource-server-id

Specifies the Resource Server ID. The Resource Server must be

configured before configuring OAuth Server on the BIG-IP system.

**resource-server-secret**  
Specifies the Resource Server Secret. The Resource Server must be configured before configuring OAuth Server on the BIG-IP system.

**resource-serverssl-profile-name**  
SSL profile to be used by the BIG-IP system when connecting to resource server.

**rules**  
The list of iRule events. You can apply an iRule event to modify a request or a response (except an authorization code request from the BIG-IP OAuth client to the OAuth authentication server).

**token-validation-interval**  
Specifies the number of minutes that the token can remain valid. The token becomes invalid when this interval elapses or at the token expiry that the authentication server specifies, whichever is shorter. When the token expires, the subsession times out. (This setting applies only to a per-request policy).

list ocsp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
```

one-line  
partition

DELETE  
delete ocsf [name]

#### DESCRIPTION

To implement the SSL OCSF authentication module, create an OCSF responder object and assign it to the OCSF auth agent in your access policy.

#### OPTIONS

##### allow-certs

Specifies whether the addition of certificates to an OCSF request is enabled. The default is true.

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### ca-file

Specifies the name of the certificate file object containing trusted CA certificates used to verify the signature on the OCSF response. The default is none.

##### ca-path

Specifies the path to the trusted CA certificates used to verify the signature on the OCSF response. The default is none.

##### cert-id-digest

The cert ID digest is part of the OCSF protocol. The OCSF client (in this case, the BIG-IP system) calculates the cert ID using a hash of the Issuer and serial number for the certificate that it is trying to verify. The options are:

sha1 Newer algorithm that provides a higher security level with a 160 bit hash length. This is the default.

md5 Older algorithm with a 128 bit hash length.

##### chain

Specifies whether the system constructs a chain from certificates in the OCSF response. The default is true.

##### check-certs

Specifies whether the LTM system makes additional checks to see if the signer's certificate is authorized to provide the necessary status information. Use this option only for testing purposes. The default is true.

##### explicit-ocsf

Specifies whether the BIG-IP system explicitly trusts that the OCSF response signer's certificate is authorized for OCSF response signing. If the signer's certificate does not contain the OCSF signing extension, setting this option to true causes a response to be untrusted. The default is true.

##### ignore-aia

Specifies whether to ignore the URL contained in the certificate's AIA fields, and to always use the URL specified by the responder instead. The default is false.

##### intern

Specifies whether to ignore certificates contained in an OCSF response when searching for the signer's certificate. When you set this option to true, you must also specify the signer's certificate using either the verify-other or va-file option. The default is true.

##### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

##### [name]

Specifies a unique name for the component. This option is required.

##### nonce

Specifies whether a nonce will be sent in an OCSF request. When set to false, the request is sent without a nonce. The default is true.

##### partition

Displays the partition within which the OCSF responder object resides.

##### sign-digest

Specifies the algorithm (md5 or sha1) used to sign a request using a signing certificate and key. The default is sha1. If you use this option, you must also set the sign-key and sign-key-passphrase options.

##### sign-key

Specifies the key used to sign an OCSF request. If you use this option, you must also set the sign-digest and sign-key-passphrase options. The default is none.

**sign-key-passphrase**  
Specifies the passphrase for the signing key. If you use this option, you must also set the sign-digest and sign-key options. The default is none.

**sign-other**  
Specifies additional certificates to add to an OCSF request. The options are default.crt and ca-bundle.crt. The default is none.

**signer**  
Specifies the certificate used to sign an OCSF request. If the certificate is specified but the key is not specified, then the private key is read from the same file as the certificate. If neither the certificate nor the key is specified, then the request is not signed. If the certificate is not specified and the key is specified, then the configuration is considered to be invalid. The default is none.

**status-age**  
Specifies the amount of time (in seconds) to compare to the notBefore value of a status response. Use this option only when a status response does not include the notAfter field. The default is 0 (zero).

**trust-other**  
Specifies whether the BIG-IP system trusts the certificates specified using the verify-other option. The default is false.

**url** Specifies the URL used to contact the OCSF service on the responder. This option is required. The default is none.

**va-file**  
Specifies the name of the file containing explicitly-trusted responder certificates. Use this option when the responder is not covered by the certificates already loaded into the responder's CA store. The default is none.

**validity-period**  
Specifies an acceptable error range in seconds. Use this option when the OCSF responder clock and a client clock are not synchronized, which could cause a certificate status check to fail. This value must be a positive number. This option is required. The default is 300.

**verify**  
Specifies whether verification of an OCSF response signature or the nonce values is enabled. Use this option only for debugging purposes. The default is true.

**verify-cert**  
Specifies whether the BIG-IP system verifies the certificate in the OCSF response. The default is true.

**verify-other**  
Specifies the name of the file used to search for an OCSF response signing certificate when the certificate has been omitted from the response. The default is none.

**verify-sig**  
Specifies whether the BIG-IP system checks the signature on the OCSF response. Use this option only for testing purposes. The default is true.

## apm aaa radius

**NAME**  
radius - Manages an AAA RADIUS server.

**MODULE**  
apm aaa

**SYNTAX**  
Configure the radius component within the aaa module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create radius [name]  
modify radius [name]

```

options:
  acct-port [integer]
  address [[ip addr] | none]
  auth-port [integer]
  app-service [[string] | none]
  description [[string] | none]
  mode [acct | auth | both]
  nas-ip-address [[ip addr] | none]
  nas-ipv6-address [[ip addr] | none]
  location-specific [true | false]
  pool [[string] | none]
  retries [integer]
  secret [string]
  service-type [default | login | framed | callback-login | callback-framed | outbound | administrative | nas-promp
  timeout [integer]
  use-pool [enabled | disabled]

edit radius [glob] [regex] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list radius
list radius [ [name] | glob | regex ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

DELETE
delete radius [name]

DESCRIPTION
You can use the radius component to create and manage an AAA RADIUS
server.

EXAMPLES
create rad_auth { address 172.30.6.144 secret "test" use-pool
"disabled"}
Creates the AAA RADIUS server named rad_auth that has an IP
address of 172.30.6.144 and has a shared secret of test.

delete radius MyRadiusServer
Deletes the AAA RADIUS server named MyRadiusServer from the
system.

OPTIONS
acct-port
Specifies the port number of the external AAA RADIUS accounting
server. The default is radius-acct.

address
Specifies the IP address of the AAA RADIUS server. This option is
required.

auth-port
Specifies the port number for the service. The default is radius.
This option is required.

app-service
Specifies the name of the application service to which the object
belongs. The default value is none. Note: If the strict-updates
option is enabled on the application service that owns the object,
you cannot modify or delete the object. Only the application
service can modify or delete the object.

description
Specifies a unique description for the AAA RADIUS server. The
default is none.

mode Specifies the configuration mode you want to use for RADIUS
authentication. Note that you cannot modify the mode once you
create the server. The options are:

acct Configures the system to perform only RADIUS accounting. Use
this option to pass accounting information about your users
to the external RADIUS accounting server.

auth Configures the system to perform only RADIUS authentication.
Use this option to authenticate your users through a RADIUS
server.

both Configures the system to perform both RADIUS authentication
and RADIUS accounting simultaneously.

[name]
Specifies the name of an AAA RADIUS server. This option is
required.

nas-ip-address
Specifies an IP address as RADIUS attribute 4 that you can
configure without changing the source IP address in the IP header
of the RADIUS packets. Use this option in situations where you are
using an NAS cluster to be recognized as a single RADIUS client.

nas-ipv6-address
Specifies an IPv6 address as RADIUS attribute 4 that you can
configure without changing the source IP address in the IP header
of the RADIUS packets. Use this option in situations where you are
using an NAS cluster to be recognized as a single RADIUS client.

```

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**partition**  
Displays the partition within which the component resides.

**pool** Specifies the name of the pool to which this server belongs. The default is none.

**retries**  
Specifies the number of times the BIG-IP system tries to make a connection to the RADIUS AAA server after the first attempt fails. The default is 3.

**secret**  
Specifies the shared secret password of the AAA RADIUS server. This option is required.

**service-type**  
Specifies the type of service used for the RADIUS server. The default is default, which behaves as authenticate-only.

**timeout**  
Specifies a timeout interval (in seconds) for the AAA RADIUS server after which the server closes a connection. The default is 5.

**use-pool**  
Enables or disables the use of the pool specified using the pool option. The default is none.

## apm aaa saml-idp-automation

**NAME**  
saml-idp-automation - Specify SAML IdP automation configuration used to automate creation and management of 'IdP Connectors' from the remotely published metadata file(s).

**MODULE**  
apm aaa

**SYNTAX**  
Configure the saml-idp-automation component within the aaa module using the syntax shown in the following sections.

```
CREATE/MODIFY
create saml-idp-automation [name]
modify saml-idp-automation [name]
options:
  aaa-saml-server [string]
  app-service [[string] | none]
  connection-properties [add | delete | modify | none | replace-all-with] {
    name [string] {
      app-service [[string] | none]
      dns-resolver-name [[string] | none]
      serverssl-profile-name [[string] | none]
    }
  }
  description [[string] | none]
  frequency [integer]
  idp-matching-source [string]
  idp-obj-name-tag [string]
  metadata-matching-tag [string]
  metadata-urls {
    [string]
  }
}

edit saml-idp-automation [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```

DISPLAY
list saml-idp-automation
list saml-idp-automation [ [ [name] | [glob] | [regex] ] ... ]
show running-config saml-idp-automation
show running-config saml-idp-automation [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

```

```

DELETE
delete saml-idp-automation [name]

```

#### DESCRIPTION

You can use saml-idp-automation to create and manage SAML IdP automation objects that are used to automate creation and management of 'IdP Connectors' from the remotely published metadata files.

#### EXAMPLES

```

create saml-idp-automation my_idp_automation1 { aaa-saml-server
my_saml_sp frequency 60 idp-matching-source "${session.server.idpname}"
metadata-matching-tag IdpName idp-obj-name-tag displayname metadata-
urls add { https://f5.com/metadata.xml } connection-properties add {
cp1 { dns-resolver-name myResolver serverssl-profile-name serverssl } }
}

```

Creates a SAML IdP automation object named my\_idp\_automation1 bound to a SAML SP service my\_saml\_sp with frequency set to 60 minutes, idp-matching-source as \${session.server.idpname}, metadata-matching-tag as IdpName, idp-obj-name-tag as displayname, one entry for metadata-url as https://f5.com/metadata.xml and connection-properties with dns-resolver-name as myResolver and serverssl-profile-name as serverssl.

```

list saml-idp-automation
Displays a list of SAML IdP automation objects.

```

```

delete saml-idp-automation my_idp_automation1
Deletes the my_idp_automation1 SAML IdP automation object.

```

#### OPTIONS

**aaa-saml-server**  
Specifies the AAA SAML server to which the IdP connectors created by this automation are bound.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**connection-properties**  
Specifies the connection properties for fetching the metadata files. dns-resolver-name specifies the DNS resolver object to be used and serverssl-profile-name specifies the SSL profile to be used by the BIG-IP system when connecting to the server. Both DNS resolver and SSL profile should be configured if metadata files are located behind an SSL protected endpoint.

**description**  
Specifies the description for the IdP automation object.

**frequency**  
The frequency in minutes at which APM polls the IdP metadata files and updates the IdP connectors and bindings to the specified AAA SAML server. The default value is 60.

**idp-matching-source**  
Specifies the selection criteria for IdP connectors. It must be in session variable format. It is used in configuration as a 'matching source' when binding created IdP connectors to configured AAA SAML server. At runtime, the value of this session variable is compared to metadata-matching-tag to determine which IdP connector is used to authenticate user.

**metadata-matching-tag**  
This value is used in combination with idp-matching-source. It is used in configuration as a 'matching value' when binding created IdP connectors to configured AAA SAML server. At runtime, this value is compared against the value of session variable idp-matching-source to determine which IdP connector is used to authenticate user.

**idp-obj-name-tag**  
Specifies the name of a tag within the metadata file that contains a value that APM includes in the names of the created IdP connectors.

**metadata-urls**  
Specifies a list of one or more URLs containing the metadata files.

show running-config saml-idp-connector  
show running-config saml-idp-connector [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
app-service  
non-default-properties  
one-line  
partition  
  
**DELETE**  
delete saml-idp-connector [name]

**DESCRIPTION**  
You can use the saml-idp-connector to create and manage saml idp connectors.

**EXAMPLES**  
create saml-idp-connector my\_idp\_connector { import-metadata  
/shared/tmp/meta\_data\_idp.xml}  
Creates saml idp connector named my\_idp\_connector from metadata.  
In this example "/shared/tmp/meta\_data\_idp.xml" is a file  
containing saml identity provider metadata.  
  
create saml-idp-connector my\_idp\_connector1 { entity-id  
"https://www.secureauth.com/dom1" identity-location subject sso-binding  
http-post sso-uri "https://www.secureauth.com/dom1/acs/" idp-  
certificate my\_company.crt}  
Creates a saml idp connector named my\_idp\_connector1 with  
certificate "my\_company.crt" with identity-location "subject".  
  
list saml-idp-connector  
Displays a list of saml idp connectors.  
  
delete saml-idp-connector my\_idp\_connector  
Deletes the my\_idp\_connector saml idp connector.

**OPTIONS**  
app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### artifact-resolution-service-addr

Specifies the IP address that this BIG-IP as SP will use to connect to the IdP artifact resolution service. Value must be a valid IPv4 or IPv6 address.

#### artifact-resolution-service-port

Specifies the port that this BIG-IP as SP will use to connect to the IdP artifact resolution service.

#### artifact-resolution-service-url

Specifies the URI of the IdP artifact resolution service. The URI must include protocol, hostname, and full path.

#### basic-auth-password

Specifies the password for basic authentication. When configured, basic authentication is used for the artifact resolve request sent to the IdP.

#### basic-auth-username

Specifies username for basic authentication. When configured, basic authentication is used for the artifact resolve request sent to the IdP.

#### description

Specifies a unique description for the saml idp connector. The default is none.

#### entity-id

Specifies unique URI to represent the IdP pointed by idp connector.

#### identity-location

Specifies location of user identity inside SAML assertion. It can be either one of the attributes or the subject.

#### identity-location-attribute

If the location of user identity is set to attribute then attribute name should be specified as part of this attribute.

#### idp-certificate

This is IdP's certificate and is used by BIG-IP as SP to verify the signature of the assertion.

#### import-metadata

This attribute specifies the metadata file from an external IdP system used for creating idp connector object.

For example: create saml-idp-connector my\_idp\_connector { import-metadata /shared/tmp/meta\_data\_idp.xml}

#### location-specific

Objects of this class might have location specific attribute(s). Admin can indicate if object is location specific by setting it to true.

#### metadata-cert

This specifies the certificate to use to verify the signature of metadata imported from a file.

For example: create saml-idp-connector my\_idp\_connector2 {import-metadata /shared/tmp/meta\_data\_signed\_idp.xml metadata-cert default.crt}

#### name-qualifier

Specifies the security or administrative domain of the external IdP. This value usually matches IdP Entity ID.

#### serverssl-profile-name

Specifies the SSL profile used when this BIG-IP as SP connects to the IdP artifact resolution service.

#### sign-artifact-resolution-rq

Specifies whether the IdP requires artifact resolve requests to be signed. Default value is true.

#### single-logout-binding

This attribute is reserved for future functionality.

#### single-logout-response-uri

A URI where this BIG-IP as SP will send single logout (SLO) responses.

#### single-logout-uri

A URI where this BIG-IP as SP will send single logout (SLO) requests.

#### sso-binding

This specifies the method the IdP uses to receive authentication request from BIG-IP as SP. Default value is http-post

#### sso-uri

This specifies the URL of IdP's SSO service where BIG-IP as SP sends an authentication request to IdP.

#### want-authn-request-signed

This property specifies whether IdP requires signed authentication request. Set it to true if this BIG-IP as SP is required to send signed authentication request to IdP. Default value is false.

want-detached-signature  
This property specifies signature type for messages sent by BIG-IP  
via HTTP Redirect binding. To use detached signatures set this  
property to true. Enveloped signatures are used by default.

options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE  
delete saml [name]

#### DESCRIPTION

You can use the saml component to create and manage saml aaa servers.

#### EXAMPLES

```
create saml my_saml_server { entity-id "https://spvs1.mycompany.com/id"
  want-assertion-signed true want-assertion-encrypted false is-authn-
  request-signed true sp-certificate my_company.crt sp-signkey
  my_company.key}
Creates a SAML authentication server named my_saml_server with
certificate my_company.crt and key my_company.key and security
options requiring signed assertion and want to send signed
authentication request.
```

```
list saml
Displays a list of aaa saml servers.
```

```
delete saml my_saml_server
Deletes the my_saml_server aaa saml server.
```

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### assertion-consumer-binding

Specifies method this BIG-IP as SP uses to receive assertions. Default value is http-post.

##### attribute-consuming-services

Add one or more attribute consuming services to this SP service. Each attribute consuming service is mapped to a unique attribute-consuming-service-index. The attribute consuming services added for this SP will be part of the metadata for the SP that can be exported and shared with IdP.

For example:

The following command associates two attribute consuming services to an SP and maps the first service to index 1 and the second service to index 2.

```
modify saml my_saml_server attribute-consuming-services add { my_atcs1 { attribute-consuming-service-index 1 } my
```

##### auth-context-class-list

Specifies an ordered list of authentication context classes. The BIG-IP as SP uses this list to validate the authentication context (in the assertion from the IdP) against locally configured context methods (auth-context-methods) using the specified comparison method (auth-context-comparison-method).

This property is required if you use a comparison method (auth-context-comparison-method) other than the default ('exact'). You can specify any auth-context-class-list list that you have configured on the BIG-IP system. Or, you can specify the predefined auth-context-class-list list (authentication\_contexts\_list) that the BIG-IP system provides.

##### auth-context-comparison-method

Specifies the comparison method that the IdP must use to evaluate the requested context classes auth-context-methods, one of "exact", "minimum", "maximum", or "better". The default is exact. If non-default comparison method is configured, all context classes from auth-context-methods must be present in the configured priority list of classes auth-context-class-list.

##### auth-context-methods

Specifies a list of authentication context classes that this BIG-IP as SP will request from an IdP. As a response, the IdP must return an assertion containing one of the requested authentication contexts. Each value can be a session variable if the comparison method is set to 'exact', which is the default value.

##### default-attribute-consuming-service

Specifies one of the attribute consuming services associated with this SP as default service. The metadata for the SP will flag specified service as default.

##### description

Specifies a unique description for the server. The default is none.

##### entity-id

Specifies a unique identifier for BIG-IP as SP. Typically 'entity-id' is a URI that points to the BIG-IP virtual server that is going to act as SAML SP. In case 'entity-id' is not a valid URL, the sp-host attribute is required. Examples of valid configuration include "https://mycompany-sp", "sp:my:company", and "sp.my.company.com".

##### force-authn

If enabled, this BIG-IP as SP requests the IdP to authenticate the principal directly rather than rely on a previous security context.

##### export-metadata

You can simplify SAML configuration using metadata files. When you use BIG-IP as an SP, you can export metadata for an SP to a file.

Then you can use the file to configure SP metadata on an IdP system by importing the file or using the information in the file to configure the SP. You can choose to sign metadata while exporting it for better security.

For example:

1. Exporting metadata with signing. This requires metadata-cert and metadata-signkey files.

```
modify saml aaa_obj {export-metadata with-signing metadata-file /shared/sp_signed_metadata.xml metadata-cert defa
```

2. Exporting metadata with no signing.

```
modify saml aaa_obj {export-metadata no-signing metadata-file /shared/sp_metadata.xml}
```

#### idp-connectors

Add one or more IdP connectors to this SP service. BIG-IP SP redirect users to associated IdPs for authentication. If more IdP connectors associated with the SP, BIG-IP SP selects one of the IdP based on the specified selection criteria.

For example:

1. The following command associates one IdP connect to an SP

```
modify saml my_saml_server idp-connectors add { my_idp_connector1 }
```

2. Following associates multiple IdP connectors to SP with selection criteria based on landing URI. If the landing URI is /google, the user is sent to IdP as specified by my\_idp\_connector\_google\_app and if the landing URI is /salesforce, the user is sent to IdP as specified by my\_idp\_connector\_for\_salesforce.

```
modify saml my_saml_server idp-connectors add { my_idp_connector_google_app { idp-matching-source "%{session.serv
```

#### is-authn-request-signed

This property specifies whether the SP signs authentication requests while sending them to the IdP. Set it to true if this BIG-IP SP should sign authentication requests. The default value for this is false.

#### location-specific

Objects of this class might have location specific attributes. Admin can indicate if object is location specific by setting it to true.

#### metadata-cert

Specifies the certificate with public key of the key pair used in signing the metadata. See export-metadata for more information on metadata export functionality. This is the certificate to be included in signed metadata when we export metadata. This might or might not be SP certificate.

#### metadata-file

Specifies the file to which metadata is saved. See export-metadata for more information on metadata export functionality.

#### metadata-signkey

Specifies the key that is used to sign SP's metadata. See export-metadata for more information on metadata export functionality.

#### name-id-policy-allow-create

A Boolean value used to indicate whether external IdP is allowed, when processing requests from this BIG-IP as SP, to create a new identifier to represent the principal. Default value is false

#### name-id-policy-format

A URI reference representing the classification of string-based identifier information. For example, if a Service Provider (SP) initiates SSO by sending an AuthnRequest to the IDP with format "urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress", then the IDP response should contain subject identity in email format. This attribute can be a session variable.

#### name-id-policy-sp-name-qualifier

Optionally specifies that the assertion subject's identifier be returned in the namespace of an SP other than the requester, or in the namespace of a SAML affiliation group of SPs. This attribute can be a session variable.

#### relay-state

Specifies the value where the BIG-IP as SP redirects users after they are successfully authenticated and have been allowed by access policy. When BIG-IP receives the relay state from the IdP in addition to assertion, then it uses the value received from IdP to redirect the user to after authentication. Otherwise, BIG-IP uses the value from this configuration.

#### provider-name

Optionally specifies the human-readable name of this SAML SP for use by the identity provider.

#### sp-certificate

BIG-IP includes this certificate in the SAML SP metadata that you export. After the SAML SP metadata is imported on the IdP, the IdP can use this certificate to verify signed authentication request and to encrypt assertion.

#### sp-host

Hostname of this BIG-IP as SP. This attribute is required when "entity-id" is not a valid URL.

sp-scheme  
Scheme used by this BIG-IP as SP. This attribute is only used when sp-host is not empty. Default value is https.

sp-signkey  
This specifies the private key used to sign authentication requests if "is-authn-request-signed property" is set to true or to decrypt assertions when "want-assertion-encrypted" is set to true.

want-assertion-encrypted  
This property specifies whether SP requires encrypted assertions. Set it to true if this BIG-IP SP requires encrypted assertions from the SAML IdP. The default value for this is false.

want-assertion-signed  
This property specifies whether SP requires signed assertions. Set it to true if this BIG-IP SP requires signed assertions from the SAML IdP. The default value for this is true.

## apm aaa securid

NAME  
securid - Manages an RSA SecurID authentication server.

MODULE  
apm aaa

SYNTAX  
Configure the securid component within the aaa module using the syntax shown in the following sections.

```
CREATE/MODIFY
create securid [name]
modify securid [name]
options:
  app-service [[string] | none]
  config-files [[string] | none]
  description [[string] | none]
  location-specific [true | false]
  source-ip [ip addr]

edit securid [ [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list securid
list securid [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

DELETE
delete securid [name]
```

DESCRIPTION  
You can use the securid component to create and manage an RSA SecurID authentication server.

EXAMPLES  
create securid mySecuridServer { config-files add { sdconf.rec { local-path /shared/tmp/1 } } source-ip 172.31.54.138 }  
Creates the mySecuridServer AAA RSA SecurID server.

list securid all  
Displays a list of AAA RSA SecurID servers on the system.

delete securid mySecuridServer  
Deletes the mySecuridServer AAA RSA SecurID server from the system.

OPTIONS  
app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### config-files

Specifies which files to use for SecurID authentication. Upload a copy of the sdconf.rec file from your RSA Authentication Manager server.

#### description

Specifies a description for the configuration file you are uploading.

#### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

#### source-ip

Specifies the source IP address of the RSA SecurID agent. This option is required when authenticating to the RSA Authentication Manager server.

#### partition

Displays the partition within which the component resides.

#### SEE ALSO

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## apm aaa tacacsplus

#### NAME

tacacsplus - Configure a TACACS+ server for implementing remote TACACS+-based client authentication.

#### MODULE

apm aaa

#### SYNTAX

Configure the tacacsplus component within the apm aaa module using the syntax shown in the following sections.

#### CREATE/MODIFY

create tacacsplus

modify tacacsplus

#### options:

address [ip addr]

auth-service [arap | enable | fwproxy | login | nasi | none | ppp | pt | rcmd | x25]

auth-type [arap | ascii | chap | mschap | pap]

app-service [[string] | none]

description [[string] | none]

encrypt [enabled | disabled]

location-specific [true | false]

pool [[string] | none]

port [[string] | none]

priv-lvl [max | min | user]

protocol [atalk | deccp | ftp | http | ip | ipx | lat | lcp | osicp | pad | rlogin | telnet | tn3270 | unknown | v

secret [[string] | none]

service [none | arap | connection | firewall | ppp | shell | slip | system | tty-daemon]

use-pool [[string] | none]

edit tacacsplus [ [glob] | [regex] ] ... ]

#### options:

all-properties

non-default-properties

#### DISPLAY

list tacacsplus

list tacacsplus [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE  
delete tacacsplus [name]

#### DESCRIPTION

You can use the tacacsplus component to create and manage a TACACS+ authentication server.

#### EXAMPLES

create tacacsplus mytacacs auth-service enable encrypt enabled  
Creates a TACACS server named mytacacs with encryption enabled.

#### OPTIONS

address  
Specifies the IP address of the TACACS+ server. This option is required.

auth-service  
Specifies the name of the service that the user is requesting to be authenticated to use. This enables the TACACS+ server to behave differently for different types of authentication requests. This option is required.

auth-type  
Specifies the type of authentication to be used for authenticating the user.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description  
Specifies a unique description for the component. The default is none.

encrypt  
Enables or disables encryption of TACACS+ packets. Recommended for normal use. The default is enabled.

location-specific  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]  
Specifies the name of an AAA TACACS+ server. This option is required.

partition  
Displays the partition within which the component resides.

pool  
Specifies the name of the pool to which this server belongs. The default is none.

port  
Specifies the port number of the server. The default is 49.

priv-lvl  
Specifies the privilege level at which the user is authenticating. The options are:

max  
min This is the default.

user  
protocol  
Specifies the protocol associated with the value specified in the service option, which is a subset of the associated service being used for client authorization or system accounting. The default is unknown.

secret  
Sets the secret key used to encrypt and decrypt packets sent or received from the server. This option is required.

service  
use-pool  
Enables or disables the use of the pool specified using the pool option. The default is none.

## apm access-info

### NAME

access-info - Shows session related information such as session id, client ip, logon user and access profile name.

### MODULE

apm access-info

### SYNTAX

Shows the access-info component using the syntax shown in the following sections.

#### DISPLAY

show access-info

options:

all-properties

save-to-file

show access-info all

show access-info logon-user username

show access-info client-ip ip-address

### EXAMPLES

show access-info

Displays the session id, client ip and logon user.

show access-info logon-user username

Displays the session id, and the corresponding client ip.

show access-info client-ip ip-address

Displays the session id and the corresponding logon user.

show access-info all-properties

The output of this command looks like this:

session	session id
partition	partition Name
status	status of the session such as established and active
logon-user	username
client-ip	client ip address
virtual-server	virtual server name
profile-access-type	profile access type
access-profile	access profile name
start-time	start time of the session
expiration-time	expiration time of the session
rx-bytes	session traffic bytes in
tx-bytes	session traffic bytes out
rx-packets	session traffic packets in
tx-packets	session traffic packets out
ingress-raw	ingress raw bytes
ingress-compressed	ingress compressed bytes
egress-raw	egress raw bytes
egress-compressed	egress compressed bytes
slot	slot number (applicable only in the cluster environment)
tmm	tmm number for the session

Displays the session id, client ip, logon user and other information of session as shown above.

### OPTIONS

session

Specifies the session id.

partition

Specifies the virtual server partition name.

status

Specifies the access status and valid values are established or pending.

logon-user

Specifies the logged in user name for the session.

client-ip

Specifies the client IP from which the session is established.

virtual-server

Specifies the name of the virtual server to which the session is established.

profile-access-type

Specifies access profile type; examples of valid values are: all, ltm-apm, ssl-vpn, sso, swg-explicit and swg-transparent.

access-profile

Specifies the access profile name.

start-time

Specifies the start time of the session.

expiration-time

Specifies the expiration time of the session.

rx-bytes)

Specifies the traffic bytes in for the session.

tx-bytes)

Specifies the traffic bytes out for the session.

rx-packets  
Specifies the traffic packets in for the session.

tx-packets  
Specifies the traffic packets out for the session.

ingress-raw  
Specifies the ingress raw bytes for the session.

ingress-compressed  
Specifies the ingress compressed bytes for the session.

egress-raw  
Specifies the egress raw bytes for the session.

egress-compressed  
Specifies the egress compressed bytes for the session.

slot Specifies the slot number for the session. Applicable only in the cluster environment.

tmm Specifies the tmm number that holds the session.

SEE ALSO

apm session

## apm acl

NAME

acl - Manages an access control list (ACL).

MODULE

apm

SYNTAX

Configure the acl component within the apm module using the syntax shown in the following sections.

```
CREATE/MODIFY
create acl [name]
modify acl [name]
options:
  acl-order [integer]
  app-service [[string] | none]
  description [[string] | none]
  entries {
    {
options:
  action [allow | continue | discard | reject | unspec]
  dst-end-port [[service] | none]
  dst-start-port [[service] | none]
  dst-subnet [[ip addr] | [[ip addr] [mask]]
  host [[string] | none]
  log [config | none | packet | summary | verbose]
  paths [[string] | none]
  protocol [integer]
  scheme [any | http | https]
  src-end-port [[service] | none]
  src-start-port [[service] | none]
  src-subnet [[ip addr] | [[ip addr] [mask]]
    }
  }
  location-specific [true | false]
  path-match-case [false | true]
  type [dynamic | static]

DISPLAY
list acl
list acl [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show acl
show acl [ [ [name] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
```

field-fmt

DELETE  
delete acl [name]

#### DESCRIPTION

You can use the acl component to configure a set of restrictions associated with a resource or favorite that defines access for users and groups.

#### EXAMPLES

```
create acl MyACL { acl-order 3 entries src-start-port ip default inet
dst-end-port ip default inet action allow }
Creates the static access control list named MyACL that is the
third ACL in the list of ACLs in the visual policy editor, and
adds an access control entry that allows traffic using the default
source IP address and the default destination IP address.
```

```
list acl all-properties
Displays a list of ACLs that includes the attributes of each ACL.
```

```
delete acl MyACL
Deletes the MyACL access control list.
```

#### OPTIONS

acl-order  
Specifies the order of the access control entries in this access control list. This option is required.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description  
Describes the access control list.

entries  
Configures an entry for an access control list.

action  
Specifies the action that an access control list takes when this access control list entry is encountered. This option is required. You can specify one of the following actions:

allow  
Allows traffic.

continue  
Skips checking against the remaining access control list entries in this access control list, and continues evaluation at the next access control list.

discard  
Drops packets silently.

reject  
Drops a packet and sends TCP RST on TCP flows or proper ICMP messages on UDP flows. Silently drops a packet on other protocols.

dst-end-port  
Specifies the destination IP address and network mask of the access control list entry. The default is 0.

dst-start-port  
Specifies the source port or range of ports of the access control list entry.

dst-subnet  
Specifies the destination subnet.

host Specifies the host name of the access control list entry.

location-specific  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

log Specifies the log level that is logged when actions of this type occur. Your options are:

config  
Logs the configuration of a matched entry.

none Logs nothing. This is the default value.

packet  
Logs a matched packet.

summary  
Logs the name and entry number of a matched access control list and access control list entry.

verbose  
Logs everything.

**paths**  
Specifies an L7 access control list of matching URL paths.

**protocol**  
Specifies the protocol number (TCP=6, UDP=17) of the access control list entry. The default is 0.

**src-end-port**  
Specifies the source IP address and network mask of the access control list entry.

**src-start-port**  
Specifies the source port or range of ports of the access control list entry.

**src-subnet**  
Specifies the source subnet.

**[name]**  
Specifies the name of the access control list. This setting is required.

**partition**  
Displays the partition within which the object resides. The default is Common.

**path-match-case**  
Indicates whether the path is case sensitive. The default is true.

**type** Specifies the type of access control list. The default is static. The available types are static and dynamic.

SEE ALSO

## apm apm-avr-config

**NAME**  
apm-avr-config - Configures AVR overview/statistics settings for Secure Web Gateway Functionality

**MODULE**  
apm

**SYNTAX**  
Configure an apm-avr-config component within the apm module using the syntax shown in the following sections.

**MODIFY**  
The AVR Configuration consists of the following information: boolean flag to turn off data collection by AVR; Boolean flag to turn off sampling by AVR; Both are on by default. No create or delete function is allowed.

```
modify apm-avr-config apm-avr-config {
    avr-collect-data [true | false]
    avr-sampling [true | false]
}
```

**DISPLAY**  
list apm-avr-config  
list apm-avr-config [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DESCRIPTION**  
Configures AVR Configuration for SWG Statistical Reporting

**EXAMPLES**  
modify apm-avr-config apm-avr-config { avr-collect-data false }  
  
Modify apm-avr-config by setting avr collect data to false.

**OPTIONS**  
avr-collect-data  
Specifies whether data should be collected or not for statistical reporting.  
  
avr-sampling

Specifies whether sampling should be turned on or off.

BIG-IP 2014-02-18 apm apm-avr-config(1)

---

## apm client image

#### NAME

image - Manages APM client software images.

#### MODULE

apm client

#### SYNTAX

Install, display information about, or delete a software image using the syntax in the following sections.

##### INSTALL

list image [name]

##### DISPLAY

list image

list image [ [ [ name [/slot\_id] ] | [glob] | [regex] ] ... ]

##### options:

checksum

config-source

file-size

last-modified

one-line

##### DELETE

delete image [ [ [name] ... ] | [all] ]

#### DESCRIPTION

You can use the image component to install images, view information about available images, or delete unwanted images.

##### INSTALLING A SOFTWARE IMAGE

Before you begin installing an image, you must download the image file into the /shared/apm/images directory. You can find new software images at <http://downloads.f5.com>. We recommend downloading both the .iso file and the .md5 file. Download the file (or files) to your local machine, then transfer it to the /shared/apm/images directory on the BIG-IP. Use the Manager (GUI) interface to make this transfer, or quit tmsh to the Unix command line and use scp or a similar Unix command.

If you downloaded the .md5 file, you can use the Unix md5sum command to check the MD5 hash of the .iso file, and you can compare it to the contents of the .md5 file. They should match. If they do not, retry the download and/or transfer of the .iso file.

Use the install command with this component to install the .iso file.

Note: You use the slot\_id option only for chassis systems and only when displaying the values for the options of a specific image. You do not use the slot\_id option when installing or deleting an image, because these commands operate on all blades or the entire system.

#### EXAMPLES

list image apmclients-13.0.0-1914.0.iso

Displays information about the specified image, apmclients-13.0.0-1914.0.iso.

list image \*/1

Displays information about all of the images located on the first slot.

install image apmclients-13.0.0-1914.0.iso

Attempts to install the specified image, apmclients-13.0.0-1914.0.iso.

delete image apmclients-13.0.0-1914.0.iso

Removes the specified image, apmclients-13.0.0-1914.0.iso from /shared/apm/images directory.

#### OPTIONS

checksum

Displays the checksum of the image. You can use this option to verify the integrity of the image.

config-source

Displays the source of the image: "user" or "base".

file-size  
Displays the size of the image file in megabytes.

last-modified  
Displays the date the file was last modified.

name Specifies the name of the image that you want to install or delete.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### SEE ALSO

delete, glob, install, list, regex, tmsh, show

#### COPYRIGHT

## apm configuration captcha

#### NAME

captcha - Manages CAPTCHA version 2 configuration

#### MODULE

apm configuration

#### SYNTAX

Configure the captcha component within the configuration module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create captcha [name]
modify captcha [name]
options:
  captcha-data-size [data-size-compact | data-size-normal]
  captcha-data-theme [data-theme-dark | data-theme-light]
  captcha-data-type [data-type-audio | data-type-image]
  captcha-theme [theme-red | theme-white | theme-blackglass | theme-clean | theme-custom]
  challenge-url [string]
  description [string]
  exposition-threshold [integer]
  noscript-url [string]
  private-key [hexadecimal string]
  proceed-on-verification-error [false | true]
  public-key [hexadecimal string]
  secret [hexadecimal string]
  site-key [hexadecimal string]
  track-by-ip [false | true]
  track-by-username [false | true]
  verification-url [string]
```

```
edit captcha [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list captcha
list captcha [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete captcha [name]
```

#### DESCRIPTION

You can use the captcha component to create and manage CAPTCHA configuration.

#### EXAMPLES

```
create captcha mycaptcha {secret 123456789abcdef site-key
fedcba987654321 }
Creates a CAPTCHA version 2 configuration named mycaptcha that
```

uses site secret 123456789abcdef and site key fedcba987654321.

`delete captcha mycaptcha`  
Deletes the CAPTCHA version 2 configuration named mycaptcha from the system.

#### OPTIONS

`captcha-data-size`  
Specifies the size of the reCAPTCHA widget. The default is data-size-normal.

`captcha-data-theme`  
Specifies the color theme of the reCAPTCHA widget. The default is data-theme-light.

`captcha-data-type`  
Specifies the type of CAPTCHA to server. The default is data-type-image.

`captcha-theme`  
This option is specific to reCAPTCHA v1 and is deprecated in version 13.0.0.

`challenge-url`  
Specifies the URL of the service that provides the CAPTCHA challenge. The default is [www.google.com/recaptcha/api.js](http://www.google.com/recaptcha/api.js).

`description`  
Specifies a unique description for the CAPTCHA configuration.

`exposition-threshold`  
Specifies the number of logon attempts to allow before issuing a CAPTCHA challenge. The default is 0.

`noscript-url`  
Specifies the URL to use for obtaining the challenge if JavaScript is disabled. The default is [www.google.com/recaptcha/api/fallback](http://www.google.com/recaptcha/api/fallback).

`private-key`  
This option is specific to reCAPTCHA v1 and is deprecated in version 13.0.0.

`proceed-on-verification-error`  
Specifies whether to allow user access when CAPTCHA verification cannot be completed for some reason. The default is true.

`public-key`  
This option is specific to reCAPTCHA v1 and is deprecated in version 13.0.0.

`secret`  
Specifies the secret provided by the CAPTCHA service provider. This option is required.

`site-key`  
Specifies the site key provided by the CAPTCHA service provider. This option is required.

`track-by-ip`  
Specifies whether to track logon failures using IP address. The default is true.

`track-by-username`  
Specifies whether to track logon failures using username. The default is true.

`verification-url`  
Specifies the URL of the service that verifies the response to the CAPTCHA challenge. The default is [www.google.com/recaptcha/api/siteverify](http://www.google.com/recaptcha/api/siteverify).

#### SEE ALSO

## apm epsec epsec-package

NAME  
epsec-package - Manages an EPSEC package.

MODULE  
apm epsec

**SYNTAX**

Configure the epsec-package component within the apm epsec module using the syntax shown in the following sections.

**CREATE**

```
create epsec-package
options:
  local-path [string]
  server [[string] | none]
```

**DISPLAY**

```
list epsec-package
options:
  all-properties
  non-default-properties
  recursive
```

```
list epsec-package [name]
```

**INSTALL**

```
install epsec-package [name]
options:
  device-group [string]
```

**DELETE**

```
delete epsec-package [name]
```

**DESCRIPTION**

You can use the epsec-package component to create, install and manage an EPSEC package.

**EXAMPLES**

```
create epsec-package my_epsec_package local-path /tmp/my_epsec_package
Creates an EPSEC package named my_epsec_package under the
/Common/EPSEC/Upload folder.
```

```
list epsec-package
Displays a list of EPSEC packages under the specific folder. To
list all EPSEC packages use the recursive option.
```

```
install epsec-package my_epsec_package
Installs the EPSEC package named my_epsec_package on this device.
You cannot install a package from the /Common folder as it is a
pre-installed package.
```

```
install epsec-package my_epsec_package device-group /Common/my_epsec_dg
Installs the EPSEC package named my_epsec_package on the devices
in the device group /Common/my_epsec_dg. You cannot install a
package from the /Common folder as it is a pre-installed package.
```

```
delete epsec-package my_epsec_package
Deletes the EPSEC package named my_epsec_package.
```

**OPTIONS**

[name]  
Specifies the name of the component. This option is required.

local-path  
Specifies the local path of the package to be uploaded. This option is valid only with CREATE command and is a required option.

device-group  
Specifies the device group on which the package will be installed. This option is valid only with INSTALL command

## apm epsec software-status

**NAME**

software-status - Displays the status of the EPSEC software installation.

**MODULE**

apm epsec

**SYNTAX**

Display information about the software-status component within the apm epsec module using the following syntax.

DISPLAY  
show software-status

DESCRIPTION  
You can use the software-status component to display the status of the EPSEC software installation, including the version of the EPSEC package being installed and the OESIS software version.

EXAMPLES  
show software-status

Displays the status of the EPSEC software installation in a table.

OPTIONS  
SEE ALSO  
epsec-package

## apm license

NAME  
license - Shows the session information related to apm license.

MODULE  
apm

SYNTAX  
Displays the apm license information.

DISPLAY  
show apm license

DESCRIPTION  
APM module license is based on the session count depending on the platform. This module shows the total session information for access, ccu (connectivity), swg, swg limited and the currently used sessions for access, ccu, swg, swg limited. In addition, the statistics include the threshold percent for all the sessions.

EXAMPLES  
show apm license

Displays the apm license usage information.

total access sessions  
Total access sessions for BIG-IP. This number is based on the license and platform type.

current active sessions  
The number of access sessions that are currently in use.

current established sessions  
Total number of currently established sessions.

access sessions threshold percent  
Access sessions threshold warning percent set by the user. The default is 75%.

total connectivity sessions  
Total connectivity sessions (ccu) for BIG-IP. This number is based on the license and platform type.

current connectivity sessions  
The number of connectivity sessions (ccu) that are currently in use.

connectivity sessions threshold percent  
Connectivity sessions threshold warning percent set by the user. The default is 75%.

total swg sessions  
Total swg sessions for BIG-IP. This number is based on the subscription-based swg license.

current swg sessions  
The number of swg sessions that are currently in use.

swg sessions threshold percent  
SWG sessions threshold warning percent set by the user. The default is 75%.

total swg limited sessions  
Total swg limited sessions for BIG-IP. This number is based on the license and platform type.

current swg limited sessions  
The number of swg limited sessions that are currently in use.

swg limited sessions threshold percent  
SWG limited sessions threshold warning percent set by the user.  
The default is 75%.

## apm log-setting

#### NAME

log-setting - Configures log configurations for various features in APM, such as URL Filter/Classification (URL Filter).

#### MODULE

apm

#### SYNTAX

Configure the log-setting component within the module using the syntax shown in the following sections.

#### CREATE/MODIFY

Consider log-setting as a container for log configurations belonging to different features. At this time URL Filter is the only feature with a log setting.

```
create log-setting [name]
modify log-setting [name]
options:
  description
  url-filters [add | delete | modify | replace-all-with] {
    [item name] {
      filter { log-allowed-url [true|false] log-blocked-url [true|false] }
      publisher [string]
    }
  }
  access [add | delete | modify | replace-all-with] {
    [item name] {
      log-level {
        access-control [emerg|alert|crit|err|warn|notice|info|debug]
        access-per-request [emerg|alert|crit|err|warn|notice|info|debug]
        apm-acl [emerg|alert|crit|err|warn|notice|info|debug]
        eca [emerg|alert|crit|err|warn|notice|info|debug]
        paa [emerg|alert|crit|err|warn|notice|info|debug]
        sso [emerg|alert|crit|err|warn|notice|info|debug]
        swg [emerg|alert|crit|err|warn|notice|info|debug]
      }
      publisher [string]
    }
  }
```

#### DISPLAY

```
list log-setting
list log-setting [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

#### DESCRIPTION

Configures a container for log configurations.

NOTE: Each container can enclose log configurations for many different features. However, each feature can only have one log configuration in a container.

NOTE: For the log configuration to take effect, the log-setting must be associated with an access profile (See man page for apm access profile).

NOTE: A log-setting container cannot be deleted if it is associated with an access profile.

#### EXAMPLES

```
create log-setting my-log-cfg
```

Creates a container without any log configuration.

```
create log-setting my-log-cfg url-filters add { my-urlf { filter { log-allowed-url true } publisher my-publisher } }
```

Creates a container with a log configuration for the URL Filter feature. At this version, URL Filter is the only feature with a log configuration.

```
modify log-setting my-log-cfg url-filters modify { my-urlf { publisher my-other-publisher } }
```

Modify the publisher of a log configuration.

```
modify log-setting my-log-cfg url-filters modify { my-urlf { filter { log-allowed-url false } } }
```

Modify the setting of a log filter

```
create log-setting my-log-cfg access add { my-access { publisher my-publisher } }
```

Creates a container with a log configuration for APM logging.

```
modify log-setting my-log-cfg access modify { my-access { log-level { access-control debug } } }
```

Modify the log level for module access-control.

#### OPTIONS

description

Specifies a unique description for the log-setting container.

url-filters

This is the list to store log configurations for the URL Filter feature.

item name

Specifies the name of the log configuration to be added to the list url-filters. Currently, the list supports only one item.

filter

Specifies the value for different log filters. In particular, URL Filter log configuration has two filters:

```
log-allowed-url [true|false]
log-blocked-url [true|false]
```

publisher

Specifies the publisher of the log configuration. See sys log-config publisher.

access

This is the list to store log configurations for APM logging.

log-level

This is the list of log level settings for different modules in the APM family.

#### SEE ALSO

apm profile access and sys log-config

## apm ntlm machine-account

#### NAME

machine-account - Configures an APM NTLM machine account object.

#### MODULE

apm ntlm

#### SYNTAX

Configure the ntlm machine account using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create machine-account [name]
```

##### options:

```
action [noop]
administrator-name [[string] | none]
administrator-password [[string] | none]
app-service [[string] | none]
```

```

    domain-controller-fqdn [fqdn]
    domain-fqdn [fqdn]
    machine-account-name [[string] | none]

modify machine-account [name]
options:
    action [change-password | noop]
    app-service [[string] | none]
    domain-controller-fqdn [fqdn]

edit machine-account [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list machine-account
list machine-account [ [ [name] | [glob] | [regex] ] ... ]

DELETE
delete machine-account [name]

```

#### DESCRIPTION

You can use the machine-account component to configure a NTLM machine account.

#### EXAMPLES

```

create machine-account myaccount { machine-account-name
    "my_account_name" domain-fqdn "company.com" domain-controller-fqdn
    "server01.company.com" administrator-name "administrator"
    administrator-password "!My123Password" }
Creates a NTLM machine account named myaccount in the company.com
domain, with domain controller server01.company.com, administrator
name administrator and administrator password !My123Password.

```

```

list machine-account
Displays a list of all NTLM machine accounts created on the
system.

```

```

delete machine-account myaccount
Deletes the NTLM machine account named myaccount the system.

```

#### OPTIONS

**machine-account-name**  
Specifies the name of the machine account.

**domain-fqdn**  
Specifies the Fully Qualified Domain Name. This setting is required.

**domain-controller**  
Specifies the Fully Qualified Domain Name (FQDN) of the domain controller for the domain specified in the domain-fqdn option. The default is none.

**administrator-name**  
Specifies the name of a user that has administrative permissions on an Active Directory server. This setting is required only when a new machine account is being created.

**administrator-password**  
Specifies the password associated with administrator-name. This setting is required only when a new machine account is being created.

**action**  
Specifies the action type. To change the machine account password, type this action: change-password else noop

**change-password**  
Specifies that you want to change the machine account password.

**noop** Specifies "no operation performed". This is the default.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### SEE ALSO

ntlm-auth

#### COPYRIGHT

## apm ntlm ntlm-auth

**NAME**  
ntlm-auth - Configures an APM NTLM authentication object.

**MODULE**  
apm ntlm

**SYNTAX**  
Configure the ntlm-auth using the syntax shown in the following sections.

**CREATE/MODIFY**  
create ntlm-auth [name]  
options:  
  app-service [[string] | none]  
  dc-fqdn-list [add | delete | modify | replace-all-with] {  
  [[string]]  
  }  
  machine-account-name [[string] | none]  
modify ntlm-auth [name]  
options:  
  app-service [[string] | none]  
  dc-fqdn-list [add | delete | modify | replace-all-with] {  
  [[string]]  
  }  
  machine-account-name [[string] | none]  
edit ntlm-auth [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

**DISPLAY**  
list ntlm-auth  
list ntlm-auth [ [ [name] | [glob] | [regex] ] ... ]

**DELETE**  
delete ntlm-auth [name]

**DESCRIPTION**  
You can use the ntlm-auth component to configure an NTLM authentication object.

**EXAMPLES**  
create ntlm-auth myaccount { dc-fqdn-list add { server01.company.com }  
  machine-account-name "my\_account" }  
Creates a NTLM authentication object named myaccount with machine account my\_account, and the list of domain controllers specified by dc-fqdn-list  
  
list ntlm-auth  
Displays a list of all NTLM authentication objects created on the system.  
  
delete ntlm-auth myaccount  
Deletes the NTLM authentication object named myaccount from the system.

**OPTIONS**  
dc-fqdn-list  
Specifies a list of Fully Qualified Domain Names (FQDNs) for the domain controllers to use for NTLM authentication.  
  
machine-account-name  
Specifies the NTLM machine account object name to use for this NTLM authentication  
  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**SEE ALSO**  
machine-account

**COPYRIGHT**

## apm oauth db-instance

**NAME**

db-instance - Manages various OAuth database instances for this partition.

**MODULE**

apm oauth

**SYNTAX**

Configure the db-instance component within the oauth module using the following syntax.

**CREATE/MODIFY**

```
create db-instance [name]
modify db-instance [name]
options:
  app-service [[string] | none]
  description [[string] | none]
  purge-frequency [daily | hourly | monthly | never | weekly]
  purge-now
  purge-time [string]
edit db-instance [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

**DISPLAY**

```
list db-instance
list db-instance [ [ [name] | [glob] | [regex] ] ... ]
show running-config db-instance
show running-config db-instance [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

**DELETE**

```
delete db-instance [name]
```

**DESCRIPTION**

OAuth authorization server supports persistence for OAuth tokens and related data using on-disk databases. This data can be grouped into separate logical entities using database instances. The db-instance component can be used to manage such database instances within a partition.

Because disk size is a limited resource, expired/obsolete tokens need to be purged in order to make space for newly issued tokens. The db-instance component provides options to purge either periodically, using combination of purge-frequency and purge-time or on-demand, using purge-now. The default setting for purge-frequency is daily and for purge-time is 02:00 hours for a newly created database instance. When executed, database instance purging removes revoked, expired access tokens, refresh tokens, auth code and associated entries from the particular instance. Expired access tokens will not be removed if the reuse-access-token setting is enabled in the corresponding OAuth profile.

**EXAMPLES**

```
create db-instance myDbInstance {
description "Sales Team"
purge-frequency weekly
purge-time "00:00"
}
```

Creates a database instance named myDbInstance that, when associated with an OAuth profile, stores tokens related to the OAuth profile in a separate database. This database instance is for the Sales team within the company. Stored data is purged weekly at 12AM.

```
list db-instance
```

Displays a list of all DB instances on the Authorization server.

```
delete db-instance myDbInstance
```

Deletes the database instance myDbInstance.

**OPTIONS**

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**db-name**

Specifies the actual name of the DB on BIG-IP. The value is unique for each DB instance and can be used to debug oauth DB interactions with BIG-IP storage.

**description**

Specifies a user-defined description for the database instance. The default value is none.

[name]  
Specifies the name of the OAuth database instance. This setting is required.

partition  
Displays the partition within which the component resides.

purge-frequency  
Specifies the frequency at which data should be purged. The default value is daily. Other possible values are hourly, monthly, never and weekly.

purge-now  
Indicates a request to purge the data right now.

purge-time  
Specifies the time at which data should be purged. The default value is 02:00. HH:MM format must be used to specify time value.

## apm oauth jwk-config

NAME

jwk-config - Manages JSON Web Keys to be used with Authorization Server/Client/Resource Server

MODULE

apm oauth

SYNTAX

Configure the jwk-config component within the oauth module using the following syntax.

CREATE/MODIFY

create jwk-config [name] modify jwk-config [name]

options:

alg-type [none | HS256 | HS384 | HS512 | RS256 | RS384 | RS512 | ES256 | ES384]  
app-service [[string] | none]  
auto-generated [enabled | disabled]  
cert [certificate-name | none]  
cert-chain [chain-name | none]  
cert-key [key-name | none]  
cert-thumbprint-shal [[string] | none]  
cert-thumbprint-sha256 [[string] | none]  
curve [[string] | none]  
include-x5c [enabled | disabled]  
key-id [[string] | none]  
key-type [rsa | octet | elliptic-curve]  
key-use [signing]  
modulus [[string] | none]  
passphrase [[string] | none]  
public-exponent [[string] | none]  
shared-secret [[string] | none]  
use-client-secret [true | false]  
x-coordinate [[string] | none]  
y-coordinate [[string] | none]

edit jwk-config [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties  
non-default-properties  
one-line

DISPLAY

list jwk-config  
list jwk-config [ [ [name] | [glob] | [regex] ] ... ]  
show running-config jwk-config  
show running-config jwk-config [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line

DELETE

delete jwk-config [name]

DESCRIPTION

You can use the jwk-config component to configure a cryptographic JSON Web Key. This key may be used by the Authorization server to sign JSON Web Tokens or by the Client/Resource Server to verify the JSON Web Token signature.

#### EXAMPLES

```
create jwk-config myJwk {
  alg-type RS256
  key-id b2719f31c6bale5fe664fbb1bf0f7c05b3d3a0a1
  modulus ovtSwEWv9Q97JbB5Knfq4iAn8gl-ONzsFoxEasbh9-14CgeTImIXH31cOxu5tjVjAxeFifPW9w8EdEa-o8kUSJ40Fp2qMRN9wFAHmu5pms
  public-exponent AQAB
}
```

Creates a JSON Web Key named myJwk that uses algorithm RS256.

```
create jwk-config myJwk {
  alg-type RS256
  key-id b2719f31c6bale5fe664fbb1bf0f7c05b3d3a0a1
  cert myCrt.crt
  cert-key myKey.key
}
```

Creates a JSON Web Key named myJwk that will automatically generate other fields based on the values in 'cert' and 'cert-key'. This JSON Web Key uses algorithm RS256 and can be used by the Authorization server to sign JSON Web Tokens.

```
list jwk-config
```

Displays a list of registered JSON Web Keys.

```
delete jwk-config myJwk
```

Deletes the JSON Web Key myJwk

#### OPTIONS

**alg-type**

Specifies which cryptographic algorithm is used by this JSON Web Key. The default value is none.

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**auto-generated**

Specifies whether this key was created manually or generated through OpenID Connect metadata discovery. The default value is false.

**cert** Specifies the certificate this JSON Web Key uses to verify the JWT. Values derived from this field are a part of the JWKS endpoint response.

**cert-chain**

Specifies the certificate chain this JSON Web Key uses to validate the certificate in the cert field. Values derived from this field are a part of the JWKS endpoint response.

**cert-key**

Specifies the certificate key this JSON Web Key uses to sign the JWT.

**cert-thumbprint-sha1**

Specifies the base64url-encoded SHA-1 thumbprint of the DER encoding of X.509 certificate. If the 'cert' field is present, this value is auto-generated.

**cert-thumbprint-sha256**

Specifies the base64url-encoded SHA-256 thumbprint of the DER encoding of X.509 certificate. If the 'cert' field is present, this value is auto-generated.

**curve**

Specifies the curve used by the Elliptic Curve JSON Web Key. If the 'cert' field is present, this value is auto-generated.

**include-x5c**

Specifies whether or not JWKS endpoint response contains a chain of one or more PKIX certificates. The default value is false.

**key-id**

Specifies the parameter to identify a specific JSON Web Key.

**key-type**

Specifies the cryptographic algorithm family used by the JSON Web Key. This setting is required. The default value is rsa.

**key-use**

Specifies whether the JSON Web Key is used for signature generation and verification. At this time, the only supported value is signing.

**modulus**

Specifies the modulus value for the RSA public key in base64url-encoded format. If the 'cert' field is present, this value is auto-generated.

**partition**

Displays the partition within which the component resides.

**passphrase**

Specifies the passphrase used to encrypt the certificate key provided in 'cert-key' field.

#### public-exponent

Specifies the exponent value for the RSA public key in base64url-encoded format. If the 'cert' field is present, this value is auto-generated.

#### shared-secret

Specifies the shared secret for the symmetric JSON Web Key when 'key-type' is set to octet.

#### use-client-secret

Specifies that this JSON Web Key uses client-secret instead of shared-secret. This field is relevant only when key-type is set to octet. The default value is false.

x5c Specifies a chain of one or more PKIX certificates represented as a JSON array of certificate value strings. The JSON array is generated using 'cert' and 'cert-chain' field values.

#### x-coordinate

Specifies the x coordinate for the Elliptic Curve point in base64url-encoded format. If the 'cert' field is present, this value is auto-generated.

#### y-coordinate

Specifies the y coordinate for the Elliptic Curve point in base64url-encoded format. If the 'cert' field is present, this value is auto-generated.

```

#### DESCRIPTION

You can use jwt-config component for JWT config management to be used by Client/RS.

#### EXAMPLES

```
create jwt-config myJwt {  
  allowed-keys {  
    myJwk1 { }  
    myJwk2 { }  
    myJwk3 { }  
  }  
  allowed-signing-algorithms { RS256 }  
  issuer https://abc.com  
}
```

Creates a JSON web token named myJwt that allows signing algorithm RS256 and JSON web keys myJwk1, myJwk2, myJwk3 and the issuer is https://abc.com.

```
list jwt-config
```

Displays a list of registered JSON web tokens.

```
delete jwt-config myJwt
```

Deletes the JSON web token myJwt.

#### OPTIONS

##### access-token-expires-in

Specifies the number of minutes the access token should live.  
Default value is 0, which means the token never expires.

##### allowed-keys

Specifies the list of allowed JSON web keys for the token.

##### allowed-signing-algorithms

Specifies the list of allowed signing algorithms for the token.

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### audience

Specifies the audience for the token.

##### auto-generated

Specifies whether this token was configured manually or was generated through auto-discovery. This is a read-only attribute.

##### blacklist-access-tokens

Specifies key-value-list that can be used to blacklist tokens based on the key and the list of values for that key.

##### blocked-keys

Specifies the list of blocked JSON web keys for the token.

##### blocked-signing-algorithms

Specifies the list of blocked signing algorithms for the token.

##### issuer

Specifies the issuer of the token.

##### jwt-uri

Specifies the location of public signing keys for an OAuth Provider. This field is read-only.

##### use-jwt-provider-list-settings

Specifies whether the settings configured in jwt-provider-list of which this JWT config is a part, should be used. The default value is true.

## apm oauth jwt-provider-list

### NAME

jwt-provider-list - Configure a list of providers for JSON web token management to be used by Client/RS.

### MODULE

apm oauth

### SYNTAX

Configure the jwt-provider-list component within the oauth module using the following syntax.

#### CREATE/MODIFY

```
create jwt-provider-list [name] modify jwt-provider-list [name]
```

#### options:

```
access-token-expires-in [integer]
app-service [[string] | none]
providers [add | delete | none | replace-all-with] {
  [provider-name]
}
```

```
edit jwt-provider-list [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
one-line
```

#### DISPLAY

```
list jwt-provider-list
list jwt-provider-list [ [ [name] | [glob] | [regex] ] ... ]
show running-config jwt-provider-list
show running-config jwt-provider-list [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

#### DELETE

```
delete jwt-provider-list [name]
```

### DESCRIPTION

You can use the jwt-provider-list component to configure a list of OAuth Providers on Client/RS. A provider list enables a single OAuth Scope agent in an access policy to validate tokens issued by multiple OAuth providers.

### EXAMPLES

```
create jwt-config myProviderList {
  providers {
    myProvider1 { }
    myProvider2 { }
    myProvider3 { }
  }
}
```

Creates a Provider list named myProviderList with Providers myProvider1, myProvider2 and myProvider3.

```
list jwt-provider-list
```

Displays a list of Provider lists.

```
delete jwt-provider-list myProviderList
```

Deletes the Provider List myProviderList.

### OPTIONS

#### access-token-expires-in

Specifies the number of minutes the JSON web token should live. Default value is 0, which means the token never expires.

#### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### providers

Specifies the list of providers that can be used by a single OAuth Scope agent in an access policy to validate tokens issued by multiple OAuth providers.

## apm oauth oauth-claim

**NAME**  
oauth-claim - Manages claims for OAuth Authorization Server.

**MODULE**  
apm oauth

**SYNTAX**  
Configure the oauth-claim component within the oauth module using the following syntax.

**CREATE/MODIFY**  
create oauth-claim [name]  
modify oauth-claim [name]  
options  
app-service [[string] | none]  
claim-description [[string] | none]  
claim-type [boolean | custom | number | string]  
claim-name [string]  
claim-value [[string] | none]

edit oauth-claim [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line

**DISPLAY**  
list oauth-claim  
list oauth-claim [ [ [name] | [glob] | [regex] ] ... ]  
show running-config oauth-claim  
show running-config oauth-claim [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line

**DELETE**  
delete oauth-claim [name]

**DESCRIPTION**  
You can use the oauth-claim component to create and manage claims that provide different levels of access control based on end user's role or any other criteria.

**EXAMPLES**  
create oauth-claim profileClaim {  
claim-description "Employee Profile"  
claim-type string  
claim-name profile  
claim-value https://company.com/username  
}  
  
Creates a claim named profileClaim with claim-type set to string,  
claim-name set to profile and corresponding value being  
https://company.com/username.  
  
list oauth-claim  
  
Displays a list of OAuth Claims.  
  
delete oauth-claim profileClaim  
  
Deletes the OAuth Claim named profileClaim.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
  
[name]  
Specifies the name of the OAuth Claim object. This setting is required.  
  
claim-description  
Specifies the description of the claim.  
  
claim-type  
Specifies the type of the claim Value.  
  
claim-name  
Specifies the name of the claim.

claim-value  
Specifies the value of the claim. This value can be any string or session variable.

## apm oauth oauth-client-app

NAME

oauth-client-app - Manages client applications to use with OAuth Authorization Server.

MODULE

apm oauth

SYNTAX

Configure the oauth-client-app component within the oauth module using the following syntax.

CREATE/MODIFY

```
create oauth-client-app [name]
modify oauth-client-app [name]
options:
  access-token-lifetime [integer]
  app-description [[string] | none]
  app-name [string]
  app-service [[string] | none]
  audience [add | delete | none | replace-all-with] {
    [string]
  }
  auth-code-lifetime [integer]
  auth-type [none | secret | certificate]
  client-cert-dn [[string] | none]
  contact [[string] | none]
  customization-group [[string] | none]
  generate-jwt-refresh-token [true | false]
  generate-refresh-token [true | false]
  grant-code [enabled | disabled]
  grant-password [enabled | disabled]
  grant-token [enabled | disabled]
  id-token-claims [add | delete | none | replace-all-with] {
    [claim-name]
  }
  id-token-lifetime [integer]
  jwt-access-token-claims [add | delete | none | replace-all-with] {
    [claim-name]
  }
  jwt-access-token-lifetime [integer]
  jwt-refresh-token-lifetime [integer]
  logo-url [[string] | none]
  openid-connect [enabled | disabled]
  redirect-uris [add | delete | none | replace-all-with] {
    [URI]
  }
  refresh-token-lifetime [integer]
  refresh-token-usage-limit [integer]
  regenerate-client-secret
  reuse-access-token [true | false]
  reuse-refresh-token [true | false]
  scopes [add | delete | replace-all-with] {
    [scope-name]
  }
  use-profile-token-mgmt-settings [true | false]
  userinfo-claims [add | delete | none | replace-all-with] {
    [claim-name]
  }
  website-url [[string] | none]
edit oauth-client-app [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DISPLAY

```
list oauth-client-app
list oauth-client-app [ [ [name] | [glob] | [regex] ] ... ]
show running-config oauth-client-app
show running-config oauth-client-app [ [ [name] | [glob] | [regex] ] ... ]
```

options:  
all-properties  
non-default-properties  
one-line

DELETE  
delete oauth-client-app [name]

#### DESCRIPTION

You can use the oauth-client-app component to register and manage client applications that will make protected resource requests to the OAuth Authorization server on behalf of the resource owner and with its authorization.

#### EXAMPLES

```
create oauth-client-app myClientApplication {
  app-description "Test App is an application that tests all grant types."
  app-name "Test App"
  grant-code enabled
  grant-password enabled
  grant-token enabled
  logo-url "https://abc.cloud.net/www/public/assets/images/logos/testapp.png"
  redirect-uris add { https://vm1.lab.fp.f5net.com/oauth2/f5_test.php }
  scopes add { scope1 scope2 }
  website-url "https://www.test.com"
  use-profile-token-mgmt-settings false
  audience add { rs1 rs2 }
  jwt-access-token-claims add { claim1 claim2 }
}
```

Creates a client application named myClientApplication that will use the generated client credentials to send requests to this Authorization server. It can send token requests using any of the three supported grant types (authorization code, resource owner password credentials or implicit) and uses the default authentication type "secret".

The authorization server will use the configured redirect uri to re-direct back to the client. The client application is associated with configured scopes named scope1 and scope2.

The authorization server will not use the token management settings from the profile, and hence it will use the configured audience rs1 and rs2 and claim claim1 and claim2 values when a JWT access token is returned to the client.

```
list oauth-client-app
```

Displays a list of registered client-apps.

```
delete oauth-client-app myClientApplication
```

Deletes the OAuth client application myClientApplication

#### OPTIONS

**access-token-lifetime**  
Specifies the number of minutes for which the access token should be valid. The default is 5 minutes.

**app-description**  
Specifies a user-defined description for the client-app. The default value is none.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**audience**  
Specifies the audience claim for which the JWT access token is intended. This is a list of values. Each value in this list can be a string, URI, or session variable.

**auth-code-lifetime**  
Specifies the number of minutes for which the authorization code should be valid. The default is 5 minutes.

**auth-type**  
Specifies the authentication type the client will use when it makes requests to the Authorization Server. The default value is secret and other possible values are none and certificate.

**client-cert-dn**  
Specifies the distinguished name of the client certificate that is used to validate a request from client when authentication type is set to certificate.

**client-id**  
Specifies the client ID that uniquely identifies the client application. This field will be auto-generated and should not be specified or modified. Also, this entry cannot be edited once it has been generated.

**client-secret**  
Specifies the client secret that is used to validate a request from client when authentication type is set to secret. This field will be auto-generated and should not be specified or modified.

**contact**  
Specifies a means to contact the developer of the client application.

`customization-group`  
Specifies the customization settings for the client application.

`generate-jwt-refresh-token`  
Specifies whether a refresh token should be generated along with the JWT access token. This is applicable only for "Authorization Code" and "Resource Owner Password Credentials" grant types. The default is true.

`generate-refresh-token`  
Specifies whether a refresh token should be generated along with the access token. This is applicable only for "Authorization Code" and "Resource Owner Password Credentials" grant types.

`grant-code`  
Specifies whether the client application will use the "authorization code" grant type. This grant type must be enabled in order to support hybrid flow in OpenID Connect. The default value is disabled. At least one grant type must be set to enabled.

`grant-password`  
Specifies whether the client application will use the "resource owner password credentials" grant type. The default value is disabled.

`grant-token`  
Specifies whether the client application will use the "implicit" grant type. The default value is disabled.

`id-token-claims`  
Specifies the list of claims that are part of ID token.

`id-token-lifetime`  
Specifies the number of minutes for which the ID token should be valid. The default is 5 minutes.

`jwt-access-token-claims`  
Specifies the list of claims that are part of JWT access token.

`jwt-access-token-lifetime`  
Specifies the number of minutes for which the JWT access token should be valid. The default is 5 minutes.

`jwt-refresh-token-lifetime`  
Specifies the number of minutes for which the JWT refresh token should be valid. The default is 60 minutes.

`logo-url`  
Specifies the path from which the logo of the client application can be displayed.

`openid-connect`  
Specifies whether this client app supports OpenID Connect or not.

`[name]`  
Specifies the name of the OAuth Client Application. This setting is required.

`partition`  
Displays the partition within which the component resides.

`redirect-uris`  
Specifies the list of re-direct URIs that the Authorization Server will use to re-direct back to the client after processing a request. This setting should have at least one entry if the client application uses the authorization code grant type or the implicit grant type.

`refresh-token-lifetime`  
Specifies the number of minutes for which the refresh token should be valid. The default is 480 minutes.

`refresh-token-usage-limit`  
Specifies the maximum number of times the access token can be obtained using the refresh token request. The default value is 64. Value 0 represents unlimited number of times.

`regenerate-client-secret`  
Indicates a request to regenerate the client secret. Do not use other means to modify the secret.

`reuse-access-token`  
Specifies whether an access token is reused or a new access token is generated when it is obtained using refresh token request. When the access token is reused, its expiry time is extended.

`reuse-refresh-token`  
Specifies whether a refresh token is reused or a new refresh token is generated when it is obtained using refresh token request.

`scopes`  
Specifies the list of scopes that is to be associated with the client application.

`use-profile-token-mgmt-settings`  
Specifies whether the default settings that come from OAuth profile must be used or not.

`userinfo-claims`  
Specifies the list of claims that are part of UserInfo.

`website-url`  
Specifies the website URL of the client application.

## apm oauth oauth-resource-server

NAME

oauth-resource-server - Manages resource servers to use with OAuth Authorization Server.

MODULE

apm oauth

SYNTAX

Configure the oauth-resource-server component within the oauth module using the following syntax.

CREATE/MODIFY

```
create oauth-resource-server [name]
modify oauth-resource-server [name]
options:
  app-service [[string] | none]
  description [[string] | none]
  auth-type [none | secret | certificate]
  regenerate-resource-server-secret
  resource-server-cert-dn [[string] | none]
edit oauth-resource-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DISPLAY

```
list oauth-resource-server
list oauth-resource-server [ [ [name] | [glob] | [regex] ] ... ]
show running-config oauth-resource-server
show running-config oauth-resource-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete oauth-resource-server [name]
```

DESCRIPTION

You can use the oauth-resource-server component to register and manage resource servers that host resources that will be accessed by the user. Resource servers can accept and respond to protected resource requests using access tokens.

EXAMPLES

```
create oauth-resource-server myResourceServer {
  resource-server-cert-dn "/C=US/ST=CA/L=SJ/O=Company Name,Inc/OU=Engg/CN=user-name/emailAddress=username@company-domain.com"
}
```

Creates a resource server named myResourceServer that will use the generated resource server credentials to send requests to the Authorization server. It uses the default authentication type "certificate".

```
list oauth-resource-server
```

Displays a list of registered resource servers.

```
delete oauth-resource-server myResourceServer
```

Deletes the OAuth resource server myResourceServer.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**auth-type**  
Specifies the authentication type the resource server will use when it makes requests to the Authorization Server. The default value is certificate and other possible values are none and secret.

**[name]**  
Specifies the name of the OAuth Resource Server. This setting is required.

**description**  
Specifies the description of the OAuth Resource Server Object.

**partition**  
Displays the partition within which the component resides.

**regenerate-resource-server-secret**  
Indicates a request to regenerate the resource server secret. Do not use other means to modify the secret.

**resource-server-cert-dn**  
Specifies the distinguished name of the resource server certificate that is used to validate a request from the resource server when authentication type is set to certificate.

**resource-server-id**  
Specifies the resource server ID that uniquely identifies the resource server. This field will be auto-generated and should not be specified or modified. Also, this entry cannot be edited after it has been generated.

**resource-server-secret**  
Specifies the resource server secret that is used to validate a request from the resource server when authentication type is set to secret. This field will be auto-generated and should not be specified or modified.

## apm oauth oauth-scope

**NAME**  
oauth-scope - Manages scopes for OAuth Authorization Server.

**MODULE**  
apm oauth

**SYNTAX**  
Configure the oauth-scope component within the oauth module using the following syntax.

```
CREATE/MODIFY
create oauth-scope [name]
modify oauth-scope [name]
options
  app-service [[string] | none]
  customization-group [[string] | none]
  scope-description [[string] | none]
  scope-name [string]
  scope-value [[string] | none]
```

```
edit oauth-scope [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

```
DISPLAY
list oauth-scope
list oauth-scope [ [ [name] | [glob] | [regex] ] ... ]
show running-config oauth-scope
show running-config oauth-scope [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

```
DELETE
delete oauth-scope [name]
```

#### DESCRIPTION

You can use the oauth-scope component to create and manage scopes that provide different levels of access control based on end user's role or any other criteria.

#### EXAMPLES

```
create oauth-scope myOAuthScope {
  customization-group "company_my_oauth_scope"
  scope-description "Group in company"
  scope-name "profile"
  scope-value "Product Development"
}
```

Creates a scope named myOAuthScope that uses customization group company\_my\_oauth\_scope to customize scope information in the OAuth Authorization page. It is configured with profile and Product Development as its name and value respectively.

```
list oauth-scope
```

Displays a list of OAuth Scopes.

```
delete oauth-scope myOAuthScope
```

Deletes the OAuth Scope named myOAuthScope.

#### OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

customization-group

Specifies the customization settings for the scope.

[name]

Specifies the name of the OAuth Scope. This setting is required.

partition

Displays the partition within which the component resides.

scope-description

Specifies the description of the scope.

scope-name

Specifies the name of the scope.

scope-value

Specifies the value of the scope. This value can be any string or session variable.

#### SEE ALSO

## apm oauth purged-entries

#### NAME

Purged-Entries - Displays OAuth records purged from the respective database instance.

#### MODULE

apm oauth purged-entries

#### SYNTAX

Displays all the purged-entries within the oauth module using the syntax shown below.

DISPLAY

show purged-entries

show purged-entries [db-instance]

options:

all-properties

non-default-properties

one-line

recursive

output only properties:

oauth\_id [string]

```

    purged_time [string]

DESCRIPTION
    You can use the purged-entries component to manage purged records.

EXAMPLES
    show apm oauth purged-entries
    Lists all the OAuth purged entries for the oauth default db
    instance oauthdb. Also displays the total number of records
    purged.

    show apm oauth purged-entries db-instance test
    Lists all the purged entries for the oauth db instance test. Also
    displays the total number of records purged.

OPTIONS
    db-instance
    This specifies the db instance. If no value is specified, the
    default db instance, oauthdb, is used.

    oauth-id
    Specifies oauth id. Displays in the output of the show command.

    purged_time
    Specifies the timestamp at which each record was purged. The
    format is "YYYY-MM-DD HH:MM:SS". Displays in the output of the
    show command.

SEE ALSO
    apm oauth db-instance

COPYRIGHT
    No part of this program may be reproduced or transmitted in any form or

## apm oauth token-details

```

NAME
    Token-Details - Displays OAuth token properties and revokes access
    tokens and refresh tokens.

MODULE
    apm oauth token-details

SYNTAX
    Lists the token-details within the oauth module using the syntax shown
    in the following sections.

    DISPLAY
    list token-details
    list token-details [ [ [oauth-id] | [app-name] | [client-id] | [offset] | [db-instance] ] ... ]
    options:
        all-properties
        non-default-properties
        one-line
        recursive
    output only properties:
        access-token-status [[string] | none]
        access-token-issued-at [[string] | none]
        access-token-expires-at [[string] | none]
        refresh-token-status [[string] | none]
        refresh-token-issued-at [[string] | none]
        refresh-token-expires-at [[string] | none]
        grant-type [[string] | none]
        user-agent [[string] | none]

    show token-details
    show token-details [ [ [app-name] | [client-id] | [offset] | [db-instance] ] ... ]
    options:
        field-fmt
        recursive

    REVOKE
    revoke token-details [ [oauth-id client-id] ]

DESCRIPTION
    You can use the token-details component to manage oauth tokens.

EXAMPLES
    list apm oauth token-details
    Lists all the token details for the oauth default db instance of
    oauthdb.

    list apm oauth token-details db-instance test

```

Lists all the token details for the oauth db instance test.

list apm oauth token-details client-app myapp  
Lists all the token details for the client app myapp in the default db instance.

show apm oauth token-details  
Shows the number of tokens in the oauth default db instance of oauthdb.

show apm oauth token-details db-instance test  
Shows the number of tokens in oauth db instance test.

show apm oauth token-details client-app myapp  
Shows the number of token for the client app myapp in default db instance.

revoke apm oauth token-details  
93b225478484f0fa0addc527b2c50001d7e3yyb70c3eda99e56 client-id

Revokes the access/refresh token for oauth id  
93b225478484f0fa0addc527b2c50001d7eb70c3eda99e56 and client id  
ae8b6cd3708a5805e84ae48369ab0001d7eb70c1325c8d56.

revoke apm oauth token-details  
93b225478484f0fa0addc527b2c50001d7e3yyb70c3eda99e56 db-instance test  
client-id ae8b6cd3708a5805e84ae48369ab0001d7eb70c1325c8d56  
Revokes the access/refresh token for oauth id  
93b225478484f0fa0addc527b2c50001d7eb70c3eda99e56 and client id  
ae8b6cd3708a5805e84ae48369ab0001d7eb70c1325c8d56 in the db  
instance test.

#### OPTIONS

client-id  
Specifies the client id for which the token is generated. Must be specified for revoke command.

app-name  
Specifies the app name for which the token is generated. This is an optional parameter for list and show commands.

offset  
Specifies the number of tokens to skip before beginning to display the remaining tokens.

Example: list apm oauth token-details offset 10

This will return the tokens from the count of 11 and will skip the first 10.

db-instance  
This specifies the db instance. If no value is specified, oauthdb (the default db instance) is used.

user-id  
Specifies the user id for which the token is generated.

oauth-id  
Specifies oauth id. Displays in the output of the list command.

access-token-status  
Specifies the access token status, such as active,inactive,expired and revoked. Displays in the output of the list command.

access-token-issued-at  
Specifies the access token issued timestamp. The format is "YYYY-MM-DD HH:MM:SS". Displays in the output of the list command.

access-token-expires-at  
Specifies the access token expiry timestamp. The format is "YYYY-MM-DD HH:MM:SS". Displays in the output of the list command.

refresh-token-status  
Specifies the refresh token status such as active,inactive,expired and revoked. Displays in the output of the list command.

refresh-token-issued-at  
Specifies the refresh token issued timestamp. The format is "YYYY-MM-DD HH:MM:SS". Displays in the output of the list command.

refresh-token-expires-at  
Specifies the refresh token expiry timestamp. The format is "YYYY-MM-DD HH:MM:SS". Displays in the output of the list command.

grant-type  
Specifies the grant type; valid values are ropc, implicit and auth-code. Displays in the output of the list command.

user-agent  
Specifies the user agent information for the token. Displays in the output of the list command.

## apm policy access-policy

**NAME**  
access-policy - Manages an access policy.

**MODULE**  
apm policy

**SYNTAX**  
Warning: F5 Networks recommends that you use the visual policy editor in the Configuration utility to create and manage access policies. If you are using tmsh scripts to create an access policy, please do the following:

1. Create transaction.
2. Create policy agents; each policy must include an ending agent type.
3. Create access policy items for start and end and attach the corresponding agents.
4. Create access policy and add all the policy items.
5. Create access profile with the corresponding access policy.
6. Submit transaction.

Failure to follow the above mentioned steps will result in error messages or invalid configuration. This sample script creates a policy with start and end agents only:

```
1. create cli transaction
2. create apm policy agent ending-allow /Common/rest_end_allow_ag { }
3a. create apm policy policy-item /Common/rest_end_allow { agents add { /Common/rest_end_allow_ag { type ending-allow
3b. create apm policy policy-item /Common/rest_end { caption Start color 1 rules { { caption fallback next-item /Common
4. create apm policy access-policy /Common/rest { default-ending /Common/rest_end_allow items add { rest_end_allow { }
5. create apm profile access /Common/rest { accept-languages add { en } access-policy /Common/rest log-settings add {
6. submit cli transaction
```

## apm policy agent aaa-active-directory

**NAME**  
aaa-active-directory - Manages an AAA Active Directory(r) agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the aaa-active-directory component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create aaa-active-directory [name]  
modify aaa-active-directory [name]  
options  
app-service [[string] | none]  
auth-max-logon-attempt [integer]  
fetch-nested-groups [true | false]  
fetch-primary-groups [true | false]  
hints [true | false]  
query-attrname [[string] | none]  
query-filter [[string] | none]  
server [[string] | none]  
trusted-domains [[string] | none]  
show-extended-error [true | false]  
type [query | auth | last]  
upn [true | false]

**DISPLAY**  
list aaa-ldap  
list aaa-ldap [ [ [name] | [glob] | [regex] ] ... ]  
show running-config aaa-ldap

```
show running-config aaa-ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition
```

```
DELETE
delete aaa-active-directory ([name] | all)
```

#### DESCRIPTION

You can use the aaa-active-directory component to configure an AAA Active Directory agent.

#### EXAMPLES

```
create aaa-active-directory MyADQueryagent {query-filter "(be
sAMAccountName={session.logon.last.username})" type query server
"companyAD" }
Creates the query type AAA Active Directory agent named
MyADQueryagent that uses the (be
sAMAccountName={session.logon.last.username}) filter and the
companyAD AAA AD Server.

create agent aaa active MyADAuthagent { type auth server "companyAD" }
Creates the authorization type AAA Active Directory agent named
MyADAuthagent that uses the companyAD AAA AD server.

list aaa-active-directory all
Displays a list of AAA Active Directory agents and their
properties.

delete aaa-active-directory MyADagent
Deletes the MyADagent AAA Active Directory agent.
```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**auth-max-logon-attempt**  
Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

**fetch-nested-groups**  
When enabled, the system administrator can retrieve the full list of groups that user belongs to, even if the retrieval privileges are nested through other groups to which the user belongs to directly. The default value is false.

**fetch-primary-groups**  
When enabled, the system administrator can retrieve the primary group of a user, and use that name as a group in access policy item rules. The default value is false.

**hints**  
When enabled, the system offers the user an option to create a hint that assists in remembering a password. The default value is false.

**query-attrname**  
Specifies the attribute name that you are adding or deleting for the agent.

**query-filter**  
Specifies the search criteria the system uses when querying an AAA Active Directory(r) server for authentication information. The system supports session variables as part of search query string.

**[name]**  
Specifies the name of an AAA Active Directory agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

**server**  
Specifies an AAA Active Directory server the system uses for Active Directory queries and authentication.

**server**  
Specifies an AAA Active Directory Trusted Domains object that the system uses for Active Directory queries and authentication. This option requires upn option to be enabled

**show-extended-error**  
Specifies to display a verbose error message. The default value is false.

**type** Specifies the type of AAA Active Directory agent. The default value is last.

**query**  
Specifies that the agent makes a query against the AAA Active

Directory Server to retrieve information in accordance with the query-filter and query-attributes options.

auth Specifies that the agent is an authentication agent only. It uses the AAA Active Directory Server, but only for authentication purposes. APM does not get any information from the Domain.

last

upn When enabled, APM supports the user principal name (UPN) naming style and process cross-domain authentication requests. Some examples of UPNs are: user@fqdn.of.domain.com, user@upnsuffix.com, and user@domain. The default value is false.

## apm policy agent aaa-client-cert

NAME

aaa-client-cert - Manages an AAA Client Certification agent.

MODULE

apm policy agent

SYNTAX

Configure the aaa-client-cert component within the policy-agent module using the following syntax.

CREATE/MODIFY

```
modify aaa-client-cert [name]
create aaa-client-cert [name]
options:
  app-service [[string] | none]
  mode [request | require]
```

DISPLAY

```
list aaa-client-cert
list aaa-client-cert [ [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-client-cert
show running-config aaa-client-cert [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition
```

DELETE

```
delete aaa-client-cert [name]
```

DESCRIPTION

You can use this component to configure an AAA Client Certification agent.

EXAMPLES

```
create aaa-client-cert MyCCagent
Creates the AAA Client Certification agent named MyCCagent in the
Common partition.
```

```
list aaa-client-cert all
Displays a list of AAA Client Certification agents.
```

```
delete aaa-client-cert MyCCagent
Deletes the MyCCagent AAA Client Certification agent.
```

OPTIONS

[name]

Specifies the name of an AAA client cert agent. This setting is required.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

mode Specifies the mode (request/require) for this certificate. The options are:

request

Specifies that the system requests a valid certificate from a client, but always authenticates the client.

require

Specifies that the system requires a client to present a valid certificate.

partition

Displays the partition within which the component resides.

## apm policy agent aaa-crldp

NAME

aaa-crldp - Manages an AAA CRLDP (Constraint-Based Routed Label Distributed Protocol) agent.

MODULE

apm policy agent

SYNTAX

Configure the aaa-crldp component within the policy agent module using the following syntax.

CREATE/MODIFY

create aaa-crldp [name]

modify aaa-crldp [name]

options:

app-service [[string] | none]

server ( | none)

DISPLAY

list aaa-crldp

list aaa-crldp [ [ [name] | [glob] | [regex] ] ... ]

show running-config aaa-crldp

show running-config aaa-crldp [ [ [name] | [glob] | [regex] ] ... ]

options:

all

all-properties

app-service

current-module

non-default-properties

one-line

partition

DELETE

delete aaa-crldp [name]

DESCRIPTION

You can use the aaa-crldp component to create and manage an AAA CRLDP agent.

EXAMPLES

create aaa-crldp MyCCagent

Creates an AAA CRLDP agent named MyCCagent in the Common partition.

list aaa-crldp all

Displays a list of AAA CRLDP agents.

delete aaa-crldp MyCCagent

Deletes the MyCCagent AAA CRLDP agent.

OPTIONS

[name]

Specifies the name of an agent that you want to display or delete. This setting is required.

partition

Displays the partition within which the component resides.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**server**

Specifies the name of the server on which this agent resides. This option is required.

## apm policy agent aaa-http

**NAME**

aaa-http - Manages an AAA HTTP agent.

**MODULE**

apm policy agent

**SYNTAX**

Configure the aaa-http component within the policy agent module using the following syntax.

**CREATE/MODIFY**

```
create aaa-http [name]
modify aaa-http [name]
options
  app-service [[string] | none]
  max-logon-attempt [integer]
  server [[string] | none]
```

**DISPLAY**

```
list aaa-http
list aaa-http [ [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-http
show running-config aaa-http [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition
```

**DELETE**

```
delete aaa-http [name]
```

**DESCRIPTION**

You can use the aaa-http component to configure an AAA HTTP agent.

**EXAMPLES**

```
create aaa-http MyCCagent
Creates the aaa-http agent named MyCCagent in the Common
partition.
```

```
list all aaa-http
Displays a list of aaa-http agents.
```

```
delete aaa-http MyCCagent
Deletes the MyCCagent aaa-http agent.
```

**OPTIONS**

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**max-logon-attempt**

Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

[name]

Specifies the name of an AAA HTTP agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

**server**  
Specifies which AAA HTTP server the system uses for Active Directory queries and authentication.

SEE ALSO

## apm policy agent aaa-ldap

**NAME**  
aaa-ldap - Manages an AAA LDAP(r) agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the aaa-ldap component within the policy agent module using the following syntax.

```
CREATE/MODIFY
create aaa-ldap [name]
modify aaa-ldap [name]
options:
  app-service [[string] | none]
  attr-name ( | none) [add | delete]
  filter [[string] | none]
  group-member-scope [none | direct | all]
  group-membership-scope [none | direct | all]
  max-logon-attempt [integer]
  search-dn [[string] | none]
  server [[string] | none]
  show-extended-error [true | false]
  type [query | auth | modify | last]
  user-dn [[string] | none]
  modify-type [add | modify | delete | modify-last]
  ldapmod-attributes ( | none) [add | delete]

DISPLAY
list aaa-ldap
list aaa-ldap [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-ldap
show running-config aaa-ldap [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition

DELETE
delete aaa-ldap [name]
```

**DESCRIPTION**  
Use this component to create, modify, display, or delete an AAA LDAP agent.

**EXAMPLES**  
create aaa-ldap MyLDAPagent { user-dn "cn={{session.logon.last.username}},cn=users,dc=lab,dc=fp,dc=com" type auth server "companyLDAP" } aaa-ldap MyLDAPagent { search-dn "cn=users,dc=lab,dc=fp,dc=com" filter "(SAMAccountName={{session.logon.last.username}})" type auth server "companyLDAP" }  
Creates the authorization type AAA LDAP agent named MyLDAPagent that is associated with the companyLDAP server that uses the cn={{session.logon.last.username}},cn=users,dc=lab,dc=fp,dc=f5net,dc=com user domain name, the cn=users,dc=lab,dc=fp,dc=com search domain, and the (SAMAccountName={{session.logon.last.username}}) filter.  
  
create aaa-ldap MyLDAPagent { search-dn "cn=users,dc=lab,dc=fp,dc=com" filter "(SAMAccountName={{session.logon.last.username}})" type query server "companyLDAP" }  
Creates the query type AAA LDAP agent named MyLDAPagent that is

associated with the companyLDAP server that uses the  
cn=users,dc=lab,dc=fp,dc=com search domain and the  
(SAMAccountName=%{(session.logon.last.username)}) filter.

```
create aaa-ldap MyLDAPagent { user-dn
  "cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=com" type
  modify modify-type add server "companyLDAP" ldapmod-attributes add {
    objectClass { mod-op add mod-values add { top person
      organizationalPerson user } } cn { mod-op add mod-values add { demo } }
  } }
```

Creates the modify type AAA LDAP agent named MyLDAPagent that is  
associated with the companyLDAP server that uses the  
cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=f5net,dc=com  
user domain name, the add modify type, and the ldapmod attributes

```
create aaa-ldap MyLDAPagent { user-dn
  "cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=com" type
  modify modify-type modify server "companyLDAP" ldapmod-attributes add {
    givenName { mod-op replace mod-values add { demo } } } }
```

Creates the modify type AAA LDAP agent named MyLDAPagent that is  
associated with the companyLDAP server that uses the  
cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=f5net,dc=com  
user domain name, the modify modify type, and the ldapmod  
attributes which uses givenName modify attribute replace mod  
operation and the demo mod values

```
create aaa-ldap MyLDAPagent { user-dn
  "cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=com" type
  modify modify-type delete server "companyLDAP" }
```

Creates the modify type AAA LDAP agent named MyLDAPagent that is  
associated with the companyLDAP server that uses the  
cn=%{session.logon.last.username},cn=users,dc=lab,dc=fp,dc=f5net,dc=com  
user domain name, the delete modify type

```
list aaa-ldap
Displays a list of AAA LDAP agents.
```

```
delete aaa-ldap MyLDAPagent
Deletes the MyLDAPagent AAA LDAP agent.
```

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object  
belongs. The default value is none. Note: If the strict-updates  
option is enabled on the application service that owns the object,  
you cannot modify or delete the object. Only the application  
service can modify or delete the object.

##### attr-name

Adds an attribute name to the agent or deletes an attribute name  
from the agent.

##### group-member-scope

Specifies the scope of user lookup for a group. When the search  
returns a group, this attribute specifies whether to also look up  
the members of the group. The options are:

none No members required.

direct Only direct members required.

all All members required. This includes those that derive  
membership in this group through membership in other groups and  
those that are direct members.

##### group-membership-scope

Specifies the scope of group lookup for a user or a group. When  
the search returns a user or a group, this attribute specifies  
whether to also look up the groups to which this user or group  
belong. The options are:

none No groups required.

direct Only the groups to which the current user or group belong  
directly are required.

all All groups required. This includes the groups to which the  
user or the group belong directly and the groups to which the user  
or group belong indirectly (through membership in another group).

##### filter

Specifies the LDAP filter that APM uses when querying an AAA LDAP  
server for authentication information. You must use the filter  
option with the search-dn option.

##### max-logon-attempt

Specifies the maximum number of opportunities that users have to  
re-enter credentials after their first attempt to log in fails. If  
you set this value to a number from 2 to 5 inclusive, the system  
allows users the specified number of opportunities to log in after  
the first attempt to log in fails. If you set the value to 1, the  
system does not allow a second log in opportunity after a first  
log in attempt fails. The default value is 3.

##### [name]

Specifies the name of an AAA LDAP agent. This setting is required.

##### partition

Displays the partition within which the component resides.

##### search-dn

Specifies the base domain name that APM uses for internal LDAP  
search operations. You must use the search-dn option with the  
filter option.

##### server

Specifies the AAA LDAP server that the system uses for LDAP  
queries and authentication.

##### show-extended-error

Specifies to display a verbose error message. The default value is false.

type Specifies a type of AAA LDAP agent. This setting is required. The default is last.

user-dn  
Specifies the fully qualified domain name of the Access Policy Manager. F5 Networks recommends that you specify this value in lower case and without spaces for compatibility with some specific LDAP servers. The specific content of this string depends on your directory layout.

## apm policy agent aaa-oauth

NAME  
aaa-oauth - Manages an AAA OAuth(r) agent.

MODULE  
apm policy agent

SYNTAX  
Configure the aaa-oauth component within the policy agent module using the following syntax.

```
CREATE/MODIFY
create aaa-oauth [name]
modify aaa-oauth [name]
options:
  app-service [[string] | none]
  auth-redirect-request [name]
  grant-type [authorization-code | password]
  redirection-uri [string]
  response [name]
  scope [[string] | none]
  scope-data-request [name]
  server [name]
  token-refresh-request [name]
  token-request [name]
  type [client | scope]
  validation-scopes-request [name]

DISPLAY
list aaa-oauth
list aaa-oauth [ [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-oauth
show running-config aaa-oauth [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition

DELETE
delete aaa-oauth [name]
```

DESCRIPTION  
Use this component to create, modify, display, or delete an OAuth Client or OAuth Scope agent.

EXAMPLES  
create aaa-oauth MyGoogleClient { auth-redirect-request  
GoogleAuthRedirectRequest grant-type authorization-code scope  
"https://www.googleapis.com/auth/userinfo.email  
https://www.googleapis.com/auth/userinfo.profile" server myGoogleServer  
token-request GoogleTokenRequest type client validation-scopes-request  
GoogleValidationScopesRequest } Creates the OAuth Client agent to  
acquire an access token from Google authorization server using  
authorization-code grant type. Defines two scopes. The user's  
permission will be requested for the scopes.  
create aaa-oauth MyGoogleScope { scope-data-request {  
https://www.googleapis.com/auth/userinfo.profile { request  
GoogleScopeUserInfoProfileRequest } } server myGoogleServer type scope

validation-scopes-request GoogleValidationScopesRequest }  
Creates OAuth Scope agent to get the list of scopes associated with the access\_token, and defines the scope-data-request to retrieve more information about user identity if the access\_token contains the scope  
"https://www.googleapis.com/auth/userinfo.profile".

list aaa-oauth  
Displays a list of OAuth agents.

delete aaa-oauth MyGoogleScope  
Deletes the MyGoogleScope OAuth agent.

#### OPTIONS

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auth-redirect-request  
OAuth Request name to be used for user redirect in order to obtain authorization code.

grant-type  
Specifies grant type that should be used to request an access\_token.

redirection-uri  
Specifies redirection URI. The redirection URI is used by the Authorization Server to redirect user back after authentication. The URI is a property of client application registered at authorization server. This option is used along with 'authorization-code' grant type only.

response  
Specifies the response config object name.

scope  
The list of scopes to request user's permission for.

scope-data-request  
Defines OAuth Request to obtain additional information from the resource server for the specified scope, using access\_token.

server  
Specifies OAuth Server that represents the authorization server to work with.

token-refresh-request  
Specifies OAuth Request to refresh an expired access\_token.

token-request  
Specifies OAuth Request to request an access\_token.

type Type of the OAuth agent. Available options are: client or scope. Default value client. The type cannot be changed for an existing OAuth agent.

validation-scopes-request  
Specifies OAuth Request to validate the access\_token (when agent type is client) or to retrieve list of scopes associated with the access\_token (when agent type is scope).

## apm policy agent aaa-ocsp

NAME  
aaa-ocsp - Manages an AAA OCSP (Online Certificate Status Protocol) agent.

MODULE  
apm policy agent

SYNTAX  
Configure the aaa-ocsp component within the policy agent module using

the following syntax.

```
CREATE/MODIFY
create aaa-ocsp [name]
modify aaa-ocsp [name]
options:
  app-service [[string] | none]
  certificate-type
  ocspp-responder

DISPLAY
list aaa-ocsp
list aaa-ocsp [ [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-ocsp
show running-config aaa-ocsp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition

DELETE
delete aaa-ocsp [name]

DESCRIPTION
Use this command to create, modify, display, or delete an AAA OSCP
agent.

EXAMPLES
  create aaa-ocsp MyCCagent
  Creates the AAA OSCP agent named MyCCagent in the Common
  partition.

  list aaa-ocsp all
  Displays a list of AAA OSCP agents.

  delete aaa-ocsp MyCCagent
  Deletes the MyCCagent AAA OSCP agent.

OPTIONS
  [name]
  Specifies the name of an agent that you want to display or delete.
  This setting is required.

  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  certificate-type
  Specifies the type of certificate to check against OSCP responder.
  The value can be either user or machine. The default value is
  user.

  ocspp-responder
  Specifies which OSCP responder object to use to validate a
  certificate.

  partition
  Displays the partition within which the object resides.
```

## apm policy agent aaa-radius

```
NAME
  aaa-radius - Manages an AAA RADIUS agent.

MODULE
  apm policy agent

SYNTAX
  Configure the aaa-radius component within the policy agent module using
  the following syntax.
```

```

CREATE/MODIFY
create aaa-radius [name]
modify aaa-radius [name]
options:
  app-service [[string] | none]
  max-logon-attempt
  password-source [[string] | none]
  server ( | none)
  show-extended-error (true | false)
  username-source [[string] | none]

```

```

DISPLAY
list aaa-radius
list aaa-radius [ [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-radius
show running-config aaa-radius [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition

```

```

DELETE
delete aaa-radius [name]

```

**DESCRIPTION**  
Use this command to create, modify, display, or delete an AAA RADIUS agent.

**EXAMPLES**  
create aaa-radius Myradiusagent {server "companyradius"}  
Creates an AAA RADIUS agent named Myradiusagent that is associated with the companyradius server.

```
list aaa-radius
```

Displays a list of AAA RADIUS agents.

```
delete aaa-radius Myradiusagent
```

Deletes the Myradiusagent AAA RADIUS agent.

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**max-logon-attempt**  
Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

**[name]**  
Specifies the name of an AAA RADIUS agent. This setting is required.

**partition**  
Displays the partition within which the object resides.

**password-source**  
Specifies the session variable name from which RADIUS agent should read the password. The default value is  
%{session.logon.last.password}.

**server**  
Specifies the AAA RADIUS server that the system uses for RADIUS queries and authentication.

**show-extended-error**  
Specifies to display a verbose error message. The default value is false.

**username-source**  
Specifies the session variable name from which RADIUS agent should read the username. The default value is  
%{session.logon.last.username}.

**SEE ALSO**

## apm policy agent aaa-saml

**NAME**  
aaa-saml - Manages a AAA SAML agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the aaa-saml component within the policy agent module using the following syntax.

```
CREATE/MODIFY
create aaa-saml [name]
modify aaa-saml [name]
options:
  app-service [[string] | none]
  attr-consuming-service-session-var ( | none)
  attribute-consuming-service ( | none)
  server ( | none)

DISPLAY
list aaa-saml
list aaa-saml [ [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-saml
show running-config aaa-saml [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition

DELETE
delete aaa-saml [name]
```

**DESCRIPTION**  
Use this command to create, modify, display, or delete a AAA SAML agent.

**EXAMPLES**

```
create aaa-saml Mysamlagent {server "companysaml"}
Creates a AAA SAML agent named Mysamlagent that is associated with
the companysaml server.

list aaa-saml
Displays a list of AAA SAML agents.

delete aaa-saml Mysamlagent
Deletes the Mysamlagent AAA SAML agent.
```

**OPTIONS**

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**attr-consuming-service-session-var**  
Specifies the session variable used as the source for the attribute consuming service index. The index will be included in the SAML authentication request generated. The IdP maps the index to the list of attributes derived from the metadata previously shared and returns those attributes in the SAML Response. attr-consuming-service-session-var and attribute-consuming-service cannot be configured at the same time.

**attribute-consuming-service**  
Specifies the name of one of the attribute consuming services associated with the server. The index associated with the selected attribute consuming service will be included in the SAML authentication request generated. The IdP maps the index to the list of attributes derived from the metadata previously shared and returns those attributes in the SAML Response. attribute-consuming-service and attr-consuming-service-session-var cannot be configured at the same time.

**partition**  
Displays the partition within which the object resides.

**server**  
Specifies the AAA SAML server that the system uses for SAML queries and authentication.

## apm policy agent aaa-securid

**NAME**

aaa-securid - Manages an AAA SecurID agent.

**MODULE**

apm policy agent

**SYNTAX**

Configure the aaa-securid component within the policy agent module using the following syntax.

**CREATE/MODIFY**

```
create aaa-securid [name]
modify aaa-securid [name]
options:
  app-service [[string] | none]
  max-logon-attempt [integer]
  password-source [[string] | none]
  server [[string] | none]
  show-extended-error [true | false]
  username-source [[string] | none]
```

**edit aaa-securid** | [glob] | [regex] ] ... ]

**options:**

- all-properties
- non-default-properties

**DISPLAY**

```
list aaa-securid
list aaa-securid [ [ [name] | [glob] | [regex] ] ... ]
show running-config aaa-securid
show running-config aaa-securid [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition
```

**DELETE**

```
delete aaa-securid [name]
```

**DESCRIPTION**

You can use the aaa-securid component to create and manage an AAA SecurID agent.

**EXAMPLES**

```
create aaa-securid mySecuridAgent { server rsal_106 }
Creates an AAA SecurID agent named mySecuridAgent that is
associated to AAA RSA Server rsal_106.
```

```
list all aaa-securid
Displays a list of AAA SecurID agents.
```

```
delete aaa-securid MyCCagent
Deletes the MyCCagent AAA Client Certification agent.
```

**OPTIONS**

[name]

Specifies the name of an agent that you want to display or delete. This setting is required.

partition

Displays the partition within which the component resides.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

max-logon-attempt

Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

password-source

Specifies the session variable name from which RSA SecurID agent should read the password. The default value is

```
{session.logon.last.password}.
```

server  
Specifies the AAA RSA SecurID server that the system uses for LDAP queries and authentication.

show-extended-error  
Specifies to display a verbose error message. The default value is false.

username-source  
Specifies the session variable name from which RSA SecurID agent should read the username. The default value is  
%{session.logon.last.username}.

## apm policy agent acct-radius

NAME  
acct-radius - Manages a RADIUS Accounting agent.

MODULE  
apm policy agent

SYNTAX  
Configure the acct-radius component within the policy agent module using the following syntax.

```
CREATE/MODIFY
create acct-radius [name]
modify acct-radius [name]
options:
  app-service [[string] | none]
  server [[string] | none]
  username-source [[string] | none]
```

```
edit acct-radius | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list acct-radius
list acct-radius [ [ [name] | [glob] | [regex] ] ... ]
show running-config acct-radius
show running-config acct-radius [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  current-module
  non-default-properties
  one-line
  app-service
  partition
```

```
DELETE
delete acct-radius [name]
```

DESCRIPTION  
You can use the acct-radius component to create and manage a RADIUS Accounting agent.

EXAMPLES  
create acct-radius MyRADIUSagent { server "MyRADIUS" }  
Creates the MyRADIUSagent RADIUS Accounting agent that is associated with the MyRADIUS server.

list acct-radius  
Displays a list of RADIUS Accounting agents and the servers associated with the agents.

delete acct-radius MyRADIUSagent  
Deletes the MyRADIUSagent RADIUS Accounting agent.

OPTIONS  
[name]  
Specifies the name of a RADIUS Accounting server. This setting is required.

**partition**  
Displays the partition within which the component resides.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**server**  
Specifies a RADIUS Accounting server the system uses to send RADIUS Accounting START and RADIUS Accounting STOP messages. This option is required.

**username-source**  
Specifies the session variable name from which RADIUS Accounting agent should read the username. The default value is `%{session.logon.last.username}`.

## apm policy agent acct-tacacsplus

**NAME**  
acct-tacacsplus - Manages a TACACS+(r) Account agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the acct-tacacsplus component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create acct-tacacsplus [name]  
modify acct-tacacsplus [name]  
options  
app-service [[string] | none]  
server [[string] | none]

**DISPLAY**  
list acct-tacacsplus  
list acct-tacacsplus [ [ [name] | [glob] | [regex] ] ... ]  
show running-config acct-tacacsplus  
show running-config acct-tacacsplus [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
all-properties  
current-module  
non-default-properties  
app-service  
partition

**DELETE**  
delete acct-tacacsplus [name]

**DESCRIPTION**  
You can use the acct-tacacsplus component to configure a TACACS+ Account agent.

**EXAMPLES**  
create acct-tacacsplus MyADQueryagent { server "companyAD" }  
Creates the agent type TACACS+ Account named MyADQueryagent that uses the companyAD server.

list acct-tacacsplus all  
Displays a list of TACACS+ Account agents and the server associated with each agent.

delete acct-tacacsplus MyADagent  
Deletes the MyADagent TACACS+ Account agent.

**OPTIONS**  
[name]  
Specifies the name of an acct-tacacsplus agent. This setting is required.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

server  
Specifies the TACACS+ Account server that the system uses for queries and authentication.

## apm policy agent api-authentication

NAME  
api-authentication - Manages API Authentication agent.

MODULE  
apm policy agent

SYNTAX  
Configure the api-authentication component within the policy agent module using the syntax shown in the following sections.

CREATE/MODIFY  
create api-authentication [name]  
modify api-authentication [name]  
options:  
app-service [[string] | none]  
  
edit api-authentication [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
  
DISPLAY  
list api-authentication  
list api-authentication [ [ [name] | [glob] | [regex] ] ... ]  
show running-config api-authentication  
show running-config api-authentication [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
partition  
  
show api-authentication  
show api-authentication [name]  
  
DELETE  
delete api-authentication [name]

DESCRIPTION  
You can use the api-authentication component to create an API Authentication agent to inspect authentication header in the request and set appropriate sub-session variable.

EXAMPLES  
create api-authentication my\_api\_authentication\_agent  
Creates the my\_api\_authentication\_agent API Authentication agent.  
  
list api-authentication  
Displays a list of API Authentication agents.  
  
delete api-authentication my\_api\_authentication\_agent  
Deletes the API Authentication agent named my\_api\_authentication\_agent.

OPTIONS  
[name]  
Specifies the name of a API Authentication agent. This option is required.  
  
partition  
Displays the partition within which the component resides.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

## apm policy agent api-server-selection

NAME

**api-server-selection** - Manages API Server Selection agent.

MODULE

apm policy agent

SYNTAX

Configure the api-server-selection component within the policy agent module using the syntax shown in the following sections.

**CREATE/MODIFY**

create api-server-selection [name]

modify api-server-selection [name]

options:

app-service [[string] | none]

server [[string] | none]

edit api-server-selection [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties

non-default-properties

**DISPLAY**

list api-server-selection

list api-server-selection [ [ [name] | [glob] | [regex] ] ... ]

show running-config api-server-selection

show running-config api-server-selection [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties

non-default-properties

partition

show api-server-selection

show api-server-selection [name]

**DELETE**

delete api-server-selection [name]

DESCRIPTION

You can use the api-server-selection component to create an API Server Selection agent to assign a server config object to send the request.

EXAMPLES

create api-server-selection my\_api\_server\_sel\_ag server my\_server

Creates the my\_api\_server\_sel\_ag API Server Selection agent.

list api-server-selection

Displays a list of API Server Selection agents.

delete api-server-selection my\_api\_server\_sel\_agent

Deletes the API Server Selection agent named

my\_api\_server\_sel\_agent.

OPTIONS

[name]

Specifies the name of a API Server Selection agent. This option is required.

partition

Displays the partition within which the component resides.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

server  
Specifies the server config object name.

## apm policy agent decision-box

NAME  
decision-box - Manages a Decision Box agent.

MODULE  
apm policy agent

SYNTAX  
Configure the decision-box component within the policy agent module using the following syntax.

CREATE/MODIFY  
create decision-box [name]  
modify decision-box [name]  
options  
app-service [[string] | none]  
customization-group [name]

DISPLAY  
list decision-box  
list decision-box [ [ [name] | [glob] | [regex] ] ... ]  
show running-config decision-box  
show running-config decision-box [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
all-properties  
app-service  
current-module  
non-default-properties  
one-line  
partition

DELETE  
delete decision-box ([name] | all)

DESCRIPTION  
You can use the decision-box component to configure a Decision Box agent.

EXAMPLES  
create dynamic-acl MyADQueryagent  
Creates the Decision Box agent named MyADQueryagent.

list decision-box all  
Displays a list of Decision Box agents.

delete decision-box MyADagent  
Deletes the MyADagent Decision Box agent.

OPTIONS  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

customization-group  
Specifies the name of the existing customization group to which the agent belongs.

[name]  
Specifies the name of a Decision Box agent. This setting is required.

partition  
Displays the partition within which the component resides.

SEE ALSO

## apm policy agent dynamic-acl

**NAME**  
dynamic-acl - Manages a Dynamic ACL agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the dynamic-acl component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create dynamic-acl [name]  
modify dynamic-acl [name]  
options  
app-service [[string] | none]  
entries [ add | delete | modify | none | replace-all-with]

**DISPLAY**  
list dynamic-acl  
list dynamic-acl [ [ [name] | [glob] | [regex] ] ... ]  
show running-config dynamic-acl  
show running-config dynamic-acl [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
all-properties  
app-service  
current-module  
non-default-properties  
one-line  
partition

**DELETE**  
delete dynamic-acl [name]

**DESCRIPTION**  
You can use the dynamic-acl component to create and manage a Dynamic access control list (acl) agent that parses ACL text input with a specified format from a specified session variable, assigns the parsed entry into a Dynamic ACL object, and assigns it into a current user session. An ACL is a set of restrictions associated with a resource or favorite that defines access for users and groups.

**EXAMPLES**  
create dynamic-acl {  
{ acl [ format [f5 | cisco] ] source  
} } }>  
Creates the Dynamic ACL agent named MyDynamicAclAgent.  
  
list dynamic-acl  
Displays a list of Dynamic ACL agents.  
  
delete dynamic-acl MyDynamicAclAgent  
Deletes the Dynamic ACL agent named MyDynamicAclAgent.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
  
entries  
Specifies the name of the entry to assign this dynamic access control list.  
  
[name]  
Specifies the name of the Dynamic Acl agent. This setting is required.  
  
partition  
Displays the partition within which the component resides.

**SEE ALSO**

## apm policy agent ending-allow

**NAME**  
ending-allow - Manages an Ending Allow agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the ending-allow component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create ending-allow [name]  
modify ending-allow [name]  
options:  
app-service [[string] | none]

**DISPLAY**  
list ending-allow  
list ending-allow [ [ [name] | [glob] | [regex] ] ... ]  
show running-config ending-allow  
show running-config ending-allow [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
all-properties  
app-service  
current-module  
non-default-properties  
one-line  
partition

**DELETE**  
delete ending-allow ([name] | all)

**DESCRIPTION**  
Access policy endings indicate the final outcome of a branch of an access policy. An Allow ending is a successful ending in which the system displays the user's home page and grants access to a webtop connection.

**EXAMPLES**  
create ending-allow MyEndingAllowAgent { }  
Creates the Ending Allow agent named MyEndingAllowAgent.  
  
list ending-allow  
Displays a list of Ending Allow agents.  
  
delete ending-allow MyEndingAllowAgent  
Deletes the Ending Allow agent named MyEndingDeniedAgent.

**OPTIONS**  
[name]  
Specifies the name of an Ending Allow agent. This option is required.  
  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
  
partition  
Displays the partition within which the component resides.

## apm policy agent ending-deny

**NAME**  
ending-deny - Manages an Ending Deny agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the ending-deny component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create ending-deny [name]  
modify ending-deny [name]  
options  
    app-service [[string] | none]  
    customization-group [name]

**DISPLAY**  
list ending-deny  
list ending-deny [ [ [name] | [glob] | [regex] ] ... ]  
show running-config ending-deny  
show running-config ending-deny [ [ [name] | [glob] | [regex] ] ... ]  
options:  
    all  
    all-properties  
    app-service  
    current-module  
    non-default-properties  
    one-line  
    partition

**DELETE**  
delete ending-deny ([name] | all)

**DESCRIPTION**  
Access policy endings indicate the final outcome of a branch of an access policy. The Logon Deny ending is the final result of an unsuccessful logon attempt (the failure could be caused by an incorrect logon attempt, a security requirement incompatibility, or the use of an unsupported device). Upon reaching a Logon Deny ending, the user sees an error message. You can use the ending-deny component to create and manage an Ending Deny agent.

**EXAMPLES**  
create ending-deny MyEndingDenyAgent customization-group MyLogOffCG  
Creates the Ending Deny agent named MyEndingDenyAgent that is associated with the MyLogOffCG customization group.

list ending-deny  
Displays a list of Ending Deny agents.

delete ending-deny MyEndingDenyAgent  
Deletes the Ending Deny agent named MyEndingDenyAgent.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

customization-group  
Specifies the name of the existing customization-group to which the agent belongs. It enables you to customize the logon deny page. For example, you can indicate a specific reason for the denial of access. This setting is required, and the customization group that you assign must be of the type logout.

[name]  
Specifies the name of an Ending Deny agent. This setting is required.

partition  
Displays the partition within which the component resides.

**SEE ALSO**  
tmsh

**COPYRIGHT**

## apm policy agent ending-redirect

**NAME**  
ending-redirect - Manages an Ending Redirect agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the ending-redirect component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create ending-redirect [name]  
modify ending-redirect [name]  
options  
    app-service [[string] | none]  
    close-session [true | false]  
    url [value]

**DISPLAY**  
list ending-redirect  
list ending-redirect [ [ [name] | [glob] | [regex] ] ... ]  
show running-config ending-redirect  
show running-config ending-redirect [ [ [name] | [glob] | [regex] ] ... ]  
options:  
    all  
    all-properties  
    app-service  
    current-module  
    non-default-properties  
    one-line  
    partition

**DELETE**  
delete ending-redirect ([name] | all)

**DESCRIPTION**  
The Redirect ending can be used to redirect the user, rather than allowing or denying a connection. It can also send a user directly to an update script or to different server or landing URI. Upon reaching a Redirect ending, the user sees a screen indicating that they are being redirected to a different URL. You can use the ending-redirect component to create and manage an Ending Redirect agent.

**EXAMPLES**  
create ending-redirect MyEndingRedirectAgent { url  
    "http://www.myweb.com" }  
Creates the Ending Redirect agent named MyEndingRedirectAgent that redirects a connection to http://www.myweb.com.

=item

Creates an agent using the current protocol and the session variable \${session.server.network.protocol}

list ending-redirect  
Displays a list of Ending Redirect agents.

delete ending-redirect MyEndingRedirectAgent  
Deletes the Ending Redirect agent named MyEndingRedirectAgent.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

close-session  
Redirects to the specified URI after closing the session if enabled. Otherwise, redirect to the specified URI without closing the session. The default is enabled.

[name]  
Specifies the name of an Ending Redirect agent. This option is required.

url Specifies the URL to which the system redirects the original request. This option is required, and you must specify an absolute URL.

An absolute URL specifies the exact location of a file or directory on the Internet.

**SEE ALSO**  
tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## apm policy agent endpoint-check-machine-cert

**NAME**  
endpoint-check-machine-cert - Manages an End-point Check Machine certificate agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the endpoint-check-machine-cert component within the apm policy agent module using the following syntax.

**CREATE/MODIFY**  
create endpoint-check-machine-cert [name]  
modify endpoint-check-machine-cert [name]  
options:  
allow-elevation [ true | false]  
app-service [[string] | none]  
ca-profile-name [value]  
issuer [value]  
save-cert [ true | false]  
serial-number [integer]  
store-location [machine | user]  
store-name [value]  
subject-alt-name [value]  
subject-match-fqdn [value]

edit endpoint-check-machine-cert [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list endpoint-check-machine-cert  
list endpoint-check-machine-cert [ [ [name] | [glob] | [regex] ] ... ]  
show running-config endpoint-check-machine-cert  
show running-config endpoint-check-machine-cert [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
all-properties  
app-service  
current-module  
non-default-properties  
one-line  
partition

**DELETE**  
delete endpoint-check-machine-cert [name]

**DESCRIPTION**  
Endpoint security is a centrally-managed method of monitoring and maintaining client-system security.

The endpoint-check-machine-cert component checks for the presence of a valid machine certificate on Windows/Mac client systems during access policy validation.

**EXAMPLES**  
create endpoint-check-machine-cert MyMCagent  
Creates the Endpoint Check Machine certificate agent named MyMCagent in the Common partition.

list endpoint-check-machine-cert  
Displays a list of Endpoint Check Machine certificate agents.

delete endpoint-check-machine-cert MyMCagent  
Deletes the MyMCagent Endpoint Check Machine certificate agent.

**OPTIONS**  
allow-elevation  
Specifies that User Account Control (UAC) prompts are allowed during private key checking.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

ca-profile-name  
Specifies the name of the certificate authority profile to validate the certificate.

issuer

Specifies the name used to match the issuer name in the machine certificate.

[name]

Specifies the name of an external logon page agent. This option is required.

partition

Displays the partition within which the component resides.

save-cert

Specifies to store the entire machine certificate in a session variable.

serial-number

Specifies the serial number used to match the serial number of the machine certificate.

store-location

Specifies the location of the certificate store on the client machine.

store-name

Specifies the name of the certificate store on the client machine.

subject-alt-name

Specifies the name used to match the subject-alt-name in the machine certificate.

subject-match-fqdn

Specifies if lookup must match fully qualified domain name (FQDN) in the machine certificate.

## apm policy agent endpoint-check-software

#### NAME

endpoint-check-software - Manages an Endpoint Software Check agent.

#### MODULE

apm policy agent

#### SYNTAX

Configure the endpoint-check-software component within the apm policy agent module using the following syntax.

##### CREATE/MODIFY

create endpoint-check-software [name]

modify endpoint-check-software [name]

##### options:

collect [ true | false ]

continuous-check [ true | false ]

type [ antivirus | firewall | patch-management | antispyware | peer-to-peer | hard-disk-encryption | health-agent

check-list-type [ required | allow | deny ]

items [ vendor\_id | product\_id | state | version | db-age | db-version | last-scan | missing-updates | platform ]

edit endpoint-check-software [ [ [name] | [glob] | [regex] ] ... ]

##### options:

all-properties

non-default-properties

##### DISPLAY

list endpoint-check-software

list endpoint-check-software [ [ [name] | [glob] | [regex] ] ... ]

show running-config endpoint-check-software

show running-config endpoint-check-software [ [ [name] | [glob] | [regex] ] ... ]

##### options:

all

all-properties

app-service  
current-module  
non-default-properties  
one-line  
partition

#### DELETE

delete endpoint-check-software ([name] | all)

#### DESCRIPTION

Endpoint security is a centrally-managed method of monitoring and maintaining client-system security. You can use the endpoint-check-software component to create and manage an agent that enforces monitoring of various client-system security third party software. Different types of third party software supported are described below in options.

The configuration attributes in the items option are generic and therefore for a given software type only certain items attributes are useful, rest of the attributes are ignored even if they are configured. For example: for type=peer-to-peer only vendor\_id, product\_id, state and version are considered and rest of the items like db-age, db-version etc are ignored. Following is the list of useful attributes corresponding to the software type:

Common to all software type:

vendor\_id, product\_id, version, platform, state

antivirus & antispysware:

db-age, db-version, last-scan

patch-management:

missing-updates

#### EXAMPLES

create endpoint-check-software MyEndpointWCagent items state enabled  
add

Creates the Endpoint Check Software agent named MyEndpointWCagent, which verifies that the specified third party software on the client is compliant with system administrators configuration, which my just check for the installation or monitor the state of the software

list endpoint-check-software

Displays a list of Endpoint Software Check agents.

delete endpoint-check-software MyEndpointWCagent

Deletes the Endpoint Software Check agent named MyEndpointWCagent.

#### OPTIONS

items

Adds items to or deletes items from an Endpoint Software Check agent. You can specify the following attributes for the software:

check-list-type Specifies how the list of software should be checked

required:

Client is required to have at least one of the software configured in the list in order to pass the access policy. And that software should satisfy all the configuration fields e.g. state, version etc.

allow: Client is allowed to have any of the software configured in the list but NOT any other than that, in order to pass the access policy. List is treated as whitelist. A given client software will not match unless it satisfies all the configuration fields (e.g. state, version etc). NOTE: The check will also be successful if client has no software installed at all. List of software is treated as whitelist.

deny: Client should NOT have any software configured in the list in order to pass the access policy. And that software should satisfy all the configuration fields (e.g. state, version etc). NOTE: The check will also be successful if client has no software installed at all. List of software is treated as blacklist.

db-age

Specifies the maximum age of the anti-virus/anti-spyware database that you want an Endpoint Software Check agent to verify the presence of on the client in order to allow the access policy to pass.

db-version

Specifies the version of the anti-virus/anti-spyware database that you want an Endpoint Software Check agent to verify the presence of on the client in order to allow the access policy to pass.

product\_id

Specifies the product ID of the software that you want an Endpoint Software Check agent to verify the presence of on the client in order to allow the access policy to pass.

vendor\_id

Specifies the vendor ID of the software that you want an Endpoint Software Check agent to verify the presence of on the client in order to allow the access policy to pass.

NOTE: If none of the vendor id or product id is defined then check is performed for any of the software of given type If both vendor id and product id are configured then, product id is ignored and only vendor id is considered. Vendor ID always takes precedence. A vendor can have many products. Each

product (of every vendor) has unique ID assigned to them. Similarly, every vendor is assigned a unique ID too which is separate from product ID. If you want to check every software from a vendor then specify vendor\_id only.

**state**  
State means different things to different software type. The state can be enabled, disabled or unspecified. The default is unspecified.

**antivirus and antispyware:**  
When the state is set to enabled or disabled, agent verifies that the specified antivirus/antispyware software has real time protection enabled or disabled on the client that is attempting to connect. When state is unspecified, it ignores the state.

**patch-management:**  
When the state is set to enabled, agent verifies that the specified PM software is running on the client that is attempting to connect. When its set to unspecified, state of the software is ignored.

**firewall:**  
When the state is enabled or disabled, agent verifies that the specified firewall software has real time protection enabled or disabled on the client that is attempting to connect. When state is unspecified, the software state is ignored.

**peer-to-peer:**  
When the state is set to enabled agent verifies that the peer-to-peer software is running on the client that is attempting to connect. When state is unspecified, the agent only verifies that the software is installed or not.

**hard-disk-encryption:**  
When the state is set to enabled agent verifies that all disk volumes are encrypted on the client that is attempting to connect. When the state is set to disabled agent verifies that system disk volume is encrypted on the client that is attempting to connect. When state is unspecified, the agent only verifies that the software is installed or not.

**health-agent:**  
When the state is set to enabled agent verifies that endpoint client is compliant with the health policy set out by the site administrator.

**version**  
Specifies the version of the software that you want an Endpoint Software Check agent to verify the presence of on the client in order to allow the access policy to pass.

**last-scan**  
Specifies the maximum allowed duration without the full system scan of endpoint client that software agent can accept in order to allow the access policy to pass. It is specified in number of days.

**missingupdates**  
Specifies the maximum number of allowed missing critical updates of the PM software at the endpoint client in order to allow the access policy to pass. Leave blank to ignore number of missing critical updates. Specify 0 to make sure endpoint client is up-to-date

**platform**  
Specifies the platform. It could be any of the following: windows, linux, mac or any. The default is any.

**type** Its the type of the third party software to be monitored on the client system. It could be any of the following: antivirus, firewall, patch-management, antispyware, peer-to-peer, hard-disk-encryption, health-agent

**collect**  
This setting is ignored.

**continuous-check**  
Continuously check the items, and end the session if the result changes. The default is false.

**[name]**  
Specifies the name of an Endpoint Software Check agent. This option is required.

**partition**  
Displays the partition within which the component resides.

## apm policy agent endpoint-linux-check-file

**NAME**  
endpoint-linux-check-file - Manages an Endpoint Linux Check File agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the endpoint-linux-check-file component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create endpoint-linux-check-file [name]  
modify endpoint-linux-check-file [name]  
options:  
continuous-check [ true | false ]  
app-service [[string] | none]  
files [ filename | md5 | modified | size ]  
  
edit endpoint-linux-check-file [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list endpoint-linux-check-file  
list endpoint-linux-check-file [ [ [name] | [glob] | [regex] ] ... ]  
show running-config endpoint-linux-check-file  
show running-config endpoint-linux-check-file [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
all-properties  
app-service  
current-module  
non-default-properties  
one-line  
partition

**DELETE**  
delete endpoint-linux-check-file ([name] | all)

**DESCRIPTION**  
Access Policy Manager checks for the presence of one or more files on a client that is attempting to connect. If a file with the described properties exists, the action goes to the successful branch. If the file does not exist, or a file exists but one or more properties are not correct, the action goes to the fallback branch.  
  
You can use the endpoint-linux-check-file component to create or manage an Endpoint Linux Check File agent that verifies the presence of specified Linux files on a client.

**EXAMPLES**  
create endpoint-linux-check-file Myprofile\_act\_file\_check\_ag { files { filename "/tmp/demo/demofile" md5 "6b6lad518c23650b17e738elfa2bb04e" modified 2007-06-01 10:30:10 size 12 } { filename "/tmp/demo/testfile" md5 "f20d9f2072bbeb6691c0f9c5099b01f3" size 9 } }  
Creates the Endpoint Linux Check File agent named Myprofile\_act\_file\_check\_ag that checks that the client contains two files located in the /tmp/demo directory: a 12 byte file named demofile that was modified no later than January 6, 2007 at 10:30 and has an MD5 checksum of 6b6lad518c23650b17e738elfa2bb04e, and a 9-byte file named testfile that has an MD5 check sum of f20d9f2072bbeb6691c0f9c5099b01f3.  
  
list all endpoint-linux-check-file Company8profile\_act\_file\_check\_ag  
Displays information about the Endpoint Linux Check File agent named Company8profile\_act\_file\_check\_ag.  
  
delete endpoint-linux-check-file Company8profile\_act\_check\_file { files { filename "/tmp/demo/demofile" }}  
Deletes the /tmp/demo/demofile file from the Endpoint Linux Check File agent named Company8profile\_act\_file\_check\_ag.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application

service can modify or delete the object.

#### files

Adds files to or deletes files from an Endpoint Linux Check File agent. You can specify the following attributes of the files that you want an Endpoint Linux Check File agent to verify the presence of on the client in order to allow the access policy to pass.

#### filename

Specifies the name of the file and includes the full path. The Endpoint Linux Check File agent that you are creating must be able to verify the file's presence on the client for the access policy to pass. When you add a file to or delete a file from the agent, this setting is required.

**md5** Specifies the value of an MD5 checksum. The Endpoint Linux Check File agent you are creating must be able to match the checksum on the client for the access policy to pass. The default is none.

#### modified

Specifies the last modified date of the specified file. The Endpoint Linux Check File agent you are creating must verify this date on the client for the access policy to pass. The default is 1970-01-01 00:00:00.

**size** Specifies the size, in bytes, of the specified file. The Endpoint Linux Check File agent you are creating must verify this size on the client for the access policy to pass. The default is 0.

#### continuous-check

Continuously check the files, and end the session if the result changes. The default is false.

#### [name]

Specifies the name of an Endpoint Linux Check File agent. This setting is required.

#### partition

Displays the partition within which the component resides.

#### SEE ALSO

## apm policy agent endpoint-linux-check-process

#### NAME

endpoint-linux-check-process - Manages an Endpoint Linux Check Process agent.

#### MODULE

apm policy agent

#### SYNTAX

Configure the endpoint-linux-check-process component within the policy agent module using the following syntax.

#### CREATE/MODIFY

```
create endpoint-linux-check-process [name]
modify endpoint-linux-check-process [name]
```

#### options

```
continuous-check [ true | false ]
app-service [[string] | none]
expression [ string | none ]
```

```
edit endpoint-linux-check-process [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

```
all-properties
non-default-properties
```

#### DISPLAY

```
list endpoint-linux-check-process
list endpoint-linux-check-process [ [ [name] | [glob] | [regex] ] ... ]
```

```

show running-config endpoint-linux-check-process
show running-config endpoint-linux-check-process [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  app-service
  current-module
  non-default-properties
  one-line
  partition

DELETE
delete endpoint-linux-check-process [name]

```

**DESCRIPTION**  
 You can use the endpoint-linux-check-process component to create and manage an Endpoint Linux Check Process agent that collects information about the Linux processes running on the client.

**EXAMPLES**  

```

create endpoint-linux-check-process MyEndpointWCPagent { (bash OR top)
AND firefox }

```

 Creates the Endpoint Linux Check Process agent named MyEndpointWCPagent that checks that the client has either bash or top, and firefox launched.  

```

list endpoint-linux-check-process

```

 Displays a list of Endpoint Linux Check Process agents.  

```

delete endpoint-linux-check-process MyEndpointWCPagent

```

 Deletes the Endpoint Linux Check Process agent named MyEndpointWCPagent.

**OPTIONS**  
**app-service**  
 Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
**expression**  
 Specifies the expression that you want an Endpoint Linux Check Process agent to use to verify the processes that are running on the client to allow the access policy to pass. You can use the following operators: AND, OR, NOT, (and). You can use wildcards in the process name, for example, navapsvc.\*.  
 If the check is successful, the system returns 1. If the check fails, the system returns 0. If the expression is incorrect, the system returns -1.  
**continuous-check**  
 Continuously check the expression, and end the session if the result changes. The default is false.  
**[name]**  
 Specifies the name of an Endpoint Linux Check Process agent. This setting is required.  
**partition**  
 Displays the partition within which the component resides.

**SEE ALSO**  
 endpoint-check-software, endpoint-linux-check-file, endpoint-mac-check-file, endpoint-mac-check-process, endpoint-windows-browser-cache-cleaner, endpoint-windows-check-file, endpoint-check-machine-cert, endpoint-windows-check-process, endpoint-windows-check-registry, endpoint-windows-group-policy, endpoint-windows-info-os, endpoint-machine-info, endpoint-windows-protected-workspace

## apm policy agent endpoint-mac-check-file

**NAME**  
 endpoint-mac-check-file - Manages an Endpoint Macintosh Check File agent.  
**MODULE**  
 apm policy agent

## SYNTAX

Configure the endpoint-mac-check-file component within the policy agent module using the following syntax.

```
CREATE/MODIFY
create endpoint-mac-check-file [name]
modify endpoint-mac-check-file [name]
options

```

## DESCRIPTION

Access Policy Manager checks for the presence of one or more files on a client that is attempting to connect. If a file with the described properties exists, the action goes to the successful branch. If the file does not exist, or a file exists but one or more properties are not correct, the action goes to the fallback branch.

You can use the endpoint-mac-check-file component to create or manage an Endpoint Macintosh Check File agent that verifies the presence of specified Macintosh files on a client.

## EXAMPLES

```
create endpoint-mac-check-file Myprofile_act_file_check_ag { files {
  filename "/tmp/demo/demofile" md5 "6b61ad518c23650b17e738e1fa2bb04e"
  modified 2007-06-01 10:30:10 size 12 } { filename "/tmp/demo/testfile"
  md5 "f20d9f2072bbeb6691c0f9c5099b01f3" size 9 } }
Creates the Endpoint Macintosh Check File agent named
Myprofile_act_file_check_ag that checks that the client contains
two files located in the /tmp/demo directory: a 12 byte file named
demofile that was modified no later than January 6, 2007 at 10:30
and has an MD5 checksum of 6b61ad518c23650b17e738e1fa2bb04e, and a
9 byte file named testfile that has an MD5 check sum of
f20d9f2072bbeb6691c0f9c5099b01f3.

list all endpoint-mac-check-file Company8profile_act_file_check_ag
Displays information about the Endpoint Macintosh Check File agent
named Company8profile_act_file_check_ag.

delete endpoint-mac-check-file Company8profile_act_check_file { files {
  filename "/tmp/demo/demofile" }}
Deletes the /tmp/demo/demofile file from the Endpoint Macintosh
Check File agent named Company8profile_act_file_check_ag.
```

## OPTIONS

### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

### files

Adds files to or deletes files from an Endpoint Macintosh Check File agent. You can specify the following attributes of the files that you want an Endpoint Macintosh Check File agent to verify the presence of on the client to allow the access policy to pass:

#### filename

Specifies the name of the file and includes the full path. The Endpoint Macintosh Check File agent that you are creating must be able to verify the file's presence on the client for the access policy to pass. When you add a file to or delete a file from the agent, this setting is required.

**md5** Specifies the value of an MD5 checksum. The Endpoint Macintosh Check File agent you are creating must be able to match the checksum on the client for the access policy to pass. The default is none.

#### modified

Specifies the last modified date of the specified file. The Endpoint Macintosh Check File agent you are creating must verify this date on the client for the access policy to pass. The default is 1970-01-01 00:00:00.

**size** Specifies the size, in bytes, of the specified file. The Endpoint Macintosh Check File agent you are creating must verify this size on the client for the access policy to pass. The default is 0.

continuous-check  
Continuously check the files, and end the session if the result changes. The default is false.

[name]  
Specifies the name of an Endpoint Macintosh Check File agent. This setting is required.

partition  
Displays the partition within which the component resides.

#### SEE ALSO

## apm policy agent endpoint-mac-check-process

#### NAME

endpoint-mac-check-process - Manages an Endpoint Macintosh Check Process agent.

#### MODULE

apm policy agent

#### SYNTAX

Configure the endpoint-mac-check-process component within the policy agent module using the following syntax.

##### CREATE/MODIFY

```
create endpoint-mac-check-process [name]
modify endpoint-mac-check-process [name]
options
  continuous-check [ true | false ]
  app-service [[string] | none]
  expression [ string | none ]
```

```
edit endpoint-mac-check-process [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list endpoint-mac-check-process
list endpoint-mac-check-process [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-mac-check-process
show running-config endpoint-mac-check-process [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  app-service
  current-module
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete endpoint-mac-check-process ([name] | all)
```

#### DESCRIPTION

You can use the endpoint-mac-check-process component to create and manage an Endpoint Macintosh Check Process agent that collects information about the Macintosh processes running on the client.

#### EXAMPLES

```
create endpoint-mac-check-process MyEndpointWCPagent { (bash OR top)
AND firefox }
Creates the Endpoint Macintosh Check Process agent named
MyEndpointWCPagent that checks that the client has either bash or
top, and firefox launched.
```

```
list endpoint-mac-check-process
Displays a list of Endpoint Macintosh Check Process agents.
```

```
delete endpoint-mac-check-process MyEndpointWCPagent
Deletes the Endpoint Macintosh Check Process agent named
MyEndpointWCPagent.
```

## OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**expression**  
Specifies the expression that you want an Endpoint Macintosh Check Process agent to use to verify the processes that are running on the client in order to allow the access policy to pass. You can use the following operators: AND, OR, NOT, (and). You can use wildcards in the process name, for example, navapvc.\*.

If the check is successful, the system returns 1. If the check fails, the system returns 0. If the expression is incorrect, the system returns -1.

**continuous-check**  
Continuously check the expression, and end the session if the result changes. The default is false.

**[name]**  
Specifies the name of an Endpoint Macintosh Check Process agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

## apm policy agent endpoint-machine-info

**NAME**  
endpoint-machine-info - Manages an Endpoint Machine Information agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the endpoint-machine-info component within the policy agent module using the following syntax.

```
CREATE/MODIFY
create endpoint-machine-info [name]
modify endpoint-machine-info [name]
options:
  app-service [(string) | none]

edit endpoint-machine-info [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

DISPLAY
list endpoint-machine-info
list endpoint-machine-info [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-machine-info
show running-config endpoint-machine-info [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show endpoint-machine-info
show endpoint-machine-info [name]

DELETE
delete endpoint-machine-info [name]
```

**DESCRIPTION**  
You can use the endpoint-machine-info component to create and manage an agent that collects information about the machine that is attempting to connect.

## OPTIONS

**[name]**  
Specifies the name of the an Endpoint Check Machine Information

agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### SEE ALSO

## apm policy agent endpoint-windows-browser-cache-cleaner

#### NAME

endpoint-windows-browser-cache-cleaner - Manages an Endpoint Windows Browser Cache Cleaner agent.

#### MODULE

apm policy agent

#### SYNTAX

Configure the endpoint-windows-browser-cache-cleaner component within the policy agent module using the following syntax.

##### CREATE/MODIFY

```
create endpoint-windows-browser-cache-cleaner [name]
modify endpoint-windows-browser-cache-cleaner [name]
options
  app-service [[string] | none]
  cache-clean-type [all | all-except-css-js | all-except-img-css-js | none ]
  clean-passwords [false | true ]
  empty-recycle-bin [false | true ]
  idle-timeout [ | immediate | indefinite]
  idle-timeout-screen-lock [ ]
  monitor-webtop [enable | disable]
  partition
  remove-connection-entry [false | true ]
```

```
edit endpoint-windows-browser-cache-cleaner [ [ [name] | [glob] | [regex] ] ... ]
```

##### options:

```
all-properties
non-default-properties
```

##### DISPLAY

```
list endpoint-windows-browser-cache-cleaner
list endpoint-windows-browser-cache-cleaner [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-windows-browser-cache-cleaner
show running-config endpoint-windows-browser-cache-cleaner [ [ [name] | [glob] | [regex] ] ... ]
options:
all
all-properties
app-service
current-module
non-default-properties
one-line
partition
```

##### DELETE

```
delete endpoint-windows-browser-cache-cleaner ([name] | all)
```

#### DESCRIPTION

Endpoint security is a centrally-managed method of monitoring and maintaining client-system security. You can use the endpoint-windows-browser-cache-cleaner component to create and manage an Endpoint Windows Browser Cache Cleaner agent. This agent cleans items from the client browser and computer after logoff, and also enforces session inactivity timeouts.

#### EXAMPLES

```
create endpoint-windows-browser-cache-cleaner MyEndpointWBCCagent idle
timeout 0
```

Creates the Endpoint Windows Browser Cache Cleaner agent named MyEndpointWBCCagent that does not enforce a timeout.

```
create endpoint-windows-browser-cache-cleaner MyEndpointWBCCagent {
  idle timeout 0 clean passwords enable }
Creates the Endpoint Windows Browser Cache Cleaner agent named
MyEndpointWBCCagent that does not enforce a timeout, but does
clear saved passwords from the client after logoff.

list endpoint-windows-browser-cache-cleaner
Displays a list of Endpoint Windows Browser Cache Cleaner agents.

delete endpoint-windows-browser-cache-cleaner MyEndpointWBCCagent
Deletes the Endpoint Windows Browser Cache Cleaner agent named
MyEndpointWBCCagent.
```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**cache-clean-type**  
Specifies which browser cache temporary files are removed. If set to all, the temporary files are removed. If set to all-except-css-js, the browser cache is cleared, but all style sheets and JavaScript are left on the browser cache. If set to all-except-img-css-js, the browser cache is cleared, but all style sheets, JavaScript, and images are left on the browser cache. The default is all.

**clean-passwords**  
When true, the Endpoint Windows Browser Cache Cleaner agent ensures that saved passwords are cleared from the client after logoff. The default is false.

**empty-recycle-bin**  
When true, the Endpoint Windows Browser Cache Cleaner agent empties the Recycle Bin on the client after logoff. The default is false.

**idle-timeout**  
Specifies the number of minutes that the client session can be idle before the Endpoint Windows Browser Cache Cleaner agent disconnects the session. The default is 0, which enforces no timeout. This is a required setting.

**Idle-timeout-screen-lock**  
Specifies the number of minutes the system can receive no user input before the workstation is locked. The default is 0, which specifies no timeout enforced.

**monitor-webtop**  
When true, the Endpoint Windows Browser Cache Cleaner agent forces session termination if the browser or webtop is closed. The default is false.

**[name]**  
Specifies the name of the Endpoint Windows Browser Cache Cleaner agent. This is a required setting.

**partition**  
Displays the partition within which the component resides.

**remove-connection-entry**  
When true, the Endpoint Windows Browser Cache Cleaner agent removes the connection from the Network Connections Dial-up Networking folder on the client. The default is false.

#### SEE ALSO

show running-config endpoint-windows-check-file [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all
    all-properties
    app-service
    current-module
    non-default-properties
    one-line
    partition

DELETE
delete endpoint-windows-check-file ([name] | all)
  
```

**DESCRIPTION**  
 Access Policy Manager checks for the presence of one or more files on a client that is attempting to connect. If a file with the described properties exists, the action goes to the successful branch. If the file does not exist, or a file exists but one or more properties are not correct, the action goes to the fallback branch.

You can use the endpoint-windows-check-file component to create or manage an Endpoint Windows Check File agent that verifies the presence of specified Windows files on a client.

**EXAMPLES**

```

create endpoint-windows-check-file Myprofile act_file_check_ag { files
{ filename "C:\\demo\\demofile" md5 "6b61ad518c23650b17e738e1fa2bb04e"
modified 2007-06-01 10:30:10 size 12 } { filename "C:\\demo\\test.file"
md5 "f20d9f2072bbeb6691c0f9c5099b01f3" size 9 } }
  
```

Creates the Endpoint Windows Check File agent named Myprofile\_act\_file\_check\_ag that checks that the client contains two files located in the C:\demo directory: a 12 byte file named demofile that was modified no later than January 6, 2007 at 10:30 and has an MD5 checksum of 6b61ad518c23650b17e738e1fa2bb04e, and a 9 byte file named test.file that has an MD5 check sum of f20d9f2072bbeb6691c0f9c5099b01f3.

```

list all endpoint-windows-check-file Company8profile act_file_check_ag
  
```

Displays information about the Endpoint Windows Check File agent named Company8profile\_act\_file\_check\_ag.

```

delete endpoint-windows-check-file Company8profile_act_check_file {
  files { filename "C:\\demo\\demofile" } }
  
```

Deletes the C:\demo\demofile file from the Endpoint Windows Check File agent named Company8profile\_act\_file\_check\_ag.

**OPTIONS**

**app-service**  
 Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**files**  
 Adds files to or deletes files from an Endpoint Windows Check File agent. You can specify the following attributes for the files that you want an Endpoint Windows Check File agent to verify the presence of on the client to allow the access policy to pass.

**filename**  
 Specifies a file name and includes the full path. The Endpoint windows Check File agent you are creating must be able to verify the file's presence on the client for the access policy to pass. When you add a file to or delete a file from the agent, this setting is required.

**md5** Specifies the value of an MD5 checksum. The Endpoint windows Check File agent that you are creating must match the checksum on the client for the access policy to pass. The default is none.

**modified**  
 Specifies the last modified date of the specified file. The

Endpoint windows Check File agent you are creating must verify this date on the client for the access policy to pass. The default is 1970-01-01 00:00:00.

#### operation

Specifies the operator that you want your Endpoint Windows Check File agent to use when verifying the attributes of the specified file on the client. The default is equal.

#### signer

Specifies that the Endpoint Windows Check File agent must verify that the specified file on the client is signed for the access policy to pass. The default is none.

size Specifies the size, in bytes, of the specified file. The Endpoint Windows Check File agent you are creating must verify this file size on the client for the access policy to pass. The default is 0.

#### version

Specifies the version of the specified file that you want your Endpoint Windows Check File agent to verify on the client for the access policy to pass. Specify the version using the following form: x.x.x.x. The maximum value is 65535.65535.65535.65535. The default is none.

#### continuous-check

Continuously check the files, and end the session if the result changes. The default is false.

#### [name]

Specifies the name of an Endpoint Windows Check File agent. This option is required.

#### partition

Displays the partition within which the component resides.

#### SEE ALSO

## apm policy agent endpoint-windows-check-process

#### NAME

endpoint-windows-check-process - Manages an Endpoint Windows Check Process agent.

#### MODULE

apm policy agent

#### SYNTAX

Configure the endpoint-windows-check-process component within the policy agent module using the following syntax.

##### CREATE/MODIFY

```
create endpoint-windows-check-process [name]
modify endpoint-windows-check-process [name]
options:
  continuous-check [ true | false ]
  app-service [[string] | none]
  expression ( | none)
```

```
edit endpoint-windows-check-process [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list endpoint-windows-check-process
list endpoint-windows-check-process [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-windows-check-process
show running-config endpoint-windows-check-process [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```

    partition

show endpoint-windows-check-process
show endpoint-windows-check-process [name]

DELETE
delete endpoint-windows-check-process [name]

DESCRIPTION
    You can use the endpoint-windows-check-process component to create and
    manage an agent that collects information about the Windows processes
    running on the client.

EXAMPLES
    create endpoint-windows-check-process MyEndpointWCPagent { (NISUM.exe
    OR blackd.exe) AND navapsvc.* }
    Creates the Endpoint Windows Check Process agent named
    MyEndpointWCPagent that checks that the client has either
    NISUM.exe or blackd.exe, and navapsvc.* installed.

    list endpoint-windows-check-process
    Displays a list of Endpoint Windows Check Process agents.

    delete endpoint-windows-check-process MyEndpointWCPagent delete
    Deletes the Endpoint Windows Check Process agent named
    MyEndpointWCPagent.

OPTIONS
    app-service
    Specifies the name of the application service to which the object
    belongs. The default value is none. Note: If the strict-updates
    option is enabled on the application service that owns the object,
    you cannot modify or delete the object. Only the application
    service can modify or delete the object.

    expression
    Specifies the expression that you want an Endpoint Windows Check
    Process agent to use to verify the processes that are running on
    the client in order to allow the access policy to pass. You can
    use the following operators: AND, OR, NOT, (and). You can use
    wildcards in the process name, for example, navapsvc.*.

    If the check is successful, the system returns 1. If the check
    fails, the system returns 0. If the expression is incorrect, the
    system returns -1.

    continuous-check
    Continuously check the expression, and end the session if the
    result changes. The default is false.

    [name]
    Specifies the name of an Endpoint Windows Check Process agent.
    This setting is required.

    partition
    Displays the partition within which the component resides.

SEE ALSO

## apm policy agent endpoint-windows-check-registry

```

NAME
    endpoint-windows-check-registry - Manages an Endpoint Windows Check
    Registry agent.

MODULE
    apm policy agent

SYNTAX
    Configure the endpoint-windows-check-registry component within the
    policy agent module using the following syntax.

    CREATE/MODIFY
    create endpoint-windows-check-registry [name]

```

```

modify endpoint-windows-check-registry [name]
options:
  continuous-check [ true | false ]
  app-service [[string] | none]
  expression [[string] | none]

edit endpoint-windows-check-registry [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list endpoint-windows-check-registry
list endpoint-windows-check-registry [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-windows-check-registry
show running-config endpoint-windows-check-registry [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show endpoint-windows-check-registry
show endpoint-windows-check-registry [name]

DELETE
delete endpoint-windows-check-registry [name]

```

#### DESCRIPTION

You can use the endpoint-windows-check-registry component to create and manage an agent that collects information about the Windows registry keys on the client that is attempting to connect.

#### EXAMPLES

```

create endpoint-windows-check-registry MyEndpointWCRagent
{"\"HKEY_LOCAL_MACHINE\\SOFTWARE\\Microsoft\\Internet
Explorer\".\"Version\"=\"5.0.2800.0\""}
Creates the Endpoint Windows Check Registry agent named
MyEndpointWCRagent that checks the registry on the client for
version 5.0.2800.0 of Internet Explorer in the
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft directory.

```

```

create endpoint-windows-check-registry MyEndpointWCRagent
{"\"HKEY_LOCAL_MACHINE64\\SOFTWARE\\Microsoft\\Internet
Explorer\".\"Version\"=\"5.0.2800.0\""}
Creates the Endpoint Windows Check Registry agent named
MyEndpointWCRagent that checks the registry on the client for
version 5.0.2800.0 of Internet Explorer in the
HKEY_LOCAL_MACHINE64\SOFTWARE\Microsoft directory.

```

Note that the registry value HKEY\_LOCAL\_MACHINE64 is one of the 32 and 64-bit registry keys that you can specify on 64-bit Windows versions. On 64-bit Windows systems, you can check for registry keys in either the 64-bit registry or the 32-bit registry. To specify the registry to check, append a number to the registry root key name. The following key names are supported:

```

HKEY_CURRENT_USER
HKEY_CURRENT_USER32
HKEY_CURRENT_USER64
HKEY_LOCAL_MACHINE

HKEY_CLASSES_ROOT
HKEY_CLASSES_ROOT32
HKEY_CLASSES_ROOT64
HKEY_USERS
HKEY_USERS32
HKEY_USERS64

```

HKEY\_USERS64 HKEY values specified with a 32 allow you to check values in the 32-bit view of 64-bit registry. This is the perspective used by 32-bit applications running with on a 64-bit operating system.

HKEY values with a 64 appended allow you to check values in the 64-bit view of the registry. This is the perspective used by native 64-bit applications. When checking values on 32-bit Windows, the number of bits specified in the registry key name is ignored.

```

list endpoint-windows-check-registry
Displays a list of Endpoint Windows Check Registry agents.

```

```

delete endpoint-windows-check-registry MyEndpointWCRagent delete
Deletes the Endpoint Windows Check Registry agent named
MyEndpointWCRagent.

```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**expression**  
Specifies the expression that you want an Endpoint Windows Check Registry agent to use to verify the registry entries that are present on the client in order to allow the access policy to pass. You can use the following operators: AND, OR, NOT, (and).

If the check is successful, the system returns 1. If the check fails, the system returns 0. If the expression is incorrect, the system returns -1.

**Important:** You must use quotation marks ( " ") around key and value arguments, and in data when the content contains spaces, commas,

slashes, tabs, or other delimiters. If quotation marks exist as part of a registry path or value name, you must use quotation marks around those quotation marks.

Tip: The system treats data in the formats "d.d[d][.d]" or "d,d[d][,d]" (where d is a number) as a version number. The system treats data in the format "mm/dd/yyyy" as a date.

**continuous-check**  
Continuously check the expression, and end the session if the result changes. The default is false.

**[name]**  
Specifies the name of the an Endpoint Windows Check Registry agent. This option is required.

**partition**  
Displays the partition within which the component resides.

## apm policy agent endpoint-windows-group-policy

**NAME**  
endpoint-windows-group-policy - Manages an Endpoint Windows Group Policy agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Warning: This page is obsolete. Windows Group Policy is no longer supported.  
  
Configure the external-logon-page component within the policy agent module using the following syntax.

**CREATE/MODIFY**  
create endpoint-windows-group-policy [name]  
modify endpoint-windows-group-policy [name]  
    options:  
        app-service [[string] | none]  
        policy-file { [name] }  
  
edit endpoint-windows-group-policy [ [ [name] | [glob] | [regex] ] ... ]  
    options:  
        all-properties  
        non-default-properties  
  
**DISPLAY**  
list endpoint-windows-group-policy  
list endpoint-windows-group-policy [ [ [name] | [glob] | [regex] ] ... ]  
show running-config endpoint-windows-group-policy  
show running-config endpoint-windows-group-policy [ [ [name] | [glob] | [regex] ] ... ]  
    options:  
        all-properties  
        non-default-properties  
        partition  
  
show endpoint-windows-group-policy  
show endpoint-windows-group-policy [name]  
  
**DELETE**  
delete endpoint-windows-group-policy [name]

**DESCRIPTION**  
Endpoint Windows Group Policy agents enable you to apply an Endpoint Windows Group Policy to a client machine and create a result session variable.

**EXAMPLES**  
create endpoint-windows-group-policy { Firewall\_Settings\_Template }  
Creates a policy for the Access Policy using the Firewall Settings template.

edit endpoint-windows-group-policy Firewall\_Settings\_Template  
Edits the Firewall Settings Template.

#### OPTIONS

[name]  
Specifies a name for the Endpoint Windows Group Policy agent.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

policy-file  
Specifies the group policy template that is applied to the client. This option is required.

## apm policy agent endpoint-windows-info-os

#### NAME

endpoint-windows-info-os - Manages an Endpoint Windows Information Operating System agent.

#### MODULE

apm policy agent

#### SYNTAX

Configure the endpoint-windows-info-os component within the policy agent module using the following syntax.

##### CREATE/MODIFY

```
create endpoint-windows-info-os [name]
modify endpoint-windows-info-os [name]
options:
  app-service [[string] | none]
```

```
edit endpoint-windows-info-os [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list endpoint-windows-info-os
list endpoint-windows-info-os [ [ [name] | [glob] | [regex] ] ... ]
show running-config endpoint-windows-info-os
show running-config endpoint-windows-info-os [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition
```

```
show endpoint-windows-info-os
show endpoint-windows-info-os [name]
```

##### DELETE

```
delete endpoint-windows-info-os [name]
```

#### DESCRIPTION

You can use the endpoint-windows-info-os component to create and manage an agent that retrieves information about the Microsoft Windows operating system from the client, such as version and hotfix number.

#### EXAMPLES

```
create endpoint-windows-info-os MyEndpointWIOSAgent { }
Creates the Endpoint Windows Operating System Information agent
named MyEndpointWIOSAgent.
```

list endpoint-windows-info-os  
Displays a list of Endpoint Windows Operating System Information agents.

delete endpoint-windows-info-os MyEndpointWIOSagent delete  
Deletes the Endpoint Windows Operating System Information agent named MyEndpointWCRagent.

#### OPTIONS

[name]  
Specifies the name of an Endpoint Windows Info OS agent. This setting is required.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### SEE ALSO

endpoint-check-software, endpoint-linux-check-file, endpoint-linux-check-process, endpoint-mac-check-file, endpoint-mac-check-process, endpoint-windows-browser-cache-cleaner, endpoint-windows-check-file, endpoint-check-machine-cert, endpoint-windows-check-process, endpoint-windows-check-registry, endpoint-windows-group-policy, endpoint-machine-info, endpoint-windows-protected-workspace

## apm policy agent endpoint-windows-protected-workspace

NAME  
endpoint-windows-protected-workspace - Manages an Endpoint Windows Protected Workspace agent.

MODULE  
apm policy agent

SYNTAX  
Configure the endpoint-windows-protected-workspace component within the policy agent module using the following syntax.

CREATE/MODIFY  
create endpoint-windows-protected-workspace [name]  
modify endpoint-windows-protected-workspace [name]  
options:  
  allow-burn-cid [true | false]  
  allow-printer-use [true | false]  
  allow-user-switch [true | false]  
  allowed-network-shares [add | delete | modify | replace-all-with] {  
    [[string]]  
  }  
  app-service [[string] | none]  
  close-google-desktop-search [true | false]  
  usb-flash-access [all | ironkey | none]  
  
edit endpoint-windows-protected-workspace [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  
DISPLAY  
list endpoint-windows-protected-workspace  
list endpoint-windows-protected-workspace [ [ [name] | [glob] | [regex] ] ... ]  
show running-config endpoint-windows-protected-workspace  
show running-config endpoint-windows-protected-workspace [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  partition  
  
show endpoint-windows-protected-workspace  
show endpoint-windows-protected-workspace [name]  
  
DELETE  
delete endpoint-windows-protected-workspace [name]

#### DESCRIPTION

You can use the endpoint-windows-protected-workspace component to create and manage an agent that enables an administrator to impose limitations on applications running on Windows client machines.

#### OPTIONS

allow-burn-cid

Specifies that the user can burn CDs from within protected workspace. The default is false.

allow-printer-use

Specifies whether a user can print inside a protected workspace. The default is true.

allow-user-switch

Specifies whether a user can temporarily switch from a protected workspace. The default is true.

allowed-network-shares

Specifies a list of Windows network shares to which user has Write access. The default is none.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

[name]

Specifies the name of the Endpoint Windows Protected Workspace agent. This option is required.

partition

Displays the partition within which the component resides.

usb-flash-access

Specifies whether a user has access to a USB port. The default is false.

#### SEE ALSO

endpoint-check-software, endpoint-linux-check-file, endpoint-linux-check-process, endpoint-mac-check-file, endpoint-mac-check-process, endpoint-windows-browser-cache-cleaner, endpoint-windows-check-file, endpoint-check-machine-cert, endpoint-windows-check-process, endpoint-windows-check-registry, endpoint-windows-info-os, endpoint-machine-info

## apm policy agent external-logon-page

#### NAME

external-logon-page - Manages an External Logon Page agent.

#### MODULE

apm policy agent

#### SYNTAX

Configure the external-logon-page component within the policy agent module using the following syntax.

##### CREATE/MODIFY

create external-logon-page [name]

modify external-logon-page [name]

options:

app-service [[string] | none]

split-username [true | false]

uri [[string]> | none]

edit external-logon-page [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties

non-default-properties

##### DISPLAY

list external-logon-page

list external-logon-page [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties

non-default-properties

partition

```

DELETE
delete external-logon-page [name]

DESCRIPTION
The External Logon Page agent creates an external Logon page that
redirects the client browser.

EXAMPLES
    create external-logon-page MyExternalLogonPageAgent { uri
    "MyExternalLogonPageServerURI" }
Creates the External Logon Page agent named
MyExternalLogonPageAgent that is associated with the URI
MyExternalLogonPageServerURI.

    create external-logon-page MyExternalLogonPageAgent { uri
    "%{session.my_server_uri}" }
Creates the External Logon Page agent named
MyExternalLogonPageAgent with a URI of session.my_server_uri.

    list external-logon-page
Displays a list of External Logon Page agents.

    delete external-logon-page MyExternalLogonPageAgent
Deletes the External Logon Page agent named
MyExternalLogonPageAgent.

OPTIONS
    [name]
Specifies the name of an External Logon Page agent. This option is
required.

    partition
Displays the partition within which the component resides.

    app-service
Specifies the name of the application service to which the object
belongs. The default value is none. Note: If the strict-updates
option is enabled on the application service that owns the object,
you cannot modify or delete the object. Only the application
service can modify or delete the object.

    split-username
Specifies whether user's input is split into username and domain.
This option supports UPN style logon ID (userid@domainid) and
Windows Domain User account ID (domainid\userid). The default is
false. Set this to true when you want to store the username and
domain separately.

    uri
Specifies a predefined configuration that contains several
settings that you want the agent to use to configure an External
Logon page. This option is required.

SEE ALSO
    logon-page

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or
by any means, electronic or mechanical, including photocopying,
recording, or information storage and retrieval systems, for any
purpose other than the purchaser's personal use, without the express
written permission of F5 Networks, Inc.

## apm policy agent http-header-modify

```

NAME
    http-header-modify - HTTP header and cookie manipulation agent for
    per-request access policy.

MODULE
    apm policy agent

SYNTAX
    Manipulate HTTP headers or cookies within the policy agent module using
    the syntax shown in the following sections.

    CREATE/MODIFY
    create http-header-modify [name]
    modify http-header-modify [name]
    options:
        app-service [[string] | none]
        cookie-entries [add | delete | modify | none | replace-all-with] {
            [name] {
        options:
            app-service [[string] | none]
            cookie-name [string]
            cookie-operation [cookie-delete | cookie-update]
            cookie-value [string]

```

```

    }
  }
  header-entries [add | delete | modify | none | replace-all-with] {
    [name] {
  options:
    app-service [[string] | none]
    header-delimiter [string]
    header-name [string]
    header-operation [header-append | header-insert | header-remove | header-replace]
    header-value [string]
    }
  }
}

edit http-header-modify [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

DISPLAY
list http-header-modify
list http-header-modify [ [ [name] | [glob] | [regex] ] ... ]
show running-config http-header-modify
show running-config http-header-modify [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    app-service
    cookie-entries
    header-entries
    non-default-properties
    partition

DELETE
delete http-header-modify [name]

```

#### DESCRIPTION

You can use the http-header-modify component to create and manage a http-header-modify agent that manipulates the HTTP and Cookie headers. Operations supported for HTTP header include insert, append, replace and remove while for cookie only update and delete operations are available. Please note that this agent applies only to per-request access policy.

#### EXAMPLES

```

create http-header-modify MyProfile_act_http-header-modify_ag {
  cookie-entries {
    0 {
      cookie-name PHPSESSID
      cookie-value 1234
    }
    1 {
      cookie-name mySession
      cookie-operation cookie-delete
      cookie-value 5678
    }
  }
  header-entries {
    0 {
      header-name Cache-Control
      header-value no-cache
    }
    1 {
      header-delimiter ;
      header-name User-Agent
      header-operation header-append
      header-value "Mozilla/5.0"
    }
    2 {
      header-name Pragma
      header-operation header-replace
      header-value no-store
    }
    3 {
      header-name Pragma
      header-operation header-remove
      header-value no-cache
    }
  }
}

```

In above example, http-header-modify agent named MyProfile\_act\_http-header-modify\_ag in partition Common and adds 2 cookie and 4 HTTP header entries. cookie entry 0 updates cookie value PHPSESSID to '1234' while entry 1 deletes when cookie value 'mySession=5678'. Header entries refer to various header operations. Entry 0 inserts header 'Cache-Control: 5678'. Entry 1 updates value of header User-Agent to include ';Mozilla/5.0'. Entry 2 replaces value of header Pragma by 'no-store'. Finally, 3 entry will remove header-value matching 'Pragma: no-cache' from HTTP headers.

```
list http-header-modify
```

Displays a list of http-header-modify agents.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies the name of HTTP header modify agent. This setting is required.

**cookie-entries**  
Specifies a list of entries specifying cookie header manipulations.

**cookie-name**  
Specifies cookie name to match. This setting is required for cookie-entries.

**cookie-operation**  
Specifies operation on the cookie name specified in cookie-name. Possible values include cookie-update and cookie-delete.

**cookie-update**  
Update the cookie value in the cookie-name, cookie-value pair. This is the default cookie-operation.

**cookie-delete**  
Delete the cookie that matches the cookie-name, cookie-value pair.

**cookie-value**  
Specifies cookie value to be operated on. This is required for cookie-entries.

**header-entries**  
Specifies a list of entries specifying HTTP header manipulations.

**header-delimiter**  
Specifies delimiter character to use when header-operation is header-append.

**header-name**  
Specifies HTTP header to match to be operated on. This setting is required for header-entries.

**header-operation**  
Specifies operation on the HTTP header specified in header-name. Options include the following:

**header-append**  
Append header-value to the value of HTTP header header-name delimited by header-delimiter.

**header-insert**  
Insert HTTP header containing header-name, header-value pair. This is the default header-operation.

**header-remove**  
Remove the HTTP header, value pair that matches the header-name, header-value pair.

**header-replace**  
Replace value of HTTP header matching header-name by value header-value.

**header-value**  
Specifies HTTP header value to be operated on. This is required for header-entries.

**partition**  
Displays the partition within which the component resides.

## apm policy agent ip-geolocation-lookup

**NAME**  
ip-geolocation-lookup - Manages an IP Geolocation Lookup agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the ip-geolocation-lookup component within the policy agent module using the syntax shown in the following sections.

CREATE/MODIFY

```

create ip-geolocation-lookup [name]
modify ip-geolocation_lookup [name]
  options:
    app-service [[string] | none]

edit ip_geolocation_lookup [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties

DISPLAY
list ip_geolocation_lookup
list ip_geolocation_lookup [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    partition

DELETE
delete ip_geolocation_lookup [name]

DESCRIPTION
  You can use the ip_geolocation_lookup component to create and manage an
  IP Geolocation Lookup agent.

EXAMPLES
  create ip_geolocation_lookup example_ip_geolocation_lookup_ag
  Creates the example_ip_geolocation_lookup_ag IP Geolocation Lookup
  agent that searches for the IP Geolocation of the chosen IP
  address.

  delete ip_geolocation_lookup example_ip_geolocation_lookup_ag delete
  Deletes the IP Geolocation Lookup agent named
  example_ip_geolocation_lookup_ag.

OPTIONS
  [name]
  Specifies the name of a IP Geolocation Lookup agent. This setting
  is required.

  partition
  Displays the partition within which the component resides.

  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

## apm policy agent ip-reputation-lookup

```

NAME
  ip-reputation-lookup - Manages an IP Reputation Lookup agent.

MODULE
  apm policy agent

SYNTAX
  Configure the ip-reputation-lookup component within the policy agent
  module using the syntax shown in the following sections.

  CREATE/MODIFY
  create ip-reputation-lookup [name]
  modify ip-reputation_lookup [name]
    options:
      app-service [[string] | none]

  edit ip_reputation_lookup [ [ [name] | [glob] | [regex] ] ... ]
    options:
      all-properties
      non-default-properties

  DISPLAY
  list ip_reputation_lookup
  list ip_reputation_lookup [ [ [name] | [glob] | [regex] ] ... ]
    options:
      all-properties
      non-default-properties

```

```

    partition

DELETE
delete ip_reputation_lookup [name]

DESCRIPTION
    You can use the ip_reputation_lookup component to create and manage an
    IP Reputation Lookup agent.

EXAMPLES
    create ip_reputation_lookup example_ip_reputation_lookup ag
Creates the example_ip_reputation_lookup_ag IP Reputation Lookup
agent that searches for the IP Reputation of the chosen IP
address.

    delete ip_reputation_lookup example_ip_reputation_lookup_ag delete
Deletes the IP Reputation Lookup agent named
example_ip_reputation_lookup_ag.

OPTIONS
    [name]
Specifies the name of a IP Reputation Lookup agent. This setting
is required.

    partition
Displays the partition within which the component resides.

    app-service
Specifies the name of the application service to which the object
belongs. The default value is none. Note: If the strict-updates
option is enabled on the application service that owns the object,
you cannot modify or delete the object. Only the application
service can modify or delete the object.

## apm policy agent irule-event

```

NAME
    irule-event - Manages an iRule Event agent.

MODULE
    apm policy agent

SYNTAX
    Configure the irule-event component within the policy agent module
    using the syntax shown in the following sections.

    CREATE/MODIFY
create irule-event [name]
modify irule-event [name]
    options:
        app-service [[string] | none]
        id [[string] | none]
        expect-data [[client-accepted] | [ssl-client-hello] | [ssl-cert-available] | [http] | [none]]

edit irule-event [ [ [name] | [glob] | [regex] ] ... ]
    options:
        all-properties
        non-default-properties

    DISPLAY
list irule-event
list irule-event [ [ [name] | [glob] | [regex] ] ... ]
show running-config irule-event
show running-config irule-event [ [ [name] | [glob] | [regex] ] ... ]
    options:
        all-properties
        non-default-properties
        partition

show irule-event
show irule-event [name]

    DELETE
delete irule-event [name]

DESCRIPTION
    You can use the irule-event component to add a custom Access iRule
    event to an access policy. This agent enables you to combine access
    policy execution with iRule execution.

```

For example, you can retrieve the current agent ID (using an iRule command `ACCESS::policy agent id` ) to determine which of the iRule agents raised the event and then perform some custom logic execution.

The Per-Request Policy's Access iRule event functions similarly to the Access iRule event in the main access policy, but retrieval of the current agent ID uses the iRule command `"ACCESS::perflow get perflow.irule_agent_id"` to determine which of the iRule agents raised the event.

The expect-data component is used in the Per-Request Policy when adding an Access iRule event. You must specify the last piece of data that the policy should wait for before raising the event. The default is HTTP.

#### EXAMPLES

```
when ACCESS_POLICY_AGENT_EVENT { if {[ACCESS::policy agent_id] eq
"lastLogon" } { # our limit in seconds set 2weeks 1209600 # diff in 100
nanosecond increments between MS time attribute (year 1601) and start
of epoch set offset 11644473600000 set adtime "[ACCESS::session data
get session.ad.last.attr.lastLogon]" # convert adtime to milliseconds
set millisecs [expr {$adtime / 10000}] # subtract offset set
lastLogintime [expr {$millisecs - $offset}] # convert to seconds
because milliseconds for 'now' were negative (maybe vmware issue) set
secs [expr {$lastLogintime / 1000}] set now [clock seconds] # finally
calculate the difference set diff [expr {$now - $secs}] log local0.
"lastLogon: $diff seconds from current time" if { $diff $2weeks } {
ACCESS::session data set session.custom.lastLogonWithin2Weeks 0 } else
{ ACCESS::session data set session.custom.lastLogonWithin2Weeks 1 } } }
```

In this example, `ACCESS_POLICY_AGENT_EVENT` gathers data containing the users whose last logon was within the last two weeks. Note that you can access session variables and create new session variables inside this event.

```
list irule-event all
Displays a list of OAM agents.
```

```
delete irule-event my_irule_agent
Deletes the iRule Event agent named my_irule_agent.
```

#### OPTIONS

`app-service`  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`id` Specifies the ID of the iRule event. The default is none. You can use the ID to determine which agent caused the `ACCESS_POLICY_AGENT_EVENT`. You can also use the ID to perform different processing inside iRule for different agents.

`[name]`  
Specifies the name of the component. This option is required.

`partition`  
Displays the partition within which the component resides.

## apm policy agent kerberos

**NAME**  
kerberos - Manages a Kerberos agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the kerberos component within the policy agent module using the syntax shown in the following sections.

```
CREATE/MODIFY
create kerberos [name]
modify kerberos [name]
options:
  app-service [[string] | none]
  max-logon-attempt [integer]
```

```

server [string]

edit kerberos [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list kerberos
list kerberos [ [ [name] | [glob] | [regex] ] ... ]
show running-config kerberos
show running-config kerberos [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show kerberos
show kerberos [name]

DELETE
delete kerberos [name]

DESCRIPTION
  You can use the kerberos component to create and manage a Kerberos
  agent.

EXAMPLES
  create kerberos my_kerberos_agent
  Creates a Kerberos agent named my_kerberos_agent.

  list kerberos all
  Displays a list of Kerberos agents.

  delete kerberos my_kerberos_agent
  Deletes the Kerberos agent named my_kerberos_agent.

OPTIONS
  [name]
  Specifies the name of the component. This option is required.

  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  max-logon-attempt
  Specifies the maximum number of opportunities that users have to
  re-enter credentials after their first attempt to log in fails. If
  you set this value to a number from 2 to 5 inclusive, the system
  allows users the specified number of opportunities to log in after
  the first attempt to log in fails. If you set the value to 1, the
  system does not allow a second log in opportunity after a first
  log in attempt fails. The default value is 3.

  partition
  Displays the partition within which the component resides.

  server
  Specifies the name of the Kerberos server. This option is
  required.

SEE ALSO
COPYRIGHT

## apm policy agent l7-protocol-lookup

```

NAME
  l7-protocol-lookup - Manages a L7 Protocol Lookup agent.

MODULE
  apm policy agent

SYNTAX
  Configure the l7-protocol-lookup component within the policy agent
  module using the syntax shown in the following sections.

  CREATE/MODIFY
  create l7-protocol-lookup [name]
  modify l7_protocol_lookup [name]

```

```

options:
  app-service [[string] | none]

edit l7_protocol_lookup [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list l7_protocol_lookup
list l7_protocol_lookup [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

DELETE
delete l7_protocol_lookup [name]

DESCRIPTION
  You can use the l7_protocol_lookup component to create and manage a L7
  Protocol Lookup agent.

EXAMPLES
  create l7_protocol_lookup example_l7_protocol_lookup_ag
  Creates the example_l7_protocol_lookup_ag L7 Protocol Lookup agent
  that identifies the layer 7 protocol.

  delete l7_protocol_lookup example_l7_protocol_lookup_ag delete
  Deletes the L7 Protocol Lookup agent named
  example_l7_protocol_lookup_ag.

OPTIONS
  [name]
  Specifies the name of a L7 Protocol Lookup agent. This setting is
  required.

  partition
  Displays the partition within which the component resides.

  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

## apm policy agent logging

```

NAME
  logging - Manages a Logging agent.

MODULE
  apm policy agent

SYNTAX
  Configure the logging component within the policy agent module using
  the syntax shown in the following sections.

  CREATE/MODIFY
  create logging [name]
  modify logging [name]
  options:
    app-service [[string] | none]
    log-message [[string] | none]
    variables [[string] | none]

  edit logging [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

  DISPLAY
  list logging
  list logging [ [ [name] | [glob] | [regex] ] ... ]
  show running-config logging
  show running-config logging [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties

```

app-service  
log-message  
non-default-properties  
partition  
variables

DELETE  
delete logging [name]

#### DESCRIPTION

You can use the logging component to create and manage a logging agent that monitors the value of session variables and identifies the path taken by access policy execution. A logging agent can also be used to create and monitor custom or predefined session variables. Note that a session variable may or may not exist depending on the result of the access policy execution.

#### EXAMPLES

```
create logging MyProfile_act_logging_ag {  
  variables  
  {  
    {session-var "session.logon.*"}  
    {session-var "session.windows_check_file.Company8profile_act_file_check_ag.item_x.filename"}  
  }  
}
```

Creates the logging agent named MyProfile\_act\_logging\_ag in partition Common and adds two session variables that define actions that the agent logs: session.logon.\* indicates to log application logon attempts and session.windows\_check\_file.Company8profile\_act\_file\_check\_ag.item\_x.filename indicates to log the outcome of the file check on the client. The x in item\_x indicates the order of the files in the list configured for the file checker. The list starts with index 0 (zero).

```
create logging MyProfile_act_logging_ag {  
  log-message "Logon Name: %{session.logon.last.username}."  
}
```

Above example applies only to logging agent tied to per-request access policy. Here logging agent named MyProfile\_act\_logging\_ag in partition Common will print log messages containing logon name. This removes the requirement to configure variables separately for per-request access policy.

list logging

Displays a list of logging agents.

#### OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

log-message

Specifies the log message to display. This option is required. For per-request access policy only, this option can contain session or per-request variables. However, session variables containing wildcard (\*) are not supported.

name Specifies the name of a logging agent. This option is required.

partition

Displays the partition within which the component resides.

variables

Adds a variable to or deletes a variable from a logging agent. You use the sessionvar option to specify a session variable that indicates which actions the system logs. This option does not apply to per-request access policy agent.

## apm policy agent logon-page

#### NAME

logon-page - Manages a Logon Page agent.

#### MODULE

## SYNTAX

Configure the logon-page component within the policy agent module using the following syntax.

## CREATE/MODIFY

```
create logon-page [name]
modify logon-page [name]
options:
  app-service [[string] | none]
  basic-auth-realm [[string] | none]
  customization-group [[string] | none]
  field-modifiable1 [true | false]
  field-modifiable2 [true | false]
  field-modifiable3 [true | false]
  field-modifiable4 [true | false]
  field-modifiable5 [true | false]
  field-type1 [checkbox | none | password | text]
  field-type2 [checkbox | none | password | text]
  field-type3 [checkbox | none | password | text]
  field-type4 [checkbox | none | password | text]
  field-type5 [checkbox | none | password | text]
  http-401-auth-level [basic | basic-negotiate | negotiate | none]
  post-var-name1 [[integer] | none]
  post-var-name2 [[integer] | none]
  post-var-name3 [[integer] | none]
  post-var-name4 [[integer] | none]
  post-var-name5 [[integer] | none]
  session-var-name1 [[integer] | none]
  session-var-name2 [[integer] | none]
  session-var-name3 [[integer] | none]
  session-var-name4 [[integer] | none]
  session-var-name5 [[integer] | none]
  clean-sess-var1 [true | false]
  clean-sess-var2 [true | false]
  clean-sess-var3 [true | false]
  clean-sess-var4 [true | false]
  clean-sess-var5 [true | false]
  split-username [true | false]
  type [401 | form-based]
```

```
edit logon-page [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

## DISPLAY

```
list logon-page
list logon-page [ [ [name] | [glob] | [regex] ] ... ]
show running-config logon-page
show running-config logon-page [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition
```

```
show logon-page
show logon-page [name]
```

## DELETE

```
delete logon-page [name]
```

## DESCRIPTION

You can use the logon-page component to create and manage a Logon Page agent. This agent creates a logon page that includes the form in which users input the credentials required by an access policy. You can use the customization-group option to customize the logon page.

## EXAMPLES

```
create logon-page MyLoginPageAgent my { type 401 basic-auth-realm
myrealm split-username false http-401-auth-level none }
Creates a basic authentication Logon Page agent named
MyLoginPageAgent that results in a 401 response.
```

```
list logon-page
Displays a list of Logon Page agents.
```

```
delete logon-page MyLoginPageAgent
Deletes the Logon Page agent named MyLoginPageAgent.
```

## OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**basic-auth-realm**  
Specifies the system being accessed for HTTP basic authentication. This value is shown in the 401 response. Use this option only for basic authentication Logon pages.

**clean-sess-var1 - clean-sess-var5**  
Specifies whether session variable under corresponding sess-var-name would be cleaned before logon page appearance (i.e. agent execution) or not. Works only with form-based authentication.

**customization-group**  
Specifies a predefined configuration that contains several settings that you want the agent to use to configure a logon page. This setting is required, and the customization group that you assign must be of the type logon. Use this option only for basic

authentication Logon pages.

**field-modifiable1 - field-modifiable5**  
Specifies whether the user can modify the contents of the field on a form-based Logon page. The default is true. You can use this option to display read-only information. A Logon page contains can have a maximum of five fields. Use this option only for form-based Logon pages.

**field-type1 - field-type5**  
Specifies the type of fields on a form-based Logon page. The default is text. Use this option only for form-based Logon pages. The options are:

checkbox  
none  
password  
text

**http-401-auth-level**  
Use this option only for basic authentication Logon pages. The options are:

basic  
basic-negotiate  
negotiate  
none

**[name]**  
Specifies the name of a Logon Page agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

**post-var-name1 - post-var-name5**  
Specifies the name of the variable that is sent with POST request. Use this option only for form-based Logon pages.

**sess-var-name1 - sess-var-name5**  
Specifies the session variable from which the initial value is taken. Use this option only for form-based Logon pages.

**split-username**  
Specifies whether the user's input is split into username and domain. This option supports UPN style logon ID (userid@domainid) and Windows Domain User account ID (domainid\userid). The default is false. Set this to true when you want to store the username and domain separately.

Use this option only for basic authentication Logon pages.

**type** Specifies the type of logon page that appears. The options are:

401 Displays a basic HTTP authentication form.

form-based  
Displays a logon page.

SEE ALSO  
external-logon-page

**COPYRIGHT**

## apm policy agent message-box

**NAME**  
message-box - Manages a Message Box agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the message-box component within the policy agent module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create message-box [name]  
modify message-box [name]  
options:  
app-service [[string] | none]  
customization-group [string]

```

edit message-box [ [ [name] | [glob] | [regex] ] ... ]
    options:
        all-properties
        non-default-properties

DISPLAY
list message-box
list message-box [ [ [name] | [glob] | [regex] ] ... ]
show running-config message-box
show running-config message-box [ [ [name] | [glob] | [regex] ] ... ]
    options:
        all-properties
        non-default-properties
        partition

show message-box
show message-box [name]

DELETE
delete message-box [name]

DESCRIPTION
    You can use the message-box agent to create, display, or delete a
    Message Box agent. You cannot use the command line interface to create
    or modify the messages that display in a message box. You can also edit
    customizable messages using the visual policy editor.

EXAMPLES
    create message-box MyMessageBoxAgent { customization group
    "MyMessageBoxCG" }
    Creates the Message Box agent named MyMessageBoxAgent that is
    associated with the customization group named MyMessageBoxCG.

    list message-box
    Displays a list of Message Box agents.

    delete message-box MyMessageBoxAgent
    Deletes the Message Box agent named MyMessage BoxAgent.

OPTIONS
    [name]
    Specifies the name of a Message Box agent. This option is
    required.

    app-service
    Specifies the name of the application service to which the object
    belongs. The default value is none. Note: If the strict-updates
    option is enabled on the application service that owns the object,
    you cannot modify or delete the object. Only the application
    service can modify or delete the object.

    customization-group
    Specifies the name of the customization group that contains the
    messages you want to apply to an access policy. This option is
    required.

    partition
    Displays the partition within which the component resides.

SEE ALSO
COPYRIGHT
    No part of this program may be reproduced or transmitted in any form or

## apm policy agent oam

```

NAME
    oam - Manages an OAM agent.

MODULE
    apm policy agent

SYNTAX
    Warning: This page is obsolete. AAA OAM agent is no longer supported.

    Configure the oam component within the policy agent module using the
    syntax shown in the following sections.

CREATE/MODIFY
create oam [name]
modify oam [name]
options:
    app-service [[string] | none]
    max-logon-attempt [integer]

```

```

server [[string] | none]
show-extended-error [true | false]
url [[string] | none]

edit oam [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list oam
list oam [ [ [name] | [glob] | [regex] ] ... ]
show running-config oam
show running-config oam [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show oam
show oam [name]

DELETE
delete oam [name]

```

#### DESCRIPTION

You can use the oam component to create and manage an OAM agent.

#### EXAMPLES

```

create oam oam_agent1 { server oam10g max-logon-attempt 3 show-
extended-error false url "http://www.mydomain.com/protected/" }
Creates an OAM agent named oam_agent1 that uses authentication
server oam10g and prompts a user for credentials three times
before denying access to http://www.mydomain.com/protected/.

```

```

modify oam oam_agent1 max-logon-attempt 4
list oam all
Displays a list of OAM agents.

```

```

delete oam my_oam_agent
Deletes the OAM agent named my_tacacsplus_agent.

```

#### OPTIONS

**[name]**  
Specifies the name of the component. This option is required.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**max-logon-attempt**  
Specifies the maximum number of opportunities that users have to re-enter credentials after their first attempt to log in fails. If you set this value to a number from 2 to 5 inclusive, the system allows users the specified number of opportunities to log in after the first attempt to log in fails. If you set the value to 1, the system does not allow a second log in opportunity after a first log in attempt fails. The default value is 3.

**partition**  
Displays the partition within which the component resides.

**server**  
Specifies the name of the OAM server used for user authentication. This option is required.

**url** Specifies the URL of the resource that is protected by the OAM server. It is used to authenticate the user using the specified user credentials. This option is required, and you must specify an absolute URL. An absolute URL specifies the exact location of a file or directory on the Internet.

**show-extended-error**  
Specifies to display a verbose error message on the retry logon page. The default value is false.

  partition
  prompt-for-authorization
  recursive

DELETE
delete oauth-authz [name]
```

DESCRIPTION  
    You can use the oauth-authz component to create and manage an OAuth Authorization agent that provides OAuth Authorization server functionality, and also manage scopes and claims to provide different level of access control based on end user's role or any other criteria. For JWT type tokens, you can use the agent to manage audience and subject values.

EXAMPLES  
    create oauth-authz MyOAuthAuthzAgent {  
    audience add { "company-oauth-rs.com" "partner-oauth-rs.com" }  
    customization-group "company\_authz"  
    entries add {  
    0 {  
        expression "expr {return true}"  
        id-token-claim-entries add {  
        0 {  
            claim-name "group"

```

claim-value "%{session.ad.last.attr.memberOf}"
    }
    jwt-access-token-claim-entries add {
    0 {
claim-name "group"
claim-value "%{session.ad.last.attr.memberOf}"
    }
    1 {
claim-name "profile"
claim-value "https://company.com/username"
    }
    }
    userinfo-claim-entries add {
    0 {
claim-name "profile"
claim-value "https://company.com/username"
    }
    }
    scope-entries add {
    0 {
scope-name "name"
scope-value "%{session.logon.last.name}"
    }
    1 {
scope-name "email"
scope-value "test@company.com"
    }
    2 {
scope-name "domain"
scope-value "%{session.logon.last.domain}"
    }
    }
    1 {
expression "expr {[mcget {session.logon.last.name}] == "testuser"}"
jwt-access-token-claim-entries add {
    0 {
claim-name "service"
claim-value "medium"
    }
    }
    scope-entries add {
    0 {
scope-name "project"
scope-value "project-one"
    }
    }
    }
}
subject "%{session.assigned.uuid}"
}

```

Creates an OAuth Authorization agent named MyOAuthAuthzAgent that uses customization group company\_authz to customize the OAuth Authorization page.

The agent associates these scopes name, email, and domain and their values to each access token because the first expression always evaluates to true. If an id\_token is issued, it contains claim group. If the token type issued is JWT, each access token also includes claims group and profile and the UserInfo response will contain claim profile. The agent also associates scope project with value project-one to the token if the user is testuser. If JWT access token is issued to user testuser, it will contain claim service with value medium.

The agent additionally includes audience containing values company-oauth-rs.com and partner-oauth-rs.com along with subject and its value if the token issued is a JWT access token.

```
list oauth-authz
```

Displays a list of OAuth Authorization agents.

```
delete oauth-authz MyOAuthAuthzAgent
```

Deletes the OAuth Authorization agent named MyOAuthAuthzAgent.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### audience

Specifies a list of audience values used in JWT tokens issued. If audience list is specified in the OAuth Authorization agent, it overwrites the values in OAuth profile and OAuth client app.

##### customization-group

Specifies the customization group that defines the appearance of the OAuth Authorization page.

##### entries

Specifies a list of entries consisting of an expression and a list of scope entries. If the expression evaluates to true, then the OAuth Authorization agent associates the corresponding list of scope entries to an issued token. Scope entries determine the access control that the OAuth Authorization server requests on behalf of the client application.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**expression**  
Specifies the expression that you want an OAuth Authorization agent to use to verify in order to associate the corresponding scopes to an issued token. You can use the following operators: AND, OR, NOT, (and).

**id-token-claim-entries**  
Specifies a list of entries consisting of an ID token claim name and its value.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**claim-name**  
Specifies the name of the claim.

**claim-value**  
Specifies a value to the corresponding claim. This value can be any string or session variable.

**jwt-access-token-claim-entries**  
Specifies a list of entries consisting of a JWT access-token claim name and its value.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**claim-name**  
Specifies the name of the claim.

**claim-value**  
Specifies a value to the corresponding claim. This value can be any string or session variable.

**scope-entries**  
Specifies a list of entries consisting of a scope name and its value.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**scope-name**  
Specifies the name of the scope.

**scope-value**  
Specifies a value to the corresponding scope. This value can be any string or session variable.

**userinfo-claim-entries**  
Specifies a list of entries consisting of a UserInfo claim name and its value.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**claim-name**  
Specifies the name of the claim.

**claim-value**  
Specifies a value to the corresponding claim. This value can be any string or session variable.

**[name]**  
Specifies the name of the OAuth Authorization agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

**prompt-for-authorization**  
Specifies whether the OAuth Authorization page, for user authorization, is displayed. This is applicable only for "Authorization code" and "Implicit" grants.

**subject**  
Specifies the value of subject in JWT tokens issued. If subject is

specified in the OAuth Authorization agent, it overwrites the the value specified in the OAuth profile.

## apm policy agent request-classification

NAME

request-classification - Manages a Request Classification agent.

MODULE

apm policy agent

SYNTAX

Configure the request-classification component within the policy agent module using the syntax shown in the following sections.

CREATE/MODIFY

create request-classification [name]

modify request-classification [name]

options:

app-service [[string] | none]

edit api-server-selection [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties

non-default-properties

DISPLAY

list request-classification

list request-classification [ [ [name] | [glob] | [regex] ] ... ]

show running-config request-classification

show running-config request-classification [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties

non-default-properties

partition

DELETE

delete request-classification [name]

DESCRIPTION

Use the request-classification component to create, modify, display, or delete a Request Classification agent. A Request Classification agent classifies the API requests based on their URIs and http methods according to the API path definition in the corresponding API Protection profile.

EXAMPLES

create request-classification my\_rca\_ag

Creates the my\_rca\_ag Request Classification agent.

list request-classification

Displays a list of Request Classification agents.

delete request-classification my\_rca\_ag

Deletes the my\_rca\_ag Request Classification agent.

OPTIONS

[name]

Specifies the name of a Request Classification agent. This option is required.

partition

Displays the partition within which the component resides.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

SEE ALSO

## apm policy agent resource-assign

**NAME**  
resource-assign - Manages a Resource Assign agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the resource-assign component within the policy agent module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create resource-assign [name]  
modify resource-assign [name]  
options:  
app-service [[string] | none]  
rules ( | none)  
type [acls | general | resources | webtop-and-webtop-links]  
  
edit resource-assign [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list resource-assign  
list resource-assign [ [ [name] | [glob] | [regex] ] ... ]  
show running-config resource-assign  
show running-config resource-assign [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
partition  
  
show resource-assign  
show resource-assign [name]

**DELETE**  
delete resource-assign [name]

**DESCRIPTION**  
You can use the resource-assign component to create and manage an agent that assigns an ACL, a resource group, or both to an access policy. A resource group is a collection of resources, access control lists, and protection criteria, which includes your company intranet servers, applications, and network shares. An ACL is a set of restrictions associated with a resource or favorite that defines access for users and groups.

**EXAMPLES**  
create resource-assign MyAssignResourceAgent my rules { { expression "expr { [mcget {session.ad.last.authresult}] == 1 }" webtop-links add { google } } }  
Creates the Resource Assign agent named MyAssignResourceAgent and assigns webtop-link google when authentication is passed.  
  
list resource-assign all  
Displays a list of Resource Assign agents.  
  
delete resource-assign MyAssignResourceAgent  
Deletes the Resource Assign agent named MyAssignResourceAgent.

**OPTIONS**  
[name]  
Specifies the name of the Resource Assign agent. This option is required.  
  
partition  
Displays the partition within which the component resides.  
  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
  
rules  
Adds a rule to or deletes a rule from the Resource Assign agent. You can use the following attributes to define a rule:  
  
acl Specifies an access control list that this rule assigns to

users.

connectivity-resource-group  
Specifies the name of the connectivity resource group to which this rule applies.

expression  
Specifies the expression that indicates which resource groups this rule assigns to users.

type Specifies the type of Resource Assign agent. The default is general.

## apm policy agent response-selection

NAME  
response-selection - Manages a Response Selection agent.

MODULE  
apm policy agent

SYNTAX  
Configure the response-selection component within the policy agent module using the syntax shown in the following sections.

CREATE/MODIFY  
create response-selection [name]  
modify response-selection [name]  
options:  
app-service [[string] | none]  
response [[string] | none]  
  
edit response-selection [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
  
DISPLAY  
list response-selection  
list response-selection [ [ [name] | [glob] | [regex] ] ... ]  
show running-config response-selection  
show running-config response-selection [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
partition  
  
show response-selection  
show response-selection [name]  
  
DELETE  
delete response-selection [name]

DESCRIPTION  
You can use the response-selection component to create a Response Selection agent to assign a response config object for error response generation.

EXAMPLES  
create response-selection my\_resp\_sel\_ag response my\_response  
Creates the my\_resp\_sel\_ag Response Selection agent.  
  
list response-selection  
Displays a list of Response Selection agents.  
  
delete response-selection my\_resp\_sel\_agent  
Deletes the Response Selection agent named my\_resp\_sel\_agent.

OPTIONS  
[name]  
Specifies the name of a Response Selection agent. This option is required.  
  
partition  
Displays the partition within which the component resides.  
  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

response  
Specifies the response config object name.

SEE ALSO  
api-protection response

COPYRIGHT

## apm policy agent route-domain-selection

NAME  
route-domain-selection - Manages a Route Domain Selection agent.

MODULE  
apm policy agent

SYNTAX  
Configure the route-domain-selection component within the policy agent module using the syntax shown in the following sections.

CREATE/MODIFY  
create route-domain-selection [name]  
modify route-domain-selection [name]  
options:  
app-service [[string] | none]  
location-specific [true | false]  
route-domain [[integer] | none]  
snat [automap | none]  
snatpool [[string] | none]  
  
edit route-domain-selection [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
  
DISPLAY  
list route-domain-selection  
list route-domain-selection [ [ [name] | [glob] | [regex] ] ... ]  
show running-config route-domain-selection  
show running-config route-domain-selection [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
partition  
  
show route-domain-selection  
show route-domain-selection [name]  
  
DELETE  
delete route-domain-selection [name]

DESCRIPTION  
You can use the route-domain-selection component to create a Route Domain Selection agent.

EXAMPLES  
create route-domain-selection my\_rds\_ag route-domain 0 snat automap  
Creates the my\_rds\_ag Route Domain Selection agent.  
  
show route-domain-selection  
Displays a list of Route Domain Selection agents.  
  
delete route-domain-selection my\_rd\_selection\_agent  
Deletes the Route Domain Selection agent named my\_rd\_selection\_agent.

OPTIONS  
[name]  
Specifies the name of a Variable Assignment agent. This option is required.  
  
partition  
Displays the partition within which the component resides.  
  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object,

you cannot modify or delete the object. Only the application service can modify or delete the object.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**route-domain**  
Specifies the route domain. The default is 0 (zero).

**snat**  
**automap**  
none Snat is not used.

**snatpool**

## apm policy agent server-cert-response-control

**NAME**  
server-cert-response-control - Manages a Server Cert Response Control agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the server-cert-response-control component within the policy agent module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create server-cert-response-control [name]  
modify server-cert-response-control [name]  
options:  
app-service [[string] | none]  
action [integer]

edit server-cert-response-control [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list server-cert-response-control  
list server-cert-response-control [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
app-service  
non-default-properties  
partition

**DELETE**  
delete server-cert-response-control [name]

**DESCRIPTION**  
You can use the server-cert-response-control component to create and manage a Server Cert Response Control agent.

**EXAMPLES**  
create server-cert-response-control  
example\_server\_cert\_response\_control\_ag  
Creates the example\_server\_cert\_response\_control\_ag Server Cert Response Control agent that allows admin to either ignore or mask expired/untrusted server certificate.

delete server-cert-response-control  
example\_server\_cert\_response\_control\_ag delete  
Deletes the Server Cert Response Control agent named example\_server\_cert\_response\_control\_ag.

**OPTIONS**  
[name]  
Specifies the name of a Server Cert Response Control agent. This setting is required.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

action  
Allows admin to specify how to handle connections from a client whose server certificate is either expired or untrusted. The default is ignore which specifies that the system ignores untrusted/expired certificate and may allow the connection. When mask option is selected, end users will see the block page without the cert expired/untrusted warning message from clients/browsers.

## apm policy agent server-cert-status

NAME  
server-cert-status - Manages a Server Cert Status agent.

MODULE  
apm policy agent

SYNTAX  
Configure the server-cert-status component within the policy agent module using the syntax shown in the following sections.

CREATE/MODIFY  
create server-cert-status [name]  
modify server-cert-status [name]  
options:  
  app-service [[string] | none]  
  
edit server-cert-status [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

DISPLAY  
list server-cert-status  
list server-cert-status [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  partition

DELETE  
delete server-cert-status [name]

DESCRIPTION  
You can use the server-cert-status component to create and manage a Server Cert Status agent.

EXAMPLES  
create server-cert-status example\_server\_cert\_status\_ag  
Creates the example\_server\_cert\_status\_ag Server Cert Status agent that checks the server certificate status.

delete server-cert-status example\_server\_cert\_status\_ag delete  
Deletes the Server Cert Status agent named example\_server\_cert\_status\_ag.

OPTIONS  
[name]  
Specifies the name of a Server Cert Status agent. This setting is required.

partition  
Displays the partition within which the component resides.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

## apm policy agent session-check

NAME

session-check - Manages a Session Check agent.

MODULE

apm policy agent

SYNTAX

Configure the session-check component within the policy agent module using the syntax shown in the following sections.

CREATE/MODIFY

create session-check [name]

modify session-check [name]

options:

app-service [[string] | none]

edit session-check [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties

non-default-properties

DISPLAY

list session-check

list session-check [ [ [name] | [glob] | [regex] ] ... ]

options:

all-properties

non-default-properties

partition

DELETE

delete session-check [name]

DESCRIPTION

You can use the session-check component to create and manage an agent that check for the existence of access policy session in a flow.

EXAMPLES

create session-check example\_session\_check\_ag

Creates the example\_session\_check\_ag Session Check agent that performs the access policy session existence check for the flow.

delete session-check ExampleSessionCheckAgent delete

Deletes the Session Check agent named ExampleSessionCheckAgent.

OPTIONS

[name]

Specifies the name of a Session Check agent. This setting is required.

partition

Displays the partition within which the component resides.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

## apm policy agent ssl-check

**NAME**  
ssl-check - Manages a SSL Check agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the ssl-check component within the policy agent module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create ssl-check [name]  
modify ssl-check [name]  
options:  
app-service [[string] | none]  
  
edit ssl-check [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list ssl-check  
list ssl-check [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
partition

**DELETE**  
delete ssl-check [name]

**DESCRIPTION**  
You can use the ssl-check component to create and manage an agent that check for the existence of SSL traffic in a flow.

**EXAMPLES**  
create ssl-check example\_ssl\_check\_ag  
Creates the example\_ssl\_check\_ag SSL Check agent that performs the SSL traffic existence check for the flow.  
  
delete ssl-check ExampleSSLCheckAgent delete  
Deletes the SSL Check agent named ExampleSSLCheckAgent.

**OPTIONS**  
[name]  
Specifies the name of a SSL Check agent. This setting is required.  
  
partition  
Displays the partition within which the component resides.  
  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

## apm policy agent tacacsplus

**NAME**  
tacacsplus - Manages a TACACS+ agent.

**MODULE**  
apm policy agent

**SYNTAX**  
Configure the tacacsplus component within the policy agent module using the syntax shown in the following sections.

```

CREATE/MODIFY
create tacacsplus
modify tacacsplus
  options:
    app-service [[string] | none]
    max-logon-attempt [integer]
    server [[string] | none]

edit tacacsplus [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

DISPLAY
list tacacsplus
list tacacsplus [ [ [name] | [glob] | [regex] ] ... ]
show running-config tacacsplus
show running-config tacacsplus [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    partition

show tacacsplus
show tacacsplus [name]

DELETE
delete tacacsplus [name]

DESCRIPTION
  You can use the tacacsplus component to create and manage a TACACS+
  agent.

EXAMPLES
  list tacacsplus all
  Displays a list of TACACS+ agents.

  delete tacacsplus my_tacacsplus_agent
  Deletes the TACACS+ agent named my_tacacsplus_agent.

OPTIONS
  [name]
  Specifies the name of the component. This option is required.

  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  max-logon-attempt
  Specifies the maximum number of opportunities that users have to
  re-enter credentials after their first attempt to log in fails. If
  you set this value to a number from 2 to 5 inclusive, the system
  allows users the specified number of opportunities to log in after
  the first attempt to log in fails. If you set the value to 1, the
  system does not allow a second log in opportunity after a first
  log in attempt fails. The default value is 3.

  partition
  Displays the partition within which the component resides.

  server
  Specifies the name of the TACACS+ server. This option is required.

SEE ALSO
COPYRIGHT
  No part of this program may be reproduced or transmitted in any form or
  by any means, electronic or mechanical, including photocopying,

## apm policy agent variable-assign

```

NAME
  variable-assign - Manages a Variable Assignment agent.

MODULE
  apm policy agent

SYNTAX
  Configure the variable-assign component within the policy agent module
  using the syntax shown in the following sections.

```

```

CREATE/MODIFY
create variable-assign [name]
modify variable-assign [name]
options:
  app-service [[string] | none]
  type [citrix-smart-access | general | intranet-webtop | sso-cred-mapping | virtual-keyboard]
  variables { [varname [name] expression {[string]}]}

edit variable-assign [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list variable-assign
list variable-assign [ [ [name] | [glob] | [regex] ] ... ]
show running-config variable-assign
show running-config variable-assign [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show variable-assign
show variable-assign [name]

DELETE
delete variable-assign [name]

```

#### DESCRIPTION

You can use the variable-assign component to create and manage an agent that assigns one or more variables to an access policy. F5 Networks recommends that you use the visual policy editor to create complex variable assignments.

#### EXAMPLES

```

create variable-assign username_variable_assign_ag { variables {
  varname "session.logon.last.username" expression "[mcget
  {session.ssl.cert.cn}]" } }

```

Creates the username\_variable\_assign\_ag Variable Assignment agent that automatically assigns the value of the common name field in the client certificate to the username field of the logon page. This is useful when an access policy contains the Variable Assignment agent between the client certification and the AAA Active Directory server query actions.

```

create variable-assign acl_variable_assign_ag { variables { varname
  "config.connectivity_resource.network_access.MyprofileNR2.acl_name"
  expression "expr {\`MY_ACL1\`}" } }

```

Creates a Variable Assignment agent that carries out a configured ACL when a particular branch in the access policy is followed, using the Variable Assignment agent to populate the appropriate variables with the ACL name.

```

show variable-assign

```

Displays a list of Variable Assignment agents.

```

delete variable-assign MyAssignVariableAgent delete

```

Deletes the Variable Assignment agent named MyAssignVariableAgent.

#### OPTIONS

**[name]**  
Specifies the name of a Variable Assignment agent. This setting is required.

**partition**  
Displays the partition within which the component resides.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**type** Specifies the type of agent. The default is general.

**variables**  
Adds a variable to or deletes a variable from the Variable Assignment agent. You must specify the following attributes for each variable:

**expression**  
A Tcl expression that the system evaluates, and then assigns the value of the expression to a specific property of the assigned Network Access resource or to a newly created session variable.

**varname**  
A variable that forms the left-hand side of the expression. You can use the name of an existing variable or a new session variable.

show access [name]

DELETE
delete access [name]

DESCRIPTION
    You can use the access component to configure an access profile. An
    access profile is a pre-configured group of settings that you can use
    to configure secure Network Access for an application.

EXAMPLES
    create access MyAccessProfile { defaults-from access access-policy
    "my_access_policy" accepted-languages "my_accepted_languages" default-
    language "en" customization-group "company_logout" eps-group
    'myepsgroup' framework-installation-group "company_header"
    "company_footer" errormap-group "company_errormap" }
    Creates an access profile named MyAccessProfile that is based on
    the default access profile named access, uses the access policy
    named my_access-policy, accepts the languages in the
    my_accepted_languages class, uses English as the default language,
    and uses these groups to customize the application pages and
    messages: company_logout, company_header, company_footer, and
    company_errormap.

    list access all all-properties
    Displays a list of access profiles, including parameter values.

    delete access MyAccessProfile
    Deletes the access profile named MyAccessProfile.

OPTIONS
    accept-languages
    Specifies the name of a class that defines the languages supported
    by the access profile. The default languages are en (English), ja
    (Japanese), zh-cn (simplified Chinese (PRC)), and zh tw
    (traditional Chinese (Taiwan)). This option is required.

    access-policy
    Specifies the access policy that you want to enforce using this
    access profile. An access profile contains various security checks
    that a client must pass before the BIG-IP Access Policy Manager
    grants access to a protected application. This option is required.

    access-policy-timeout
    Specifies, for this access profile, the number of seconds within
    which a user must complete the steps to gain access to an
    application. The default is 300 seconds. This option is designed
    to quickly release session resources when a user does not complete
    the access process, for example, when the user closes the browser
    before completing the access process.

    app-service
    Specifies the name of the application service to which the object
    belongs. The default value is none. Note: If the strict-updates
    option is enabled on the application service that owns the object,
    you cannot modify or delete the object. Only the application
    service can modify or delete the object.

    customization-group
    Specifies the customization group that defines the appearance of
    the logout and error pages. This option is required.

    default-language
    Specifies the default language for the BIG-IP Access Policy
    Manager that you want to implement with this access profile. The
    default is en (English). If the client requests a language that is
    not supported, the BIG-IP Access Policy Manager uses the default
    value. This option is required.

    defaults-from
    Specifies the default access policy from which this profile is
    created. This option is required.

```

#### domain-cookie

Specifies a domain cookie to use with an application access control connection. If you specify a domain cookie, then the line `domain=specified_domain` is added to the MRHsession cookie. The default is none.

#### domain-groups

Specifies a group of multiple domains or multiple hosts in multiple domains to which a single user session has access. For example, you can use this option to configure a single user session to have access to three domains: `www.a.com`, `www.b.com`, and `www.c.com`. When a user logs in to any of these domains, that user can access the other domains without logging in again. This option is required when you set the `domain-mode` option to `multi-domain`. This option is ignored when you set the `access domain-mode` option to `single-domain`.

For each domain in the domain group, you can specify the following settings:

#### cookie-host

Specifies the host name for which to create the user's session cookie.

#### cookie-domain

Specifies the domain for which to create the user's session cookie.

#### secure-cookie

Adds a security attribute to the user's session cookie.

#### persistent-cookie

Adds a persistence attribute to the user's session.

#### sso-name

Specifies the SSO method to use when accessing a backend application.

#### domain-mode

Specifies how the SSO configuration is applied. The options are:

#### single-domain

Applies the SSO configuration to a single domain. This is the default.

When you set `domain-mode` to `single-domain`, you must also set the `sso-name` option.

#### multi-domain

Applies the SSO configuration across multiple domains. This option allows users a single APM login/session and applies the credentials across multiple Local Traffic Manager or Access Policy Manager virtual servers in front of different domains. Note that to apply SSO configurations across multiple domains, all virtual servers must be on one BIG-IP system.

When you set `domain-mode` to `multi-domain`, you must also configure the `domain-group` option, and provide a URI for the `primary-auth-service` option.

#### user-identity-method

Specifies how access will bind a session to a request.

`http` Use http information such as cookies and URI query string to identify user.

#### ip-address

Use IP address to identify a user. Do not use this setting if clients may be behind a NAT.

#### enforce-policy

Set this option to false, if you don't want to enforce the access-policy. The default is true which means the access-policy is always enforced. This option can only be modified for SWG-Transparent type profile.

#### eps-group

This option is required.

#### errormap-group

Specifies the customization settings for the error map that you want to implement with this access profile. This setting is required.

#### framework-installation-group

Specifies the customization settings for the header and footer that you want to implement with this access profile. This setting is required.

#### generation-ui-group

Specifies the generation of the user interface group for the new generation access configuration. This option is required.

#### generation-timeout

Specifies the timeout, in seconds, for the new generation access configuration.

#### generation-action

`increment`  
Activates the current access policy configuration for an access profile. For example, the following command activates current access policy configuration for profile

myAccessProfile: tmsh modify apm profile access  
myAccessProfile generation-action increment

noop Specifies "no operation to be performed". This is the default.

sync Specifies that the policy is being modified due to APM policy sync operation. This is an internal action; you should not set it.

#### httponly-cookie

Specifies whether HttpOnly directive should be inserted in HTTP response from BIG-IP. The client browser should prevent script from accessing cookie, if this flag is set in the response. The default is false.

#### inactivity-timeout

Specifies, for this access profile, the number of seconds that the session on the client can be idle before the server disconnects the VPN tunnel. The default is 900 seconds.

#### logout-uri-include

Specifies a list of URIs to include in the access profile for initiating session logout.

#### logout-uri-timeout

Specifies the timeout used to delay logout for the customized logout URIs defined in the logout uri include list

#### log-settings

Specifies one or more log-setting containers to associate with this profile

#### max-concurrent-sessions

Specifies, for this access profile, the number of concurrent sessions allowed. The default is 0 (zero), which represents unlimited sessions. Users assigned an administrative role of Application Editor can view the value of this option. Users assigned any other administrative role can modify this option.

#### max-concurrent-users

Specifies, for this access profile, the number of concurrent sessions allowed. The default is 0 (zero), which represents unlimited sessions. This field is Read-only for Application Editors. Users assigned any other administrative role can modify this field.

#### max-failure-delay

Specifies the maximum random delay after authentication failure during the access policy. It is the maximum number of seconds before the user is shown an error message on the logon page and prompted to re-enter credentials. The default is 5 seconds. 0 (zero) represents no delay. Note: Set max-failure-delay to no more than one-half the access-policy-timeout value and no more than 65 seconds greater than min-failure-delay.

#### max-in-progress-sessions

Specifies the maximum number of in-progress concurrent sessions a user can have. The in-progress sessions are the sessions for which an access policy has not completed. The default is 0, which represents an unlimited number of such sessions.

#### max-session-timeout

Specifies the maximum lifetime of one session. The maximum lifetime is the number of seconds between session creation and session termination.

#### min-failure-delay

Specifies the minimum random delay after authentication failure during the access policy. It is the minimum number of seconds before the user is prompted for credentials again or shown an error message on the logon page. The default is 2 seconds.

#### [name]

Specifies the name of the access profile. This option is required.

#### oauth-profile

Specifies an oauth profile for use with an OAuth Authorization Server.

#### persistent-cookie

Specifies to retain the cookie for a user session, even when the user session is terminated, when set to true. Although this is an insecure method, this setting is useful and required in cases where you have a third-party application, such as Sharepoint, and need to store the cookie in a local database so that any attempt to access backend server applications through Access Policy Manager succeeds. The default is false.

#### primary-auth-service

Specifies the address of your primary authentication URI. This setting is required when you set the domain-mode option to multi-domain.

For example, when you set this option to <https://logon.yourcompany.com>, the user session is stored on this primary domain, and the user can access multiple backend applications from multiple domains and hosts without re-entering credentials.

#### restrict-to-single-client-ip

Specifies whether a user session is tied to a single client IP. If during session's lifetime, the user's client IP address changes, the current session is terminated. The user needs to re-login to

create a new session from the new client IP address. The default is false.

#### sandboxes

Specifies the association between the access profile and the sandbox. If retain-public-access is set to true, this association is retained even if there is no resource that uses sandbox files in the access policy that corresponds to this access profile.

#### scope

Specifies the confining scope for sessions created by the profile. Set this option to profile (which is also the default-value) to confine the validity of a session to the profile from which it was created. Set this option to virtual-server to further confine the validity of a session to the virtual server from which it was created. Setting this option to global allows the session to be valid on any virtual server with any access profile that also specifies global scope. Setting this option to named allows the session to be valid for any virtual server with access profile using the same named-scope value. The option public is allowed for only SSLO access profiles and sessions aren't created.

#### named-scope

Specifies the string to which the validity of a session is confined to. This setting is required when you set the scope option to named.

#### secure-cookie

Set this option to true, if you want to add a secure keyword to the session cookie. Set this option to false, if you want to configure an application access control scenario that uses an HTTPS virtual server to authenticate the user, and then sends the user to an existing HTTP virtual server to use applications. The default is true.

#### sso-name

Specifies the SSO configuration that you want BIG-IP Access Policy Manager to use to submit the user's credentials to the backend application. This allows the user to log in once to the Access Policy Manager and then gain access to backend applications without logging in again.

type Specifies the type of access profile. You can specify the following types for an access profile.

all Supports ltm-apm and ssl-vpn access types.

#### identity-service

Used internally to provide identity service for a supported integration. Only APM creates this type of profile.

#### ltm-apm

For web access management configuration.

#### oauth-resource-server

Supports apps and devices that use OAuth tokens but do not support cookies.

#### rdg-rap

For validating connections to hosts behind APM when APM acts as a gateway for RDP clients.

#### ssl-vpn

For network access, portal access, or application access.

sso For configuring matching virtual servers for Single Sign-On (SSO).

#### swg-explicit

For Secure Web Gateway explicit forward proxy.

#### swg-transparent

For Secure Web Gateway transparent forward proxy.

#### system-authentication

For configuring administrator access to the BIG-IP system (when using APM as a pluggable authentication module).

#### use-http-503-on-error

Set this option to true to use HTTP response code 503 for error pages sent by BIG-IP Access Policy Manager to clients. Set this option to false to use HTTP response code 200. The default is false.

DESCRIPTION
  You can use the connectivity component to configure a connectivity
  profile. By using the connectivity profile, you can configure L2 and L4
  tunnels, compression, Windows and mobile client settings, and client
  component downloads from F5 Networks and Citrix.

EXAMPLES
  create connectivity myconnectivityprofile { }

  Creates a connectivity profile named myconnectivityprofile that
  inherits its settings from the system default connectivity
  profile.

OPTIONS
  adaptive-compression
  Enables or disables adaptive compression. Use this option to
  configure compression settings for application tunnels and to
  optimize applications and RDP traffic. The default is enabled.

  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  citrix-client-bundle
  Specifies the Citrix client bundle used by this connectivity
  profile. The default is default-citrix-client-bundle.

  client-policy
  Adds, deletes, or modifies the client policy for any of the
  following clients:

  android-ec Android Edge Client

  android-ep Android Edge Portal

  chromeos-ec Chrome OS Edge Client

  macos-ec Mac OS F5 Access

  ec Windows/OSX Edge Client

  ios-ec iOS Edge Client

  ios-ep iOS Edge Portal

  Options (please refer to the SYNTAX section to see if a certain
  option is supported for a particular client):

  component-update
  Specifies how the client handles automatic updates. The
  options are:

  yes Automatically installs a client update when one is
  available.

  prompt
  Prompts the user about installing a client update.

  No Disables the client from receiving automatic updates.

```

**device-lock-method**  
Specifies the device lock quality that the client should enforce on the device. The options are:

- alphabetic**  
Device passcode must contain at least alphabetic (or other symbol) characters.
- alphanumeric**  
Device passcode must contain at least both numeric and alphabetic (or other symbol) characters.
- any** A device passcode must be set but does not matter what it is.
- numeric**  
Device passcode must contain at least numeric characters.

**enable-mobilesafe**  
Enables or disables MobileSafe checks. Use this option to configure whether client should execute the MobileSafe security checks as part of the logon. The default is false.

**enforce-device-lock**  
Specifies whether client should enforce a device passcode policy on the device. The default is true.

**enforce-logon-mode**  
Specifies whether client should enforce a logon mode on the device. The default is false. Set to true if external logon page is used.

**logon-mode**  
Specifies logon mode to be enforced on the device. The default is native. Set to web if external logon page is used.

**enforce-pin-lock**  
Specifies whether client should enforce an app-level PIN before allowing access to the app. The default is true.

**location-dns**  
Specifies a list of DNS suffixes used by the Network Location Awareness feature of the client. This list represents the internal network where local resources are available without the need of a Network Access connection. The default is none.

**max-grace-period**  
Specifies the length of time (in minutes) the app was taken to the background before the user will be asked for a PIN. With the option set to 0, user will be asked for the PIN every time the app is taken from the background. The default is 2.

**max-inactivity-time**  
Sets the length of time (in minutes) since the user last touched the screen or pressed a button before the device locks the screen. The default is 5.

**min-passcode-length**  
Specifies the minimum required number of characters for the device passcode. The default is 4.

**require-device-auth**  
Specifies whether device authentication is needed before accessing cached credentials. The default is false.

**reuse-winlogon-creds**  
Specifies whether client can reuse logon credentials entered by a user for a subsequent log in. The default is false.

**reuse-winlogon-session**  
Specifies whether client should attempt to use the same Windows logon session. The default is false.

**save-password**  
Specifies whether client allows user password caching. The default is false.

**save-password-method**  
Specifies whether client saves encrypted passwords on disk or caches passwords in memory only. The default is disk.

**save-password-timeout**  
Specifies the number of minutes that a cached password remains valid (applies only to in-memory password caching). The default is 240.

**save-servers-on-exit**  
Specifies whether client maintains a list of Access Policy Manager systems that the client accessed. The default is true.

**servers**  
Specifies a list of server and alias pairs in the client's server list.

**compress-buffer-size**  
Specifies the size of compressed data for Network Access tunnels. The default is 4096.

**compress-cpu-saver**  
Specifies whether the system monitors the percentage of CPU usage

and adjusts compression rates automatically when CPU usage reaches either the CPU saver high threshold or the CPU saver low threshold. The default is true.

**compress-cpu-saver-high**

Specifies the percentage of CPU usage at which the system starts automatically decreasing the amount of content being compressed, as well as the amount of compression which the system is applying. The default is 90 percent.

**compress-cpu-saver-low**

Specifies the percentage of CPU usage at which the system resumes content compression at the user-defined rates. The default is 75 percent.

**compress-gzip-level**

Specifies the degree to which the system compresses the content. Higher compression levels slow down the compression process. The default is 6, which provides a higher amount of compression at the expense of more CPU processing time. 1 is the lowest level and 9 is the highest level. 0 disables compression.

**compress-gzip-memlevel**

Specifies the number of kilobytes of memory that the system uses for internal compression buffers when compressing data. You can select a value between 1 and 256. The default is 8192.

**compress-gzip-window-size**

Specifies the number of kilobytes in the window size that the system uses when compressing data. You can select a value between 1 and 128. The default is 16384.

**compress-ingress**

Specifies whether incoming data is compressed. The default is false.

**compress-preferred-method**

Specifies the preferred method of data compression. The default is zlib.

**compression**

Enables or disables compression between the client and the server. The default is enabled.

**compression-codecs**

Specifies the available compression codecs for server-to-client connections. The server compares the available compression types you configure with the available compression types on the client, and then chooses the most effective mutual compression setting. Compression for the client is configured separately. The default includes all three available codecs:

**lzo** Offers a balance between CPU resources and compression ratio, compressing more than deflate, but with less CPU resources than bzip2.

**deflate**

Uses the least CPU resources, but compresses the least effectively.

**bzip2**

Uses the most CPU resources, but compresses the most effectively.

**customization-group**

Specifies which customization groups are applied. This option is required.

**defaults-from**

Specifies the profile from which this profile inherits properties that are not specified explicitly. The default is connectivity.

**deflate-compression-level**

Specifies the level of compression performed by the deflate codec. The default is 1.

**description**

Specifies a user-defined description for the connectivity profile.

**location-specific**

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**

Specifies the profile that you want to use as the parent profile. The new profile inherits all settings and values from the parent profile.

**tunnel-name**

Specifies the name of the tunnel through which data passes. The default is none.

## apm profile exchange

**NAME**

exchange - Configures an exchange profile.

**MODULE**

apm profile

**SYNTAX**

Configure the exchange component within the profile module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create exchange [name]
modify exchange [name]
options:
  ntlm-auth-name [[string] | none]
  active-sync-url [[string] | none]
  active-sync-auth-type [basic | ntlm | basic-ntlm]
  active-sync-sso-config [[string] | none]
  auto-discover-url [[string] | none]
  auto-discover-auth-type [basic | ntlm | basic-ntlm]
  auto-discover-sso-config [[string] | none]
  description [[string] | none]
  offline-address-book-url [[string] | none]
  offline-address-book-auth-type [basic | ntlm | basic-ntlm]
  offline-address-book-sso-config [[string] | none]
  rpc-over-http-url [[string] | none]
  rpc-over-http-auth-type [basic | ntlm | basic-ntlm]
  rpc-over-http-sso-config [[string] | none]
  user-agent-pattern-for-utf8 [[string] | none]
  web-service-url [[string] | none]
  web-service-auth-type [basic | ntlm | basic-ntlm]
  web-service-sso-config [[string] | none]

edit exchange [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

**DISPLAY**

```
list exchange
list exchange [ [ [name] | [glob] | [regex] ] ... ]
show running-config exchange
show running-config exchange [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition

show exchange
show exchange [name]
```

**DELETE**

```
delete exchange [name]
```

**DESCRIPTION**

You can use the exchange component to configure an exchange profile. An exchange profile is a preconfigured group of settings that you can use to configure authentication for exchange services such as Outlook Anywhere, ActiveSync, Autodiscover and Offline Address Book, so that those work with BIG-IP.

**EXAMPLES**

```
create exchange MyExchangeProfile {
  ntlm-auth-name "MyNTLMAuth"
  rpc-over-http-url "/rpc/rpcproxy.dll"
  rpc-over-http-auth-type ntlm
  rpc-over-http-sso-config "MyKerberosSSOConfig"
}>
```

Creates an exchange profile named MyExchangeProfile that is based on the general settings such as NTLM Authentication configuration MyNTLMAuth. The profile is configured for Outlook Anywhere (RPC over HTTP) service with url "/rpc/rpcproxy.dll", client authentication type ntlm and SSO configuration type MyKerberosSSOConfig

```
list exchange all all-properties
```

Displays a list of exchange profiles, including parameter values.

```
delete access MyExchangeProfile
```

Deletes the exchange profile named MyExchangeProfile.

## OPTIONS

### ntlm-auth-name

Specifies the NTLM configuration object that clients can use to authenticate on the front-end. Backend SSO type must be Kerberos for ntlm or basic-ntlm front end.

### active-sync-auth-type

Specifies the client-side authentication type for ActiveSync exchange service. The valid value is basic.

### active-sync-sso-config

Specifies the back end SSO config for ActiveSync exchange service. This is optional.

### active-sync-url

Specifies the URL for ActiveSync exchange service. URL is required for ActiveSync service to be enabled through BIG-IP.

### auto-discover-auth-type

Specifies the client-side authentication type for Autodiscover exchange service. The valid values are basic, ntlm and basic-ntlm.

### auto-discover-sso-config

Specifies the back end SSO config for Autodiscover exchange service. This is optional.

### description

Specifies a user-defined description for the exchange profile.

### auto-discover-url

Specifies the URL for Autodiscover exchange service. URL is required for Autodiscover service to be enabled through BIG-IP.

### offline-address-book-auth-type

Specifies the client-side authentication type for Offline Address Book exchange service. The valid values are basic, ntlm and basic-ntlm.

### offline-address-book-sso-config

Specifies the back end SSO config for Offline Address Book exchange service. This is optional.

### offline-address-book-url

Specifies the URL for Offline Address Book exchange service. URL is required for Offline Address Book service to be enabled through BIG-IP.

### rpc-over-http-auth-type

Specifies the client-side authentication type for Outlook Anywhere (RPC over HTTP) exchange service. The valid values are basic, ntlm and basic-ntlm.

### rpc-over-http-sso-config

Specifies the back end SSO config for Outlook Anywhere (RPC over HTTP) exchange service. This is optional.

### rpc-over-http-url

Specifies the URL for Outlook Anywhere (RPC over HTTP) exchange service. URL is required for Outlook Anywhere (RPC over HTTP) service to be enabled through BIG-IP.

### user-agent-pattern-for-utf8

Specifies the user agent pattern for UTF8.

### web-service-auth-type

Specifies the client-side authentication type for Web Exchange service. The valid values are basic, ntlm and basic-ntlm.

### web-service-sso-config

Specifies the back end SSO config for Web Exchange service. This is optional.

### web-service-sync-url

Specifies the URL for Web Exchange service. URL is required for Web Service to be enabled through BIG-IP.

```
DELETE
delete oauth [name]
```

DESCRIPTION  
    You can use the oauth component to configure an oauth profile. An oauth profile is a pre-configured group of settings that you can use to configure OAuth Authorization Server.

NOTE: For the oauth profile to take effect, this profile must be associated with an access profile. (See man page for apm access profile.)

EXAMPLES  
    create oauth myOAuthProfile {  
    defaults-from oauth

```

client-apps add { client_1 client_2}
resource-servers add { rs_1 rs_2}
opaque-token enabled
db-instance db_test
jwt-token enabled
openid-connect enabled
issuer https://example.f5.com
primary-key jwk1_hs256
id-token-primary-key jwk1_rs256
generate-jwt-refresh-token true
jwt-refresh-token-enc-secret password
auth-url /f5-oauth2/v1/authorize
token-issuance-url /f5-oauth2/v1/token
token-revocation-url /f5-oauth2/v1/revoke
token-introspection-url /f5-oauth2/v1/introspect
openid-cfg-url /f5-oauth2/v1/.well-known/openid-configuration
jwks-url /f5-oauth2/v1/jwks
userinfo-url /f5-oauth2/v1/userinfo
}

```

Creates an oauth profile named myOAuthProfile that is based on the default oauth profile named oauth. The profile serves OAuth requests from client applications named client\_1 and client\_2 and resource servers named rs\_1 and rs\_2.

The profile is configured to generate both Opaque and JWT access tokens. For Opaque access token, it uses db instance named db\_test. For JWT access token, it uses issuer named https://example.f5.com, primary key named jwk1\_hs256 to sign JWT tokens and JWT refresh token encryption secret named password for encryption of refresh token generated with the JWT access token. The profile also supports OpenID Connect. It uses key named jwk1\_rs256 to sign ID Tokens.

It uses /f5-oauth2/v1/authorize as the authorization endpoint, /f5-oauth2/v1/token as token issuance endpoint, /f5-oauth2/v1/revoke as revocation endpoint, /f5-oauth2/v1/introspect as token introspection endpoint for validating Opaque tokens, /f5-oauth2/v1/.well-known/openid-configuration as OpenID Connect metadata configuration endpoint, /f5-oauth2/v1/jwks as JWKS endpoint and /f5-oauth2/v1/userinfo as UserInfo endpoint.

list oauth all all-properties

Displays a list of oauth profiles, including parameter values.

delete oauth myOAuthProfile

Deletes the oauth profile named myOAuthProfile.

#### OPTIONS

access-token-lifetime

Specifies the number of minutes for which the access token should be valid. The default is 5 minutes.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

audience

Specifies the audience claim for which the JWT access token is intended. This is a list of values. Each value in this list can be a string, URI, or session variable.

auth-code-lifetime

Specifies the number of minutes for which the authorization code should be valid. The default is 5 minutes.

auth-url

Specifies the path of the authorization endpoint that is used to authenticate the resource owner and provide the authorization code. The default is /f5-oauth2/v1/authorize.

client-apps

Specifies the list of client applications that is served by the OAuth Authorization Server associated with this profile.

db-instance

Specifies the db instance that is used to store tokens generated by the OAuth Authorization Server that is associated with this profile.

defaults-from

Specifies the default oauth profile from which this profile is created. The default is oauth.

generate-jwt-refresh-token

Specifies whether a refresh token should be generated along with the JWT access token. This is applicable only for "Authorization Code" and "Resource Owner Password Credentials" grant types. The default is true.

generate-refresh-token

Specifies whether a refresh token should be generated along with the access token. This is applicable only for "Authorization Code" and "Resource Owner Password Credentials" grant types.

id-token-claims

Specifies the list of claims that are part of ID token.

**id-token-lifetime**  
Specifies the number of minutes for which the ID token should be valid. The default is 5 minutes.

**id-token-primary-key**  
Specifies the JWK config that is used to retrieve the shared key (symmetric) or private key (asymmetric) used to sign ID token. If the key is asymmetric, the configured public key will be returned as part of JWKS URL response.

**ignore-expired-cert**  
Specifies whether to ignore the expiry of the certificate used for signing JWT access token. If this value is true, then the certificate will be used for signing JWT access token even if it is expired. The default is false.

**issuer**  
Specifies the issuer claim that is part of JWT access token. This value must be a URI.

**jwks-url**  
Specifies the path of the JWKS endpoint that returns public signing keys. These keys are used by OAuth Resource Servers to verify the digital signature of JWT access token. The default is /f5-oauth2/v1/jwks.

**jwt-access-token-claims**  
Specifies the list of claims that are part of JWT access token.

**jwt-access-token-lifetime**  
Specifies the number of minutes for which the JWT access token should be valid. The default is 5 minutes.

**jwt-ec-signature-format**  
Specifies the JWT token signature format for Elliptic Curve. The default is binary format.

**jwt-refresh-token-enc-secret**  
Specifies the JWT refresh token encryption secret that is used to generate an encryption key. This key is used to encrypt the refresh token when JWT token is enabled.

**jwt-refresh-token-lifetime**  
Specifies the number of minutes for which the JWT refresh token should be valid. The default is 60 minutes.

**jwt-token**  
Specifies whether JWT access token should be generated. The default is false.

**opaque-token**  
Specifies whether opaque (non-JWT) access token should be generated. The default is true.

**openid-cfg-url**  
Specifies the path of OpenID Connect endpoint that returns OpenID Connect configuration. The default is /f5-oauth2/v1/.well-known/openid-configuration.

**openid-connect**  
Specifies whether this OAuth profile supports OpenID connect or not.

**per-user-token-limit**  
Specifies the maximum number of active access tokens that can be generated for a user. The default is 255. The range is 0 to 5000.

**primary-key**  
Specifies the JWK config that is used to retrieve the shared key (symmetric) or private key (asymmetric) used to sign JWT access token. If the key is asymmetric, the configured public key will be returned as part of JWKS URL response.

**refresh-token-lifetime**  
Specifies the number of minutes for which the refresh token should be valid. The default is 480 minutes.

**refresh-token-usage-limit**  
Specifies the maximum number of times the access token can be obtained using the refresh token request. The default value is 0, which represents unlimited number of times.

**resource-servers**  
Specifies the list of resource servers that is served by the OAuth Authorization Server that is associated with this profile.

**reuse-access-token**  
Specifies whether an access token is reused or a new access token is generated when it is obtained using refresh token request. When the access token is reused, its expiry time is extended.

**reuse-refresh-token**  
Specifies whether a refresh token is reused or a new refresh token is generated when it is obtained using refresh token request.

**rotation-keys**  
Specifies one or more JWK configs that contain public keys used as rotation keys. The public keys derived from this set will be returned as part of JWKS URL response.

**subject**  
Specifies the subject claim that is part of JWT access token. This value can be a string, URI, or session variable. The default is \${session.assigned.uuid}

token-issuance-url

Specifies the path of token issuance endpoint that is used to issue an access token and possibly a refresh token. The default is /f5-oauth2/v1/token.

token-revocation-url

Specifies the path of token revocation endpoint that is used to revoke an access token or a refresh token. The default is /f5-oauth2/v1/revoke.

token-introspection-url

Specifies the path of token introspection endpoint that is used to introspect an access token. The default is /f5-oauth2/v1/introspect.

trusted-ca-bundle

Specifies the trusted ca bundle that is used during verification of JWK config specified in primary-key that uses asymmetric key.

userinfo-claims

Specifies the list of claims that are part of UserInfo.

userinfo-primary-key

Specifies the JWK config that is used to retrieve the shared key (symmetric) or private key (asymmetric) used to sign UserInfo. If the key is asymmetric, the configured public key will be returned as part of JWKS URL response.

userinfo-url

Specifies the path of userinfo endpoint that is used to obtain claims about the authenticated end-user. The default is /f5-oauth2/v1/userinfo.

## apm profile remote-desktop

NAME

remote-desktop - Displays information about a default profile that supports a Citrix remote desktop resource.

MODULE

apm profile

SYNTAX

Displays the properties of the remote-desktop component within the profile module.

DISPLAY

```
list remote-desktop
list remote-desktop [ [ [name] | [glob] | [regex] ] ... ]
show running-config remote-desktop
show running-config remote-desktop [ [glob] | [regex] ] ... ]
options:
  all-properties
  location-specific [true | false]
  non-default-properties
  one-line
```

DESCRIPTION

You can use the remote-desktop component to display the properties of the default remote desktop profile.

A remote desktop profile is for internal use only. You should not create or modify a remote desktop profile.

EXAMPLES

```
list remotedesktop all-properties
```

Displays all of the properties of the default remote desktop profile.

OPTIONS

location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference

objects, such as authentication servers, that are specific to a certain location.

SEE ALSO

## apm profile vdi

NAME

vdi - Configures a VDI profile.

MODULE

apm profile

SYNTAX

Configure the vdi component within the profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create vdi [name]
modify vdi [name]
options:
  msrdp-ntlm-auth-name [[string] | none]
  citrix-storefront-replacement [enabled | disabled]
```

```
edit vdi [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list vdi
list vdi [ [ [name] | [glob] | [regex] ] ... ]
show running-config vdi
show running-config vdi [ [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete vdi [name]
```

DESCRIPTION

You can use the vdi component to configure a VDI profile. A VDI profile is a group of settings that you can use to enable and configure VDI services such as Citrix, VMware View and MSRDp, so that those work with the BIG-IP system.

EXAMPLES

```
create vdi MyVdiProfile {
  msrdp-ntlm-auth-name "MyNTLMAuth"
  citrix-storefront-replacement disabled
}
```

Creates a VDI profile named MyVdiProfile with NTLM Authentication configuration MyNTLMAuth to be used for MSRDp clients authentication.

```
list vdi all-properties
Displays a list of VDI profiles, including parameter values.
```

```
delete vdi MyVdiProfile
Deletes the VDI profile named MyVdiProfile.
```

OPTIONS

msrdp-ntlm-auth-name  
Specifies the NTLM auth configuration object to be used by this VDI profile for MSRDp client authentication.

citrix-storefront-replacement  
Specifies whether Citrix StoreFront functionality is enabled on APM. When this option is enabled, APM will respond to StoreFront-specific requests from Citrix Receiver clients. When disabled, APM will fallback to PNAgent protocol.

## apm report custom-report-field

**NAME**  
custom-report-field - Configures a custom report field.

**MODULE**  
apm report

**SYNTAX**  
Configure the custom-report-field component within the custom-report module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create custom-report-field name [string] field-id [integer] field-position [integer] report-name [string]  
options  
alias [string]  
app-service [string]  
sort-direction [asc|desc|unsorted]  
sort-order [integer]  
modify custom-report-field [alias | app-service | field-id | field-position | name | report-name | sort-direction | so  
options  
alias [string]  
app-service [string]  
field-position [integer]  
report-name [string]  
sort-direction [asc|desc|unsorted]  
sort-order [integer]

**DISPLAY**  
list custom-report-field  
list custom-report-field [alias | app-service | field-id | field-position | name | report-name | sort-direction | sort

**DESCRIPTION**  
Configures a custom report field with options.  
  
It is highly recommended that you use the web GUI to configure this custom object.

**EXAMPLES**  
create alias UserName field-id 12 field-position 1 name  
APDNOTICE\_USERNAME.User\_Name report-name cust1 sort-direction asc  
sort-order 100000  
  
Creates a custom-report-field named UserName under custom report named cust1, field-position is 1, sort direction is ascending and sort-order is 100000.  
  
Note: Some field-id's and names are predefined and fixed values and not customizable, see below for details:  
  
apm report custom-report-field {  
field-id 21  
name APDNOTICE\_CLIENT\_INFO.Client\_Version  
}  
apm report custom-report-field {  
field-id 19  
name APDNOTICE\_CLIENT\_INFO.Client\_UI\_Mode  
}  
apm report custom-report-field {  
field-id 16  
name APDNOTICE\_ASSIGN\_WEBTOP\_LINKS.Webtop\_Links  
}  
apm report custom-report-field {  
field-id 18  
name APDNOTICE\_ACCESS\_POLICY\_RESULT.Access\_Policy\_Result  
}  
apm report custom-report-field {  
field-id 20  
name APDNOTICE\_CLIENT\_INFO.Client\_Type  
}  
apm report custom-report-field {  
field-id 15  
name APDNOTICE\_ASSIGN\_WEBTOP.Webtop\_Name  
}  
apm report custom-report-field {  
field-id 13  
name APDNOTICE\_ASSIGN\_ACL.ACL\_variable  
}  
apm report custom-report-field {  
field-id 12  
name APDNOTICE\_USERNAME.User\_Name

```

    }
    apm report custom-report-field {
field-id 14
name APDNOTICE_ASSIGN_RESOURCE.resource_var
    }
    apm report custom-report-field {
field-id 17
name APDNOTICE_CLIENT_INFO.Client_Platform
    }

```

#### OPTIONS

**alias**  
Specifies the alias of the custom report field.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**field-id**  
Specifies a unique id of the custom report field. This item is fixed and not customizable.

**field-position**  
Specifies field's position among all available fields.

**name** Specifies a unique name for the custom report field. This item is fixed and not customizable.

**report-name**  
Specifies the custom report that the custom-report-field belongs to.

**sort-direction**  
Specifies the sort direction of the custom-report-field. It can be asc, desc, or unsorted. Default is asc.

**sort-order**  
Specifies the sort order of the custom-report-field. Default is 100000.

## apm resource app-tunnel

#### NAME

app-tunnel - Configures an application tunnel.

#### MODULE

apm resource

#### SYNTAX

Configure the app-tunnel component within the resource module using the syntax shown in the following sections.

```

CREATE/MODIFY
create app-tunnel [name]
modify app-tunnel [name]
options:
  acl-order [integer]
  app-service [[string] | none]
  application-launch-warning [true | false]
  apps [add | delete | modify | replace-all-with] {
    [name]
  }
  customization-group [add | delete | modify | replace-all-with] {
    [name]
  }
  description [[string] | none]
  location-specific [true | false]
  type [app-tunnel | last | network-access | remote-desktop | web-application]

edit app-tunnel [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

```

```
DISPLAY
list app-tunnel
list app-tunnel [ [name] | [glob] | [regex] ] ... ]
show running-config app-tunnel
show running-config app-tunnel [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line

show app-tunnel
show app-tunnel [name]
```

```
DELETE
delete app-tunnel [name]
```

DESCRIPTION

You can use the app-tunnel component to configure an application tunnel to provide secure access to a network, remote desktop, or specific applications.

EXAMPLES

```
item create app-tunnel myapptunnel customization-group
myapptunnelcg
```

Creates an application tunnel named myapptunnel that uses the policies in the customization group myapptunnelcg.

```
item delete app-tunnel myapptunnel
```

Deletes the application tunnel named myapptunnel.

OPTIONS

**acl-order**  
Specifies the location of this app tunnel in the ACL hierarchy in Access Policy Manager ACL lists. The default is 0 (zero).

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**application-launch-warning**  
Specifies whether to display a warning before launching an application. The options are:

**true** The system displays security warnings before launching an application, regardless of whether the site is considered a Trusted site. This is the default value.

**false**  
The system displays security warnings before launching an application, only if the site is not in the Trusted Sites list.

**apps** Specifies the applications that a user can access using this application tunnel. The default is none.

**customization-group**  
Specifies whether customizations are applied to the application tunnel. You can add, modify, delete, or replace all customization groups. This option is required.

**description**  
Specifies a description for the application tunnel. The default is none.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies a name for the component.

**partition**  
Displays the partition within which the app-tunnel component resides. The default is common.

**type** Specifies the type of application tunnel. The options are:

**app-tunnel**  
This is the default.

**network-access**  
Provides access to a network.

**remote-desktop**  
Provides access to a remote desktop.

**web-application**  
Provides access to a Web application.

COPYRIGHT

## apm resource client-rate-class

**NAME**  
client-rate-class - Configures a client rate class resource.

**MODULE**  
apm resource

**SYNTAX**  
Configure the client-rate-class component within the resource module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create client-rate-class [name]  
modify client-rate-class [name]  
options:  
  app-service [[string] | none]  
  burst [integer]  
  ceiling [integer]  
  description [[string] | none]  
  dscp [integer]  
  location-specific [true | false]  
  mode [borrow | discard | shape]  
  rate [integer]  
  type [best-effort | controlled-load | guaranteed]  
  
edit client-rate-class [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

**DISPLAY**  
list client-rate-class  
list client-rate-class [ [ [name] | [glob] | [regex] ] ... ]  
show running-config client-rate-class  
show running-config client-rate-class [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  
show client-rate-class  
show client-rate-class [name]

**DELETE**  
delete client-rate-class [name]

**DESCRIPTION**  
You can use the client-rate-class component to configure a client rate class resource, which is used in traffic control.

**EXAMPLES**  
create client-rate-class sf1{ dscp 40 rate 60000 ceiling 80000 mode shape }  
Creates a client rate class resource named sf1 used in traffic control. Sets the dscp to 40 and the rate to 60000, sets the ceiling to 80000, and sets the mode to shape.  
  
list client-rate-class all  
Displays a list of all client rate class on the system.  
  
delete client-rate-class sf1  
Deletes the client rate class named sf1 from the system.

**OPTIONS**  
**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
  
**burst**  
Specifies in bytes the maximum amount of data that can reach the ceiling rate at one time. The default is 0 (zero).  
  
**ceiling**  
Specifies how far, beyond the value specified for the rate option, that traffic can flow when bursting. This number sets an absolute limit. No traffic can exceed this rate. The rate class might limit traffic throughput to the value of the rate option when there is high contention among siblings of a parent-child class hierarchy. The default value is the value of the rate option. The minimum value is 296 bp.

**description**  
Specifies a description for the client rate class. The default is none.

**dscp** Specifies six bits of DS field used as a codepoint to select the PHB (Per Hop Behavior) for a packet in each network node. The default is -1.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies a unique name to identify the client rate class.

**mode** Specifies the mode to use for this client rate class. The options are:

**borrow**  
Allows traffic on the client rate class to borrow resources from other flows that are temporarily idle. Traffic that borrows resources is marked as nonconforming and receives a lower priority. This is the default.

**discard**  
Discards packets that do not conform to the specified traffic control descriptor.

**shape**  
Delays packets submitted for transmission until the packets conform to the specified flow parameters

**partition**  
Displays the partition within which this component resides. The default is common.

**rate** Specifies the guaranteed throughput rate of the traffic handled by this rate class. You can configure the rate in bits per second (bps), kilobits per second (Kbps), megabits per second (Mbps), or gigabits per second (Gbps).

**type** Specifies the service type in use for the client rate class. The options are:

**best-effort**  
Windows traffic control creates a flow for this client traffic class, and traffic on the flow is handled with the same priority as other Best Effort traffic. This is the default.

**controlled-load**  
Traffic control transmits a very high percentage of packets to the intended receivers. Packet loss for this type closely approximates the basic packet error rate of the transmission medium. Transmission delay for a very high percentage of the delivered packets does not greatly exceed the minimum transit delay experienced by any successfully delivered packet.

**guaranteed**  
Guarantees that datagrams arrive within a specified delivery time and will not be discarded due to queue overflows, provided that the flow of traffic stays within specified traffic parameters. This type is intended for applications that require guaranteed packet delivery.

## apm resource client-traffic-classifier

**NAME**  
client-traffic-classifier - Configures client traffic classifier entries.

## MODULE

apm resource

## SYNTAX

Configure the client-traffic-classifier component within the resource module using the syntax shown in the following sections.

### CREATE/MODIFY

create client-traffic-classifier [name]

modify client-traffic-classifier [name]

#### options:

```
app-service [[string] | none]
entries [add | delete | modify | replace-all-with] {
  [name] {
    app-service [[string] | none]
    client-rate-class [[string] | none]
    dst-ip [[ipv4 address] | none]
    dst-mask [[integer] | none]
    dst-port [[integer] | none]
    protocol [[integer] | none]
    src-ip [[ipv4 address] | none]
    src-mask [[integer] | none]
    src-port [[integer] | none]
  }
}
```

location-specific [true | false]

}

edit client-traffic-classifier [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties  
non-default-properties

### DISPLAY

list client-traffic-classifier

list client-traffic-classifier [ [ [name] | [glob] | [regex] ] ... ]

show running-config client-traffic-classifier

show running-config client-traffic-classifier [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties  
app-service  
non-default-properties  
one-line  
partition

show client-traffic-classifier

show client-traffic-classifier [name]

### DELETE

delete client-traffic-classifier [name]

## DESCRIPTION

You can use the client-traffic-classifier component to configure a client traffic classifier, which is used by traffic control agent.

## EXAMPLES

```
create client-traffic-classifier tf1{ entries entry1 { protocol "6"
dst-ip "192.168.0.0" dst-mask "255.255.0.0" dst-port "0" client-rate-
class "sf1" }
entry2{protocol "6"
src-ip "10.10.0.0"
src-mask "255.255.255.0"
client-rate-class "sf2"}}}
```

Creates a client traffic classifier named tf1, sets the entry to entry1, the protocol to 6, the DST IP to 192.168.0.0, the DST mask to 255.255.0.0, the DST port to 0 (zero), and the client rate class to sf1.

```
list client-traffic-classifier all
```

Displays a list of all client traffic classifiers on the system.

```
modify client-traffic-classifier tf1 entries entry1 protocol 17
```

Modifies the client traffic classifier named tf1.

```
delete client-traffic-classifier tf1
```

Deletes the client traffic classifier named tf1 from the system.

## OPTIONS

### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

### dst-ip

Specifies the IP address of the receiver of the packet.

### dst-mask

Specifies the subnet mask for the destination address.

### dst-port

Specifies the 16-bit number to identify the sending port for either UDP or TCP network application.

### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]  
Specifies the name of the component.

partition  
Displays the partition within which the component resides. The default is Common.

protocol  
Specifies which traffic protocol to use in the filtering rule.

src-ip  
Specifies the address from which the packet is being sent.

src-mask  
Specifies the subnet mask for the source address.

src port  
Specifies a 16-bit number to identify the sending port for either UDP or TCP network application.

## apm resource ipv6-leasepool

NAME  
ipv6-leasepool - Configures a lease pool.

MODULE  
apm resource

SYNTAX  
Configure the ipv6-leasepool component within the resource module using the syntax shown in the following sections.

CREATE/MODIFY  
create ipv6-leasepool [name]  
modify ipv6-leasepool [name]  
options  
app-service [[string] | none]  
description [[string] | none]  
location-specific [true | false]  
members [add | delete | modify | replace-all-with] {  
[[first ip address in range] - [last ip address in range]]  
}  
DISPLAY  
list ipv6-leasepool  
list ipv6-leasepool [ [ [name] | [glob] | [regex] ] ... ]  
show running-config ipv6-leasepool  
show running-config ipv6-leasepool [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition  
show ipv6-leasepool  
show ipv6-leasepool [name]  
DELETE  
delete ipv6-leasepool [name]

DESCRIPTION  
Configures an IPv6 lease pool to create a collection of IPv6 addresses grouped as a single object. You can use a lease pool to associate that collection of IP addresses with a network access resource.

EXAMPLES  
create ipv6-leasepool myipv6-leasepool {fd1f::1-fd1f::64}  
  
Creates a ipv6-leasepool named myipv6-leasepool that contains the IPv6 addresses in the range fd1f::1 - fd1f::64.  
  
Note: No spaces are allowed between the first IPv6 address, hyphen, and second IPv6 address.

OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**description**  
Specifies a unique description of the lease pool.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies a unique name for the lease pool.

**members**  
Specifies a range of IPv6 addresses separated by a hyphen.

**partition**  
Displays the partition within which the component resides. The default is Common.

## apm resource leasepool

**NAME**  
leasepool - Configures a lease pool.

**MODULE**  
apm resource

**SYNTAX**  
Configure the leasepool component within the resource module using the syntax shown in the following sections.

```
CREATE/MODIFY
create leasepool [name]
modify leasepool [name]
options
  app-service [[string] | none]
  description [[string] | none]
  location-specific [true | false]
  members [add | delete | modify | replace-all-with] {
    [[first ip address in range] - [last ip address in range]]
  }
```

```
DISPLAY
list leasepool
list leasepool [ [ [name] | [glob] | [regex] ] ... ]
show running-config leasepool
show running-config leasepool [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show leasepool
show leasepool [name]
```

```
DELETE
delete leasepool [name]
```

**DESCRIPTION**  
Configures a lease pool to create a collection of IPv4 addresses grouped as a single object. You can use a lease pool to associate that collection of IPv4 addresses with a network access resource.

**EXAMPLES**  
create leasepool myleasepool {10.10.10.1-10.10.10.10}

Creates a leasepool named myleasepool that contains the IPv4 addresses in the range 10.10.10.1 - 10.10.10.10.

Note: No spaces are allowed between the first IPv4 address, hyphen, and second IPv4 address.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### description

Specifies a unique description of the lease pool.

##### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

##### [name]

Specifies a unique name for the lease pool.

##### members

Specifies a range of IP addresses separated by a hyphen.

##### partition

Displays the partition within which the component resides. The default is Common.

#### SEE ALSO

show network-access [name]

DELETE
delete network-access [name]

DESCRIPTION
  You can use the network-access component to configure the general
  settings for a network access connection.

EXAMPLES
  create network-access mynetwork-access customization-group mynetaccess
  Creates a network access connection configuration object named
  mynetwork-access that uses the policies in the customization group
  named mynetaccess.

  delete network-access mynetwork-access
  Deletes the network access connection configuration object named
  mynetwork-access.

OPTIONS
  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  address-space-dhcp-requests-excluded
  Specifies whether requests from IP addresses using DHCP are
  excluded from accessing the network. The default is true.

  address-space-exclude-subnet
  Specifies the IPv4 address spaces whose traffic you want to
  exclude from access to a subnet on the network. The default is
  none.

  ipv6-address-space-exclude-subnet
  Specifies the IPv6 address spaces whose traffic you want to
  exclude from access to a subnet on the network. The default is
  none.

  address-space-include-dns-name
  Specifies a list of domain names describing the target LAN DNS
  addresses for split tunneling only. You can add multiple address
  spaces to the list. For each address space, type the domain name,
  in the form site.siterequest.com or *.siterequest.com. The default
  is none.

  address-space-exclude-dns-name
  Specifies the DNS address spaces whose traffic you want to exclude
  from access to a subnet on the network. You can add multiple
  address spaces to the list. For each address space, type the

```

domain name, in the form site.siterequest.com or \*.siterequest.com. The default is none.

**address-space-include-subnet**

Specifies a list of IPv4 addresses or address/mask pairs describing the target LAN. When using split tunneling, only the traffic to these addresses and network segments goes through the tunnel configured for Network Access. You can add multiple address spaces to the list. For each address space, type the IPv4 address and network mask. The default is none.

**ipv6-address-space-include-subnet**

Specifies a list of IPv6 addresses or address/mask pairs describing the target LAN. When using split tunneling, only the traffic to these addresses and network segments goes through the tunnel configured for Network Access. You can add multiple address spaces to the list. For each address space, type the IPv6 address and network mask. The default is none.

**address-space-local-subnets-excluded**

Specifies whether to exclude local access to any host or subnet in routes that you have specified in the client routing table. The default is false. When you set this option to true, the system does not support integrated IP filtering.

**address-space-loc-dns-servers-excluded**

Specifies whether to exclude local access to DNS servers configured on client prior to establishing network access connection. The default is false.

**address-space-protect**

Specifies whether the IP address spaces whose traffic is forced through the tunnel are protected. The default is false.

**app-service**

The default is none.

**application-launch**

Specifies the applications to launch when the client accesses the network. The default is none.

**application-launch-warning**

Specifies whether the user is warned that an application is being launched. The default is true.

**auto-launch**

Specifies whether NA resource is to be launched automatically from full webtop. The default is false.

**client-interface-speed**

Specifies the baud rate of the client interface with the network. The default is 100000000.

**client-ip-filter-engine**

Specifies whether the client IP address is filtered. The default is .

**client-power-management**

Specifies how to interact with Windows power management features.

**prevent**

Prevents Windows from entering standby/hibernate during connection.

**terminate**

Terminate network access connection if Windows is entering standby/hibernate

**ignore**

Do nothing. Ignore power management events. This is the default value.

**client-proxy**

Specifies whether this resource handles a client proxy. The default is false.

**client-proxy-address**

Specifies the IP address of the proxy client. The default is any6.

**client-proxy-enforce-subnets**

Specifies whether address space subnets must be enforced in proxy auto-configuration. The default is true.

**client-proxy-exclusion-list**

Specifies the Web addresses that do not need to be accessed through your proxy server. You can use wild cards to match domain and host names or addresses, for example, www.\*.com, 128.\*, 240.8, 8., mygroup.\*, and \*.\*. The default is none.

**client-proxy-ignore-auto-config-error**

Allow client to connect even after an error in merging or downloading a proxy auto-configuration file. The default is false.

**client-proxy-local-bypass**

Specifies whether you want to allow local (intranet) addresses to bypass the proxy server. The default is false.

**client-proxy-port**

Specifies the port number of the proxy server you want Network Access clients to use to connect to the Internet. The default is 0 (zero).

**client-proxy-script**

Specifies the URL for a proxy auto-configuration script, if one is

used with this connection. The default is none.

#### client-proxy-use-http-pac

Specifies whether the browser uses http:// to locate the proxy the autoconfig file, instead of file://. Set this to true for applications, like Citrix MetaFrame, that cannot use the client proxy autoconfig script when the browser attempts to use the prefix file:// to locate the script. The default is false.

#### client-proxy-use-local-proxy

Specifies whether the browser uses the proxy configured on client prior to establishing network access connection. The default is false.

#### client-traffic-classifier

Specifies a client traffic classifier to use with this network access connection. The default is none.

#### compression

Specifies whether you want to compress all traffic between the Network Access client and the controller. The default is none.

#### customization-group

Specifies the customization group that defines the policies that apply to network access. This option is required.

#### description

Specifies a unique description of the network access configuration object. The default is none.

#### dns-primary

For split tunneling, specifies the IPv4 address of the primary name server that is conveyed to the remote access point for IPv4 traffic. The default is any6.

#### ipv6-dns-primary

For split tunneling, specifies the IPv6 address of the primary name server that is conveyed to the remote access point for IPv6 traffic. The default is any6.

#### dns-secondary

For split tunneling, specifies the IPv4 address of the secondary name server that is conveyed to the remote access point for IPv4 traffic. The default is any6.

#### ipv6-dns-secondary

For split tunneling, specifies the IPv6 address of the secondary name server that is conveyed to the remote access point for IPv6 traffic. The default is any6.

#### dns-suffix

Type in a DNS suffix to send to the client. If this field is left blank, the controller sends its own DNS suffix. You can specify multiple default domain suffixes separated with commas. The default is none.

#### drive-mapping

For split tunneling, specifies the drive to which this resource provides a network access connection. The default is none.

**dtls** Specifies whether the network access connection uses Datagram Transport Level Security (DTLS). DTLS uses UDP instead of TCP, to provides better throughput for high demand applications like VoIP or streaming video, especially with lossy connections. The default is false.

#### dtls-port

Specifies the port number that the network access resource uses for secure UDP traffic with DTLS. The default is 4433.

#### execute-logoff-scripts

Specifies whether the system to executes logoff scripts (configured on the Active Directory domain) when the connection is terminated. The default is false.

#### idle-timeout-threshold

Defines the average byte rate that either ingress or egress tunnel traffic must exceed for the tunnel to update a session. If the average byte rate falls below the specified threshold, the system applies the inactivity timeout, which is defined in the session's Access Profile. The default is 0 (zero).

#### idle-timeout-window

Defines the value that the system uses to calculate the Exponential Moving Average (EMA) byte rate of ingress and egress tunnel traffic. The default is 0 (zero).

#### leasepool-name

Specifies the IPv4 lease pools that the user can access with this network access connection. The default is none.

#### ipv6-leasepool-name

Specifies the IPv6 lease pools that the user can access with this network access connection. The default is none.

#### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**microsoft-network-client**  
Specifies whether the client PC can access remote resources over a VPN connection. The default is true.

**microsoft-network-server**  
Specifies whether the server can access remote resources over a VPN connection. The default is false.

**network-tunnel**  
Enables or disables the network tunnel. The default is enabled.

**optimized-app**  
Specifies the optimized applications that you want to users to access using this network access connection resource. You can add, delete, modify, or replace the current optimized applications. The default is none.

**partition**  
Displays the partition within which this network access connection component resides. The default is Common.

**provide-client-cert**  
Specifies whether client certificates are required to establish an SSL connection. You can set this option to false if the client certificates are only requested in an SSL connection. In this case, the client is configured to not send client certificates. The default is true.

**proxy-arp**  
Select Enable to enable Proxy ARP for this network access resource. When you implement Proxy ARP for a network access resource, remote VPN tunnel clients can use IP addresses from the LAN IP subnet without additional network infrastructure changes. Ranges of IP addresses from the LAN subnet can be configured in the lease pools and assigned to tunnel clients. When a host on the LAN sends traffic to a tunnel client, an ARP query is sent to request the client address. Access Policy Manager then responds with its own MAC address. Traffic is then sent to network access and forwarded to the client over the network access tunnel. No configuration changes are required on devices other than the Access Policy Manager.

See your Network Access documentation for more information about Proxy ARP configuration. The default is false.

**split-tunneling**  
Specifies whether only traffic targeted to a specified address space is sent over the network access tunnel. With split tunneling, all other traffic bypasses the tunnel. The default is false. When you set this option to true, all traffic passing over the network access connection uses this setting.

**static-host**  
Specifies the static hosts to which this resource provides a network access connection. The default is none.

**supported-ip-version**  
Specifies the supported IP protocol version. The default is ipv4.

**sync-with-active-directory**  
Specifies whether you want the network access connection to emulate the Windows logon process for a client on an Active Directory domain. The default is false.

When this option is set to true, network policies are synchronized when the connection is established, or at logoff. The following items are synchronized:

- o Logon scripts are started as specified in the user profile.
- o Drives are mapped as specified in the user profile.
- o Group policies are synchronized as specified in the user profile. Group Policy logon scripts are started when the connection is established, and Group Policy logoff scripts are run when the network access connection is stopped.

**type** Specifies the type of network access connection this component provides. The default is network-access.

**wins-primary**  
Specifies the primary IP address to which this resource provides a network access connection. The default is any6.

**wins-secondary**  
Specifies the secondary IP address to which this resource provides a network access connection. The default is any6.

## apm resource portal-access

**NAME**

portal-access - Configures a portal access resource.

**MODULE**

apm resource

**SYNTAX**

Configure the portal-access component within the resource module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create portal-access [name]
modify portal-access [name]
options:
  acl-order [integer]
  application-uri [string] | none
  app-service [[string] | none]
  css-patching [true | false]
  customization-group [string] | none
  description [string] | none
  flash-patching [true | false]
  host-replace-string [string] | none
  host-search-strings [string] | none
  html-patching [true | false]
  items [add | delete | modify | replace-all-with] {
    [string]
  }
  javascript-patching [true | false]
  location-specific [true | false]
  patching-type [full-patch | min-patch]
  path-match-case [true | false]
  proxy-host [string] | none
  proxy-port [string] | none
  publish-on-webtop [true | false]
  scheme-patching [true | false]

edit portal-access [ all-properties | non-default-properties ]
options:
  all-properties
  non-default-properties
```

**DISPLAY**

```
list portal-access
list portal-access [ [ [name] | [glob] | [regex] ] ... ]
show running-config portal-access
show running-config portal-access [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show portal-access
show portal-access [name]
```

**DELETE**

```
delete portal-access [name]
```

**DESCRIPTION**

You can use the portal-access component to specify a portal access resource.

**EXAMPLES**

```
item create portal-access myportalaccess acl-order 14 patching-
type full-patch items add { item1 { host www.mywebsite.com paths
/* }}
```

Creates a portal access resource named myportalaccess.

```
item delete portal-access myportalaccess
```

Deletes the portal access resource named myportalaccess.

**OPTIONS**

**acl-order**  
Specifies the order of this portal access in Access Policy Manager ACL lists. This option is required.

**application-uri**  
**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**css-patching**  
Specifies whether the response content type CSS is patched. The default is true.

**customization-group**

The customization group is created automatically if not specified.

**description**  
Specifies a description of the resource. The default is none.

**flash-patching**  
Specifies whether the system patches Flash content. The default is true.

**host-replace-string**  
Specifies the replacement host string, when you specify minimal for the patching-type option.

**host-search-strings**  
Specifies the host string to replace, when you specify minimal for the patching-type option.

**html-patching**  
Specifies whether the system patches HTML content. The default is true.

**items**  
Configures the host name or IP address, the network mask (if the resource is a network), the port, and any paths specified for a portal access resource. The default is none.

**javascript-patching**  
Specifies whether the system patches JavaScript content. The default is true.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies a unique name for the component.

**patching-type**  
Specifies whether this resource provides minimal or full path patching.

**path-match-case**  
Specifies whether the application URI is case-sensitive. The default is true.

**proxy-host**  
Specifies the proxy host that the portal access uses. The default is none. If you configure this option, you must also configure the option proxy-port.

**proxy-port**  
Specifies the port that the portal access proxy uses. The default is none. Configure this option, only when you configure the option proxy-host.

**publish-on-webtop**  
Specifies whether to publish this resource on the webtop. The default is false. If you set this option to true, you must also specify the Application URI using the application-uri option.

**scheme-patching**  
Specifies whether this resource replaces all HTTP scheme addresses with HTTPS scheme addresses. This option is effective only when minimal patching is selected for patching-type. The default is false.

## apm resource remote-desktop citrix-client-bundle

NAME  
citrix-client-bundle - Configures a Citrix Client Bundle remote desktop resource configuration object.

## MODULE

apm resource remote-desktop

## SYNTAX

Configure the citrix-client-bundle component within the resource remote desktop module using the syntax shown in the following sections.

### CREATE/MODIFY

create citrix-client-bundle [name]

modify citrix-client-bundle [name]

#### options:

app-service [[string] | none]

download-url [[url] | none]

packages [[string] | none]

windows-download-url [[url] | none]

windows-min-version [[string] | none]

windows-package [[string] | none]

sb-windows-package [[string] | none]

edit citrix-client-bundle [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties

non-default-properties

### DISPLAY

list citrix-client-bundle

list citrix-client-bundle [ [ [name] | [glob] | [regex] ] ... ]

show running-config citrix-client-bundle

show running-config citrix-client-bundle [ [ [name] | [glob] | [regex] ] ... ]

#### options:

all-properties

non-default-properties

one-line

partition

show citrix-client-bundle

show citrix-client-bundle [name]

### DELETE

delete citrix-client-bundle [name]

## DESCRIPTION

You can use the citrix-client-bundle component to configure a Citrix Client Bundle remote desktop resource.

## EXAMPLES

```
create citrix-client_bundle myccb { windows-min-version xp }
```

Creates a Citrix Client Bundle remote desktop resource named myccb that can be downloaded from receiver.citrix.com (the default value), where the client must have at least Windows XP installed.

## OPTIONS

### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

### download-url

Specifies the default location receiver.citrix.com from which to download the Citrix installation package.

### packages

This option is deprecated and is maintained here for backward compatibility reasons.

### [name]

Specifies an object name. This option is required; however, the parameter name is implicit and must not be typed in the syntax.

### windows-download-url

Specifies the location from which to download the Windows version. You can provide a value for either the windows-download-url or windows-package option, but not both. The default is none.

### windows-min-version

Specifies the oldest version of the Citrix client that can be used with this remote desktop resource. The default is none.

### windows-package

This option is deprecated and is replaced by sb-windows-package and is maintained here for backward compatibility reasons.

### sb-windows-package

Specifies the location of the Citrix Receiver client or Citrix HTML5 package to be uploaded. You can provide a value for either the sb-windows-package or windows-download-url option, but not for both. The default is none. The package can be uploaded via BIG-IP TMUI or can be assigned with TMSH. Follow the below mentioned steps to assign package to sb-windows-package.

Configure the component of the sandbox, citrix-client-package, within the resource module under apm using the syntax shown in the following sections.

### MODIFY

modify sandbox citrix-client-package

#### options

base-uri [string]

description [[string] | none]

files [add | delete | modify | replace-all-with] {

[item name] {

```

content-type [string]
filename [string]
file-type citrix-bundle
folder [string]
local-path [string]
name [string] } }

```

#### DISPLAY

```

list sandbox
list sandbox [ [ [name] | [glob] | [regex] ] ... ]
    all-properties
    non-default-properties
    one-line
    partition

```

A sandbox is a container for files stored on the BIG-IP, to which you want to provide client access. The local-path indicates the location of the file on the BIG-IP to be added into the sandbox e.g. /shared/tmp/FILENAME. Once the item is created on modifying citrix-client-package sandbox, it can be referenced as citrix-client-package:[item name] while assigning it to sb-windows-package.

## apm resource remote-desktop citrix-client-package-file

#### NAME

citrix-client-package-file - Configures a Citrix client package file configuration object.

#### MODULE

apm resource remote-desktop

#### SYNTAX

Configure the citrix-client-package-file component within the resource remote desktop module using the syntax shown in the following sections.

##### CREATE/MODIFY

```

create citrix-client-package-file [name]
modify citrix-client-package-file [name]
options:
    app-service [[string] | none]
    location-specific [true | false]
    original-file-name [[string] | none]
    source-path [[string] | none]

```

```

edit citrix-client-package-file [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

```

##### DISPLAY

```

list citrix-client-package-file
list citrix-client-package-file [ [ [name] | [glob] | [regex] ] ... ]
show running-config citrix-client-package-file
show running-config citrix-client-package-file [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
    partition

```

##### DELETE

```

delete citrix-client-package-file [name]

```

#### DESCRIPTION

You can use the citrix-client-package-file component to configure access to a Citrix client package file.

#### EXAMPLES

```

create citrix-client-package myccpackage { source-path
    www.siterequest.citrix_download.com }
Creates a Citrix client package remote desktop resource named
myccpackage that is available from
www.siterequest.citrix_download.com.

```

#### OPTIONS

[name]

Specifies an object name. This option is required; however, the parameter name is implicit and must not be typed in the syntax.

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**location-specific**

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**original-file-name**

Specifies the original file name of the Citrix Installation package file name to download. The default is none.

**source-path**

Specifies the location from which to download the Citrix client package file. This option is required.

**SEE ALSO**

citrix, citrix-client-bundle, rdp

**COPYRIGHT**

## apm resource remote-desktop citrix

**NAME**

citrix - Configures a Citrix remote desktop resource configuration object.

**MODULE**

apm resource remote-desktop

**SYNTAX**

Configure the citrix component within the resource remote desktop module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create citrix [name]
modify citrix [name]
options:
  app-service [[string] | none]
  auto-logon [enabled | disabled]
  customization-group [add | delete | modify | replace-all-with] {
    [name] {
  options:
    caption [[string] | none]
    detailed-description [[string] | none]
    }
  }
  description [[string] | none]
  domain-source [session.logon.last.domain | none]
  enable-serverside-ssl [enabled | disabled]
  pool [pool name]
  host [fqdn]
  ip [ip address]
  location-specific [true | false]
  password-source [session.logon.last.password | none]
  port [[string] | none]
  username-source [session.logon.last.username | none]

edit citrix [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

**DISPLAY**

```
list citrix
list citrix [ [ [name] | [glob] | [regex] ] ... ]
show running-config citrix
show running-config citrix [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
show citrix
show citrix [name]
```

```
DELETE
delete citrix [name]
```

#### DESCRIPTION

You can use the B component to configure a Citrix remote desktop resource.

#### EXAMPLES

```
create citrix mycitrix { ip 172.29.67.130 }
Creates a Citrix remote desktop resource named mycitrix with
Citrix XML Broker server specified as IP address 172.29.67.130.

create citrix mycitrix { host mycitrix.mycompany.com auto-logon enabled
}
Creates a Citrix resource with Citrix XML Broker server specified
as hostname mycitrix.mycompany.com and auto-logon enabled with APM
credentials (that user types on Logon Page).

create citrix mycitrix { pool /Common/mycitrix-pool enable-serverside-
ssl enabled }
Creates a Citrix resource with Citrix XML Broker server(s)
specified in pool named /Common/mycitrix-pool and SSL
communication enabled to the server(s) (SSL should also be enabled
on the servers and APM virtual should have serverssl profile).
```

#### OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**auto-logon**  
Enables or disables automatic log on to the Citrix server. If you enable this option, you must also provide values for the username-source, password-source, and domain-source options. The default is disabled.

**customization-group**  
Specifies whether customization groups are applied to the Citrix remote desktop. You can add, modify, or delete customization groups. You can also replace all current customization groups with new customization groups. The default is none.

**description**  
Specifies a description for your Citrix remote desktop. The default is none.

**domain-source**  
Specifies the Session variable used as a source for the auto-logon user password. The default is session.logon.last.domain.

**enable-serverside-ssl**  
Enables or disables SSL capabilities between the BIG-IP system and the Citrix server. When enabled, the port number automatically changes to 443. The default is disabled.

**pool** Specifies the pool name that contains your Citrix XML Broker server(s). You must use one of these options to specify the server address: pool, host, or ip.

**host** Specifies the hostname of your Citrix XML Broker server. You must use one of these options to specify the server address: pool, host, or ip.

**ip** Specifies the IP address of your Citrix XML Broker server. You must use one of these options to specify the server address: pool, host, or ip.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies an object name. This option is required; however, the parameter name is implicit and must not be typed in the syntax.

**password-source**  
Specifies the session variable that is used as a source for the auto-logon password. The default is session.logon.last.password.

**port** Specifies the port for your Citrix server. The default is 80.

**username-source**  
Specifies the session variable that is used as a source for the auto-logon user name. The default is session.logon.last.username.

## apm resource remote-desktop quest

### NAME

quest - Configures a Quest vWorkspace remote desktop resource configuration object.

### MODULE

apm resource remote-desktop

### SYNTAX

Configure the quest component within the resource remote desktop module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create quest [name]
modify quest [name]
  options:
    app-service [[string] | none]
    auto-logon [enabled | disabled]
    customization-group [add | delete | modify | replace-all-with] {
      [name] {
        options:
          caption [[string] | none]
          detailed-description [[string] | none]
        }
      description [[string] | none]
      domain-source [session.logon.last.domain | none]
      enable-serverside-ssl [enabled | disabled]
      pool [pool name]
      host [fqdn]
      ip [ip address]
      location-specific [true | false]
      password-source [session.logon.last.password | none]
      port [[string] | none]
      username-source [session.logon.last.username | none]
    }
edit quest [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
```

#### DISPLAY

```
list quest
list quest [ [ [name] | [glob] | [regex] ] ... ]
show running-config quest
show running-config quest [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
```

```
show quest
show quest [name]
```

#### DELETE

```
delete quest [name]
```

### DESCRIPTION

You can use the B component to configure a Quest vWorkspace remote desktop resource.

### EXAMPLES

```
create quest myquest { ip 172.29.67.130 }
Creates a Quest vWorkspace remote desktop resource named myquest
with the Quest vWorkspace connection broker server specified as IP
address 172.29.67.130.

create quest myquest { host myquest.mycompany.com auto-logon enabled }
Creates a Quest vWorkspace resource with the Quest vWorkspace
connection broker server specified as hostname
myquest.mycompany.com and with auto-logon enabled using the
credentials that the user types into the access policy Logon Page.

create quest myquest { pool /Common/myquest-pool enable-serverside-ssl
enabled }
Creates a Quest vWorkspace resource with the Quest vWorkspace
connection broker servers specified in a pool named
/Common/myquest-pool and with SSL communication enabled to the
servers. Note: SSL should also be enabled on the servers
themselves and the APM virtual server should specify a server SSL
profile.
```

### OPTIONS

```
app-service
Specifies the name of the application service to which the object
```

belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### auto-logon

Enables or disables automatic log on to the Quest vWorkspace connection broker server. If you enable this option, you must also provide values for the username-source, password-source, and domain-source options. The default is disabled.

#### customization-group

Specifies whether customization groups are applied to the Quest vWorkspace resource. You can add, modify, or delete customization groups. You can also replace all current customization groups with new customization groups. The default is none.

#### description

Specifies a description for your Quest vWorkspace remote desktop. The default is none.

#### domain-source

Specifies the session variable to use as a source for the auto-logon user password. The default is session.logon.last.domain.

#### enable-serverside-ssl

Enables or disables SSL capabilities between the BIG-IP system and the Quest vWorkspace connection broker server. When enabled, the port number automatically changes to 443. The default is disabled.

**pool** Specifies the pool name that contains your Quest vWorkspace connection broker servers. (You must specify the server address using one of these options: pool, host, or ip.)

**host** Specifies the hostname of your Quest vWorkspace connection broker server. (You must specify the server address using one of these options: pool, host, or ip.)

**ip** Specifies the IP address of your Quest vWorkspace connection broker server. (You must specify the server address using one of these options: pool, host, or ip.)

#### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

#### [name]

Specifies an object name. This option is required. Note: The parameter name is implicit. Do not type name in the syntax.

#### password-source

Specifies the session variable to use as a source for the auto-logon password. The default is session.logon.last.password.

**port** Specifies the port for your Quest vWorkspace connection broker server. The default is 8080.

#### username-source

Specifies the session variable to use as a source for the auto-logon user name. The default is session.logon.last.username.

#### SEE ALSO

## apm resource remote-desktop rdp

#### NAME

rdp - Configures a Microsoft Remote Desktop Protocol (MSRDP) configuration object.

#### MODULE

apm resource remote-desktop

#### SYNTAX

Configure the rdp component within the resource remote desktop module

using the syntax shown in the following sections.

```
CREATE/MODIFY
create rdp [name]
modify rdp [name]
options:
  acl-order [[integer] | none]
  application [[string] | none]
  app-service [[string] | none]
  auto-logon [enabled | disabled]
  color-depth [4 | 8 | 16 | 24]
  customization-group [add | delete | modify | replace-all-with] {
    [name] {
      options:
        app-service [[string] | none]
        caption [[string] | none]
        detailed-description [[string] | none]
      }
    description [[string] | none]
    domain-source [session.logon.last.domain | none]
    host [fqdn]
    ip [ip address]
    java-client [enabled | disabled]
    native-client [enabled | disabled]
    location-specific [true | false]
    log [config | none | packet | summary | verbose]
    password-source [session.logon.last.password | none]
    port [[integer] | none]
    rdp-cache-bitmaps [true | false]
    rdp-show-contents-while-dragging [true | false]
    rdp-show-desktop-wallpaper [true | false]
    rdp-show-themes [true | false]
    rdp-window-animations [true | false]
    redirect-com-parts [true | false]
    redirect-drives [true | false]
    redirect-keyboard-commands [true | false]
    redirect-printers [true | false]
    redirect-sound [true | false]
    username-source [session.logon.last.username | none]
    window-height [[integer] | none]
    window-percent-of-desktop [[integer] | none]
    window-size [custom-size | full-screen | percent-of-desktop | seamless]
    window-width [[integer] | none]
    work-dir [[string] | none]
  }

edit rdp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list rdp
list rdp [ [ [name] | [glob] | [regex] ] ... ]
show running-config rdp
show running-config rdp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

show rdp
show rdp [name]

DELETE
delete rdp [name]
```

#### DESCRIPTION

You can use the rdp component to configure an MSRDP resource.

#### EXAMPLES

```
create rdp myrdp { host 172.29.67.130 }
Creates a MSRDP remote desktop resource named myrdp with an MSRDP
server with an IP address of 172.29.67.130.
```

```
create rdp myrdp { host 172.29.67.130 rdp-cache-bitmaps true }
Creates a MSRDP remote desktop resource named myrdp with an MSRDP
server with an IP address of 172.29.67.130 where bitmaps are
cached on the client PC.
```

#### OPTIONS

##### acl-order

Specifies the order in which you want the RDP server to appear in the ACL Order list. The default is 0 (zero).

##### application

Specifies the executable name of the application, for example notepad.exe. You can include the full path to the application, for example "C:\my\mybinary.exe".

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### auto-logon

Specifies if automatic log on to the Microsoft RDP server is used. If you enable this option, you must also provide values for the username-source, password-source, and domain-source options. The default is disabled.

##### color-depth

Specifies the requested remote session color depth. The default is

32. The options are:

24-bit  
16-bit  
8-bit  
4-bit

customization-group

Specifies whether customization-groups are applied to the remote desktop. You can add, modify, delete, or replace all customization-groups. The default is none.

description

Specifies a description of an MSRDp resource. The default is none.

domain-source

Specifies the session variable used as a source for the auto-logon user password. The default is session.logon.last.domain.

host Specifies the hostname of your Microsoft RDP server. Either the host or ip option is required; however, you cannot specify both options.

ip Specifies the IP address of your Microsoft RDP server. Either the host or ip option is required; however, you cannot specify both options.

java-client

Specifies whether to use Java RDP client to launch this resource. The default is disabled. Java RDP client is deprecated and will be removed in next release, native-client is recommended instead.

native-client

Specifies whether to use native RDP client to launch this resource. The default is disabled. java-client and native-client can't be enabled at the same time. When both java-client and native-client are disabled, RDP resource is launched using ActiveX control. ActiveX control based RDP client is deprecated and will be removed in next release, native-client is recommended instead.

location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

log Specifies the log format. The default is none. The options are:

config

none The system does not log packets sent to and from the Microsoft RDP server.

packet

The system logs packets sent to and from the Microsoft DP server.

summary

The system provides a short summary of the communications between the BIG-IP system and the Microsoft RDP server.

verbose

The system provides an extensive summary of the communications between the BIG-IP system and the Microsoft RDP server.

[name]

Specifies an object name. This option is required; however, the parameter name is implicit and must not be typed in the syntax.

password-source

Specifies the session variable used as a source for the auto-logon password. The default is session.logon.last.password.

port Specify port 3389 for your Microsoft RDP server. The default is 0 (zero).

rdp-cache-bitmaps

Specifies whether to cache bitmap files on the client. The default is true.

rdp-show-contents-while-dragging

Specifies whether to show the contents of a window when the user is dragging the window. The default is false.

rdp-show-desktop-wallpaper

Specifies whether to display the desktop background. The default is false.

rdp-show-themes

Specifies whether to display the desktop theme. The default is false.

rdp-window-animations

Specifies whether to display Window animations. The default is false.

redirect-com-ports

Specifies whether to connect to your communication ports. The default is false.

redirect-drives

Specifies whether to connect to your local drives. The default is

false.

**redirect-keyboard-commands**

Specifies when to redirect keyboard commands to a remote session. When enabled, commands such as Alt-tab and Ctrl-Alt-Del are available in remote sessions. The default is in-full-screen. The options are:

**enable**

The keyboard commands for the remote desktop are available to the user.

**disable**

The keyboard commands for the remote desktop are not available to the user.

**in-full-screen**

The keyboard commands for the remote desktop are available to the user only when the value of the window-size option is full-screen.

**redirect-printers**

Enables or disables connection to a local printer. The default is disabled.

**redirect-sound**

Enables or disables sounds playing in a remote session. The default is disabled.

**username-source**

Specifies the session variable used as a source for the auto-logon user name. The default is session.logon.last.username.

**window-height**

Specifies the height, in pixels, of the remote desktop window. Set this option only when you set the value of the window-size option to custom. The default is 600 pixels.

**window-percent-of-desktop**

Specifies the width and height of the remote session window as a percentage of the user's desktop.

**window-size**

Specifies the type of window sizing to use on the client desktop. The default is custom-size.

The options are:

**full-screen**

The remote desktop window fills the entire screen.

**percent-of-desktop**

The value you configure represents a percentage of the screen that the remote desktop fills.

**custom**

When you use this option, you must also set the window-height and window-width options.

**seamless**

**window-width**

Specifies the width, in pixels, of the remote desktop window. The default is 800 pixels.

**workdir**

Specifies the directory you want the user to access on the target server. The default is none.

## apm resource remote-desktop vmware-view

**NAME**

vmware-view - Configures a VMware View remote desktop resource configuration object.

**MODULE**

apm resource remote-desktop

## SYNTAX

Configure the vmware-view component within the resource remote desktop module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create vmware-view [name]
modify vmware-view [name]
options:
  app-service [[string] | none]
  auto-logon [enabled | disabled]
  customization-group [add | delete | modify | replace-all-with] {
    [name] {
options:
  caption [[string] | none]
  detailed-description [[string] | none]
    }
  }
  description [[string] | none]
  domain-source [session.logon.last.domain | none]
  enable-serverside-ssl [enabled | disabled]
  pool [pool name]
  host [fqdn]
  ip [ip address]
  location-specific [true | false]
  password-source [session.logon.last.password | none]
  port [[string] | none]
  username-source [session.logon.last.username | none]

edit vmware-view [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

### DISPLAY

```
list vmware-view
list vmware-view [ [ [name] | [glob] | [regex] ] ... ]
show running-config vmware-view
show running-config vmware-view [ [ [name] | [glob] | [regex] ] ... ]
options:

  non-default-properties

show vmware-view
show vmware-view [name]
```

### DELETE

```
delete vmware-view [name]
```

## DESCRIPTION

You can use the B component to configure a VMware View remote desktop resource.

## EXAMPLES

```
create vmware-view myview { ip 172.29.67.130 }
Creates a VMware View remote desktop resource named myview with
the VMware View Connection server specified as IP address
172.29.67.130.
```

```
create vmware-view myview { host myview.mycompany.com auto-logon
enabled }
Creates a VMware View resource with the VMware View Connection
server specified as hostname myview.mycompany.com and auto-logon
enabled with APM credentials (that user types on Logon Page).
```

```
create vmware-view mview { pool /Common/myview-pool enable-serverside-
ssl enabled }
Creates a VMware View resource with the VMware View Connection
server(s) specified in pool named /Common/myview-pool and SSL
communication enabled to the server(s) (SSL should also be enabled
on the servers and APM virtual should have serverssl profile).
```

## OPTIONS

### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

### auto-logon

Enables or disables automatic log on to the VMware View Connection Server server. If you enable this option, you must also provide values for the username-source, password-source, and domain-source options. The default is disabled.

### customization-group

Specifies whether customization groups are applied to the VMware View resource. You can add, modify, or delete customization groups. You can also replace all current customization groups with new customization groups. The default is none.

### description

Specifies a description for your VMware View remote desktop. The default is none.

### domain-source

Specifies the Session variable used as a source for the auto-logon user password. The default is session.logon.last.domain.

### enable-serverside-ssl

Enables or disables SSL capabilities between the BIG-IP system and the VMware View Connection server. When enabled, the port number automatically changes to 443. The default is disabled.

**pool** Specifies the pool name that contains your VMware View Connection server(s). You must use one of these options to specify the server address: pool, host, or ip.

**host** Specifies the hostname of your VMware View Connection server. You must use one of these options to specify the server address: pool, host, or ip.

**ip** Specifies the IP address of your VMware View Connection server. You must use one of these options to specify the server address: pool, host, or ip.

**location-specific**  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
Specifies an object name. This option is required; however, the parameter name is implicit and must not be typed in the syntax.

**password-source**  
Specifies the session variable that is used as a source for the auto-logon password. The default is session.logon.last.password.

**port** Specifies the port for your VMware View Connection server. The default is 80.

**username-source**  
Specifies the session variable that is used as a source for the auto-logon user name. The default is session.logon.last.username.

## apm resource sandbox

**NAME**  
sandbox - Configures a sandbox.

**MODULE**  
apm resource

**SYNTAX**  
Configure the sandbox component within the resource module using the syntax shown in the following sections.

**CREATE**  
The CREATE command is currently not available. However, a number of sandboxes have already been created. Use these to upload files.

**MODIFY**  
modify sandbox [name]  
options  
base-uri [string]  
description [[string] | none]  
files [add | delete | modify | replace-all-with] {  
[item name] {  
content-type [string]  
filename [string]  
file-type [citrix-bundle | customization | unknown]  
folder [string]  
local-path [string]  
name [string]  
}  
}  
}

**DISPLAY**  
list sandbox  
list sandbox [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

## DESCRIPTION

Configures a sandbox and its files. A sandbox is a container for files stored on the BIG-IP, to which you want to provide client access.

## EXAMPLES

```
modify sandbox hosted-content files add { BIGIPEdgeClient.exe { folder
/client local-path /tmp/BIGIPEdgeClient.exe } }
```

Adds a file called BIGIPEdgeClient.exe to sandbox named hosted-content. The virtual path to this file consists of the sandbox's base-uri, the file's folder, and the name of the file. Putting these components together, the virtual path for the uploaded file is /public/share/client/BIGIPEdgeClient.exe, where /public/share is the base-uri, /client is the folder, and BIGIPEdgeClient.exe is the filename. The local-path indicates the location of the file on the disk drive to be added into the sandbox.

Note: The file you add must already be on the BIG-IP system.

## OPTIONS

### base-uri

Specifies the first component of the virtual path to the sandbox file. The base-uri for sandbox "hosted-content" is /public/share. The virtual path to a sandbox box file is made up of three components: base-uri/folder/filename

All files in a sandbox share the same base-uri, but the folder can be different for each file.

### description

Specifies a unique description about the sandbox.

### files

Specifies the list of files in the sandbox.

### item name

Specifies the name of an item in the list of files. You can use the original filename as the item name. Each item name in a sandbox must be unique.

### content-type

Specifies the content-type field in a HTTP header such as "image/gif" or "text/plain". If none is provided, tmsh will try its best to provide this value.

### filename

Specifies the last component of the virtual path to the sandbox file. We recommend that you use the filename of the original file for this name.

### file-type

Specifies the F5 file type. Currently there are only three types: unknown, citrix-bundle, and customization. No value is required if a file is uploaded to sandbox for "citrix-client-bundle", since this sandbox is the repositories for F5 specific type of file. However, for files uploaded to sandbox "hosted-content" if no value is provided, the file type defaults to "unknown".

### folder

Specifies the second component of the virtual path to the sandbox file.

### local-path

Specifies the location of the file to be inserted into the sandbox. This file must be on the BIG-IP already.

name Specifies a value for the underlying file object. Use this only if you are trying to add more than one sandbox file in a modify command. Otherwise, don't specify a value for this attribute. The value must be specified as follows: full path of sandbox name:item name. For example, if the sandbox name is '/Common/hosted-content' and the item name is 'index.html', the value should be '/Common/hosted-content:index.html'.

## SEE ALSO

webtop, webtop-link

## COPYRIGHT

BIG-IP      2016-03-14      apm resource sandbox(1)

NAME  
webtop-link - Configures a webtop link resource.

MODULE  
apm resource

SYNTAX  
Configure the webtop-link component within the resource module using the syntax shown in the following sections.

CREATE/MODIFY

```
create webtop-link [name]
modify webtop-link [name]
options:
  application-uri [string]
  app-service [[string] | none]
  customization-group [string]
  description [[string] | none]
  location-specific [true | false]

edit webtop-link [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
```

DISPLAY

```
list webtop-link
list webtop-link [ [ [name] | [glob] | [regex] ] ... ]
show running-config webtop-link
show running-config webtop-link [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

show webtop-link
show webtop-link [name]
```

DELETE

```
delete webtop-link [name]
```

DESCRIPTION  
Configures the settings necessary to define a link to a webtop that is displayed to the end-user as part of the access policy execution.

EXAMPLES

```
create webtop-link mywebtoplinkcgl application-uri
"http://www.externalsite.com/"
Creates a webtop named mywebtoplinkcgl with the application-uri of
http://www.externalsite.com/.
```

OPTIONS

application-uri  
Specifies the application URI of the external portal to which this resource provides access for this webtop link. This is a required setting.

app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

customization-group  
Specifies the customization settings for the webtop.

Note: You must create a customization group of type webtop before you can create a webtop resource. If you do not specify a customization group, a group will be created automatically.

description  
Specifies a description of the resource. The default is none.

location-specific  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

# apm resource webtop

**NAME**

webtop - Configures a webtop resource.

**MODULE**

apm resource

**SYNTAX**

Configure the webtop component within the resource module using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create webtop [name]
modify webtop [name]
  options:
    app-service [[string] | none]
    customization-group [string]
    description [[string] | none]
    location-specific [true | false]
    minimize-to-tray [false | true]
    portal-access-start-uri [[string] | none]
    webtop-type [full | last | network-access | portal-access]
    warn-when-closed [false | true]
```

**edit webtop** [ [ [name] | [glob] | [regex] ] ... ]

```
  options:
    all-properties
    non-default-properties
```

**DISPLAY**

```
list webtop
list webtop [ [ [name] | [glob] | [regex] ] ... ]
show running-config webtop
show running-config webtop [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
```

**show webtop**

**show webtop [name]**

**DELETE**

```
delete webtop [name]
```

**DESCRIPTION**

Configures the settings necessary to define the webtop assigned to the end-user as part of the access policy execution.

**EXAMPLES**

```
create webtop mynawebtop { customization-group mywebtopcgl minimize-to-tray false }
Creates a webtop named mynawebtop with the customization group mywebtopcgl and the network access minimize-to-tray option set to false.
```

```
create webtop mywawebtop { customization-group mywebtopcgl portal-access-start-uri "http://www.siterequest.com" }
Creates a webtop named mywawebtop with the customization group mywebtopcgl and the starting URI for the portal access of http://www.siterequest.com.
```

**OPTIONS**

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**customization-group**

Specifies the customization settings for the webtop.

**Note:** You must create a customization group of type webtop before you can create a webtop resource. This option is required.

**description**

Specifies a description of the resource. The default is none.

**portal-access-start-uri**

Specifies the URI that the webtop starts. You can only configure this option if you have configured the webtop-type option for portal-access.

**location-specific**

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**minimize-to-tray**

Specifies whether the network access window (launched from the full webtop) is minimized to the system tray automatically after the network access connection starts. The default is true.

You can configure this option only if you configured the webtop-type option as network-access or full. With a network access

webtop, the webtop automatically minimizes to the tray. With a full webtop, the webtop minimizes to the system tray only after the network access connection is started.

**warn-when-closed**  
Specifies whether the network access window (launched from the full webtop) should display a warning message when the webtop closes.

You can configure this option only if you configured the webtop-type option as full.

**webtop-type**  
Specifies the type of webtop this resource creates. The options are:

**full** A webtop to which you assign a single network access resource, multiple portal access resources, and multiple application access app tunnel resources, or any combination of the three types. This is the default.

**last network-access**  
A webtop to which you assign only a single network access resource.

**portal-access**  
A webtop to which you assign only portal access resources.

## apm saml artifact-resolution-service

**NAME**  
artifact-resolution-service - Specify service used to resolve SAML artifacts

**MODULE**  
apm saml

**SYNTAX**  
Configure the artifact-resolution-service component within the saml module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create artifact-resolution-service [name]  
modify artifact-resolution-service [name]  
options:  
app-service [[string] | none]  
artifact-resolution-service-host [[string] | none]  
artifact-resolution-service-port [integer]  
artifact-send-method [http-post | http-redirect]  
artifact-validity [integer]  
basic-auth-password [[string] | none]  
basic-auth-username [[string] | none]  
description [[string] | none]  
location-specific [ true | false ]  
virtual-server-name [name]  
want-artifact-resolution-rq-signed [true | false]  
  
edit artifact-resolution-service [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
  
**DISPLAY**  
list artifact-resolution-service  
list artifact-resolution-service [ [ [name] | [glob] | [regex] ] ... ]  
show running-config artifact-resolution-service  
show running-config artifact-resolution-service [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
app-service  
non-default-properties  
one-line  
partition  
  
**DELETE**  
delete artifact-resolution-service [name]

## DESCRIPTION

You can use the artifact-resolution-service to create and manage artifact resolution services.

## EXAMPLES

```
create artifact-resolution-service my_ars {virtual-server-name my_virt}
Creates a SAML artifact resolution service named my_ars. In this
example, the virtual server my_virt will be used to receive
artifact resolve requests and send artifact responses.
```

```
create artifact-resolution-service my_ars1 {virtual-server-name
my_virt1 artifact-resolution-service-host bigip.mycompany.com basic-
auth-username user basic-auth-password password artifact-send-method
http-redirect }
```

Creates a SAML artifact resolution service named my\_ars1. The service requires that artifact resolve requests be sent using the http-redirect method with an authorization header that contains the specified credentials.

```
list artifact-resolution-service
Displays a list of artifact resolution services.
```

```
delete artifact-resolution-service my_ars
Deletes the my_ars artifact resolution service.
```

## OPTIONS

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**artifact-resolution-service-host**  
Specifies the hostname of the artifact resolution service.

**artifact-resolution-service-port**  
Specifies the port that artifact resolution service will be listening on.

**artifact-send-method**  
Specifies method resolver will use when sending artifact resolve requests. Default value is http-redirect.

**artifact-validity**  
Specifies in seconds how long an artifact remains valid. Default value is 60 seconds.

**basic-auth-password**  
Specifies the basic authentication password to send with an artifact resolve request to this BIG-IP.

**basic-auth-username**  
Specifies the basic authentication username to send with an artifact resolve request to this BIG-IP.

**description**  
Specifies a unique description for the artifact resolution service. Default is none.

**location-specific**  
Objects of this class might have location-specific attributes. If the object is location-specific, set to true.

**virtual-server-name**  
Specifies the virtual server to be used by the artifact resolution service.

**want-artifact-resolution-rq-signed**  
Specifies whether this BIG-IP requires artifact resolution requests to be signed. Default value is true.

## apm saml attribute-consuming-service

### NAME

attribute-consuming-service - Configure a list of SAML attribute consuming services.

MODULE  
apm saml

SYNTAX  
Configure the attribute-consuming-service component within the saml module using the syntax shown in the following sections.

MODIFY  
create attribute-consuming-service [name]  
modify attribute-consuming-service [name]  
options:  
  app-service [[string] | none]  
  attributes [add | delete | modify | none | replace-all-with] {  
    name [string] {  
      app-service [[string] | none]  
      attribute-name [string]  
      friendly-name [string]  
      is-required [bool]  
      name-format [string]  
    }  
  }  
  service-description [[string] | none]  
  service-name [[string] | none]  
  
edit attribute-consuming-service [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  
DISPLAY  
list attribute-consuming-service  
list attribute-consuming-service [ [ [name] | [glob] | [regex] ] ... ]  
show running-config attribute-consuming-service  
show running-config attribute-consuming-service [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  app-service  
  non-default-properties  
  one-line  
  partition  
  
DELETE  
delete attribute-consuming-service [name]

DESCRIPTION  
You can use attribute-consuming-service to create and manage SAML attribute consuming services. Each attribute consuming service contains a list of SAML attributes. Each attribute consuming service must contain at least one attribute.

EXAMPLES  
create attribute-consuming-service my\_attr consuming service attributes  
add { my\_attr { attribute-name "urn:oid:1.3.6.1.4.1.5923.1.1.1.7" is-required false friendly-name eduPersonEntitlement name-format "urn:oasis:names:tc:SAML:2.0:attrname-format:uri" } service-name "Academic Journals R US" service-description "Academic Journals R US"  
Creates a new attribute consuming service named my\_attr\_consuming\_service with one attribute named my\_attr.  
  
list attribute-consuming-service  
Displays a list of attribute consuming services.

OPTIONS  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
  
attributes  
Specifies a list of attributes. attribute-name must be unique within an attribute-consuming-service object. friendly-name is a more human-readable form of the attribute name for cases where attribute-name is complex. is-required indicates if the service requires the attribute in order to function at all. name-format is a URI reference representing the classification of the attribute name for purposes of interpreting the name.  
  
service-description  
Specifies a description for the attribute consuming service.  
  
service-name  
Specifies a unique name for the attribute consuming service.

SEE ALSO  
COPYRIGHT

## apm saml auth-context-class-list

**NAME**

auth-context-class-list - Configure a list of SAML authentication context classes.

**MODULE**

apm saml

**SYNTAX**

Configure the auth-context-class-list component within the saml module using the syntax shown in the following sections.

**MODIFY**

```
create auth-context-class-list [name]
modify auth-context-class-list [name]
  options:
    app-service [[string] | none]
    classes [add | delete | modify | none | replace-all-with] {
      name [string] {
        order [integer]
        value [string]j
      }
    }
    description [[string] | none]
```

**edit auth-context-class-list [ [ [name] | [glob] | [regex] ] ... ]**

**options:**

- all-properties
- non-default-properties

**DISPLAY**

```
list auth-context-class-list
list auth-context-class-list [ [ [name] | [glob] | [regex] ] ... ]
show running-config auth-context-class-list
show running-config auth-context-class-list [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    app-service
    non-default-properties
    one-line
    partition
```

**DELETE**

```
delete auth-context-class-list [name]
```

**DESCRIPTION**

You can use the auth-context-class-list to create and manage lists of SAML authentication context classes. Each class in the list must contain a unique order and a unique value. Order indicates the relative level of security ranging from 1 (least secure) to 255 (most secure).

**EXAMPLES**

```
create sp_authn_ctx_classes_list classes add { password { order 1 value
urn:oasis:names:tc:SAML:2.0:ac:classes:Password} kerberos { order 2
value urn:oasis:names:tc:SAML:2.0:ac:classes:Kerberos } }
Creates a new list named 'sp_authn_ctx_classes_list' with two
authentication context classes: password and kerberos. Higher
order number implies higher security associated with class. In
this example, the fact that the kerberos class order is 2 implies
that it has higher security than the password class with order 1.

modify authentication_contexts_list classes add { SmartcardPKI { order
8 value urn:oasis:names:tc:SAML:2.0:ac:classes:SmartcardPKI } }
Modifies default list of authentication context classes to include
a class 'SmartcardPKI' with priority order '8' and value
'urn:oasis:names:tc:SAML:2.0:ac:classes:SmartcardPKI'.

modify authentication_contexts_list classes delete { smartcard }
Removes authentication context class 'smartcard' from the default
list of authentication context classes
'authentication_contexts_list'.

list auth-context-class-list
Displays default list of authentication context classes.
```

**OPTIONS**

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**classes**

Specifies a list of authentication context classes. Properties 'order' and 'value' must be unique within the auth-context-class-list object. Property 'order' specifies the security of the class in the context of the BIG-IP system; order ranges from the least secure '1' to the most secure '255'. Property 'value' specifies a URL of authentication context class, for example, 'urn:oasis:names:tc:SAML:2.0:ac:classes:Kerberos'.

**description**

Specifies a unique description for the list of authentication context classes.

## apm session

#### NAME

Session - Shows apm session information including session id and all keys and values such as client ip, user name etc

#### MODULE

apm

#### SYNTAX

Shows session information with the syntax shown in the following sections.

##### LIST/DELETE

Lists all the apm session information, session id and all keys and values related to the session. This command can show all the session details or only for some sessions. Deletes all the apm sessions or some sessions at once.

##### LIST

```
list session [session_id] [session_id]
options:
  all
  all-properties
  save-to-file
```

##### DISPLAY

```
delete session [session_id] [session_id]
options:
  all
```

#### EXAMPLES

```
list session [all-properties] [session_id] [session_id]
```

Lists details related to the sessions or the given optional session\_id.

```
delete session [all] [session_id] [session_id]
```

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## apm sso basic

#### NAME

basic - Configures a single sign-on HTTP basic authentication configuration object.

#### MODULE

apm sso

#### SYNTAX

Configure the basic component within the sso module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create basic [name]
```

```

modify basic [name]
options:
  apm-log-config [[string] | none]
  app-service [[string] | none]
  headers [add | delete | modify | | replace-all-with] {
  location-specific [true | false]
  [name] {
    options:
      app-service [[string] | none]
  hname [[URL] | none]
    hvalue [[integer] | none]
  }
}
  password-source [session.sso.token.last.password | none]
  username-conversion [enabled | disabled]
  username-source [session.sso.token.last.username | none]

```

```

edit basic [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

```

```

DISPLAY
list basic
list basic [ [ [name] | [glob] | [regex] ] ... ]
show running-config basic
show running-config basic [ [ [name] | [glob] |
[regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

```

```

show basic
show basic [name]

```

```

DELETE
delete basic [name]

```

**DESCRIPTION**  
 You can use the basic component to create, modify, display, or delete an SSO HTTP basic authentication configuration object.

**EXAMPLES**  
 create basic mybasic  
 Creates an SSO basic configuration object named mybasic.

**OPTIONS**

**apm-log-config**  
 Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

**app-service**  
 Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**headers**  
 Specifies the name and value of the HTTP header content to be inserted in an HTTP Request that passes through the APM SSO module. The default is none. The options are:

**app-service**  
 Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

**hname**  
 The name of the HTTP header.

**hvalue**  
 The value of the HTTP header.

**location-specific**  
 Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**  
 Specifies a name for the SSO configuration. This option is required.

**partition**  
 Displays the partition in which the object resides.

**oam-server**  
 Specifies the name of your Oracle Access Manager server. The default value is none.

**password source**  
 Specifies the source from which you want SSO to retrieve the password to use to authenticate applications.

username-conversion  
Enables or disables conversion of PREWIN2k/UPN username input format to the format for SSO to use. The default value is disabled.

username-source  
Specifies the source from which you want SSO to retrieve the username to use to authenticate applications.

#### COPYRIGHT

## apm sso form-based

NAME  
form-based - Configures a single sign-on form-based configuration object.

MODULE  
apm sso

SYNTAX  
Configure the form-based component within the sso module using the syntax shown in the following sections.

CREATE/MODIFY  
create form-based [name]  
modify form-based [name]  
options:  
  apm-log-config [[string] | none]  
  app-service [[string] | none]  
  external-access-management [oam | none]  
  form-action [[URL] | none]  
  form-field [string]  
  form-method [get | post]  
  form-password [string]  
  form-username [string]  
  headers [add | delete | modify | | replace-all-with] {  
    [name] {  
  options:  
    app-service [[string] | none]  
    hname [[URL] | none]  
    hvalue [[integer] | none]  
  }  
  password-source [session.sso.token.last.password | none]  
  start-uri [[URLs] | none]  
  success-match-type [cookie | none | url]  
  success-match-value [string]  
  username-source [session.sso.token.last.username | none]  
edit form-based [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
DISPLAY  
list form-based  
list form-based [ [ [name] | [glob] | [regex] ] ... ]  
show running-config form-based  
show running-config form-based [ [ [name] | [glob] |  
  [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  one-line  
  partition  
show form-based  
show form-based [name]  
DELETE  
delete form-based [name]

DESCRIPTION  
You can use the form-based component to configure an SSO form-based configuration object.

EXAMPLES  
create form-based fb\_2011\_sso { start-uri  
  "/fb/auth/logon.aspxurl=https://exch2011.mvl.fp.com/fp/&reason=0"  
  form-action "/fp/auth/fpauth.dll" form-username "username" form-

```
password "password" form-field "destination"
https://exch2011.mvl.fp.com/fp/" }
```

Creates an SSO form-based configuration object named fb\_2011\_sso.

#### OPTIONS

##### apm-log-config

Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### external-access-management form-action

Specifies the form action URL that is used for HTTP form-based authentication. This is optional. If you do not specify a form action, then Access Policy Manager uses the URI from the request to perform HTTP form-based authentication. The default is none.

##### form-field

Specifies the hidden form parameters that are required by the authentication server logon form at your location. The default is none. Specify a parameter name, a space, and the parameter value, if any. Multiple parameters can be configured with each "name value" pair in one line. Use edit to add multiple parameters. Please note that create and modify do not allow using new line on the terminal.

##### form-method

Specifies the form method to use for form-based HTTP authentication. The value is either get or post. The default is post.

If you specify get, Access Policy Manager forces the authentication using HTTP GET rather than authenticating using form-based POST.

##### form-password

Specifies the parameter names used by the form that is sent the POST request.

##### form-username

Specifies the parameter names used by the form that is sent the POST request.

##### headers

Specifies the name and value of the HTTP header content to be inserted in an HTTP Request that passes through the APM SSO module. The default is none.

The options are:

##### app-service

Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

##### hname

Specifies the name of the HTTP header.

##### hvalue

Specifies the value of the HTTP header.

##### [name]

Specifies a name for the component.

##### password-source

Specifies the password you want cached for single sign-on.

The default is session.sso.token.last.password.

##### start-uri

Specifies a URL resource. For example, for FB, it would be /fb/auth/logon.aspx\*. For Citrix, /Citrix/XenApp/auth/logon.aspx. This resource must respond with a challenge to a non-authenticated request.

The default is none.

##### success-match-type

Specifies the method your authentication server uses. If you specify a value for this option, you must also specify a value for success-match-value. The default is none. The options are:

url One or more URLs. The system supports only the wildcard character (\*).

##### cookie

A cookie name.

##### success-match-value

Specifies the value used to specify either the URL(s) or cookie for the success-match-type option. The default is none.

##### username-source

Specify the username you want cached for single sign-on. The default is session.sso.token.last.username.

## apm sso form-basedv2

NAME

form-basedv2 - Configures a single sign-on form-basedv2 configuration object.

MODULE

apm sso

SYNTAX

Configure the form-basedv2 component within the sso module using the syntax shown in the following sections.

CREATE/MODIFY

```
create form-basedv2 [name]
options:
  app-service [[string] | none]
  forms [add | replace-all-with] {
    [name] {
      request-value [URIs]
      controls [add | replace-all-with] {
        [name] {
          value [string]
        }
      }
    }
  }

modify form-basedv2 [name]
options:
  apm-log-config [[string] | none]
  app-service [[string] | none]
  forms [add | delete | modify | replace-all-with] {
    [name] {
      options:
        app-service [[string] | none]
        attribute-value [[string] | none]
        controls [add | delete | modify | replace-all-with] {
          [name] {
            options:
              app-service [[string] | none]
              secure [true | false]
              value [string]
            }
          description [[string] | none]
          form-order [integer]
          id-type [action | id | inputs | name | order]
          request-method [get | post]
          request-name [[string] | none]
          request-negative [true | false]
          request-prefix [true | false]
          request-type [cookie | header | uri]
          request-value [[string] | none]
          submit-autodetect [true | false]
          submit-javascript [[string] | none]
          submit-javascript-type [auto | custom | extra]
          submit-method post
          submit-name [[string] | none]
          submit-negative [true | false]
          submit-prefix [true | false]
          submit-type [cookie | header | uri]
          submit-value [[string] | none]
          success-match-type [cookie | none | url]
          success-match-value [[string] | none]
        }
      }
    }
  headers [add | delete | modify | none | replace-all-with] {
    [name] {
      options:
        app-service [[string] | none]
        description [[string] | none]
        name [string]
```

```

    value [string]
  }

show form-basedv2
show form-basedv2 [name]

  DELETE
delete form-basedv2 [name]

```

#### DESCRIPTION

You can use the form-basedv2 component to configure an SSO form-basedv2 configuration object. When creating a new SSO form-based v2 configuration object, you must add at least one forms item and within it at least one controls item. You must also provide a value for the request-value option in the forms item.

The SSOv2 module identifies and processes two types of application HTTP requests - logon page requests and credentials submit requests. Logon page requests are identified using the request- set of options. Credentials submit requests, in most cases, are identified automatically. When this fails, you can set the submit-autodetect option to false and use the submit- set of options to identify these requests.

When the SSOv2 module identifies a logon page request, it scans the response trying to find the logon form. If the logon form is found, SSOv2 inserts a JavaScript code that will cause the logon form to be submitted automatically by the browser. The client must support JavaScript.

When the SSOv2 module identifies a credentials submit request, it compares POST data parameter names with form controls defined in the configuration. For a POST data parameter name that has a corresponding form control, the SSOv2 module replaces its value with the control value from the configuration. Control values are usually supplied through session variables, such as session.sso.token.last.username and session.sso.token.last.password. POST data parameters that have no corresponding controls in the configuration are not changed.

The majority of web applications have a single logon page with one logon form. You will need to define a single forms item for these applications. In rare cases when an application has multiple logon pages with different logon forms, you will need to create multiple forms items, one for each logon page/form. If multiple logon pages use the same form, you will need only one forms item with a list of URIs for all logon pages.

Every forms item must include at least one controls item, and can include up to 32 controls items. Each controls item represents an input element of an HTML logon form, such as form fields for entering username and password, and, optionally, any hidden form parameters. The name of the controls item must match the name attribute of the corresponding input tag of the form. For example, if the form has the following HTML tag for entering the username:

```
<input type="text" name="username" />
```

the forms item must include a controls item with the name Bugzilla login. The controls item used for entering the user's password must have the secure option set to true. The value of a control item should usually be the name of a session variable, starting with the percent (%) sign and enclosed in curly braces ({}); for example, the value for the username control item: %session.sso.token.last.username. The value can also be a string, or a combination of strings and session variable names.

#### EXAMPLES

```

create form-basedv2 fbssov2-owa2010 { forms add { owa2010 { controls
add { password { secure true value %session.sso.token.last.password\
} username { value %session.sso.token.last.username\ } } request-
value /owa/auth/logon.aspx?replaceCurrent=1 submit-javascript clkLgn()
submit-javascript-type extra success-match-type cookie success-match-
value sessionid } } }

```

Creates an SSO form-basedv2 configuration object named fbssov2-owa2010.

```
delete fbssov2-owa2010
```

Deletes an SSO form-basedv2 configuration object named fbssov2-owa2010.

#### OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### forms

Specifies one or more items, each defining SSO processing of a separate application logon form.

#### [name]

Specifies the name of the form item. It does not have to match the actual name of the HTML form and can be arbitrary.

The options are:

#### app-service

Specifies the name of the application service to which the form item belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the form item. Only the application service can modify or delete the form item.

#### attribute-value

Specifies the value of the HTML tag attribute used to identify the logon form. The attribute could be id, name, or action, and is specified by the id-type option. For other values of the id-type option, this is not used and should be set to none.

#### controls

Specifies one or more form control items (up to 32) that you want to be processed by SSOv2.

#### [name]

Specifies the name of the HTML form control item. It must match the name attribute value of the HTML form's input tag.

The options are:

#### app-service

Specifies the name of the application service to which the control item belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the control item. Only the application service can modify or delete the control item.

#### secure

Specifies whether the control item represents the HTML input tag of type "password". The default is false.

#### value

Specifies the value of the control item. This is usually the name of a session variable. If the session variable is not found when the SSO request is processed, the value of the corresponding POST parameter will be empty. The value could also be a literal string or a combination of strings and session variable names.

#### description

User-defined description.

#### form-order

Specifies the order of the HTML logon form on the logon page when the id-type option is set to order. Starts with 1.

#### id-type

Specifies how the HTML logon form is found in the HTML body of the logon page. If there is more than one form on the logon page matching the criteria, the first match is used. The default is inputs.

The options are:

#### action

The logon form is identified by the value of the tag in the action attribute. The value is specified in the attribute-value option.

id The logon form is identified by the id attribute's value of the tag. The value is specified in the attribute-value option.

name The logon form is identified by the name attribute's value of the tag. The value is specified in the attribute-value option.

#### order

The logon form is identified by its relative order on the logon page (starting from 1). The order is specified in the form-order option.

#### inputs

The logon form is identified by a combination of controls items. The controls in the configuration must have corresponding  elements in the form.

#### request-method

Specifies the HTTP method of the application's request returning logon page. Default is get.

#### request-name

Specifies the name of the HTTP cookie or the name of the HTTP header used to identify application's request for logon page. The cookie or header is selected by the request-type option. The value of the cookie or header is specified by the request-value option. When the request-type option is set to uri, this option is not used and should be set to none.

#### request-negative

When set to true, the application's request for logon page will be identified by the absence of the specified cookie or header, or by a failed match against the list of specified URIs. The default is false.

#### request-prefix

Specifies how the value of the request-value option will be used to match one of the HTTP request cookie, header, or URI. The default is true and specifies a partial match; false specifies an exact match.

#### request-type

Specifies which element of the HTTP request headers is used to identify the application's request for logon page. The default is uri.

The options are:

#### cookie

The request is identified by the presence (or absence) of a cookie. The name and value of the cookie are specified by the request-name and request-value options.

#### header

The request is identified by the presence (or absence) of the HTTP header. The name and value of the header are specified by the request-name and request-value options.

uri The request is identified by a successful (or failed) match against a list of URIs specified by the request-value option, and the request-name option is not used.

#### request-value

Specifies the value of the HTTP request element that must be matched to identify the request as the application's request for the logon page. This is one of: the cookie value, the header value, or a list of URIs (one per line) as specified by the request-type option. Cookie or header value could be set to none, in which case only the presence of the named cookie or header is checked and the value is not checked. When checking for URI, the value must be specified.

#### submit-autodetect

When set to true, the application's HTTP request that submits the user's credentials will be identified automatically and other submit- options should not be used. When false, the form submit will be identified using a combination of other submit- options. The default is true.

#### submit-javascript

Specifies user-provided JavaScript code to be inserted into the logon page to perform automatic form submission when the submit-javascript-type option is set to custom. The custom JavaScript code replaces the code automatically generated by the SS0v2 module. When the submit-javascript-type option is set to extra, it specifies the application's JavaScript functions to call from the automatically generated JavaScript code prior to submitting a logon form. When the submit-javascript-type option is set to auto, this option should be set to none.

#### submit-javascript-type

Specifies the type of JavaScript code to be inserted into the logon page by the SS0v2 module to perform automatic logon form submission.

The options are:

auto JavaScript code is automatically generated by the SS0v2 module.

#### custom

JavaScript code is provided by the user in the submit-javascript option.

#### extra

JavaScript code is automatically generated by the SS0v2 module, and additional JavaScript code provided by the user in the submit-javascript option is inserted before the form submit statement.

#### submit-method

Specifies the HTTP method of credentials submit request for the application. This must be set to post. This option is not used when submit-autodetect is true.

#### submit-name

Specifies the name of the HTTP cookie or the name of HTTP header used to identify credentials submit request for the application. The cookie or header is selected by the submit-type option. The value of the cookie or header is specified by the submit-value option. When the submit-type option is set to uri, this option is not used and should be set to none. This option is not used when submit-autodetect is true.

#### submit-negative

When set to true, the credentials submit request for the application is identified by the absence of a specified cookie or header, or by a failed match against the list of specified URIs. The default is false. This option is not used when submit-autodetect is true.

#### submit-prefix

Specifies how the value of the submit-value option will be used to match the HTTP request cookie, header, or URI. The default is true and specifies partial match; false specifies exact match. This option is not used when submit-autodetect is true.

#### submit-type

Specifies which element of HTTP request headers is used to identify the credentials submit request for the application. The default is uri. This option is not used when submit-autodetect is true.

The options are:

#### cookie

The request is identified by the presence (or absence) of a cookie. The name and value of the cookie are specified by the submit-name and submit-value options.

#### header

The request is identified by the presence (or absence) of the HTTP header. The name and value of the header are specified by the submit-name and submit-value options.

uri The request is identified by a successful (or failed) match against a list of URIs specified by the submit-value option and the submit-name option is not used.

#### submit-value

Specifies the value of the HTTP request element that must be matched to identify the request as a credentials submit request for the application. This is one of: the cookie value, the header value, or a list of URIs (one per line) as specified by the submit-type option. Cookie or header value could be set to none, in which case only the presence of the named cookie or header is checked and the value is not checked. When checking for URI, the value must be specified. This option is not used when submit-autodetect is true.

#### success-match-type

Specifies how the SSOv2 module detects whether the credentials submit request was successful. When the SSOv2 module detects that the credentials submission failed, the SSOv2 configuration used for this HTTP transaction is disabled for the user session. If you specify a value for this option, you must also specify a value for success-match-value. The default is none. The options are:

url Credentials submission was successful if the response contains the HTTP Location header with a value matching one of the URLs specified by the success-match-value option.

#### cookie

Credentials submission was successful if the response contains the HTTP cookie with the name specified by the success-match-value option.

none No check is performed. If SSO logon fails and the application server redirects back to the logon page that matches the criteria of the logon page request, SSO will be retried, possibly causing authentication loop.

#### success-match-value

Specifies the value used to detect the success or failure of the SSO logon. When the success-match-type option is set to url, this is a list of URLs. Each URL in the list can contain a single wildcard character (\*). When the success-match-type option is set to cookie, this option specifies the name of the cookie. The default is none.

#### headers

Specifies the name and value of the HTTP header to be inserted in an HTTP Request that passes through the APM SSOv2 module.

#### [name]

Specifies the name of the headers item.

The options are:

#### app-service

Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

name Specifies the name of the HTTP header.

#### value

Specifies the value of the HTTP header.

#### apm-log-config

Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

#### log-level

log-level is deprecated. Instead use apm-log-config to customize

log-setting.

show kerberos [name]

DELETE

delete kerberos [name]

DESCRIPTION

You can use the kerberos component to configure an SSO Kerberos configuration object. Kerberos is an authentication protocol, where both the user and the server verify the other's identity.

EXAMPLES

create mykerberos { realm MYREALM.COM account-name apmacount account-  
password \*\*\*\* }

Creates an SSO kerberos configuration object named mykerberos for the realm myrealm.com, where the account name is apmacount and the password is \*\*\*\*.

OPTIONS

account-name

Specifies the name of the Active Directory account configured for delegation. This account must be configured in the server's Kerberos realm (AD Domain). If servers are from multiple realms, each realm (AD Domain) must have its own delegation account. This option is required.

**account-password**

Specifies the password for the delegation account specified in account-name. This option is required.

**apm-log-config**

Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**headers**

Specifies custom HTTP headers to insert into a request. The default value is none. The options are:

**app-service**

Specifies the name of the application service to which the header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the header. Only the application service can modify or delete the header.

**hname**

Specifies the name of a header to add to a request.

**hvalue**

Specifies the value of a header to add to a request.

**kdc** Specifies the IP Address or host name of the Kerberos Key Distribution Center (KDC) for the server's realm. This is normally an Active Directory domain controller. If you leave this empty, the KDC must be discoverable through DNS, for example, BIG-IP system must be able to fetch SRV records for the server realm's domain. If the server realm's domain name is different from the server's realm name, you must specify the server realm's domain name in the /etc/krb5.conf file. Kerberos SSO processing is fastest when KDC is specified by its IP address, slower when specified by host name, and even slower (due to additional DNS queries) when left empty. When a user's realm is different from server's realm, the KDC value must be empty. This is true in cases of cross-realm SSO. The default is none.

**location-specific**

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**[name]**

Specifies the name for the SSO Kerberos configuration object. This option is required.

**realm**

Specifies the realm of application server(s), for example, pool members or portal access resource hosts. If the servers are located in multiple realms, each realm requires a separate SSO configuration. You must specify the realm in uppercase letters. The user's realm can be specified through the session.logon.last.domain session variable, and if this variable is not set, then the user's realm is assumed to be the same as the server's realm. This option is required.

**send-authorization**

Specifies when to submit a Kerberos ticket to the application server(s). The ticket is submitted in an HTTP Authorization header. The header value starts with the word Negotiate, followed by one space and a base64-encoded GSSAPI token containing the Kerberos ticket. If a request contains an Authorization header from the user's browser, it is deleted. The default is always. The options are:

401 The BIG-IP system first forwards the user's HTTP request to the web server without inserting a new Authorization header; however, the browser's Authorization header is deleted. If the server requests authentication by responding with a 401 status code, BIG-IP retries the request with the Authorization header. The Kerberos ticket GSSAPI representation uses the SPNEGO mechanism type (OID 1.3.6.1.5.5.2).

Specifying 401 results in additional BIG-IP/server request round trips in case authentication is required for the request.

**always**

The BIG-IP system inserts an Authorization header, including the Kerberos ticket, into every HTTP request, whether the request requires authentication or not. The Kerberos ticket GSSAPI representation uses the KRB5 Kerberos 5 mechanism type (OID 1.2.840.113554.1.2.2).

Specifying Always results in the additional overhead of generating a Kerberos token for every request. This is the default value.

#### spn-pattern

Specifies how the Service Principal Name (SPN) for the server is constructed. For example, HTTP/%s@[server realm name configured in the realm option], where %s will be substituted with the hostname of your server discovered through reverse DNS lookup using the server IP address. Only specify this option when you need non-standard SPN format. The default is none.

#### ticket-lifetime

Specifies the lifetime of Kerberos tickets obtained for the user. The value represents the maximum ticket lifetime. The actual ticket lifetime may be less by up to 1 hour, because a user's ticket lifetime is the same as the Kerberos Ticket Granting Ticket (TGT) lifetime. A TGT is obtained for the delegation account specified in this configuration. A new TGT is fetched every time the current TGT is older than one hour. The new TGT can only be fetched when an SSO request is processed.

The minimum ticket lifetime is 10 minutes. There is no maximum, however, the ticket lifetime of most AD domains is 10 hours (600 minutes). F5 Networks recommends that you set the ticket lifetime in an SSO configuration above what is specified in an AD domain. The default is 600 minutes.

#### upn-support

Enables or disables UPN suffix support for Kerberos SSO when integrating into Microsoft Active Directory infrastructure. The default is disabled.

#### user-realm-source

Session variable name from which Kerberos SSO should read the user's realm. The default is session.logon.last.domain.

#### username-source

Session variable name from which Kerberos SSO should read the username. The default is session.sso.token.last.username.

## apm sso ntlmv1

#### NAME

ntlmv1 - Configures a single sign-on (SSO) NT LAN Manager, version 1 (ntlmv1) configuration object.

#### MODULE

apm sso

#### SYNTAX

Configure the ntlmv1 component within the sso module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create ntlmv1 [name]
modify ntlmv1 [name]
options:
  apm-log-config [[string] | none]
  app-service [[string] | none]
  domain-source [session.logon.last.domain | none]
  headers [add | delete | modify | replace-all-with] {
    [name] {
      options:
        app-service [[string] | none]
        hname [[string] | none]
        hvalue [[integer] | none]
      }
  }
  location-specific [true | false]
  ntlm-domain [[string] | none]
  password-source [session.sso.token.last.password | none]
  username-conversion [enabled | disabled]
  username-source [session.sso.token.last.username | none]

edit ntlmv1 [ [ [name] | [glob] | [regex] ] ... ]
```

options:  
all-properties  
non-default-properties

DISPLAY

one-line  
partition  
  
show ntlmv1  
show ntlmv1 [name]

DELETE  
delete ntlmv1 [name]

DESCRIPTION  
You can use this ntlmv1 component to configure a single sign-on NT LAN Manager, version 1 configuration object.

EXAMPLES  
create ntlmv1 myntlmv1  
Creates an SSO ntlmv1 configuration object named myntlmv1.

OPTIONS  
apm-log-config  
Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.  
  
app-service  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.  
  
domain-source  
Specifies the Session variable used as a source for the single sign-on user domain. The default is session.logon.last.domain.  
  
headers  
Specifies the name and value of the HTTP header content to be inserted in an HTTP Request that passes through the APM SSO module. The default is none.

The options are:

app-service  
Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

hname  
Specifies the name of the HTTP header.

hvalue  
Specifies the value of the HTTP header.

location-specific  
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

[name]  
Specifies the name for the SSO ntlmv1 configuration object. This option is required.

ntlm-domain  
Specifies the static domain setting. If the domain is not retrieved successfully from the source specified in the domain-source option, the system uses this value for the source.

password source  
Specifies the source from which you want SSO to retrieve the password to use to authenticate applications. The default is session.sso.token.last.password.

username-conversion  
Enables or disables conversion of PREWIN2k/UPN username input format to the format you want to use for SSO. The default is disabled.

username-source  
Specifies the source from which you want SSO to retrieve the username used to authenticate applications.

## apm sso ntlmv2

### NAME

ntlmv2 - Configures a single sign-on (SSO) NT LAN Manager, version 2 (ntlmv2) configuration object.

### MODULE

apm sso

### SYNTAX

Configure the ntlmv2 component within the sso module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create ntlmv2 [name]
modify ntlmv2 [name]
options:
  apm-log-config [[string] | none]
  app-service [[string] | none]
  domain-source [session.logon.last.domain | none]
  headers [add | delete | modify | replace-all-with] {
    [name] {
      options:
        app-service [[string] | none]
        hname [[string] | none]
        hvalue [[integer] | none]
      }
    }
  location-specific [true | false]
  ntlm-domain [[string] | none]
  password-source [session.sso.token.last.password | none]
  username-conversion [enabled | disabled]
  username-source [session.sso.token.last.username | none]
```

```
edit ntlmv2 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

#### DISPLAY

```
list ntlmv2
list ntlmv2 [ [ [name] | [glob] | [regex] ] ... ]
show running-config ntlmv2
show running-config ntlmv2 [ [ [name] | [glob] |
  [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show ntlmv2
show ntlmv2 [name]
```

#### DELETE

```
delete ntlmv2 [name]
```

### DESCRIPTION

You can use the ntlmv2 component to configure a single sign-on NT LAN Manager, version 2 configuration object.

### EXAMPLES

```
create ntlmv2 myntlmv2
Creates an SSO ntlmv2 configuration object named myntlmv2.
```

### OPTIONS

**apm-log-config**  
Specifies log-setting object to associate with this sso. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**domain-source**  
Specifies the Session variable used as a source for the single sign-on user domain. The default is session.logon.last.domain.

#### headers

Specifies the name and value of the HTTP header content to be inserted in an HTTP Request that passes through the APM SSO module. The default is none.

The options are:

#### app-service

Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

#### hname

Specifies the name of the HTTP header.

#### hvalue

Specifies the value of the HTTP header.

#### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

#### [name]

Specifies a name for the sso ntlmv2 configuration object. This option is required.

#### ntlm-domain

Specifies the static domain setting. If the domain is not retrieved successfully from the source specified in the domain-source option, the system uses this value for the source.

#### password source

Specifies the source from which you want SSO to retrieve the password to use to authenticate applications. The default is session.sso.token.last.password.

#### username-conversion

Enables or disables conversion of PREWIN2k/UPN username input format to the format you want to use for SSO. The default is disabled.

#### username-source

Specifies the source from which you want SSO to retrieve the username used to authenticate applications.

SEE ALSO

## apm sso oauth-bearer

#### NAME

oauth-bearer - Configures a single sign-on (SSO) oauth-bearer configuration object.

#### MODULE

apm sso

#### SYNTAX

Configure the oauth-bearer component within the sso module using the syntax shown in the following sections.

#### CREATE/MODIFY

create oauth-bearer [name]

modify oauth-bearer [name]

#### options:

```
app-service [[string] | none]
headers [add | delete | modify | replace-all-with] {
location-specific [true | false]
[name] {
options:
app-service [[string] | none]
```

```

    hname [[URL] | none]
    hvalue [[integer] | none]
  }
}
location-specific [true | false]
  oauth-server [string]

edit oauth-bearer [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

DISPLAY
list oauth-bearer
list oauth-bearer [ [ [name] | [glob] | [regex] ] ... ]
show running-config oauth-bearer
show running-config oauth-bearer [ [ [name] | [glob] |
  [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition

show oauth-bearer
show oauth-bearer [name]

DELETE
delete oauth-bearer [name]

DESCRIPTION
  You can use the oauth-bearer component to create, modify, display, or
  delete an SSO oauth-bearer configuration object.

```

#### EXAMPLES

```
create oauth-bearer myoauth-bearer
```

Creates an SSO oauth-bearer configuration object named myoauth-bearer.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

##### headers

Specifies the name and value of the HTTP header content to be inserted into an HTTP Request that passes through the APM SSO module. The default is none. The options are:

##### app-service

Specifies the name of the application service to which the HTTP header belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the HTTP header. Only the application service can modify or delete the HTTP header.

##### hname

The name of the HTTP header.

##### hvalue

The value of the HTTP header.

##### location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

##### [name]

Specifies a name for the SSO oauth-bearer configuration object. This option is required.

##### partition

Displays the partition in which the object resides.

##### oauth-server

Specifies the name of your OAuth Server. This option is required.

#### SEE ALSO

```
basic, form-based,kerberos, ntlmv1, ntlmv2
```

## apm sso saml-resource

**NAME**

saml-resource - Configures saml resource.

**MODULE**

apm sso

**SYNTAX**

Configure a saml-resource using the syntax shown in the following sections.

**CREATE/MODIFY**

```
create saml-resource [name]
modify saml-resource [name]
options:
  app-service [[string] | none]
  customization-group [[string] | none]
  description [[string] | none]
  location-specific {true | false}
  publish-on-webtop {true | false}
  sso-config-saml [[string] | none]
```

**edit saml-resource [ [ [name] | [glob] | [regex] ] ... ]**

**options:**

- all-properties
- non-default-properties

**DISPLAY**

```
list saml-resource
list saml-resource [ [ [name] | [glob] | [regex] ] ... ]
show running-config saml-resource
show running-config saml-resource [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

**DELETE**

```
delete saml-resource [name]
```

**DESCRIPTION**

You can use saml-resource component to configure saml resource.

**EXAMPLES**

```
create saml-resource my_saml_resource { sso-config-saml my_saml_sso_obj
publish-on-webtop true }
Creates a saml resource named my_saml_resource with saml sso
object 'my_saml_sso_obj' and with option to display this resource
on full webtop.

delete saml-resource my_saml_resource
Deletes the saml resource named my_saml_resource.
```

**OPTIONS**

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**customization-group**

Specifies the customization group associated with saml resource.

**description**

Specifies a description for the saml resource. The default is none.

**location-specific**

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location.

**publish-on-webtop**

Specifies whether to display the SAML resource on the full webtop or not. Default value is true.

**sso-config-saml**

Specifies saml sso config object associated with this saml resource. This saml sso object should only have one saml sp connector associated with it.

**COPYRIGHT**

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## apm sso saml-sp-automation

### NAME

saml-sp-automation - Specify SAML SP connector automation configuration used to automate creation and management of 'SP Connectors' from the remotely published metadata file(s).

### MODULE

apm sso

### SYNTAX

Configure the saml-sp-automation component within the sso module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create saml-sp-automation [name]
modify saml-sp-automation [name]
options:
  app-service [[string] | none]
  description [[string] | none]
  dns-resolver-name [string]
  frequency [integer]
  metadata-urls [add | delete | modify | none | replace-all-with] {
    name [string] {
      url-value [string]
    }
  }
  serverssl-profile-name [[string] | none]
  sp-obj-name-tag [string]
  sso-config-saml [string]
```

```
edit saml-sp-automation [ [ [name] | [glob] | [regex] ] ... ]
```

#### options:

all-properties  
non-default-properties

#### DISPLAY

```
list saml-sp-automation
list saml-sp-automation [ [ [name] | [glob] | [regex] ] ... ]
show running-config saml-sp-automation
show running-config saml-sp-automation [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

#### DELETE

```
delete saml-sp-automation [name]
```

### DESCRIPTION

You can use saml-sp-automation to create and manage SAML SP automation objects that are used to create, modify, and delete 'SP Connectors' from the remotely published metadata files.

### EXAMPLES

```
create saml-sp-automation my_sp_automation { metadata-urls add { f5 {
url-value https://f5.com/metadata.xml } } dns-resolver-name . sso-
config-saml my_saml_idp serverssl-profile-name serverssl } Creates SAML
SP automation object named my_sp_automation bound to a SAML IdP service
my_saml_idp with frequency set to 60 minutes with one entry for
metadata-url as https://f5.com/metadata.xml, dns-resolver-name as . and
serverssl-profile-name as serverssl.
list saml-sp-automation
Displays a list of SAML SP automation objects.
```

```
delete saml-sp-automation my_sp_automation
Deletes the my_sp_automation SAML SP automation object.
```

### OPTIONS

#### app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

#### description

Specifies the description for the IdP automation object.

#### dns-resolver-name

Specifies the DNS resolver object to be used for connecting to servers hosting metadata file(s).

#### frequency

The frequency in minutes at which APM polls the SP metadata files and updates the SP connectors and bindings to the specified SSO

SAML server. The default value is 60.

**metadata-urls**  
Specifies a list of one or more URLs containing the metadata files.

**serverssl-profile-name**  
Specifies the SSL profile to be used by the BIG-IP system when connecting to the server hosting metadata file(s).

**sp-obj-name-tag**  
Specifies the name of a tag within the metadata file that contains a value that APM includes in the names of the created SP connectors. If no value is specified, entityID from metadata is used as part of created SP connector name.

**sso-config-saml**  
Specifies the SSO SAML server to which the SP connectors created by this automation are bound.

## apm sso saml-sp-connector

#### NAME

saml-sp-connector - Specify saml sp connector configuration.

#### MODULE

apm sso

#### SYNTAX

Configure a saml-sp-connector within the sso module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create saml-sp-connector [name]
modify saml-sp-connector [name]
options:
  app-service [[string] | none]
  assertion-consumer-services [ {
    binding [http-artifact | http-post | paos]
    index [0 - 65535]
    is-default [true | false]
    uri [string]
  } ]
  description [[string] | none]
  encryption-type [aes128 | aes192 | aes256]
  entity-id [string]
  import-metadata [ string | none ]
  is-authn-request-signed [ true | false ]
  location-specific [ true | false ]
  metadata-cert [[string] | none]
  multi-domain-location [[string] | none ]
  relay-state [[string] | none]
  signature-type [rsa-sha1 | rsa-sha256 | rsa-sha384 | rsa-sha512]
  single-logout-binding
  single-logout-response-uri [string]
  single-logout-uri [string]
  sp-certificate [[string] | none]
  sp-location [external | internal | internal-multi-domain ]
  sp-name-qualifier [[string] | none]
  want-assertion-encrypted [ true | false ]
  want-assertion-signed [ true | false ]
  want-response-signed [ true | false ]

edit saml-sp-connector [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list saml-sp-connector
list saml-sp-connector [ [ [name] | [glob] | [regex] ] ... ]
show running-config saml-sp-connector
show running-config saml-sp-connector [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
one-line
```

partition

DELETE

delete saml-sp-connector [name]

#### DESCRIPTION

You can use the saml-sp-connector component to create and manage saml sp connectors

#### EXAMPLES

```
create saml-sp-connector my_saml_sp_connector { entity-id
"https://companyx.sp.com/sp" assertion-consumer-services { { uri
"https://companyx.sp.com/acs/" is-default true } } want-assertion-
signed true want-response-signed true want-assertion-encrypted true
encryption-type aes256 is-authn-request-signed false sp-certificate
default.crt }
```

Creates a SAML sp-connector named my\_saml\_sp\_connector with security options to encrypt and sign the assertion as well as SAML response.

```
create saml-sp-connector my_saml_sp_connector1 { import-metadata
/shared/tmp/sp_metadata.xml}
```

Creates a SAML sp-connector named my\_saml\_sp\_connector1 from metadata file "/shared/tmp/sp\_metadata.xml"

```
create saml-sp-connector my_internal_sp_connector { entity-id
"https://internal.sp.com" assertion-consumer-services { { uri
"https://internal.sp.com/acs" is-default true } } sp-certificate
default.crt sp-location internal }
```

Creates a SAML sp-connector named my\_internal\_sp\_connector which is load balanced by the same virtual server as this BIG-IP as IdP [identity provider].

```
list saml-sp-connector
```

Displays a list of SAML sp connectors.

```
delete saml-sp-connector my_saml_sp_connector
```

Deletes the my\_saml\_sp\_connector SAML sp connector.

#### OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

assertion-consumer-services

List of assertion consumer services (ACS) used by external SP. Each ACS entry contains attributes 'binding', 'index', 'is-default', and 'url'. Each ACS must contain a valid URL, and a unique 'index'. One ACS entry must be set as default.

assertion-consumer-binding

This attribute is DEPRECATED. Use assertion-consumer-services instead.

assertion-consumer-uri

This attribute is DEPRECATED. Use assertion-consumer-services instead.

description

Specifies a unique description for saml sp connector. The default is none.

encryption-type

Specifies the type of encryption BIG-IP as IdP should use to encrypt the assertion. Default is aes128.

entity-id

Specifies a unique ID to identify SP pointed by sp connector.

import-metadata

Specifies the metadata file to be used to create sp connector object. For example: create saml-sp-connector my\_saml\_sp\_connector1 { import-metadata /shared/tmp/sp\_metadata.xml}

is-authn-request-signed

Specifies whether SP signs authentication requests while sending them to BIG-IP as IdP. The default value for this is false.

location-specific

Objects of this class might have location specific attribute(s). Admin can indicate if object is location specific by setting it to true.

metadata-cert

Specifies the certificate to be used to verify the signature of metadata imported from a file.

multi-domain-location

Specifies the scheme, hostname, and (optionally) port of the virtual server on this BIG-IP behind which this SP is located, e.g. "https://application.f5.com". This configuration is required only when sp-location attribute is configured as 'internal-multi-domain'

relay-state

Specifies the value sent to the SP by BIG-IP as IdP as part of the response. This value is only used if the SP did not send RelayState as part of the authentication request.

signature-type

Signature algorithms to be used for digital signing of SAML messages. Default value is rsa-shal.

single-logout-binding  
This attribute is reserved for future functionality.

single-logout-response-uri  
A URI where this BIG-IP as IdP will send single logout (SLO) responses.

single-logout-uri  
A URI where this BIG-IP as IdP will send single logout (SLO) requests.

sp-certificate  
Specifies SP certificate used by BIG-IP as IdP to verify the signature of authentication request.

sp-location  
Specifies the location of SP from network topology viewpoint. Default value external should be used with SAML WebSSO profile. This value indicates that SP is located externally from BIG-IP perspective, and therefore SP is reachable directly by the user-agent. internal - indicates that configured SP is located behind the virtual server that hosts BIG-IP IdP, and therefore SP is not reachable directly by the client. internal-multi-domain - indicates that BIG-IP is configured for multi-domain SSO, and therefore SP is located behind different virtual server of this BIG-IP.

sp-name-qualifier  
Optionally qualifies an identifier with the name of a service provider or affiliation of providers.

want-assertion-encrypted  
Specifies whether SP requires encrypted assertions. The default value for this attribute is false

want-assertion-signed  
Specifies whether SP requires signed assertions. The default value for this attribute is true

want-response-signed  
Specifies whether SP requires signed SAML responses. The default value for this attribute is false

DELETE
delete saml [name]

DESCRIPTION
  You can use the saml component to create and manage SAML SSO objects.

EXAMPLES
  create saml my_saml_sso_obj { entity-id
    "https://myidpvs.big-ip.com/idp" subject-type email-address subject-
    value test@mycompany.com idp-certificate default.crt idp-signkey
    default.key sp-connectors add { google_apps salesforce }}
  Creates a SAML SSO object named my_saml_sso_obj with SP connectors
  "google_apps" and "salesforce"

  create saml my_saml_sso_obj1 { entity-id
    "https://myidpvs.big-ip.com/idp" subject-type email-address subject-
    value test@mycompany.com idp-certificate default.crt idp-signkey
    default.key sp-connectors add { google_apps sp_salesforce } attributes
    {{name "group" multi-values { "PD" "Admin" }} {name "title" multi-
    values { "engineer1" }}} }
  Creates a SAML SSO object named my_saml_sso_obj1 with attributes
  "group" and "title".

  list saml
  Displays list of SAML SSO objects.

  delete saml my_saml_sso_obj
  Deletes the my_saml_sso_obj SAML SSO object.

```

#### OPTIONS

**apm-log-config**  
Specifies log-setting object to associate with this saml. If this value is empty, logging framework uses log-setting configuration associated with the access profile where sso is used.

**app-service**  
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

**assertion-validity**  
Specifies assertion validity period in seconds.

**artifact-resolution-service-name**  
Specifies the artifact resolution service to be used by this BIG-IP as IdP to receive artifacts and resolve them for assertions.

**attributes**  
Specifies list of attributes as part of assertion. Both attribute name and values can be session variables. Property 'value' is DEPRECATED; "multi-values" must be used instead. "name-format" can be used to optionally specify format of the attribute name.

```

create saml my_saml_sso_obj1 { entity-id
  "https://myidpvs.big-ip.com/idp" subject-type email-address
  subject-value test@mycompany.com idp-certificate default.crt idp-
  signkey default.key sp-connectors add { google_apps sp_salesforce
  } attributes {{name "group" multi-values {

```

```
"${session.ldap.last.attr.primarygroup}"}" } {name "name" multi-
values { "firstName" "lastName" } name-format basic}} }
```

Creates a SAML SSO object named `my_saml_sso_obj1` with attributes "group" and "name".

#### auth-context-method

Specifies an authentication context method used by this BIG-IP as IdP when creating assertions. This attribute can be a session variable.

#### description

Specifies a unique description for SAML SSO object. The default is none.

#### encrypt-subject

Set to true if assertion 'Subject' must be encrypted. Default value is false.

#### encryption-type-subject

Encryption algorithm used to encrypt 'Subject' element in assertion. Default value is aes128.

#### entity-id

Specifies unique identifier for BIG-IP as IdP. Typically, 'entity-id' is a URI that points to the BIG-IP virtual server that is going to act as a SAML IdP. In case 'entity-id' is not a valid URL, the `idp-host` attribute is required. Examples of valid configuration include "https://mycompany-idp", "idp:my:company", and "idp.my.company.com"

#### export-metadata

You can simplify SAML configuration using metadata files. When you use APM as an IdP, you can export metadata for IdP. You can save metadata to a file and give it to the SP to enable SP to import SP's SAML configuration or enable SP to use information from the metadata file to configure the IdP. You can choose to sign metadata while exporting it for better security.

For example:

1. Exporting metadata with signing. This requires `metadata-signkey` and `metadata-cert` files.

```
modify saml my_saml_sso_obj {export-metadata with-signing metadata-file /shared/idp_signed_metadata.xml metadata-
```

2. Exporting metadata with no signing.

```
modify saml my_saml_sso_obj {export-metadata no-signing metadata-file /shared/idp_metadata.xml}
```

#### idp-certificate

BIG-IP includes this certificate in the SAML IdP metadata that you export. After the SAML IdP metadata is imported on the SP, the SP can use this certificate to verify the signature of assertion sent by this BIG-IP as IdP.

#### idp-certificate-session-var

Specifies the certificate this BIG-IP as IdP will use to sign SAML messages including SAML assertion. This attribute must be specified in session variable format. This attribute is mutually exclusive with .

#### idp-host

Hostname of this BIG-IP as IdP. This attribute is required when "entity-id" is not a valid URL.

#### idp-scheme

Scheme used by this BIG-IP as IdP. This attribute is only used when `idp-host` is not empty. Default value is https.

#### idp-signkey

Specifies the private key used for signing assertion by BIG-IP as IdP.

#### idp-signkey-session-var

Specifies the signing key this BIG-IP as IdP will use to sign SAML messages including SAML assertion. This attribute must be specified in session variable format. This attribute is mutually exclusive with .

#### key-transport-algorithm

Specifies the key transport algorithm to be used for encrypted attributes, subject-value, or assertion. Default and recommended value is `rsa-oaep`. `rsa-v1.5` is NOT RECOMMENDED due to security risks associated with the algorithm, and should NOT be used except for compatibility with older applications.

#### location-specific

Objects of this class might have location specific attribute(s). Admin can indicate if object is location specific by setting it to true.

#### log-level

`log-level` is deprecated. Instead use `apm-log-config` to customize log-setting.

#### metadata-cert

Specifies the certificate with public key of the key pair used in signing the metadata. See `export-metadata` for more information on metadata export functionality. This is the certificate to include in signed metadata when we export metadata. This might or might not be IdP certificate.

#### metadata-file

Specifies the file to which metadata is saved. See export-metadata for more information on metadata export functionality.

metadata-signkey

This specifies the key that is used to sign IdP's metadata. See export-metadata for more information on metadata export functionality.

name-qualifier

Specifies the security or administrative domain of the IdP (this BIG-IP system). This value usually matches IdP Entity ID.

saml-profiles

List of SAML profiles enabled on this BIG-IP as IdP. Default value is web-browser-sso.

sp-connectors

Specifies list of SP connectors associated with this SAML SSO object. When this SSO object is assigned to SAML resource then only one entry is allowed for SP connectors. If SAML SSO object is assigned to access profile then you can add multiple SAML SP connectors.

subject-type

Specifies type of the subject to be used while creating SAML assertion.

subject-value

Specifies the value of the subject to be included inside SAML assertion. This can be a session variable. For example:  
#{session.last.logonname}, #{session.ad.last.attr.userEmail}

## apm swg-content-type

NAME

swg-content-type - Containers for the SWG content types

MODULE

apm

SYNTAX

List the swg-content-type objects. Creating, modifying, or deleting is not allowed.

Here are the valid values: All-Compressed, All-Executable, All-Images, Application-flash, Text-html, Text-pdf

DISPLAY

```
list swg-content-type
list swg-content-type [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DESCRIPTION

Indicates the MIME type of the response content. Used in SWG Response Analytics.

EXAMPLES

list apm swg-content-type

Lists all swg-content-type objects.

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## apm swg-scheme

**NAME**  
swg-scheme - Configures SWG Scheme

**MODULE**  
apm

**SYNTAX**  
Configure a swg-scheme component within the apm module using the syntax shown in the following sections.

**CREATE/MODIFY**  
Each swg-scheme consists of the following.

```
create swg-scheme [name]
  options:
    app-service [[string] | none]
    description [[string] | none]

modify swg-scheme [name]
  options:
    app-service [[string] | none]
    description [[string] | none]

DISPLAY
list swg-scheme
list swg-scheme [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition
```

**DESCRIPTION**  
Configures an swg-scheme object

**EXAMPLES**  
create apm swg-scheme scheme1 { app-service none description "My SWG Scheme" }  
Creates a new swg-scheme.  
modify swg-scheme scheme1 { description "My SWG Scheme" }  
Modify a swg-scheme by modifying its description string.

**OPTIONS**  
app-service  
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object.  
description  
Specifies a user-defined description for the swg scheme.

**SEE ALSO**  
apm url-filter

**COPYRIGHT**

## apm url-filter

**NAME**  
url-filter - Configures URL filters for URL classification and filtering

**MODULE**  
apm

## SYNTAX

Configure a url-filter component within the apm module using the syntax shown in the following sections.

### CREATE/MODIFY

Each url-filter consists of two url-category lists: a list of allowed URL categories and a list of blocked URL categories. The requests for URLs contained in the allowed list are allowed to pass unfettered, whereas requests for URLs in the blocked list will not go out into the Internet.

```
create url-filter [name]
options:
  allowed-categories [add | delete | modify | replace-all-with] {
    [string]
  }
  blocked-categories [add | delete | modify | replace-all-with] {
    [string]
  }
```

```
modify url-filter [name]
  allowed-categories [add | delete | modify | replace-all-with] {
    [string]
  }
  blocked-categories [add | delete | modify | replace-all-with] {
    [string]
  }
```

### DISPLAY

```
list url-filter
list url-filter [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

### CP

```
cp url-filter [source-name] [target-name]
```

## DESCRIPTION

Configures a url-filter

NOTE: A url-filter can have a large number of URL categories in each list. To facilitate the creation of url-filter, you can create a new url-filter by copying from an existing url-filter. Then modify each list by adding or removing url-categories to suit your needs.

## EXAMPLES

```
create url-filter my-url-filter allowed-categories add {
  Business_and_Economy Education } blocked-categories add { Adult_Content
  Shopping }
```

Creates a new url-filter.

```
modify url-filter my-own-filter allowed-categories delete { Education }
```

Modify a url-filter by deleting a URL category from the allowed list.

```
cp url-filter existing-filter another-filter
```

Create a new url-filter by copying from an existing filter.

## OPTIONS

**allowed-categories**  
Specifies the URL categories that should be allowed to pass.

**description**  
Specifies a unique description for the URL filter.

**blocked-categories**  
Specifies the URL categories that should be blocked.

## SEE ALSO

sys url-db download-result sys url-db download-schedule and sys url-db url-category

## COPYRIGHT

## asm device-sync

**NAME**  
device-sync - Contains the ASM timestamp for each device in the group.

**MODULE**  
asm

**SYNTAX**  
Retrieve the list of the device-sync values using the syntax shown in the following section.

**DISPLAY**  
list device-sync  
list device-sync [ [ [name] | [glob] | [regex] ] ... ]

**DESCRIPTION**  
Use this command to display the current values of the device-sync object, i.e. ASM change times for all devices in the group. This object is designed for internal purposes only (incremented on every ASM change), so do not try to create, modify, or delete it manually.

**EXAMPLES**  
list device-sync  
  
Displays all last ASM change times of the device group.

**SEE ALSO**  
tmsh, list, glob, regex

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

**BIG-IP**            2012-03-02            asm device-sync(1)

---

## asm http-method

**NAME**  
http-method - Lists the available HTTP request methods that can be used in the context of the Application Security Manager(TM).

**MODULE**  
asm

**SYNTAX**  
Retrieve the list of the http-method values using the syntax shown in the following sections.

**DISPLAY**  
list http-method  
list http-method [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all  
app-service  
default-act-as  
one-line  
partition  
recursive

**DESCRIPTION**  
Use this command to display the possible values of the http-method object to be used in the context of the Application Security Manager. These possible values include predefined and user-defined allowed methods for all security policies, and also are intended to be used in filters of Application Security Logging and in HTTP security profiles.

**EXAMPLES**  
list http-method  
  
Displays all the HTTP methods supported by the ASM.

**OPTIONS**  
app-service  
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.  
  
default-act-as  
Displays the HTTP request method, either GET or POST, based on how

you have instructed the system to treat the listed method name; a predefined method has its system default and a user-defined allowed method is configured in the security policy.

**partition**  
Displays the administrative partition within which the component resides.

SEE ALSO

glob, list, regex, security http profile, security log profile, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## asm httpclass-asm

NAME

httpclass-asm - configure initial ASM settings for applications. This component has been deprecated as of BIG-IP v11.3.0, please use the policy component in the asm module instead.

MODULE

asm

SYNTAX

Configure the httpclass-asm component within the asm module using the syntax shown in the following sections.

CREATE/MODIFY

```
create httpclass-asm [name]
modify httpclass-asm [name]
options:
  active-policy-name [string]
  app-service [[string] | none]
  language [language]
  predefined-policy [predefined-policy]
```

DISPLAY

```
list httpclass-asm
list httpclass-asm [ [ [name] | [glob] | [regex] ] ... ]
show running-config httpclass-asm
show running-config httpclass-asm [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition
```

DELETE

```
delete httpclass-asm [name]
```

DESCRIPTION

Use this command to create, modify, display, or delete an httpclass-asm profile that configures ASM security policies. Changing/setting attributes for an httpclass-asm profile affects the ASM security policy with the same name. Note that modifying the language of an existing profile reconfigures the ASM security policy and deletes the configurations, log entries and statistics of the security policy. This is for advanced usage - this command is intended to be used by the application templates system (iApps(tm)).

EXAMPLES

```
create asm httpclass-asm my_class active-policy-name my_class_policy
language utf-8 predefined-policy POLICY_TEMPLATE_RAPID_DEPLOYMENT_HTTP
```

Creates a custom httpclass-asm profile named my\_class that causes ASM to configure a security policy that uses the utf-8 application language and the Rapid Deployment security policy.

```
list httpclass-asm
```

Displays the properties of all httpclass-asm profiles.

OPTIONS

**active-policy-name**

Specifies the name of the active security policy. This property has been deprecated. As of BIG-IP v11.1.0, the active security policy name is identical to the HTTP class profile's name.

**app-service**

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application

service can modify or delete the object.

**language**  
Specifies the language of the web application that the ASM security policy is protecting. Use autocomplete or list /asm webapp-language to get the list of supported languages.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**predefined-policy**  
Specifies a predefined security policy for a web application. This security policy was prebuilt to provide out of the box security for a known application. Use autocomplete to get a list of applications for which ASM has predefined policies.

#### SEE ALSO

BIG-IP            2013-04-12        asm httpclass-asm(1)

---

## asm policy

**NAME**  
policy - Configures an application security policy.

**MODULE**  
asm

**SYNTAX**  
Configure the policy component within the asm module using the syntax shown in the following sections.

```
CREATE
create policy [name]
options:
  [active | inactive]
  app-service [[string] | none]
  blocking-mode [enabled | disabled]
  description [[string] | none]
  encoding [[name] | none]
  policy-builder [enabled | disabled]
  policy-template [name]
  policy-type [security | parent]
  parent-policy [name]

MODIFY
modify policy [name]
options:
  [active | inactive]
  app-service [[string] | none]
  blocking-mode [enabled | disabled]
  description [[string] | none]
  encoding [[name] | none]
  policy-builder [enabled | disabled]
  policy-template [name]

DISPLAY
list policy [ [ [name] | [glob] | [regex] ] ... ]
show running-config policy [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  one-line
  partition
  virtual-servers

DELETE
delete policy [name]

SAVE
save policy [name]
options:
  overwrite
  bin-file [filename]
  min-xml-file [filename]
  xml-file [filename]

LOAD
load policy [name]
options:
  overwrite
```

file [filename]  
xml-string [string]

PUBLISH  
publish policy [name]

#### DESCRIPTION

You can use the policy component to create, modify, display, delete, save, load, or publish an application security policy for use with Application Security Manager functionality.

Note: To display all policy properties available in tmsh, including initial settings used by iApp and advanced configuration accessible in ASM GUI, specify the all-properties option or the detailed properties. By default, only initial properties are displayed: encoding, policy-template and [active | inactive].

Note: The modify command with the properties encoding and/or policy-template causes ASM to reconfigure the security policy and clear all its former data.

Note: The policy-type cannot be modified after the creation of the policy.

Note: The parent-policy can only, optionally, be set while creating a policy with policy-type set to security.

#### EXAMPLES

create policy my\_asm\_policy encoding utf-8

Creates a new policy named my\_asm\_policy with the default language encoding, policy-type set to security and no parent-policy.

modify policy my\_asm\_policy active

Activates the inactive policy named my\_asm\_policy.

create policy my\_parent\_asm\_policy encoding utf-8 policy-type parent

Creates a new policy named my\_parent\_asm\_policy with the default language encoding.

create policy my\_security\_asm\_policy policy-type security parent-policy my\_parent\_asm\_policy

Creates a new policy named my\_security\_asm\_policy, policy-type set to security and my\_parent\_asm\_policy set as the parent policy.

list policy

Displays the properties of all application security policies.

save policy my\_asm\_policy xml-file my\_asm\_policy.xml

Exports the policy named my\_asm\_policy to the XML file /var/tmp/my\_asm\_policy.xml.

load policy my\_asm\_policy overwrite file /tmp/my\_asm\_policy.plc

Imports the policy named my\_asm\_policy from the file /tmp/my\_asm\_policy.plc and overwrites the policy if it already exists.

publish policy my\_asm\_policy

Applies the active policy named my\_asm\_policy.

#### OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

[active | inactive]

Activates or deactivates the policy for later association with L7 policies and virtual servers. The default value is inactive.

bin-file

Specifies the exported file name to be saved in binary format when using the save command. The file name should be simple (not a full path); it is saved to the /var/tmp directory on the system.

blocking-mode

Specifies whether the system blocks a request that triggers a security policy violation or only logs the violation event (transparent mode).

description

Specifies an optional description of the security policy.

encoding

Specifies the language encoding, which determines how the security policy processes the character sets. This property corresponds to the language property of the httpclass-asm component.

file Specifies the file name from which the policy is going to be imported when using the load command. A full path should be specified.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

min-xml-file

Specifies the exported file name to be saved in compact XML format when using the save command. The file name should be simple (not a full path); it is saved to the /var/tmp directory on the system. To display the XML output immediately, omit this property, the properties xml-file and bin-file.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, save, and publish. If it is not specified for the load command, the policy name will be taken from the imported settings.

overwrite  
Specifies that the policy file for the save command or the policy component for the load command can be overwritten if it exists.

partition  
Displays the administrative partition within which the component resides.

policy-builder  
Enables or disables automatic policy building.

policy-template  
Specifies whether the security policy is based on a predefined security policy template, and if so, which one. If you create or modify a security policy based on a template, the system automatically configures the new security policy according to the conditions of the template. This property corresponds to the predefined-policy property of the httpclass-asm component.

policy-type  
Specifies the security policy type, which cannot be changed after you create the policy. The parent policy type cannot be active and cannot have a parent. The security policy type may or may not have a single parent policy defined.

parent-policy  
Optionally, specifies the name of an existing policy, of policy-type parent, to be set as the parent policy, while creating a policy-type security.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

Note: This component supports matching by the regex expression only when displaying the initial policy properties.

virtual-servers  
Displays the name of the protected virtual server, or virtual servers, which have attached to them the security policy via L7 policies.

xml-file  
Specifies the exported file name to be saved in XML format when using the save command. The file name should be simple (not a full path); it is saved to the /var/tmp directory on the system. To display the XML output immediately, omit this property, the properties min-xml-file and bin-file.

xml-string  
Specifies the XML document from which the policy is going to be imported when using the load command.

#### SEE ALSO

## asm predefined-policy

#### NAME

predefined-policy - Lists the available predefined policies that can be used in the context of the httpclass-asm profile.

#### MODULE

asm

#### SYNTAX

Retrieve the list of the predefined-policy values using the syntax shown in the following sections.

```
DISPLAY
list predefined-policy
list predefined-policy [ [ [name] | [glob] | [regex] ] ... ]
options:
all
one-line
```

**DESCRIPTION**  
Use this command to display the possible values of the predefined-policy object to be used in the context of the httpclass-asm profile. This is for advanced usage; this command is intended for use by the application templates system (iApps).

**EXAMPLES**  
list predefined-policy  
  
Displays all the predefined policies supported by the ASM.

**SEE ALSO**  
asm httpclass-asm, glob, list, regex, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP            2013-01-27            asm predefined-policy(1)

---

## asm response-code

**NAME**  
response-code - Lists the available HTTP response status codes that can be used in the context of the Application Security Manager.

**MODULE**  
asm

**SYNTAX**  
Retrieve the list of the response-code values using the syntax shown in the following sections.

```
DISPLAY
list response-code
list response-code [ [ [number] | [glob] | [regex] ] ... ]
options:
all
app-service
name
one-line
```

**DESCRIPTION**  
Use this command to display the possible values of the response-code object to be used in the context of the Application Security Manager. These possible values are predefined and intended to be used in filters of Application Security Logging.

**EXAMPLES**  
list response-code  
  
Displays all the response codes supported by the ASM.

**OPTIONS**  
app-service  
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.  
  
name Displays a well-known textual meaning of the HTTP response code.

**SEE ALSO**  
glob, list, regex, security log profile, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.  
  
F5 Networks and BIG-IP (c) Copyright 2009-2012. All rights reserved.

## asm webapp-language

**NAME**  
webapp-language - Lists the available languages that can be used in the context of the httpclass-asm profile.

**MODULE**  
asm

**SYNTAX**  
Retrieve the list of the webapp-language values using the syntax shown in the following sections.

**DISPLAY**  
list webapp-language  
list webapp-language [ [ [name] | [glob] ... ]  
options:  
all  
one-line

**DESCRIPTION**  
Use this command to display the possible values of the webapp-language object to be used in the context of the httpclass-asm profile. This is for advanced usage - this command is intended to be used by the application templates system.

**EXAMPLES**  
list webapp-language  
  
Displays all the languages supported by the ASM.

**SEE ALSO**  
asm httpclass-asm, glob, list, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.  
  
F5 Networks and BIG-IP (c) Copyright 2009-2011. All rights reserved.

## auth

### auth apm-auth

**NAME**  
apm-auth - Configures an APM-based authentication object for implementing access policy execution-based authentication of BIG-IP(r) system users.

**MODULE**  
auth

**SYNTAX**  
Configure the apm-auth component within the auth module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create apm-auth [name]  
modify apm-auth [name]  
options:  
profile-access [string]  
  
edit apm-auth [ [ [name] | [glob] | [regex] ] ...]  
options:  
all-properties  
non-default-properties  
  
**DISPLAY**  
list apm-auth  
list apm-auth [ [ [name] | [glob] | [regex] ] ...]

```

show running-config apm-auth
show running-config apm-auth [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete apm-auth [name]

DESCRIPTION
You can configure APM-based authentication to execute an access policy
for BIG-IP system users to authenticate and authorize them.

APM authentication methods like HTTP, AD/LDAP, TACACS+ authentication
can be used in box authentication To authenticate BIG-IP system
users.To do this, create an access profile, create APM configuration
object with the above access profile, and then activate the object.

The following steps describe how to configure APM-based authentication
for BIG-IP system users:

1. Use the profile-access component in the apm module to create a
access profile.

2. Use the apm-auth component in the auth module to map an access
profile to an APM-based authentication object.

3. To activate APM-based authentication for BIG-IP system users, run
the command sequence modify / auth source type apm-auth

EXAMPLES
create apm-auth system-auth {profile-access apm-profile}

Creates an APM-based authentication object named system-auth

delete apm-auth system-auth

Deletes the APM-based authentication object named system-auth.

OPTIONS
  description
User-defined description.

  glob Displays the items that match the glob expression. See help glob
for a description of glob expression syntax.

  name Specifies a unique name for the component. This option is required
for the commands create and modify.

  partition
Displays the administrative partition within which the component
resides.

  profile-access
Specifies the access profile that the system must use for APM-
based authentication. You must specify an access profile when you
create an APM-based configuration object.

  regex
Displays the items that match the regular expression. The regular
expression must be preceded by an at sign (@[regular expression])
to indicate that the identifier is a regular expression. See help
regex for a description of regular expression syntax.

## auth cert-ldap

**NAME**

cert-ldap - Configures an LDAP configuration object for implementing Single Sign On based on a valid client certificate for BIG-IP(r) system users. The user is required to properly configure the Certificate Authority so that unique identifying attributes appear in the subjectName or subjectAltName fields of signed client certificates; the OCSP responder so that it is available to the BIG-IP at the time a client certificate is presented; and the LDAP server so that it includes the required attributes from the client certificate and the

corresponding user name.

MODULE  
auth

SYNTAX  
Configure the cert-ldap component within the auth module using the syntax shown in the following sections.

CREATE/MODIFY  
create cert-ldap [name]  
modify cert-ldap [name]  
options:  
    bind-dn [ [account dn] | none]  
    bind-pw [none | [password] ]  
    bind-timeout [integer]  
    check-host-attr [disabled | enabled]  
    check-roles-group [disabled | enabled]  
    debug [disabled | enabled]  
    description [string]  
    filter [ [filter name] | none]  
    idle-timeout [integer]  
    ignore-auth-info-unavail [no | yes]  
    ignore-unknown-user [disabled | enabled]  
    login-attribute [ [account name] | none]  
    login-filter [ [string] | none]  
    login-name [ [ldap attribute] | none]  
    port [ [name] | [integer]]  
    scope [base | one | sub]  
    search-base-dn [[search base dn] | none]  
    search-timeout [integer]  
    servers [add | delete | replace-all-with] {  
        [ [ip address] | [server name] ...] }  
    ssl [disabled | enabled]  
    ssl-ca-cert-file [ [file name] | none]  
    ssl-check-peer [disabled | enabled]  
    ssl-ciphers [ [string] | none]  
    ssl-client-cert [ [string] | none]  
    ssl-client-key [ [string] | none]  
    ssl-cname-field [ subjectname-cn | san-other | san-email  
        san-dns | san-x400 | san-dirname | san-ediparty  
        san-uri | san-ipadd | san-rid ]  
    ssl-cname-otheroid [ [OID in dotted-decimal] | none]  
    sso [on | off]  
    version [integer]  
    warnings [disabled | enabled]  
  
edit cert-ldap [ [ [name] | [glob] | [regex] ] ...]  
options:  
    all-properties  
    non-default-properties  
  
DISPLAY  
list cert-ldap  
list cert-ldap [ [ [name] | [glob] | [regex] ] ...]  
show running-config cert-ldap  
show running-config cert-ldap [ [ [name] | [glob] | [regex] ] ...]  
options:  
    all-properties  
    non-default-properties  
    one-line  
    partition

DELETE  
delete cert-ldap [name]

DESCRIPTION  
The CERT-LDAP authentication mode is required to provide Single Sign On capability to the control plane based on a valid client certificate. This mode involves configuring an Apache server to initiate a client certificate request, perform certificate validation against an OCSP server, and then authenticate/authorize certificate credentials against a configured remote LDAP server or a Microsoft(r) Windows(r) Active Directory(r). The mode is not based on basic HTTP authentication (that is, user name and password). CERT-LDAP mode is equivalent to LDAP mode with custom attributes.

To authenticate BIG-IP system users when their authentication data is stored on a remote LDAP server, you create an LDAP configuration object, and then activate the object. Make sure that Apache is configured to support the client certificate validation.

To configure CERT-LDAP authentication for BIG-IP system users:

1. Use the cert-ldap component in the auth module to configure an LDAP configuration object.
2. To activate LDAP authentication for BIG-IP system users, run the command sequence modify / auth source type cert-ldap

EXAMPLES  
create cert-ldap bigip\_cert\_ldap\_auth servers add {my\_ldap\_server}  
  
Creates a configuration object named bigip\_cert\_ldap\_auth.  
  
delete cert-ldap bigip\_cert\_ldap\_auth  
  
Deletes the configuration object named bigip\_cert\_ldap\_auth.

OPTIONS  
bind-dn  
Specifies the distinguished name of an account to which to bind to perform searches. This search account is a Read-only account. You can also use the admin account as the search account. If an

administrative distinguished name is not specified, then a bind is not attempted. The default value is none.

Note: If the remote server is a Microsoft Windows Active Directory server, the distinguished name must be in the form of an email address.

#### bind-pw

Specifies the password for the search account created on the LDAP server. This option is required if you enter a value for the bind-dn option. The default value is none.

#### bind-timeout

Specifies a bind timeout limit, in seconds. The default value is 30.

#### check-host-attr

Confirms the password for the bind distinguished name. This option is optional. The default value is disabled.

#### check-roles-group

Specifies whether to verify a user's group membership given in the remote-role definitions, formatted as \*member\*of="group-dn". The default value is disabled.

#### debug

Enables or disables syslog-ng debugging information at the LOG DEBUG level. The default value is disabled. F5 Networks does not recommend using this option for normal configuration.

#### description

User defined description.

#### filter

Specifies a filter. Use this option for authorizing client traffic. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### group-dn

Specifies the group distinguished name. The system uses this option for authorizing client traffic. The default value is none.

#### group-member-attribute

Specifies a group member attribute. The system uses this option for authorizing client traffic. The default value is none.

#### idle-timeout

Specifies the idle timeout, in seconds, for connections. The default value is 3600 seconds.

#### ignore-auth-info-unavail

Specifies whether the system ignores authentication information if it is not available. The default value is no.

#### ignore-unknown-user

Specifies whether the system ignores a user that is unknown. The default value is disabled.

#### login-attribute

Specifies a logon attribute. Normally, the value for this option is uid; however, if the server is a Microsoft Windows Active Directory server, the value must be the account name samaccountname (not case-insensitive). The default value is none.

#### login-filter

Specifies the filter to be applied on the CN of the client certificate. This filter is a regular expression to extract required information from CN of client certificate which will be used to match against LDAP search results. The default is disabled.

#### login-name

Specifies the LDAP attribute holding the client name. (The client name is extracted from the client certificate as specified by ssl-cname-field.) The default is disabled.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the component resides.

port Specifies the port number or name for the LDAP service. Port 389 is typically used for non-SSL and port 636 is used for an SSL-enabled LDAP service. The default value is ldap.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### scope

Specifies the search scope. The default value is sub. The possible values are:

base The search scope is base object. The base value is almost never useful for name service lookups.

one The search scope is one level.

sub The search scope is a subtree.

search-base-dn

Specifies the search base distinguished name. The default value is none.

search-timeout

Specifies the search timeout, in seconds. The default value is 30.

servers

Specifies the LDAP servers that the system must use to obtain authentication information. You must specify a server when you create an LDAP configuration object.

ssl Enables or disables SSL functionality. The default is disabled.

Note that when you use tmsh to enable SSL for an LDAP service, the system does not change the port number from 389 to 636, as is required. To change the port number from the command line, use the port option, for example, ldap [name] ssl enabled port 636.

ssl-ca-cert-file

Specifies the name of an SSL CA certificate using the full path to the file. The default value is none.

ssl-check-peer

Specifies whether the system checks an SSL peer. The default value is disabled.

ssl-ciphers

Specifies SSL ciphers. The default value is none.

ssl-client-cert

Specifies the name of an SSL client certificate. The default value is none.

ssl-client-key

Specifies the name of an SSL client key. The default value is none.

ssl-cname-field

Specifies the value from the client certificate that provides the client name. The client name must appear in either the subjectName or subjectAltName (SAN) fields in the X.509v3 certificate. If it appears in the subjectName field, the client name must be the commonName (CN). If the client name appears in the SAN, it will have the specified type. If san-other is specified, the ssl-cname-otheroid must provide the OID of the UTF8 string containing the client name. The choices are: subjectname-cn, san-other, san-email, san-dns, san-x400, san-dirname, san-ediparty, san-uri, san-ipadd, or san-rid. The default value is subjectname-cn.

ssl-cname-otheroid

Specifies the OID in dotted-decimal format of the UTF8 string in the client's X.509v3 subjectAltName "other" attribute. This value is required when ssl-cname-field is san-other. The default value is none.

sso Enables or disables Single Sign On (SSO) functionality. SSO eliminates the need to administer and maintain multiple user logons and eliminates the need for users to enter their credentials multiple times. When SSO is disabled, the user will be prompted to authenticate into the BIG-IP. The default is off.

user-template

Specifies a user template for the LDAP application to use for authentication. The default value is none.

version

Specifies the version number of the LDAP application. The default value is 3.

warnings

Enables or disables warning messages. The default value is enabled.

list ldap [ [ [name] | [glob] | [regex] ] ...]
show running-config ldap
show running-config ldap [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

**DELETE**

```
delete ldap [name]
```

**DESCRIPTION**

LDAP authentication is useful when the BIG-IP system users authentication or authorization data is stored on a remote LDAP server or a Microsoft(r) Windows(r) Active Directory(r) server, and you want the user credentials to be based on basic HTTP authentication (that is, user name and password).

To authenticate BIG-IP system users when their authentication data is stored on a remote LDAP server, you create an LDAP configuration object, and then activate the object.

The following steps describe how to configure LDAP authentication for BIG-IP system users:

1. Use the ldap component in the auth module to configure an LDAP configuration object.
2. To activate LDAP authentication for BIG-IP system users, run the command sequence modify / auth source type ldap

**EXAMPLES**

```
create ldap bigip_ldap_auth servers add {my_ldap_server}
```

Creates a configuration object named bigip\_ldap\_auth

```
delete ldap bigip_ldap_auth
```

Deletes the configuration object named bigip\_ldap\_auth.

**OPTIONS**

**bind-dn**

Specifies the distinguished name of an account to which to bind to perform searches. This search account is a Read-only account. You can also use the admin account as the search account. If an administrative distinguished name is not specified, then a bind is not attempted. The default value is none.

Note that if the remote server is a Microsoft Windows Active

Directory server, the distinguished name must be in the form of an email address.

**bind-pw**

Specifies the password for the search account created on the LDAP server. This option is required if you enter a value for the bind-dn option. The default value is none.

**bind-timeout**

Specifies a bind timeout limit, in seconds. The default value is 30.

**check-host-attr**

Confirms the password for the bind distinguished name. This option is optional. The default value is disabled.

**check-roles-group**

Specifies whether to verify a user's group membership given in the remote-role definitions, formatted as \*member\*of="group-dn". The default value is disabled.

**debug**

Enables or disables syslog-ng debugging information at the LOG DEBUG level. The default value is disabled. F5 Networks does not recommend using this option for normal configuration.

**description**

User defined description.

**filter**

Specifies a filter. Use this option for authorizing client traffic. The default value is none.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**group-dn**

Specifies the group distinguished name. The system uses this option for authorizing client traffic. The default value is none.

**group-member-attribute**

Specifies a group member attribute. The system uses this option for authorizing client traffic. The default value is none.

**idle-timeout**

Specifies the idle timeout, in seconds, for connections. The default value is 3600 seconds.

**ignore-auth-info-unavail**

Specifies whether the system ignores authentication information if it is not available. The default value is no.

**ignore-unknown-user**

Specifies whether the system ignores a user that is unknown. The default value is disabled.

**login-attribute**

Specifies a logon attribute. Normally, the value for this option is uid; however, if the server is a Microsoft Windows Active Directory server, the value must be the account name samaccountname (not case-insensitive). The default value is none.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**partition**

Displays the administrative partition within which the component resides.

**port** Specifies the port number or name for the LDAP service. Port 389 is typically used for non-SSL and port 636 is used for an SSL-enabled LDAP service. The default value is ldap.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**scope**

Specifies the search scope. The default value is sub. The possible values are:

**base** The search scope is base object. The base value is almost never useful for name service lookups.

**one** The search scope is one level.

**sub** The search scope is a subtree.

**search-base-dn**

Specifies the search base distinguished name. The default value is none.

**search-timeout**

Specifies the search timeout, in seconds. The default value is 30.

**servers**

Specifies the LDAP servers that the system must use to obtain authentication information. You must specify a server when you create an LDAP configuration object.

**ssl** Enables or disables SSL functionality. The default is disabled.

Note that when you use tmsh to enable SSL for an LDAP service, the system does not change the port number from 389 to 636, as is required. To change the port number from the command line, use the port option, for example, ldap [name] ssl enabled port 636.

**ssl-ca-cert-file**  
Specifies the name of an SSL CA certificate using the full path to the file. The default value is none.

**ssl-check-peer**  
Specifies whether the system checks an SSL peer. The default value is disabled.

**ssl-ciphers**  
Specifies SSL ciphers. The default value is none.

**ssl-client-cert**  
Specifies the name of an SSL client certificate. The default value is none.

**ssl-client-key**  
Specifies the name of an SSL client key. The default value is none.

**user-template**  
Specifies a user template for the LDAP application to use for authentication. The default value is none.

**version**  
Specifies the version number of the LDAP application. The default value is 3.

**warnings**  
Enables or disables warning messages. The default value is enabled.

## auth login-failures

**NAME**  
login-failures - Displays or resets the status of the accounts of users whose attempts to log in to the BIG-IP(r) system have failed.

**MODULE**  
auth

**SYNTAX**  
Configure the login-failures component within the auth module using the following syntax.

**MODIFY**  
reset-stats login-failures  
options:  
username

**DISPLAY**  
show login-failures  
options:  
field-fmt  
username

**DESCRIPTION**  
Users assigned a role of Administrator can reset the status of a user who is locked out of the BIG-IP system due to enforcement of a company's security requirements. Users assigned other roles can only view login failures.

**EXAMPLES**  
show login-failures  
  
Displays the login failure status of all users.  
  
show login-failures joe  
  
Displays login failure status for the user joe.  
  
reset-stats login-failures

Resets the failed login counters for all users to zero and unlocks all users.

reset-stats login-failures joe

Resets the failed login counter for the user joe to zero and unlocks the user joe.

#### OPTIONS

show For information about the options that you can use with the show command, see help show.

username

Specifies a user account to display or reset.

#### SEE ALSO

auth user, reset-stats, show, tmsh

BIG-IP 2012-04-03 auth login-failures(1)

---

## auth partition

#### NAME

partition - Configures administrative partitions that implement access control for BIG-IP(r) system users.

#### MODULE

auth

#### SYNTAX

Configure the partition component within the auth module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create partition [name]
modify partition [name]
options:
  default-route-domain [ID]
  description [string]
```

##### DISPLAY

```
list partition
list partition [ [ [name] | [glob] | [regex] ] ...]
show running-config partition
show running-config partition [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  non-default-properties
  one-line
```

##### DELETE

```
delete partition [name]
options:
  all
```

#### DESCRIPTION

An administrative partition is a logical container that you create, containing a defined set of BIG-IP system objects, such as virtual servers, pools, and profiles. When a specific set of objects resides in a partition, you can then give certain users the authority to view and manage the objects in that partition only, rather than all objects on the BIG-IP system. This gives a finer degree of administrative control.

You can configure administrative partitions, only if the Administrator user role is assigned to your user account.

#### EXAMPLES

```
create partition partition_A description "Repository for application_A
objects"
```

Creates a partition named partition\_A that contains objects related to application\_A.

```
delete partition partition_B
```

Deletes the partition named partition\_B.

#### OPTIONS

description

Describes the contents of the partition. If you use spaces in the description, you must put quotation marks around the descriptive

text, for example, "This partition contains local traffic management objects for managing HTTP traffic."

**default-route-domain**  
Specifies the ID of the route domain that is associated with the IP addresses that reside in the partition. For more information, see help net route-domain.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### SEE ALSO

## auth password-policy

#### NAME

password-policy - Specifies the parameters of the valid passwords for the BIG-IP(r) system.

#### MODULE

auth

#### SYNTAX

Configure the password-policy component within the auth module using the syntax shown in the following sections.

##### MODIFY

```
modify password-policy
options:
  expiration-warning [integer]
  max-duration [integer]
  max-login-failures [integer]
  min-duration [integer]
  minimum-length [integer]
  password-memory [integer]
  policy-enforcement [disabled | enabled]
  required-lowercase [integer]
  required-numeric [integer]
  required-special [integer]
  required-uppercase [integer]
  lockout-duration [integer]
```

##### DISPLAY

```
list password-policy
list password-policy
show running-config password-policy
show running-config password-policy
options:
  all-properties
  non-default-properties
  one-line
```

#### DESCRIPTION

Users assigned a role of Administrator or Resource Administrator can modify a password policy for the BIG-IP system to enforce a company's security requirements by defining the parameters for valid passwords. Users assigned other roles can view password policies.

#### EXAMPLES

```
password-policy max-duration 90 min-duration 30 minimum-length 6
required-lowercase 2 required-uppercase 2 required-special 1 required-
numeric 1 expiration-warning 5
```

Creates a password policy that specifies that passwords are valid for a maximum of 90 days and a minimum of 30 days. Also specifies that to be valid, a password must contain at least 6 characters, but not more than 10 characters, including 2 lowercase alpha characters, 2 uppercase alpha characters, and 1 number. Additionally, this policy specifies

that the system automatically warns users five days before their passwords expire.

list password-policy

Displays the password policy.

#### OPTIONS

expiration-warning

Specifies the number of days before a password expires. Based on this value, the BIG-IP system automatically warns users when their password is about to expire. The default value is 7 days.

max-duration

Specifies the maximum number of days a password is valid. The default value is 99999.

max-login-failures

Specifies the number of consecutive unsuccessful login attempts that the system allows before locking out the user. The default value is 0 (zero - disabled).

min-duration

Specifies the minimum number of days a password is valid. The default value is 0 (zero).

minimum-length

Specifies the minimum number of characters in a valid password. The default value is 6.

password-memory

Specifies whether the user has configured the BIG-IP system to remember a password on a specific computer. The default value is 0 (zero).

policy-enforcement

Enables or disables the password policy on the BIG-IP system. The default value is disabled.

required-lowercase

Specifies the number of lowercase alpha characters that must be present in a password for the password to be valid. The default value is 0 (zero).

required-numeric

Specifies the number of numeric characters that must be present in a password for the password to be valid. The default value is 0 (zero).

required-special

Specifies the number of special characters that must be present in a password for the password to be valid. The default value is 0 (zero).

required-uppercase

Specifies the number of uppercase alpha characters that must be present in a password for the password to be valid. The default value is 0 (zero).

lockout-duration

Specifies the amount of time in seconds that a locked-out user must wait before being allowed to log in again unless manually unlocked.

#### SEE ALSO

---

## auth password

#### NAME

password - Prompts for modification of a password, and asks for a confirmation of the new password.

#### MODULE

auth

#### SYNTAX

Configure the password component within the auth module using the syntax shown in the following sections.

USAGE  
modify password

#### DESCRIPTION

If you are assigned the user role of Administrator or User Manager, you can change another user's password.

For example, from within the auth module, run the following command sequence: modify password [user name].

The system prompts you for a new password for the specified user, and then to confirm the new password.

If you are assigned any other user role, the system prompts you to change your own password, and then confirm the new password.

To change a password from within another module, use the full path to the password.

#### EXAMPLES

```
(tmos.auth)# modify password
```

From within the auth module, displays the new password: prompt.

```
(tmos.gtm)# modify / auth password
```

From within the gtm module, displays the new password: prompt.

#### SEE ALSO

auth user, modify, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## auth radius-server

#### NAME

radius-server - Configures a RADIUS server for implementing remote RADIUS-based authentication of BIG-IP(r) system users.

#### MODULE

auth

#### SYNTAX

Configure the radius-server component within the auth module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create radius-server [name]
```

```
modify radius-server [name]
```

##### options:

```
app-service [[string] | none]
```

```
description [string]
```

```
port [ [name] | [number] ]
```

```
secret [none | ["string"] ]
```

```
server [ [hostname] | [IP address] | none]
```

```
timeout [integer]
```

```
edit radius-server [ [ [name] | [glob] | [regex] ] ...]
```

##### options:

```
all-properties
```

```
non-default-properties
```

##### DISPLAY

```
list radius-server
```

```
list radius-server [ [ [name] | [glob] | [regex] ] ...]
```

```
show running-config radius-server
```

```
show running-config radius-server [ [ [name] | [glob] | [regex] ] ...]
```

##### options:

```
all-properties
```

```
non-default-properties
```

```
one-line
```

```
partition
```

##### DELETE

```
delete radius-server [name]
```

#### DESCRIPTION

To authenticate BIG-IP system users when their authentication data is stored on a remote RADIUS server, you configure a RADIUS server, configure a RADIUS configuration object that references that RADIUS

server, and then activate RADIUS authentication for the BIG-IP system. In this case, client credentials are based on basic HTTP authentication (that is, user name and password).

To configure RADIUS authentication for the BIG-IP system:

1. Use the radius-server component in the auth module to configure a RADIUS server.
2. Use the radius component in the auth module to create a RADIUS configuration object that references the RADIUS server you created in the Step 1. For more information about creating a RADIUS configuration object, see help radius.
3. To activate RADIUS authentication for BIG-IP system users, type the following command sequence: modify / auth source type radius

#### EXAMPLES

```
create radius-server bigip_auth_radius_server secret "This is the secret." server 10.1.1.1
```

Creates a RADIUS server component named bigip\_auth\_radius\_server.

```
delete radius-server bigip_auth_radius_server
```

Deletes the RADIUS server component named bigip\_auth\_radius\_server.

#### OPTIONS

app-service

Specifies the name of the application service to which the RADIUS server belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the RADIUS server. Only the application service can modify or delete the RADIUS server.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the partition in which the radius server resides.

port Specifies the port for RADIUS authentication traffic. The default value is 1812.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Specifies the secret key the system uses to encrypt and decrypt packets sent from or received by the server. This option is required.

server

Specifies the host name or IP address of the RADIUS server. This option is required.

timeout

Specifies the timeout value in seconds. The default value is 3.

#### SEE ALSO

## auth radius

#### NAME

radius - Configures a RADIUS configuration object for implementing remote RADIUS-based authentication of BIG-IP(r) system users.

#### MODULE

auth

## SYNTAX

Configure the radius component within the auth module using the syntax shown in the following sections.

### CREATE/MODIFY

```
create radius [name]
modify radius [name]
  options:
    accounting-bug [disabled | enabled]
    app-service [[string] | none]
    client-id [none | [string] ]
    debug [disabled | enabled]
    description [string]
    retries [integer]
    servers [add | delete | replace-all-with]
      { [ [hostname] | [ip address] ... ] }
    servers [default | none]
    service-type [default | login | framed | callback-login |
callback-framed | outbound | administrative |
nas-prompt | authenticate-only |
callback-nas-prompt | call-check |
callback-administrative]

edit radius [ [ [name] | [glob] | [regex] ] ...]
  options:
    all-properties
    non-default-properties

DISPLAY
list radius
list radius [ [ [name] | [glob] | [regex] ] ...]
show running-config radius
show running-config radius [ [ [name] | [glob] | [regex] ] ...]
  options:
    all-properties
    non-default-properties
    one-line
    partition

DELETE
delete radius [name]
```

## DESCRIPTION

To authenticate BIG-IP system users when their authentication data is stored on a remote RADIUS server, you configure a RADIUS server, configure a RADIUS configuration object that references that RADIUS server, and then activate RADIUS authentication for the BIG-IP system. In this case, client credentials are based on basic HTTP authentication (that is, user name and password).

To configure RADIUS authentication for the BIG-IP system:

1. Use the radius-server component in the auth module to configure a RADIUS server. For more information about creating a RADIUS server, see `help radius-server`.
2. Use the radius component in the auth module to create a RADIUS configuration object that references the RADIUS server you created in Step 1.
3. To activate RADIUS authentication for BIG-IP system users, type the following command sequence: `modify / auth source type radius`

## EXAMPLES

```
create radius bigip_radius_auth servers add {myradiusserver}

Creates a RADIUS configuration object named bigip_radius_auth.

delete radius bigip_radius_auth

Deletes the RADIUS configuration component named bigip_radius_auth.
```

## OPTIONS

**accounting-bug**  
Enables or disables validation of the accounting response vector. This option is necessary only on older servers. The default value is disabled.

**app-service**  
Specifies the name of the application service to which the RADIUS configuration object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the RADIUS configuration object. Only the application service can modify or delete the RADIUS configuration object.

**client-id**  
Sends a NAS-Identifier RADIUS attribute with string bar. If you do not specify a value for this option, the system uses the pluggable authentication module (PAM) service type. You can disable this feature by specifying a blank client ID.

**debug**  
Enables or disables syslog-ng debugging information at the LOG DEBUG level. F5 Networks does not recommend this option for normal use. The default value is disabled.

**description**  
User defined description.

**glob** Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition  
Displays the partition within which the component resides.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

retries  
Specifies the number of authentication retries that the BIG-IP local traffic management system allows before authentication fails. The default value is 3.

service-type  
Specifies the type of service used for the RADIUS server. The default is default, which behaves as authenticate-only.

servers  
Specifies the host names or IP addresses of existing RADIUS servers that the BIG-IP system uses to obtain authentication data.

## auth remote-role

#### NAME

remote-role - Creates remote role information in a file that an LDAP, Active Directory(r), RADIUS, or TACACS+ server reads to determine the specific access rights to grant to groups of remotely-authenticated users.

#### MODULE

auth

#### SYNTAX

Configure the remote-role component within the auth module using the syntax shown in the following sections.

#### MODIFY

```
modify remote-role
options:
  description [string]
  role-info [add | delete | modify | replace-all-with] {
    [group-name] {
      options:
        attribute [string]
        console [disabled | tmsh]
        description [string]
        deny [enabled | disabled]
        line-order [integer]
        role [acceleration-policy-editor | admin | fraud-protection-manager |
        application-editor | auditor | certificate-manager |
        firewall-manager | guest | irule-manager | manager |
        no-access | operator | resource-admin | user-manager |
        web-application-security-administrator |
        web-application-security-editor | web-application-security-operations-administrator]
        user-partition [all | Common | [name] ]
        user-partition [%string]
      }
    }
  }
role-info none
```

#### DISPLAY

```
list remote-role
show running-config remote-role
options:
  all-properties
  non-default-properties
  one-line
```

#### DELETE

You cannot delete the remote-role defaults, you can only modify the values of the options.

## DESCRIPTION

You can use the remote-role component to grant access to a specific group of remotely-authenticated users without creating a local user account on the BIG-IP(r) system for each user in the group.

Users assigned the role of Administrator can modify remote roles. Users assigned all other roles can view remote roles.

You can use the variable substitution feature to assign access rights for a group of remote users by specifying a text string variable that is preceded by a leading % character for the options attribute, console, role and user-partition. For example, if you define the remote role for the groups DC1 and DC2 as follows:

```
remote-role {
  role info {
    dc1 {
      attribute "F5-LTM-User-Info-1=DC1"
      console %F5-LTM-User-Console
      line-order 1
      role %F5-LTM-User-Role
      user-partition %F5-LTM-User-Partition
    }
    dc2 {
      attribute "F5-LTM-User-Info-1=DC2"
      line-order 2
    }
  }
}
```

The BIG-IP(r) system attempts to match the value of the attribute option, F5-LTM-User-Info-1=DC1, and then pulls the value of the console, role and user-partition options from the other variables.

Note: If a variable includes an incorrect value, the system does not authorize the user. Additionally, if you have not defined the variables, as with the group DC2 above, the system authenticates the user with the following access rights:

```
console = disabled
role = none
user-partition = none
```

## EXAMPLES

```
modify remote-role role-info add { my_managers { attribute
"memberOF=cn=BigIPmanagerGroup,cn=users,dc=mydept,dc=mycompany,dc=com"
console disabled line-order 1000 role 100 user-partition all } }
```

Configures a remote role, named `my_managers`, for LDAP authentication, by creating the 1000th line of the `/config/bigip/auth/remoterole` file, and granting the Manager role (100) in all partitions to the remote users assigned this role.

```
modify remote-role role-info add { my_admins { attribute "NS-Admin-
Privilege" console tmsh line-order 1000 role 0 user-partition all } }
```

Configures a remote role, named `my_admins`, for LDAP authentication, by creating the 2000th line of the `/config/bigip/auth/remoterole` file, and granting the Administrator role (0) in all partitions to the remote users assigned this role.

```
modify remote-role role-info add { my_managers { attribute
"manager_group=manager" console tmsh line-order 3000 user-partition all
} }
```

Configures a remote role, named `my_managers`, for RADIUS or TACACS+ authentication, by creating the 3000th line of the `/config/bigip/auth/remoterole` file, and granting the Administrator role (0) in all partitions to the remote users assigned this role:

## OPTIONS

### description

Specifies a user-defined description.

### role-info

Configures the access rights for a specific group of remotely-authenticated users. You can configure the following information for a role:

#### attribute

Specifies an attribute-value pair that an authentication server supplies to the BIG-IP system to match against entries in `/config/bigip/auth/remoterole`. The specified pair typically identifies users with access rights in common. This option is required.

Alternatively, you can use the variable substitution feature (described in the Description section above), and specify a text string variable that is preceded by a leading % character.

#### console

Enables or disables console access for the specified group of remotely-authenticated users. The default value is disabled.

When using variable substitution, as described in the Description section of this man page, the variable for the console option must be: `tmsh`.

`deny` Enables or disables remote access for the specified group of remotely-authenticated users. The default value is disabled.

#### description

Specifies a user-defined description.

`group-name`  
Specifies the name of the remote role that you are configuring. This option is required.

`line-order`  
Specifies the number of the first populated line in the file, `/config/bigip/auth/remoterole`. The LDAP, Active Directory, RADIUS, and TACACS+ servers read this file line by line. The order of the information is important; therefore, F5 Networks recommends that you set the first line at 1000. This allows you, in the future, to insert lines before the first line. This option is required.

`role` Specifies the role that you want to grant to the specified group of remotely-authenticated users. The default value is `no-access`. The available roles are:

`admin`  
`fraud-protection-manager`  
`application-editor`  
`certificate-manager`  
`firewall-manager`  
`guest`  
`manager`  
`no-access`  
`operator`  
`resource-admin`  
`web-application-security-administrator`  
`web-application-security-editor`  
`web-application-security-operations-administrator`  
`user-manager`

When using variable substitution, as described in the Description section above, the variable for the role option must evaluate to one of these values: 0 (`admin`), 20 (`resource admin`), 40 (`user manager`), 80 (`auditor`), 100 (`manager`), 300 (`application editor`), 350 (`advanced operator`), 400 (`operator`), 450 (`firewall manager`), 500 (`certificate manager`), 510 (`irule manager`), 700 (`guest`), 800 (`web application security administrator`), 810 (`web application security editor`), 820 (`web application security operations administrator`), 850 (`acceleration policy editor`), 900 (`no-access`).

`user-partition`  
Specifies the user partition to which you are assigning access to the specified group of remotely-authenticated users. The default value is `Common`. This option is required.

Alternatively, you can use the variable substitution feature (described in the Description section above) and specify a text string variable that is preceded by a leading `%` character.

---

## auth remote-user

#### NAME

`remote-user` - Configures the default role, partition access, and console access for all remotely authenticated user accounts that have not been added as local user accounts on the BIG-IP(r) system.

## MODULE

auth

## SYNTAX

Configure the remote-user component within the auth module using the syntax shown in the following sections.

### MODIFY

```
modify remote-user
options:
  default-partition [all | Common | [partition name] ]
  default-role [acceleration-policy-editor | admin |
  fraud-protection-manager | application-editor |
  auditor | firewall-manager | guest |
  irule-manager | manager | no-access |
  operator | resource-admin | user-manager |
  web-application-security-administrator |
  web-application-security-editor | web-application-security-operations-administrator]
  description [string]
  remote-console-access [disabled | tmsh]
```

### DISPLAY

```
list remote-user
show running-config remote-user
options:
  all-properties
  non-default-properties
  one-line
```

### DELETE

You cannot delete the remote-user defaults, you can only modify the values of the options.

## DESCRIPTION

You can use the remote-user component to configure the default parameters for all the remote user accounts on the BIG-IP system as a group. To assign a different access level to a specific remote user, you must create a local user account for that user on the BIG-IP system. See the auth user man page for more information.

Users assigned the role of Administrator or Resource Administrator can modify the parameters of the remote-user component. Users assigned all other roles can view the parameters of the remote-user component.

## EXAMPLES

```
modify remote-user default-partition Common default-role no access
remote-console-access disabled
```

For all remote users, sets the default partition access to partition Common, the default role to no-access, and the default remote console access to disabled.

```
modify remote-user default-partition all default-role no access
remote-console-access disabled
```

For all remote users, sets the default partition access to all partitions, the default role to no-access, and the default remote console access to disabled.

## OPTIONS

**default-partition**  
Specifies the default partition for all remote user accounts. The default value is all.

**default-role**  
Specifies the default role for all remote user accounts. The default value is no-access.

**description**  
Specifies a user-defined description.

**remote-console-access**  
Specifies whether you are granting this user access to tmsh or disabling remote console access for this user. The default value is disabled.

## SEE ALSO

auth remote-role, auth user, list, modify, show, tmsh

## COPYRIGHT

BIG-IP 2018-12-26 auth remote-user(1)

**NAME**

source - Configures the authorization source type for a BIG-IP(r) system.

**MODULE**

auth

**SYNTAX**

Configure the source component within the auth module using the syntax in the following sections.

**MODIFY**

```

modify source
options:
  type [active-directory | ldap | local | radius | tacacs | cert-ldap | apm-auth]
  fallback [true | false]

```

**DISPLAY**

```

list source
list source [option]
options:
  all-properties
  non-default-properties
  one-line

```

**DESCRIPTION**

You can use the source component to set up the authorization source type for the BIG-IP system. The fallback setting enables system auth fallback from remote to local.

**EXAMPLES**

```

modify auth source type tacacs

Sets up the authorization source type as tacacs.

list auth source type

Displays the authorization source type.

```

**OPTIONS**

**type** Specifies the default user authorization source. The default value is local. When user accounts that access the system reside on a remote server, the value of this option is the type of server that you are using for authentication, for example, ldap.

**fallback**

When true and type is set to a remote authentication source, if the remote server is unavailable, authentication will fall back to local authentication. The default value is false.

**SEE ALSO**

list, modify, tmsh

**COPYRIGHT**

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## auth tacacs

**NAME**

tacacs - Configures a TACACS+ configuration object for implementing remote authentication of BIG-IP(r) system users based on TACACS+.

**MODULE**

auth

**SYNTAX**

Configure the tacacs component within the auth module using the syntax shown in the following sections.

**CREATE/MODIFY**

```

create tacacs [name]
modify tacacs [name]
options:
  accounting [send-to-first-server | send-to-all-servers]
  app-service [[string] | none]
  authentication [use-first-server | use-all-servers]
  debug [disabled | enabled]
  description [string]
  encryption [disabled | enabled]
  protocol [none | [protocol] ]
  secret [ "[string]" ]
  servers

```

```

    [add | delete | replace-all-with] {
    [ [hostname[:port]] | [ip address[:port]] ] ... ]
    }
    service [ [name] | none]
    timeout [integer]

edit tacacs [ [ [name] | [glob] | [regex] ] ...]
options:
    all-properties
    non-default-properties

DISPLAY
list tacacs
list tacacs [ [ [name] | [glob] | [regex] ] ...]
show running-config tacacs
show running-config tacacs [ [ [name] | [glob] | [regex] ] ...]
options:
    all-properties
    non-default-properties
    one-line
    partition

DELETE
delete tacacs [name]

```

**DESCRIPTION**

To authenticate BIG-IP system users when their authentication data is stored on a remote TACACS+ server, you create a TACACS+ configuration object, and then activate the object.

To configure TACACS+ authentication for BIG-IP system users:

1. Use the tacacs component in the auth module to configure a TACACS+ configuration object.
2. To activate TACACS+ authentication for BIG-IP system users, run the following command sequence: `modify / auth source type tacacs`

**EXAMPLES**

```

create tacacs bigip_tacacs_auth servers add {my_tacacs_server}

Creates a TACACS+ configuration object named bigip_tacacs_auth.

delete tacacs bigip_tacacs_auth

Deletes the TACACS+ configuration object named bigip_tacacs_auth.

```

**OPTIONS**

**accounting**  
If multiple TACACS+ servers are defined and pluggable authentication module (PAM) session accounting is enabled, sends accounting start and stop packets to the first available server or to all servers. The default value is `send-to-first-server`.

Possible values are:

**send-to-all-servers**  
The system sends accounting start and stop packets to all servers.

**send-to-first-server**  
The system sends accounting start and stop packets to the first available server.

**app-service**  
Specifies the name of the application service to which the TACACS+ configuration object belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the TACACS+ configuration object. Only the application service can modify or delete the TACACS+ configuration object.

**authentication**  
Specifies the process the system employs when sending authentication requests. The default value is `use-first-server`.

Possible values are:

**use-all-servers**  
The system sends an authentication request to each server until authentication succeeds, or until the system has sent a request to all servers in the list.

**use-first-server**  
The system sends authentication requests to only the first server in the list.

**debug**  
Enables syslog-ng debugging information at the LOG DEBUG level. F5 Networks does not recommend this option for normal use. The default value is disabled.

**description**  
User defined description.

**encryption**  
Enables or disables encryption of TACACS+ packets. F5 Networks recommends this option for normal use. The default value is enabled.

**glob** Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

**name** Specifies a unique name for the component. This option is required

for the commands create and modify.

**partition**  
Displays the administrative partition within which the component resides.

**protocol**  
Specifies the protocol associated with the value specified in the service option, which is a subset of the associated service being used for client authorization or system accounting.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**secret**  
Sets the secret key used to encrypt and decrypt packets sent or received from the server. This option is required.

**servers**  
Specifies the host name or IPv4 address of the TACACS+ server. For each server, a port may optionally be specified in the format hostname:port or IPv4:port. If no port is specified, the default port 49 is used. This option is required.

**service**  
Specifies the name of the service that the user is requesting to be authenticated to use. Identifying the service enables the TACACS+ server to behave differently for different types of authentication requests. This option is required.

**timeout** Specifies the connect timeout in seconds. The default value is 10 seconds. Zero indicates no timeout.

  encrypted-password  
  one-line  
  partition

```
show user
  options:
    field-fmt
```

```
DELETE
delete user [name]
```

#### DESCRIPTION

You can create user accounts where the user names differ only by case-sensitivity (for example, david and DAVID).

You can configure the partition-access property to grant a user access to more than one partition on the system. In the case where you do not grant the user access to all partitions, you can assign the user a different user role for each partition. A user can have only one role per partition. Any user with a role of Administrator, Resource Administrator, Web Application Security Administrator, or Auditor always has access to all partitions and can have no other role on the system.

Only users with the Administrator or User Manager roles are allowed to create or modify user accounts.

Additionally, only users with the Administrator, Resource Administrator, or User Manager user role can view all of the user accounts in all of the partitions to which the user has access. Therefore, if you have a user role other than one of these roles, you can only view your own user account.

#### EXAMPLES

```
create user nwinters partition-access add { all-partitions { role guest
} }
```

Creates a new user named nwinters with a role of Guest in all partitions.

```
create user tknox password aBcD007 partition-access add { partition1 {
role operator } }
```

Creates a new user named tknox with a role of operator in partition named partition1 and sets the user's login password.

```
list user
```

Displays the viewable properties of all user accounts.

```
show user
```

Displays each user role and the corresponding partition access that is currently assigned to the user.

#### OPTIONS

description

Describes the user account in free form text.

encrypted-password

Displays the encrypted password for the user account.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

Note: User account names are case-sensitive.

partition

Displays the name of the administrative partition in which the user account resides.

partition-access

Specifies the administrative partitions to which the user currently has access. Note that in addition to these partitions, the user also has read access to the shared partitions Common and Root. An exception to this is any user with the role No Access.

role Specifies the user role that pertains to the partition specified by the partition-access property. If you do not want to assign a user role to the user account, specify the value no-access. This prevents the user from accessing the system.

password

Sets the user password during creation or modification of a user account without prompting or confirmation. May not be used with prompt-for-password. Passwords are hidden in log and history files.

prompt-for-password

Indicates that when the account is created or modified, the BIG-IP system prompts the administrator or user manager for both a password and a password confirmation for the account.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

shell

Specifies the shell to which the user has access. Valid values are:

bash Provides an unrestricted system prompt. You can assign access to the bash shell only to users with the Administrator role.

none Specifies no shell access. The user must use the Configuration utility.

tmsh Provides access to the Traffic Management shell. Resource Administrator user role can use the tcpdump, ssldump, or qkview utilities within tmsh shell (run /util ). Other user roles may be given this shell, as appropriate.

## cli

### cli admin-partitions

NAME

admin-partitions - Set the administrative partition for a BIG-IP(r) configuration file.

MODULE

cli

SYNTAX

Configure the admin-partitions component within the cli module using the syntax in the following sections.

MODIFY

modify admin-partitions  
options:  
  update-partition [name]

DESCRIPTION

You can use the admin-partitions component to set the administrative partition in which configuration will be loaded when a configuration file is being loaded.

This component is only available from a configuration file that is being loaded via the sys config component with the file option.

EXAMPLES

```
cli admin-partitions { update-partition partition_A }
```

Sets the administrative partition in which configuration will be loaded. Configuration that follows this directive will be place in partition\_A.

OPTIONS

  update-partition  
Sets the administrative partition in which you can configure objects.

SEE ALSO

load, sys config, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

---

## cli alias private

**NAME**

private - Configures a user private alias.

**MODULE**

cli alias

**SYNTAX**

Configure the alias component within the cli alias module using the syntax in the following sections.

**CREATE/MODIFY**

```
create private [name]
options:
  command [commandSyntax]
  command ["command syntax"]
  command "[command syntax]; [command syntax]; ..."
  app-service [[string] | none]
  description [string]

edit private [name]
options:
  all

modify alias [name]
options:
  command [commandSyntax]
  command ["command syntax"]
  command "[command syntax]; [command syntax]; ..."
```

**DISPLAY**

```
list private
list alias [ [ [name] | [glob] | [regex] ] ...]
show running-config private
show running-config private [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  one-line
  non-default-properties
```

**DELETE**

```
delete private [all | [name ... name] ]
```

**DESCRIPTION**

You can use the private component to create a shortcut that runs a tmsh command sequence. The name of the private alias is what you type on the command line to run the command. If the command sequence for which you are creating an alias contains spaces, it must be enclosed in quotation marks. Command aliases are not case-sensitive.

You can create a private alias that runs multiple commands by entering the command sequences separated by semi-colons.

Private aliases can be used only by the user who created them.

When a batch mode transaction is active, commands that operate on the private component are run immediately and are not added to the transaction.

For more information about aliases, see the Traffic Management Shell (tmsh) Reference Guide.

**EXAMPLES**

```
create private save command "save config"
```

Creates an alias that saves the running configuration in the stored configuration files from anywhere within tmsh.

```
create private stats command "show /sys traffic"
```

Creates an alias that displays traffic statistics from anywhere within tmsh.

```
create private nodemonitor command "list /ltm node; list /ltm monitor"
```

Creates an alias that displays the Local Traffic Manager nodes and monitors.

```
create private myalias command "show /sys provision ; show /sys license"
```

Creates an alias that displays license and provisioning information.

```
create private ltmpool command "list /ltm pool"
```

Creates an alias that displays the Local Traffic Manager pools from anywhere within tmsh.

**OPTIONS**

**command syntax**

Specifies the command for which you are creating an alias. To create an alias that runs multiple commands, enter the command sequences separated by semi-colons.

**app-service**

Specifies the name of the application service to which the alias belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the alias. Only the application service can modify or delete the alias.

**description**  
Specifies the purpose of the alias. If you enable cli preference show-aliases, tmsh displays the description in context-sensitive help (?).

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**name** Specifies a name for the alias. This is what you type in tmsh to run the command for which you are creating an alias.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### SEE ALSO

create, delete, edit, glob, list, modify, regex, show, shared, tmsh

#### COPYRIGHT

## cli alias shared

#### NAME

shared - Configures a shared alias.

#### MODULE

cli alias

#### SYNTAX

Configure the shared alias component within the cli alias module using the syntax in the following sections.

```
CREATE/MODIFY
create shared [name]
options:
  command [commandSyntax]
  command ["command syntax"]
  command "[command syntax]; [command syntax]; ..."
  app-service [[string] | none]
  description [string]

edit shared [name]
options:
  all

modify alias [name]
options:
  command [commandSyntax]
  command ["command syntax"]
  command "[command syntax]; [command syntax]; ..."

DISPLAY
list shared
list alias [ [ [name] | [glob] | [regex] ] ...]
show running-config shared
show running-config shared [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  one-line
  non-default-properties

DELETE
delete shared [all | [name ... name] ]
```

#### DESCRIPTION

You can use the shared component to create a shortcut to run a tmsh command sequence. The name of the shared alias is what you type on the command line to run the command. If the command sequence for which you are creating an alias contains spaces, it must be enclosed in quotation marks. Command aliases are not case-sensitive.

You can create a shared alias that runs multiple commands by entering the command sequences separated by semi-colons.

Shared aliases can be used by all users.

When a batch mode transaction is active, commands that operate on the shared component are run immediately and are not added to the transaction.

For more information about aliases, see the Traffic Management Shell (tmsh) Reference Guide.

#### EXAMPLES

create shared save command "save config"

Creates an alias that saves the running configuration in the stored configuration files from anywhere within tmsh.

create shared stats command "show /sys traffic"

Creates an alias that displays traffic statistics from anywhere within tmsh.

create shared nodemonitor command "list /ltm node; list /ltm monitor"

Creates an alias that displays the Local Traffic Manager nodes and monitors.

create shared myalias command "show /sys provision ; show /sys license"

Creates an alias that displays license and provisioning information.

create shared ltm pool command "list /ltm pool"

Creates an alias that displays the Local Traffic Manager pools from anywhere within tmsh.

#### OPTIONS

command syntax

Specifies the command for which you are creating an alias. To create an alias that runs multiple commands, enter the command sequences separated by semi-colons.

app-service

Specifies the name of the application service to which the alias belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the alias. Only the application service can modify or delete the alias.

description

Specifies the purpose of the alias. If you enable cli preference show-alias, tmsh displays the description in context-sensitive help (?).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a name for the alias. This is what you type in tmsh to run the command for which you are creating an alias.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### SEE ALSO

create, delete, edit, glob, list, modify, regex, show, shared, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## cli global-settings

#### NAME

global-settings - Configures settings for tmsh

#### MODULE

cli

#### SYNTAX

Configure the global-settings component within the cli module using the syntax shown in the following sections.

#### MODIFY

edit global-settings

options:

all-properties

non-default-properties

```
modify global-settings
options:
  audit [disabled | enabled]
  description [string]
  idle-timeout [disabled | integer]
  scf-backup-number [integer]
  service [number | name]
```

```
DISPLAY
list global-settings
list global-settings [option]
options:
  all-properties
  non-default-properties
  one-line
```

```
DELETE
  You cannot delete the default global settings.
```

DESCRIPTION

You can use the global-settings component to configure multiple settings for tmsh.

EXAMPLES

```
modify global-settings audit enabled

  Enables auditing for tmsh.

modify global-settings idle-timeout 15

  Sets the user idle timeout from tmsh to 15 minutes.
```

OPTIONS

**audit**  
Specifies the global audit level for tmsh. The audited commands are stored in /var/log/audit. The default value is enabled. The audit levels are:

**disabled**  
tmsh does not log commands that users enter.

**enabled**  
tmsh audits only commands that users enter. Note that the system does not audit the commands that the command load runs.

**description**  
User defined description.

**idle-timeout**  
If not disabled, log a user in tmsh interactive mode out automatically after a specified set of minutes. An administrator may change the timeout value at any time and the new policy will take place immediately.

**scf-backup-number**  
Specifies the number of backup single configuration files that the system stores when you enter the following command sequence in tmsh:

```
load sys config file
```

When you run the command, the system saves the single configuration file. By default, the system saves two backup single configuration files. For example, if you set the scf-backup-number option to 3, after you run the command sequence tmsh load sys config file for the third time, the system has three versions of the single configuration file: /var/local/scf/backup.scf, /var/local/scf/backup-1.scf, and /var/local/scf/backup-2.scf. The newest file is /var/local/scf/backup.scf.

**service**  
Specifies the format in which tmsh displays a service. The default value is name. The options are:

**name** Displays a service using a protocol name, for example, http.

**number**  
Displays a service using a numeric value, for example, 192.168.10.20:80, where 80 indicates http.

SEE ALSO

edit, list, modify, run, tmsh

COPYRIGHT

## cli history

**NAME**  
history - Displays a list of commands in the order in which you ran the commands.

**MODULE**  
cli

**SYNTAX**  
Use the history component within the cli module to display a numbered list of commands in the order the commands were issued.

**DISPLAY**  
show history  
!  
!!  
![string]

**DESCRIPTION**  
You can use the history component to display a numbered list of the commands that you have run in tmsh. The commands display in the order in which you ran the commands, and each command is identified by an entry ID. The larger the entry ID of the command, the more recently you ran the command.

To rerun a command from the history list, type q to close the list and return to the tmsh prompt, and then enter an exclamation point (!) followed by the entry ID of the command that you want to run.

**EXAMPLES**  
!  
  
show history  
  
Either of the two previous commands, displays the command history list.  
  
!5  
  
Runs the fifth command in the command history list.  
  
!!  
  
Runs the previously issued command.  
  
!create  
  
Runs the last command that begins with create.

**SEE ALSO**  
show, tmsh

**COPYRIGHT**

## cli preference

**NAME**  
preference - Configures tmsh preferences.

**MODULE**  
cli

**SYNTAX**  
Configure the preference component within the cli module using the syntax shown in the following sections.

**MODIFY**  
edit preference  
modify preference [option]  
options:  
alias-path [string list]  
app-service [[string] | none]  
confirm-edit [disabled | enabled]  
display-threshold [integer]  
editor [nano | vi]  
history-date-time [disabled | enabled]  
history-file-size [integer]  
history-size [integer]

```

keymap [default | emacs | vi]
list-all-properties [disabled | enabled]
pager [disabled | enabled]
prompt { [avc-count config-sync-status current-folder
        fully-qualified-host host mcp-load-status
        mcp-state multi-line status user user-role] | none }
show-aliases [disabled | enabled]
stat-units [default | exa | gig | kil | meg | peta | raw |
tera | yotta | zetta]
suppress-warnings [ all | config-version | none ]
table-indent-width [integer]
tcl-syntax-highlighting [disabled | enabled]
video [disabled | enabled]
warn [bell | disabled | visual-bell]

```

```

edit preference
options:
  all-properties

```

```

DISPLAY
list preference
list preference [option]
show running-config preference
show running-config preference [option]
options:
  all-properties
  one-line

```

#### DESCRIPTION

You can use the preference component to configure tmsh to meet your specific needs.

#### EXAMPLES

```
modify preference display-threshold 500
```

Configures tmsh to retrieve up to 500 objects before requiring a user response to the question, "Display all items? (y/n)."

```
modify preference history-file-size 80
```

Configures the maximum number of commands that a user can view in the command history list to be 80.

```
modify preference history-size 1000
```

Configures the maximum number of commands that tmsh saves in a user's .tmsh\_history file to be 1000 commands.

```
modify preference suppress-warnings config-version
```

Configures tmsh to suppress warning messages for configuration version related (for backward compatibility of configuration).

#### OPTIONS

##### alias-path

Specifies the search paths for shared aliases. The shared aliases could be in multiple locations, only ones on the search paths can be used. If a folder is deleted from the system it will be automatically remove from the alias-path.

##### app-service

Specifies the name of the application service to which the preference belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the preference. Only the application service can modify or delete the preference.

##### confirm-edit

Specifies whether the command edit prompts for confirmation before saving changes. The default value is enabled.

Note that the value of this option does not affect the behavior of the editor if the changes made in the editor result in a failed update. In this case, tmsh always prompts the user to either re-edit the file or discard the changes. The options are:

##### enabled

tmsh prompts a user to either submit (y), discard (n), or edit (e) the changes made to a component within the editor.

##### disabled

tmsh does not prompt the user, but instead, immediately submits the changes made in the editor.

##### display-threshold

Specifies the maximum number of objects that tmsh displays without requiring a user response to the question, "Display all [number] items? (y/n)." You can specify from 0 (zero) through 4,294,967,265 objects. If you set this option to 0 (zero), tmsh displays an unlimited number of objects without requesting a response.

##### editor

Specifies the editor that the command edit invokes. Users assigned the user role of Administrator can select nano or vi. Users assigned other user roles must use nano.

##### history-date-time

Specifies whether tmsh displays in the command history the date and time that each command was issued. The default value is disabled.

Note that the command history file, ~/.tmsh-history-[user], always contains the date and time that a command was issued.

#### history-file-size

Specifies the maximum number of tmsh commands that the system saves in each user's .tmsh history file. If you set this option to 0 (zero), the system does not save tmsh commands in the file. The maximum value is 100,000. For performance reasons, the system does not truncate the file after a user enters a command. Instead, the system truncates the file after a user exits tmsh.

#### history-size

Specifies the number of commands that a user can view or search in the command history list. The maximum number of commands is 100,000. The default value is 500.

If you set this option to 0 (zero), the system does not add commands to the list of commands in memory; however, the system does write commands to the .tmsh\_history file, unless the history-file-size option is set to 0 (zero).

When you change the value of this option, the system renumbers the commands listed in memory; however, the commands remain in the same order.

#### keymap

Specifies the keyboard bindings that you want tmsh to use. The default value is default. The options are default, emacs, and vi.

#### list-all-properties

Specifies whether the system displays all of the properties of a component by default when you run the command list. The default value is disabled.

#### pager

Specifies whether the system sends the output of the tmsh commands list and show to less. The default value is enabled.

#### prompt

Specifies the information that you want to display in the tmsh prompt. By default the prompt displays user\_name@host\_name(tmos-current\_module)#. The options are:

#### avc-count

Displays the current SELinux Access Vector Cache in the tmsh prompt. The value displayed in the prompt indicates the number of times SELinux has denied access to a protected resource. The default is to not display this information.

#### config-sync-status

Displays global sync status in the tmsh prompt. The status displayed in the prompt indicates the rolled-up sync status of all the device groups where the local device resides. The default is to display this information.

#### current-folder

Displays the current working folder in the tmsh prompt. The default is to not display this information.

#### fully-qualified-host

Displays the fully qualified host name in the tmsh prompt. The default is to not display this information.

host Displays the host name in the tmsh prompt. The default is to display the host name in the prompt.

#### mcp-load-status

Displays the configuration file load status in the tmsh prompt. This information is also available in the Last Configuration Load Status of the show sys mcp command output. The default is to not display this information.

#### mcp-state

Displays the running phase of the mcpd service in the tmsh prompt. This information is also available in the Running Phase of the show sys mcp command output. The default is to not display this information.

#### multi-line

Displays the tmsh prompt on multiple lines, with information on the first line, and a pound sign (#) on the second line, for example:

```
(Common:all) operator1@6400(tmos.cli)
```

```
#
```

The multi-line option is disabled by default.

none Sets the tmsh prompt to display (tmos.current\_module)#, where the system replaces current\_module with the name of the module within which you are working.

#### status

Displays the system status in the tmsh prompt. The default is to display system status in the prompt.

user Displays the user name in the tmsh prompt. The default value is to display the user name in the prompt.

#### user-role

Display the user's current role in the tmsh prompt. By default the user role is not displayed in the prompt.

#### show-aliases

Specifies whether the system displays aliases in the results of the command completion and context-sensitive help features. The

default value is enabled.

**suppress-warnings**  
Specifies the type of warning messages which needs to be suppressed. The default value is none.

**stat-units**  
Specifies the default unit in which the system displays statistics. The options are:

**default**  
Displays data in the simplest units. For example, if the value of the data is 1,200,001, the system displays 1.20M; however, if the value of the data is 1,200, the system displays 1.2K.

**exa** Display data in parts per quintillion.

**gig** Displays data in parts per billion.

**kil** Displays data in parts per thousand.

**meg** Displays data in parts per million.

**peta** Displays data in parts per quadrillion.

**raw** Displays raw data.

**tera** Displays data in parts per trillion.

**yotta**  
Displays data in parts per septillion.

**zetta**  
Displays data in parts per sextillion.

**table-indent-width**  
Specifies the indent width when tmsh displays the child object tables in a show command. You can specify from 0 (zero) through 10. If you set this option to 0 (zero), tmsh displays child object tables without any indent.

**tcl-syntax-highlighting**  
Specifies whether Tcl syntax highlighting will be enabled in the editor. This setting only applies if your editor preference is set to vi. The default value is disabled.

**video**  
Enables or disables any video features used to highlight text. The default value is enabled.

**warn** Specifies how the system warns you when you make an incorrect keystroke. The default value is bell.

The options are:

**bell** Sounds a bell.

**disabled**  
Disables the warning function.

**visual-bell**  
Displays a visual warning.

## cli script

**NAME**  
script - Automates tmsh using Tool Command Language (Tcl).

**MODULE**  
cli

**SYNTAX**  
Configure the script component within the cli module using the syntax shown in the following sections.

```

EDIT
create script [name]
modify script [name]
options:
  app-service [[string] | none]
  description [string]
  ignore-verification [true | false]
  script-checksum [[string] | none]
  script-signature [[string] | none]

edit script [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties

DISPLAY
list script
list script [ [ [name] | [glob] | [regex] ] ... ]
show running-config script
show running-config script [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties

DELETE
delete script [name]

GENERATE
  Note: generate cryptographic signature or checksum based on cli script
  text.

generate cli script [name]
options:
  checksum
  signature

RUN
run script [name] [options ...]
options:
  file [file name] [options ...]
  verbatim-arguments [file option] [file name] [options ...]

```

The options that are available depend on which script you are running.

The file option is limited to users with the role of administrator.

#### DESCRIPTION

You can use the script component to build Tcl scripts to automate management of the BIG-IP(r) system. By combining command aliases with scripts, you can extend tmsh to build commands that are customized to your environment.

To do this, place the content of the script inside one or more Tcl procedures. The content of a script cannot exceed 65,000 bytes. However, a script can include other scripts. For more information about including scripts in other scripts, see `tmsh::include` following.

Starting with BIGIP 11.5.0, tmsh commands are versioned. The tmsh active version should be specified in scripts. This will avoid breaking scripts due to changes in tmsh syntax in the different versions. See examples below for how to use it in a script. Without tmsh active version specified, scripts will run on the current active version. By default, the active version will be the latest cli version.

You can use the following procedures in the manner specified:

`script::run`

tmsh invokes the procedure `script::run` when you issue the command `sequence run / cli script [name]`. A script is run relative to the module in which the run command is invoked.

The `script::run` procedure must be defined in the script named by the run command. Scripts that are included by `tmsh::include` are not required to implement the procedure `script::run`.

`script::help`

Provides context sensitive help. A script is not required to implement `script::help`.

`script::tabc`

Provides context sensitive help. A script is not required to implement `script::tabc`.

`script::init`

tmsh calls the procedure `script::init` before calling one of the following procedures: `script::run`, `script::help`, or `script::tabc`. The `script::init` procedure can use the Tcl variable `tmsh::csh` to determine which one of these three procedures tmsh invokes after `tmsh:init`.

Additionally, you can use the procedure `script::init` to initialize global variables. A script is not required to implement `script::init`.

#### EXAMPLES

```
edit script myscript
```

Creates or modifies the script myscript.

```
edit script myscript yourscrip
```

Creates or modifies the scripts myscript and yourscrip at the same time.

```
list script myscript
```

Displays the contents of the script myscript.

delete script [name]

Deletes the script myscript from the system.

run script myscript [arguments ...]

Runs the script myscript. The system passes arguments to the script in the following Tcl variables:

- o tms::argc contains the number of arguments including the name of the script.

- o tms::argv contains the list of argument values. The first item in tms::argv is always the name of the script.

Tip: You can create an alias for the command sequence run / cli script [name] using the cli alias component. For more information, see help cli alias.

run script verbatim-arguments myscript [arguments ...]

Runs the same commands as run script myscript [arguments...] above, except the system passes all arguments specified in the command as one argument to the script. Note that you do not need to enclose the argument list in double quotes, and you do not need to escape special characters.

generate my\_script checksum

Generate a checksum for the script text and add the checksum as a property.

generate my\_script signature signing-key my\_key

Generate a signature for the script text using the specified private key and add the signature as a property.

Note: For a script which includes a checksum or signature to successfully load, the script text contents must match the stored checksum or signature. To temporarily stop the verification of signature or checksum and still retain the checksum or signature, the ignore-verification attribute must be set to true. This is done by editing the script and adding the ignore-verification attribute.

To completely clear the signature or checksum, simply set the attribute script-signature or script-checksum to empty string "". By doing so, the script will be processed as if it was never signed or checksummed.

```
modify script /Common/my_script { proc script::init {} { }
```

```
proc script::run {} { }
```

```
proc script::help {} { }
```

```
proc script::tabc {} { }
```

```
ignore-verification true
script-checksum 74778e7b13016e0b9329a17f8d2da601
total-signing-status checksum
verification-status checksum-verified }
```

## OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

Generate a checksum for the script text and add the checksum to the script as a property. Only for use with the generate command.

description

A user defined description.

file Specifies that the script to be run should come from a file located on the file system rather than a script from the configuration.

glob Displays the scripts that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the script. This option is required for the edit and delete commands.

regex

Displays the scripts that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

signature

Generate a signature for the script text using the specified private key and add the signature to the script as a property. Only for use with the generate command.

signing-key

The private key to use for signing the script. Only for use with the signature option.

verbatim-arguments

Specifies that the arguments at the end of the command should not be tokenized by tmsh prior to being sent to the script. This is useful when the script is wrapping another utility that takes arguments.

#### CONFIGURATION AND STATUS ACCESSORS

The following Tcl commands mirror tmsh commands. For example, the Tcl `tmsh::create` command accepts the same components, object identifiers, and properties that the tmsh `create` command accepts.

`tmsh::cd [args...]`

Runs the `cd` command using the specified arguments.

`tmsh::cp [args...]`

Runs the `cp` command using the specified arguments.

`tmsh::create [args...]`

Runs the `create` command using the specified arguments.

`tmsh::delete [args...]`

Runs the `delete` command using the specified arguments.

`tmsh::install [args...]`

Runs the `install` command using the specified arguments.

`tmsh::generate [args...]`

Runs the `generate` command using the specified arguments.

`tmsh::list [args...]`

Runs the `list` command using the specified arguments. The system returns the results as a string.

`tmsh::load [args...]`

Runs the `load` command using the specified arguments.

`tmsh::modify [args...]`

Runs the `modify` command using the specified arguments.

`tmsh::publish [args...]`

Runs the `publish` command using the specified arguments.

`tmsh::pwd`

Runs the `pwd` command.

`tmsh::reset-stats [args...]`

Runs the `reset-stats` command using the specified arguments.

`tmsh::restart [args...]`

Runs the `restart` command using the specified arguments.

`tmsh::run [args...]`

Runs the `run` command using the specified arguments.

`tmsh::save [args...]`

Runs the `save` command using the specified arguments.

`tmsh::show [args...]`

Runs the `show` command using the specified arguments. The system returns the results as a string.

`tmsh::start [args...]`

Runs the `start` command using the specified arguments.

`tmsh::stop [args...]`

Runs the `stop` command using the specified arguments.

The following Tcl commands provide structured access for retrieving configuration, statistics, and status information.

`tmsh::get_config [args...]`

Returns a list of Tcl objects. Each of these objects can be passed to the commands that accept an `$obj` argument. The arguments for this command are the same as for the `tmsh list` command.

`tmsh::get_status [component] [args...]`

Returns a list of Tcl objects that can be passed to the following commands that accept an `$obj` argument. The arguments to this command are the same as the `tmsh show` command.

This command can only be used on components that accept the `field-fmt` option. The `field-fmt` option is automatically appended to the argument list. The `tmsh help` pages identify if a component supports the `field-fmt` option.

That there are very few components that have status and statistics that do not support the `field-fmt` option, and in those cases you can use the Tcl `tmsh::show` command to retrieve the object in the form of a Tcl string object.

A component must be specified, for example, `tmsh::get_status ltm pool`.

`tmsh::get_type $obj`

Returns the type identifier associated with the object. The `$obj` argument must be an object that was returned by either of the Tcl `tmsh::get_config` or `tmsh::get_status` commands.

`tmsh::get_name $obj`

Returns the object identifier associated with the object. The `$obj` argument must be an object that was returned by either of the Tcl commands `tmsh::get_config` or `tmsh::get_status`.

`tmsh::get_field_names [value | nested] $obj`

Returns a list of field names (not the value associated with a

field) that are present in an object. The value fields are simple values or lists (for example, an integer or a string). The nested fields are a collection of zero or more nested objects, where the nested objects have their own fields (for example, pool members, and virtual server profiles).

The \$obj argument must be an object that was returned by the Tcl tmsh::get\_config or tmsh::get\_status commands. If the object was retrieved using the Tcl tmsh::get\_config command, the field names are identical to those that are displayed by the tmsh list command. If the object was retrieved using the Tcl tmsh::get\_status command, the fields are identical to those that the system displays using the tmsh show command with the field-fmt option.

```
tmsh::get_field_value $obj [field name] [Tcl variable]
```

Retrieves the value of field name.

The Tcl variable is optional. The behavior of this command depends on whether field name is present in \$obj and a Tcl variable is present in the command.

- o If field name is present in \$obj, and a Tcl variable is present, the Tcl variable is set to the value of field name and the command returns 1.

- o If field name is not present in \$obj, and a Tcl variable is present, the command returns 0 (zero).

- o If field name is present in \$obj, and a Tcl variable is not present, the command returns the field value.

- o If field name is not present in \$obj, and a Tcl variable is not present, the command raises an error that causes the script to stop. You can use the Tcl command catch to recognize the error and continue to run the script.

The \$obj argument must be an object that was returned by the Tcl tmsh::get\_config or tmsh::get\_status commands, or a nested object obtained from the Tcl tmsh::get\_field\_value command.

If the field is a set of nested objects, the Tcl object that the system returns is a list of objects, where each of the objects can contain fields. Each of the objects can be passed to the Tcl tmsh::get\_field\_value command. If the field is not a nested object the system returns a single Tcl string object.

#### TRANSACTION CONTROL

The following Tcl commands are specific to the tmsh Tcl API. There are no corresponding commands available in tmsh.

```
tmsh::begin_transaction
```

Begins an update transaction. The Tcl tmsh::create, tmsh::delete, and tmsh::modify commands that are issued before the next Tcl tmsh::commit\_transaction command are submitted as a single update.

The system rolls back all of the commands if any of the commands fail.

```
tmsh::commit_transaction
```

Runs the commands that have been issued since the last Tcl tmsh::begin\_transaction command. The system validates all of the commands against the running configuration. If any one of the commands fail, the system does not apply any of the commands to the running configuration.

```
tmsh::cancel_transaction
```

Cancels all commands that you have issued since the last Tcl tmsh::begin\_transaction command.

Important: You cannot use these Tcl commands inside an active transaction:

- o tmsh::list
- o tmsh::show
- o tmsh::get\_config
- o tmsh::get\_status

#### LOGGING

You can use the following Tcl commands to generate log events. These commands affect the behavior of the script and do not affect tmsh. These commands are available only to users who have been assigned either the Administrator or Resource Administrator role.

```
tmsh::log_dest [screen | file]
```

Specifies whether the system sends events to the screen or to log files. If file is selected, log messages will be directed to /var/log/ltn.

```
tmsh::log_level [level]
```

Specifies the default severity level. The system does not log events below the specified level. The options, listed in decreasing order of severity, are:

- o emerg
- o alert
- o crit
- o err

- o warning
- o notice
- o info
- o debug

tmsh::log [level] "message..."

Logs the specified message. The level parameter is optional. The level can be one of those described in the Tcl tmsh::log\_level command.

#### CUSTOM ISTATS

Custom counter, gauge, and string fields may be created, modified, and retrieved using iRules or tmsh scripts. These custom fields are created on first write and do not need to be declared separately.

Each custom field has a "key" that can be associated with a tmsh configuration object. This key is composed of a tmsh component dotted path, a specific object name or ID, the field type, and the field name. The entire key must be enclosed in quotes.

For example, "ltm.pool /Common/my\_pool counter num\_hits" refers to the num\_hits counter associated with the LTM pool named my\_pool, located in the Common folder.

These custom fields are displayed with the tmsh show command on the associated object.

istats::incr [key] [amount]

Increments a custom counter by amount.

istats::set [key] [value]

Sets a custom gauge or string to value. Setting a counter to an exact value will only set it in the local segment, but istats::get will always read the aggregated (not local) value.

istats::get [key]

Returns the latest aggregated value of the custom field or 0 (zero) if it does not exist (" for string fields).

istats::remove [key]

Removes the custom field from all segments on all blades. Effectively resets a counter to 0.

#### UTILITIES

The following commands are TCL utility commands.

tmsh::clear\_screen

Clears the screen and places the cursor at the upper left of the screen.

tmsh::display [variable | command output]

Provides access to the tmsh pager. Output generated with the Tcl puts command is not paged.

tmsh::display\_threshold [integer]

When a script is run, the system disables the option cli preference display-threshold.

You can use the Tcl tmsh::display\_threshold command to re-enable the threshold. Re-enabling the threshold in this way causes the script to generate a prompt if you issue the tmsh::list, tmsh::show, tmsh::get\_config, or tmsh::get\_status commands, and the output that is generated exceeds the threshold. See help cli preference for a description of this option and valid ranges for its value.

tmsh::expand\_macro [macro\_text] options...

Expands a macro and returns the resulting string. A macro is a string containing macro syntax which can be used for parameter substitution, script and iRule templatization, etc. The Macro Syntax includes the following delimiters:

<% The beginning of an expansion code block.

<%= The beginning of an expansion code block. Spool the output after evaluating.

<%D[0-9][0-9] The beginning of a debug/logging code block with the debug threshold set to 0 thru 99.

<%D[0-9][0-9]= The beginning of a debug/logging code block with the debug threshold set to 0 thru 99. Spool the output after evaluating.

%> The end of the current block (works for all types).

Typically, the result of the expand\_macro command is used as the input to another command (eg. ltm rule create). The command can be called multiple times within an iApp implementation to expand multiple macros.

macro\_text is the blob of text to expand. If not specified, the command will expand the Macro section of the iApp. If no macro\_text argument is specified and no Macro section exists for the iApp, an error will be issued.

-vars name\_value\_pair\_list

Specifies a list of additional variables (name/value pairs) which

can be referenced within the macro and expanded by the command. All APL variables are automatically available from within the macro, so the -vars option allows a way to specify additional variables from the iApp Implementation section. Since the variables are defined within a Tcl list the format is: { name1 value1 name2 ... nameN valueN }

-debug debug\_levels

Specifies a single debug level or list of debug levels for controlling which debug messages get rendered in the expanded output.

-debuginclusive debug\_level

Specifies a debug level for controlling which debug messages get rendered in the expanded output. Since it's "inclusive" all messages with a level at the specified level and below will get rendered in the expanded output.

The following example expands the macro defined in the Macro section of the iApp, and sets the debug level to render all debug messages with a level of 11, 33 or 66:

```
tmsh::expand_macro -debug {11 33 66}
```

The following example expands the macro defined via a Tcl variable (mac), adds two variables (foo and enable\_mything), and sets the debug level to render all messages of level 66 and below:

```
tmsh::expand_macro $mac -vars {foo bar enable_mything true}
-debuginclusive 66
```

```
tmsh::get_ifile_text [iFile name]
```

Retrieve the text contained in the specified text iFile. When used on an iFile containing characters which are non-ascii or are not printable/space, an error will be returned.

```
tmsh::include [script name]
```

Runs the Tcl eval command on the specified script. The system evaluates the script at a global level, and all procedures in the included script are available to any other procedure. You must have previously created the script that is being included using the tmsh edit / cli script [name] command. If a full path is not given for the script name, tmsh will attempt to first locate the script from the same folder as the including script, then the root partition folder of the including script, and finally the /Common folder.

```
tmsh::run_proc [script_name:proc_name] options...
```

Runs the Tcl eval command on the specified script and process. The script script\_name is loaded as if tmsh::include was called. After the script is loaded, the Tcl eval command is run on the specified Tcl process. Any options that were specified are passed to the Tcl process. This is essentially a short form of running tmsh::include script\_name, followed by running one of the Tcl processes contained in the script that was included.

The following example invokes the display\_pool\_status proc that is contained in the pool\_utils script:

```
tmsh::run_proc pool_utils:display_pool_status
```

```
tmsh::stateless [disabled | enabled]
```

Modifies the behavior of tmsh::create and tmsh::delete.

When stateless mode is disabled, an attempt to create an object that already exists in the configuration results in an error, and an attempt to delete an object that does not exist in the configuration is an error.

When stateless mode is enabled, an attempt to create an object that already exists in the configuration does not result in an error, and an attempt to delete an object that does not exist in the configuration does not result in an error.

Enabling stateless mode enables scripts to successfully run multiple times with the same input.

The default value is disabled.

```
tmsh::version
```

Returns the version number of the BIG-IP system as a Tcl string. The version consists of three digits: a major, minor, and maintenance version, separated by periods. For example, 10.1.0 indicates minor version 1 of major version 10.

#### CONTEXT SENSITIVE HELP

Use the following commands to create a script that provides context sensitive help when a user types Tab or question mark (?).

```
script::help
```

Scripts can provide the script::help procedure. tmsh invokes the procedure when a user types a question mark (?) while entering the command sequence run / cli script [name]. If the specified script includes the script::init procedure, tmsh invokes it before the script::help procedure. The script can add context sensitive help by calling the tmsh::add\_help and tmsh::builtin\_help procedures. tmsh formats the help and displays it.

```
script::tabc
```

Scripts can provide the script::tabc procedure. The system invokes this procedure when the user types Tab while entering the command sequence run / cli script. If the script::init procedure is

included in the script, that procedure is invoked before the script::tabc procedure. The script can add tab completion datasets to the script by calling the tmsh::add tabc and tmsh::builtin\_tabc procedures. tmsh either formats and displays the tab completion datasets, or if possible, completes the current argument.

tmsh::csh

tmsh::csh is a Tcl string variable that can be used in the script::init procedure to determine the context in which the script::init procedure was invoked.

tmsh::csh is set to one of the following:

question mark (?)

Indicates that the user typed a question mark (?).

TABC Indicates the user pressed the Tab key.

an empty string ""

Indicates the script is being run.

tmsh::add\_help [ [category item description] | [description] ]

Displays context sensitive help when the user types a question mark (?). If you supply one argument, that argument displays as-is with no formatting applied to the description.

If you supply three arguments, one or more datasets are constructed. The first argument is the name of the dataset. The second argument is an item in the dataset. The third argument is a description of the item. This command has an effect only if the Tcl tmsh::csh variable is set to question mark (?).

tmsh::builtin\_help ["tmsh command" args...]

Presents the same results as typing a question mark (?) while entering a tmsh command. The system stores a set of possible completions and displays the possibilities when the script::help procedure returns. This command has an effect only if the Tcl tmsh::csh variable is set to question mark (?).

tmsh::add\_tabc [ [category item] | [item] ]

Adds tab completion datasets. If you supply one argument, the system adds that argument to an anonymous dataset. If you supply two arguments, the system constructs one or more datasets. The first argument is the name of the dataset. The second argument is an item in the dataset. Potential completions are displayed in groups based on category. This command has an effect only if the Tcl \$tmsh::csh variable is set to TABC.

tmsh::builtin\_tabc ["tmsh command" args...]

Many of the tmsh commands that are available for scripting are also available in the interactive shell. A script can use the tmsh::builtin\_tabc command to present the same tab completion results as a built-in command. The command does not return a value. The set of possible completions are stored internally and displayed when the script::tabc procedure returns. This command has an effect only if the Tcl \$tmsh::csh variable is set to TABC.

### THIRD PARTY TCL LIBRARY USAGE

A selection of third party libraries have been tested to work within the CLI script environment, including MD5, BASE64, SHA1/SHA256, HTTP, TLS, TCL Perl, LDAP client, and XML parser. The TCL packages can only reside in the directory of /usr/share/compat-tcl8.4.

Important: Only these tested packages are supported currently.

This example demonstrates the use of a Tcl package command to make use of tls/https. The TLS package is installed in the directory /usr/share/compat-tcl8.4/tls in the form of two files: tls.tcl and libtls1.6.1.so.

Modify script /Common/use\_tls {

```
proc script::run {} {
    set pkg_name tls
    set pkg_version 1.6
    package require http
    if {[catch {package require $pkg_name $pkg_version}]} {
        puts "No package found: $pkg_name!\n"
    } else {
        puts "Found package: $pkg_name!\n"
        http::register https 443 tls::socket
        set token [http::geturl https://172.27.42.161/]
        upvar #0 $token state
        puts $state(http)
        puts $state(body)
    }
}
```

This example uses the callback function to handle http data.

```
cli script /Common/use_http2 {
proc script::httpCallback {token} {
    upvar #0 $token state
    puts $state(http)
    puts $state(body)
    incr ::got_something
}
proc script::run {} {
    namespace eval :: {
        set got_something 0
    }
    set pkg_name http
    set pkg_version 2.4.5
```

```

    if {[catch {package require $pkg_name $pkg_version}]} {
puts "No package found: $pkg_name!\n"
    } else {
puts "Found package: $pkg_name!\n"
http::geturl http://172.27.42.22/index.htm -command script::httpCallback
vwait ::got_something
    }
}
}

```

This example uses the LDAP client package to query data.

```

cli script /Common/use_ldap {
proc script::run {} {
    set pkg_name ldap
    if {[catch {package require $pkg_name 1.8}]} {
puts "No package found: $pkg_name!\n"
    } else {
puts "Found package: $pkg_name!\n"
set handle [ldap::connect 172.27.1.2]
ldap::bind $handle
set results [ldap::search $handle "dc=f5,dc=com" "(uid=test)" {}]
foreach result $results {
    puts $result
}
ldap::unbind $handle
ldap::disconnect $handle
    }
}
}

```

Here are some additional examples:

```

cli script /Common/use_parray {
proc script::run {} {
puts [info patch]
namespace eval :: {
    set pkg_location /usr/share/compat-tcl8.4/
    source [file join $pkg_location package.tcl]
}
puts "NS: [namespace current]"
set pkg_location :::pkg_location
source [file join $pkg_location parray.tcl]
parray ::tcl_platform
}
}

```

```

cli script /Common/use_sha2 {
proc script::run {} {
    set pkg_name sha256
    if {[catch {package require $pkg_name}]} {
puts "No package found: $pkg_name!\n"
    } else {
puts "Found package: $pkg_name!\n"
puts "TCL does SHA2 now:"
puts [sha2::sha256 "TCL does SHA2"]
    }
}
}

```

```

cli script /Common/use_tclperl {
proc script::run {} {
    set pkg_name tclperl
    if {[catch {package require $pkg_name}]} {
puts "No package found: $pkg_name!\n"
    } else {
puts "Found package: $pkg_name!\n"
set interpreter [perl::interp new]
$interpreter eval {print "Hello World\n"}
perl::interp delete $interpreter
    }
}
}

```

#### SPECIAL CHARACTERS

There are several characters that are part of both Tcl and tmsh syntax. You must escape these characters in a shell script so that Tcl passes them to tmsh. You can use standard Tcl escape characters, such as quotes and back slashes. You must escape curly braces ({ }), for example, "{ " }".

```
tmsh::create ltm pool my_pool members add "{ 10.1.2.3:80 }"
```

Creates a Local Traffic Manager pool named my\_pool.

#### DISABLED COMMANDS

The following commands are disabled for users that have not been assigned a user role of Administrator or Resource Administrator:

- o auto\_execok
- o auto\_import
- o auto\_load
- o auto\_mkindex
- o auto\_mkindex\_old
- o auto\_qualify
- o auto\_reset
- o bgerror

- o cd
- o close
- o eof
- o exec
- o fblocked
- o fconfigure
- o fcopy
- o file
- o fileevent
- o filename
- o flush
- o glob
- o http
- o interp
- o load
- o memory
- o open
- o package
- o pid
- o pkg:create
- o pkg\_mkindex
- o pwd
- o seek
- o socket
- o source
- o tcl\_findLibrary
- o tell
- o unknown
- o updates
- o vwait

#### EXAMPLES

The following example demonstrates the use of all tmsh Tcl commands. The script displays all configuration property values or all status and statistic values for the specified component, depending on the specified arguments. The system displays all configuration settings if you replace [tmsh::get\_config \$comp all-properties] with [tmsh::get\_config / all-properties]. The use of the all-properties option ensures that all options are displayed.

This command sequence is an example of how to run the following script:  
run / cli script example.tcl config ltm pool.

```
cli script example.tcl {

    proc script::init { } {
set ::field_fmt "%-25s %s"
set ::usage_string "usage: [lindex $tmsh::argv 0] \
"
    }

    proc script::help { } {
if { $tmsh::argc < 2 } {
    tmsh::add_help Options: config "Display configuration"
    tmsh::add_help Options: status \
        "Display status and statistics"
}
else {
    build_csh tmsh::builtin_help
}
    }

    proc script::tabc { } {
if { $tmsh::argc < 2 } {
    tmsh::add_tabc config
    tmsh::add_tabc status
}
else {
    build_csh tmsh::builtin_tabc
}
    }

    proc script::run { } {
if { $tmsh::argc < 3 } {
    usage
}
```

```

}
set opt [lindex $tmsh::argv 1]
if { $opt != "config" && $opt != "status" } {
    usage
}
set comp ""
for {set idx 2} {$idx < $tmsh::argc} {incr idx} {
    append comp "[lindex $tmsh::argv $idx] "
}

if { $opt == "config" } {
    set objs [tmsh::get_config $comp all-properties]
}
else {
    set objs [tmsh::get_status $comp]
}

set idx 0
set total [llength $objs]

while { $idx < $total } {
    set obj [lindex $objs $idx]
    print_object obj
    puts ""
    incr idx;
}

proc print_fields { objVar } {
    upvar $objVar obj
    set fdx 0
    set fields [tmsh::get_field_names value $obj]
    set field_count [llength $fields]
    while { $fdx < $field_count } {
        set field [lindex $fields $fdx]
        puts [format $::field_fmt $field \
            [tmsh::get_field_value $obj $field]]
        incr fdx
    }
}

proc print_object { objVar } {
    upvar $objVar obj
    puts "[tmsh::get_type $obj] [tmsh::get_name $obj]"

        }
        if { $n_count == 0 } {
            puts [format $::field_fmt $field "none"]
        }
        incr fdx
    }
}

proc build_csh { command } {
    # generate context sensitive help, tab completion or "?"
    set args ""
    for {set idx 2} {$idx < $tmsh::argc} {incr idx} {
        lappend args [lindex $tmsh::argv $idx]
    }
    set opt [lindex $tmsh::argv 1]
    if { $opt == "config" } {
        $command list $args
    }
    elseif { $opt == "status" } {
        $command show $args
    }
    else {
        puts "\nunexpected argument: $opt"
    }
    return $args
}

proc usage { } {
    puts $::usage_string
    exit
}
}

```

#### EXAMPLES

The following example demonstrates the scripts using 11.6.0 tmsh syntax.

```

cli script example_ver.tcl {
    ...
    proc script::run {} {
        tmsh::modify cli version active 11.6.0
        # the tmsh command in the section below should contain 11.6.0 tmsh syntax
        puts stdout [tmsh::list ltm pool mypool]
    }
}

```

```

    ...
}
}

The following example demonstrates the scripts that are using multiple
tmsh syntaxes.

cli script example_multi_ver.tcl {
....
proc script::run {} {
    tmsh::modify cli version active 11.5.0
    # the tmsh command in the section below should contain 11.5.0 tmsh syntax
    puts stdout [tmsh::list ltm pool mypool]
    ...

    tmsh::modify cli version active 11.6.0
    # the tmsh command in the section below should contain 11.6.0 tmsh syntax
    puts stdout [tmsh::list ltm pool mypool]
    ...
}
}

```

## cli transaction

#### NAME

transaction - Opens batch mode within which you can submit a set of commands as a single transaction.

#### MODULE

cli

#### SYNTAX

Use the transaction component within the cli module to open batch mode, enter a series of commands, and then submit the commands as a single transaction.

##### CREATE/MODIFY

create transaction

modify transaction

options:

delete [entry\_id]

submit transaction [validate-only]

##### DISPLAY

list transaction

##### DELETE

delete transaction

#### DESCRIPTION

tmsh parses each command that you enter in batch mode. If the command passes a syntax check, tmsh saves it as part of the transaction you are creating and returns a confirmation. After you finish adding commands, you submit the transaction to change the running configuration of the system. You must run the save config command to save the changes to the stored configuration files.

If, while creating a transaction, you decide you do not want to change the running configuration, you can delete the transaction rather than submit it. However, you can recreate a transaction that you have deleted by using the cli history component.

There are a few commands that you can enter on the command line that the system immediately runs, rather than adding the commands to a transaction. These commands are list and show. Additionally, tmsh immediately runs the command sequence run bigpipe, but does not add it to the transaction.

## EXAMPLES

The following example shows the commands that you enter from within the ltm module to create and submit a transaction that creates a Local Traffic Manager pool and virtual server, and then associates the two.

1. Open tmsh batch mode:  
create /cli transaction
2. Add a command to the transaction that creates pool1 for the Local Traffic Manager using the default values for a pool:  
create pool pool1
3. Add a command to the transaction that creates the virtual server virtual1 for the Local Traffic Manager using the default values for a virtual server, and associates it with pool1.  
create virtual virtual1 pool pool1
4. Display, in a numbered list, the current set of commands in the transaction:  
list /cli transaction

Note: You can use the preceding command to determine the entry ID of a command. Then, you can use this ID to remove or replace a command in the transaction, or to identify a command before which you want to insert another command.

5. Submit the transaction:  
submit /cli transaction

## OPTIONS

### command

Specifies, in quotation marks, the full path to a command to add to or delete from the transaction that you are creating. You can also replace an existing command with another command or insert a command before a command in the transaction.

### create

Opens batch mode.

### delete

Deletes the transaction that you are creating and closes batch mode.

list Displays, in a numbered list, the current set of commands in the transaction that you are creating.

### modify

Specifies a previously entered line in the transaction that you want to change. The options are:

### delete

Deletes the specified entries from the transaction that you are creating.

### entry\_id

Specifies the number of a command in the list of commands in the transaction that you want to delete.

### submit [validate-only]

Submits the transaction that you are entering and closes batch mode. The transaction is submitted in the context of the cli admin-partitions settings that are active when the submit command is issued.

### validate-only

Validates the configuration changes without putting them in production.

## SEE ALSO

cli admin-partitions, create, delete, list, modify, submit, tmsh

## cli version

### NAME

version - Displays and Configures tmsh versions.

### MODULE

cli

**SYNTAX**

Configure the version component within the cli module using the syntax shown in the following sections.

**MODIFY**

```
modify version [option]
options:
  active [string ]
```

**DISPLAY**

```
show version
```

**DESCRIPTION**

You can use the version component to configure tmsh to run the specified version.

**EXAMPLES**

```
modify cli version active 11.5.0
```

Configures tmsh run 11.5.0 version.

```
show cli version
```

Displays the latest, active and supported versions of TMSH.

**OPTIONS**

**active**  
Specifies the active version of TMSH.

**latest**  
Displays TMSH the latest version. This is used as the default version.

**supported**  
Displays the current supported TMSH versions on the system.

**imported**  
Displays the imported TMSH versions on the system. An imported TMSH version will be imported from a UCS created from TMSH version which is not supported in the current system - a very rare case. Be aware, for an imported TMSH version, only syntax is supported, if it requires other handling other than syntax change, it will not supported. So, for an imported TMSH version, it is not fully supported. By default, this entry will not be displayed unless preference is set.

**SEE ALSO**

```
show, modify, sys ucs, tmsh
```

## cm

### cm add-to-trust

**NAME**

add-to-trust - Add a device to a trust domain.

**MODULE**

cm

**SYNTAX**

Run the add-to-trust program within the cm module using the syntax in the following section. The trust-domain name 'Root' is optional beginning version 13.0.0.

**MODIFY**

```
run add-to-trust [Root]
options:
  [ ca-device | non-ca-device ]
  device [string]
  port [ port_number ]
  device-name [string]
  password [string]
  username [string]
```

**DESCRIPTION**

You can use the add-to-trust command to add a device to a trust domain. This is an alternate helper command to the modify trust-domain ca-devices|non-ca-devices add ... command.

## EXAMPLES

```
run add-to-trust ca-device device 10.20.30.40 device-name peer1
username homer password illiad
```

Adds a device to the list of ca-devices in the trust domain.

## OPTIONS

### ca-device

Indicates that the added device is a certificate authority device.

### device

Indicates the FQDN or the management-ip of the device being added to the trust domain

port Device port number if other than 443 when adding new device. This parameter is optional.

### device-name

Used to specify the name of a new device.

### md5-fingerprint

SSL certificate md5 fingerprint is deprecated beginning version 13.0.0. Use sha1-fingerprint.

### non-ca-device

Indicates that the added device is a subordinate device. The target device cannot be used as a signing authority.

### password

Specifies the password for a new device.

### serial

SSL certificate serial number is deprecated beginning version 13.0.0. Use sha1-fingerprint.

### sha1-fingerprint

Specifies the SSL certificate (DER format) sha1 fingerprint when verifying the identity of a new device. This field is optional.

### signature

SSL certificate signature is deprecated beginning version 13.0.0. Use sha1-fingerprint.

### username

Specifies the user name required to log on to a device when adding the device to the trust domain. The user "root" is invalid, and will be disallowed. Any user that has administrator privileges and can use iControl can be used here.

## SEE ALSO

run, tmsh

## cm cert

### NAME

cert - Manages a CM trust certificate file.

### MODULE

cm

### SYNTAX

Display the cert component within the cm module using the syntax shown in the following sections.

#### DISPLAY

```
list cert
list cert [ [ [name] | [glob] | [regex] ] ... ]
show running-config cert
show running-config cert [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  certificate-key-size
  checksum
  create-time
  created-by
  email
  expiration-date
  expiration-string
  fingerprint
```

is-bundle  
issuer  
key-type  
last-update-time  
mode  
non-default-properties  
one-line  
partition  
recursive  
revision  
serial-number  
size  
source-path  
subject  
subject-alternative-name  
system-path  
updated-by  
version

#### DESCRIPTION

You can use the cert component to display CM trust certificates.

#### OPTIONS

**app-service**  
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

**certificate-key-size**  
Displays the number of bits in the key associated with this certificate.

**checksum**  
Displays a cryptographic hash or checksum of the file contents for use in verification of file integrity.

**create-time**  
Displays the time at which the trust certificate was created.

**created-by**  
Displays the name of the person, who originally created the trust certificate.

**email**  
Displays the email of the person, who originally created the trust certificate.

**expiration-date**  
Displays the date at which the trust certificate expires. The date is stored as a POSIX time.

**expiration-string**  
Displays a string representation of the trust certificate expiration date.

**fingerprint**  
Specifies the cryptographic fingerprint of the trust certificate.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**is-bundle**  
Indicates whether the trust certificate file is a bundle (that is, whether it contains more than one certificate).

**issuer**  
Displays the X.509 information for the issuer of the trust certificate. If the trust certificate is a bundle, then this displays the issuer information for the primary (first) trust certificate in the bundle.

**key-type**  
Displays the type of cryptographic key associated with this trust certificate.

**last-update-time**  
Displays the last time the trust certificate was modified.

**mode** Displays the UNIX(r) file permissions mode for the file associated with this trust certificate as a numerical value.

**partition**  
Displays the partition within which the trust certificate file resides.

**recursive**  
Displays all objects of the specified type and the folder that contains the object.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**revision**  
Displays the number of the latest revision of the trust certificate. The revision starts with 1 and increments on each update.

**serial-number**  
Displays the serial number of the trust certificate.

size Displays the size (in bytes) of the file associated with the trust certificate.

source-path [URL]  
Displays the path to the source of the trust certificate as a URL, for example:

source-path http://cert-server/cert\_store/certs/vs\_132.key

source-path https://cert-server/cert\_store/certs/vs\_132.key

source-path  
ftp://username:password@server/cert\_store/certs/vs\_132.key

subject  
Displays X.509 information about the subject of the trust certificate. If the certificate is a bundle, then the subject information for the primary (first) trust certificate in the bundle displays.

subject-alternative-name  
Displays a standard X.509 extension as shown in RFC 2459.

system-path  
Displays the path to the trust certificate.

updated-by  
Displays the name of the person, who last updated the trust certificate.

version  
Displays the X.509 version of the trust certificate.

SEE ALSO  
glob, list, regex, tmsh

---

## cm config-sync

NAME  
config-sync - Manually synchronizes the configuration between devices.

MODULE  
cm

SYNTAX  
Run the config-sync program within the cm module using the syntax in the following section.

MODIFY  
run config-sync  
options:  
from-group  
recover-sync  
to-group  
force-full-load-push

DESCRIPTION  
This command starts a configuration synchronization job. One of the from-group, to-group, or recover-sync options must be used to specify the direction of the synchronization.

EXAMPLES  
run config-sync from-group my\_dg

Updates the configuration on the local device with the configuration from the remote device in the device group /Common/my\_dg with the newest configuration. If the local device already has the newest configuration, then the configuration synchronization does nothing.

run config-sync to-group my\_dg

Updates the configurations on the remote devices in the device group /Common/my\_dg with the configuration on the local device. If the local device does not have the newest configuration, then the configuration synchronization does nothing.

run config-sync recover-sync

Resets the local device configuration and restores the trust domain,

device, and device-group information to default settings.

#### OPTIONS

##### from-group

Updates the configuration of the local device with the configuration of the remote device in the specified device group that has the newest configuration. If the local device already has the newest configuration, then the configuration synchronization does nothing. This option is mutually exclusive of the to-group and recover-sync options.

##### recover-sync

WARNING: If you have any local-only configuration, do not use this option.

This option will delete all configuration except for that which is necessary to remain in your device groups. At this point, you can sync from those groups to this device in order to restore your configuration.

Resets the local device configuration and restores the trust domain, device, and device-group information to default settings. After this recovery, you can sync the local device with its peers by running config-sync on a peer device and specifying the device group in which the local device is a member. This option is mutually exclusive of the from-group and to-group options.

##### to-group

Updates the configurations of the remote devices in the specified device group with the configuration of the local device. If the local device does not have the newest configuration, then the configuration synchronization does nothing. This option is mutually exclusive of the from-group and recover-sync options.

##### force-full-load-push

This option may only be used if to-group has also been specified. It forces all other devices to pull all synchronizable configuration from this device, even if those devices have the same or newer configuration. It will always send the entire configuration, rather than just the changes, regardless of the device group's full-load-on-sync setting.

You may lose configuration by using this option. This happens if you force a push even when another device in the device group has newer configuration.

#### SEE ALSO

run, tmsh

## cm device-group

#### NAME

device-group - Configures device groups. The device groups that are created and maintained by the system cannot be modified by the user.

#### MODULE

cm

#### SYNTAX

Modify the device-group component within the cm module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create device-group [name]
modify device-group [name]
options:
  app-service [[string] | none]
  asm-sync [ enabled | disabled ]
  auto-sync [ enabled | disabled ]
  description [string]
  devices [add | delete | modify | replace-all-with] {
    [ device_name ]
  }
  full-load-on-sync [true | false]
  incremental-config-sync-size-max [integer]
  network-failover [ enabled | disabled ]
  save-on-auto-sync [true | false]
  type [ sync-only | sync-failover ]
  clear-incremental-config-sync-cache
```

```

edit device-group [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list device-group
list device-group [ [ [name] | [glob] | [regex] ] ... ]
show running-config device-group
show running-config device-group [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    app-service
    non-default-properties
    partition
    recursive

show device-group
show device-group [name]
options:
    field-fmt

DELETE
delete device-group [name]

```

Note: The device group must be empty, and you must remove all references to the device group, before you can delete the device group.

#### DESCRIPTION

You can use the device-group component to manage sets of devices used for configuration synchronization and failover.

#### EXAMPLES

```

create device-group my_device_group devices add {
/Common/device1
/Common/device2
}

```

Creates a sync-only device group named my\_device\_group with two devices, device1 and device2.

```
delete device-group my_device_group
```

Deletes the device group named my\_device\_group.

```
list device-group my_device_group
```

Displays properties of the device group named my\_device\_group.

```
modify device-group my_device_group clear-incremental-config-sync-cache
```

Warning: Do not use this option without assistance from the F5 Technical Support team.

Clears the incremental configuration synchronization cache. The next configuration synchronization for my\_device\_group that pulls configuration from this device will be a full load.

#### OPTIONS

##### app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

##### asm-sync

Specifies whether to synchronize ASM configurations of device group members. The default value is disabled. A device can be a member of only one ASM-enabled device group.

##### auto-sync

Specifies whether the device group automatically synchronizes configuration data to its members. The default value is disabled. Configuration will be saved on remote devices after receiving configuration updates if save-on-auto-sync is enabled.

##### clear-incremental-config-sync-cache

Warning: Do not use this option without assistance from the F5 Technical Support team.

The incremental configuration synchronization mechanism keeps a cache of transactions in each device group. Specifying this option will remove all transactions from the cache for the given device groups. This will not remove configuration from the device group, but will cause the next load in that group from the current device to be a full load.

##### description

Specifies a user-defined description of the device group.

##### devices

Adds, deletes, or replaces a set of devices to a device group by specifying the device name(s). When the local device is removed from a device group then all of the sys folders that are associated with the device group are reset to have no device group and the name of each folder that was updated is logged to /var/log/ltm.

##### full-load-on-sync

Specifies that the entire configuration for a device group is sent when configuration synchronization is performed. The default value is false.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

incremental-config-sync-size-max  
Specifies the maximum size (in KB) to devote to incremental config sync cached transactions. The default is 1024 KB. Valid range is between 128 and 10240."

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

network-failover  
When the device group type is failover, specifies whether network failover is used.

partition  
Displays the administrative partition within which the device group resides.

recursive  
Displays all objects of the specified type and the folder that contains the object.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

save-on-auto-sync  
Specifies whether to save the configuration on the remote devices following an automatic configuration synchronization. A device group configured for manual synchronization will always save on the remote devices regardless of this setting.

type Specifies the type of device group. You can use this option only when you create a device group. You cannot modify the type of a device group. The default value is sync-only.

DESCRIPTION
  You can use the device component to manage devices.

  Warning: To add or remove devices on the BIG-IP system, modify the Root
  trust domain. For more information, see help trust-domain.

OPTIONS
  active-modules
  Displays the licensed modules that are currently active on the
  device.

  app-service
  Displays the application service to which the object belongs. The
  default value is none. Note: If the strict-updates option is
  enabled on the Application Service that owns the object, you
  cannot modify the object. Only the Application Service can modify
  the object.

  base-mac
  Displays the base MAC address for the device.

  build
  Displays the software build number.

  cert
  Displays the identity certificate used for device trust.

  chassis-id
  Displays the chassis identifier.

  chassis-type
  Displays the chassis type. The possible values are individual and
  viprion.

  comment
  Specifies user comments about the device.

  configsync-ip
  Specifies the IP address used for configuration synchronization.
  If you specify a self IP address, the self IP address object must
  be located in the Common folder.

  contact
  Specifies administrator contact information.

  description
  Specifies a user-defined description of the device.

  edition
  Displays the software edition.

  failover-state
  Displays the device failover state.

  glob
  Displays the items that match the glob expression. See help glob
  for a description of glob expression syntax.

  ha-capacity

```

Specifies a number that represents the relative capacity of the device to be active for a number of traffic groups. This value along with the traffic group's ha-load-factor is used by the failover daemon to make traffic groups active amongst the available devices. The value is zero by default which means the device may run any number of traffic groups. The value must be within a valid range: 0 - 100000 inclusive.

hostname

Displays the hostname of the device.

inactive-modules

Displays the licensed modules that are currently inactive on the device.

key Displays the identity key used for device trust.

location

Specifies the physical location of the device.

marketing-name

Displays the marketing name of the device platform.

mgmt-unicast-mode

When a management-ip is added as a failover unicast address; this attribute allows to specify using only an specific family instead of the default both.

mirror-ip

Specifies the IP address used for state mirroring. If you specify a self IP address, the self IP address object must be located in the Common folder.

mirror-secondary-ip

Specifies the secondary IP address used for state mirroring. If you specify a self IP address, the self IP address object must be located in the Common folder.

multicast-interface

Specifies the interface name used for the failover multicast IP address.

multicast-ip

Specifies the multicast IP address used for failover.

multicast-port

Specifies the multicast port used for failover.

optional-modules

Displays the modules that are available for the current platform, but are not currently licensed.

platform-id

Displays the device platform identifier.

product

Displays the software product name.

recursive

Displays all objects of the specified type and the folder that contains the object.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

self-device

Displays true, when the device is the self device.

time-limited-modules

Displays the licensed modules that are time-limited.

time-zone

Displays the time zone configured on the device.

unicast-address

If present, specifies the entire set of unicast addresses used for failover, and replaces all previous unicast addresses. The keyword none may be used to remove all unicast addresses.

Multiple unicast addresses may be specified, each of which has an ip, port, effective-ip, and effective-port.

Each unicast-address when specified has the following parameters:

ip The IP address that the failover daemon will listen on for packets from its peers. This address must be a non-floating self-IP or a management address.

The keyword management-ip may be used to specify that the current addresses of the device management interface are used. The mgmt-unicast-mode will narrow down the selection based on the address family.

port The IP port that the failover daemon uses to accept packets from its peers. If not specified, 1026 will be used.

effective-ip

The IP address that peers can use to reach this unicast address IP. This option is only needed if a address-translating firewall exists between the peer BIG-IPs. If not present, the effective-ip is the same as the ip.

effective-port  
The port that peers can use to reach this unicast address.  
This option is only needed if a port-translating firewall exists between the peer BIG-IPs. If not present, the effective-port is the same as the port.

version  
Displays the software version number.

## cm failover-status

NAME  
failover-status - Display the failover status of the local device.

MODULE  
cm

SYNTAX  
Display failover-status component within the cm module using the syntax in the following section.

DISPLAY  
show failover-status  
options:  
field-fmt

DESCRIPTION  
You can use the failover-status component to display the failover status of the local device.  
  
For information about the options that you can use with the command show, see help show.

EXAMPLE  
show failover-status  
  
Displays the failover status of the local device.

SEE ALSO  
show, tmsh

COPYRIGHT  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## cm key

NAME  
key - Manages a CM trust certificate private key file.

MODULE  
cm

SYNTAX

Display or delete a key component within the cm module using the syntax shown in the following sections.

```
DISPLAY
list key
list key [ [ [name] | [glob] | [regex] ] ... ]
show running-config key
show running-config key [ [ [name] | [glob] | [regex] ] ... ]
options:
all-properties
app-service
checksum
create-time
created-by
key-size
key-type
last-update-time
mode
non-default-properties
one-line
partition
recursive
revision
security-type
size
source-path
system-path
updated-by
```

```
DELETE
delete key [name]
```

#### DESCRIPTION

You can use the following options with the key component.

#### OPTIONS

**app-service**  
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

**checksum**  
Displays a cryptographic hash or checksum of the key for use in verification of key integrity.

**create-time**  
Displays the time at which the key was created.

**created-by**  
Displays the user who originally created the key.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**key-size**  
Displays the size of the cryptographic key, in bits.

**key-type**  
Displays the cryptographic algorithm that this key is compatible with. A key can be one of two types:

**rsa-private**  
The key is an RSA private key.

**dsa-private**  
The key is a DSA based private key.

**last-update-time**  
Displays the time at which the key was last modified.

**mode** Displays the UNIX file permissions mode for the file associated with this key. The mode is expressed in numerical form.

**name** Specifies the name of the key you want to delete.

**partition**  
Displays the partition within which the key resides.

**recursive**  
Displays all objects of the specified type and the folder that contains the object.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**revision**  
Displays the latest revision of the key. The revision starts with 1 increments on each update.

**security-type**  
Displays the type of security used to handle or store the key. There are four mutually exclusive options:

**normal**  
Indicate the key resides in a standard form on the file-system. This is the default security type.

**fips** Indicates that the key is protected by a FIPS device on the system, and is only applicable to devices with FIPS support.

password  
Indicates that the key is protected by a passphrase and stored in encrypted form.

nethsm  
Indicates that the key is protected by a FIPS device outside the system.

size Displays the size (in bytes) of the file associated with this file object.

source-path  
Displays the location (URI) from where the file will be copied.

system-path  
Displays the location where the key is stored on the system.

updated-by  
Displays the name of the user who last updated the key.

SEE ALSO

delete, glob, list, regex, tmsh

## cm remove-from-trust

NAME

remove-from-trust - Remove a device from a trust domain.

MODULE

cm

SYNTAX

Run the remove-from-trust program within the cm module using the syntax in the following section. The trust-domain name 'Root' is optional beginning version 13.0.0.

MODIFY

```
run remove-from-trust [Root]
options:
  [ca-device | non-ca-device]
  device-name [string]
```

DESCRIPTION

You can use the remove-from-trust command to remove a device from a trust domain. This is an alternate helper command to the modify trust-domain ca-devices|non-ca-devices delete ... command.

EXAMPLES

```
run remove-from-trust ca-device device-name peer1
```

Removes a device from the list of ca-devices in the trust domain Root.

OPTIONS

ca-device

Indicates that the added device is a certificate authority device.

device-name

Used to specify the name of a new device.

non-ca-device

Indicates that the added device is a subordinate device.

SEE ALSO

run, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP            2016-02-17            cm remove-from-trust(1)

---

## cm sha1-fingerprint

**NAME**  
sha1-fingerprint - Display SHA1 fingerprint of the local device SSL certificate in DER format.

**MODULE**  
cm

**SYNTAX**  
Run the sha1-fingerprint command sequence within the cm module using the syntax in the following section.

**DISPLAY**  
show sha1-fingerprint  
options:  
field-fmt

**DESCRIPTION**  
You can use the sha1-fingerprint component to display the local box SSL SHA1 checksum and provide this value to a remote authority device that is trying to add the local device to a trust domain. This allows the remote device to verify the identity of the local device when establishing the SSL connection.

For information about the options that you can use with the command show, run the command sequence help show.

**EXAMPLE**  
show sha1-fingerprint

Display SHA1 fingerprint of the local device SSL certificate in DER format.

**OPTIONS**  
field-fmt

Formats the sha1 fingerprint output in command syntax.

**SEE ALSO**  
show, tmsh

**COPYRIGHT**  
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2013, 2016. All rights reserved.

**BIG-IP**        2017-01-20    cm sha1-fingerprint(1)

---

## cm sniff-updates

**NAME**  
sniff-updates - Displays the commit ID updates that occur over the CMI communications channel

**MODULE**  
cm

**SYNTAX**  
run cm sniff-updates  
options:  
[-v]

**DESCRIPTION**  
You can use the sniff-updates program to monitor the internal CMI communications channel for commit ID updates. The system displays each update as it arrives, one per line.

(1)        (2)        (3)        (4)        (5) (6)        (7)        (8)        (9)        (10)  
[15:35:57] bigip1 (v0.0.0) -> device\_trust\_group: CID 105.105 (bigip2) at 15:34:39 FORCE\_SYNC

Output fields:  
1) Time that update arrived from network  
2) Source device  
3) Version of source device

- 4) Destination devicegroup
- 5) CommitId ID
- 6) DeviceData CommitId ID
- 7) CommitId originator
- 8) CommitId timestamp
- 9) FORCE\_SYNC if set (nothing if not)
- 10) Last sync error message (nothing if last sync was successful)

#### OPTIONS

You can use the following option when you run the sniff-updates program:

-v Formats the update output using fully-qualified device and device group names and exact time64\_t timestamps.

#### SEE ALSO

run, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2013, 2016. All rights reserved.

BIG-IP          2016-03-14          cm sniff-updates(1)

---

## cm sync-status

#### NAME

sync-status - Displays the configuration synchronization status of the local device.

#### MODULE

cm

#### SYNTAX

Run the sync-status command sequence within the cm module using the syntax in the following section.

##### DISPLAY

show sync-status  
options:  
field-fmt

#### DESCRIPTION

You can use the sync-status component to display the configuration synchronization status of the local device.

For information about the options that you can use with the command show, run the command sequence help show.

#### EXAMPLE

show sync-status

Displays the configuration synchronization status of the local device:

#### OPTIONS

field-fmt

Formats the status output in command syntax.

#### SEE ALSO

show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2012. All rights reserved.

BIG-IP          2012-03-19          cm sync-status(1)

---

## cm traffic-group

**NAME**  
traffic-group - Manages a CM traffic group.

**MODULE**  
cm

**SYNTAX**  
Manage the traffic-group component within the cm module using the syntax shown in the following sections.

**CREATE/MODIFY**  
 create traffic-group [name]  
 modify traffic-group [name]  
 options:  
   app-service [[string] | none]  
   auto-failback-enabled [ enabled | disabled ]  
   auto-failback-time [ integer ]  
   description [string]  
   failover-method [ ha-score | ha-order ]  
   ha-group [string]  
   ha-load-factor [ integer ]  
   ha-order [ string ... ]  
   mac [mac address]  
   monitor { ha-group [string] }

edit traffic-group [ [ [name] | [glob] | [regex] ] ... ]  
 options:  
   all-properties  
   non-default-properties

**DISPLAY**  
 list traffic-group  
 list traffic-group [ [ [name] | [glob] | [regex] ] ... ]  
 show running-config traffic-group  
 show running-config traffic-group [ [ [name] | [glob] | [regex] ] ... ]  
 options:  
   all-properties  
   app-service  
   is-floating  
   non-default-properties  
   one-line  
   partition  
   recursive  
   unit-id [integer]

show traffic-group  
 show traffic-group [name]  
 options:  
   all-properties  
   details  
   failover-objects  
 field-fmt

**DELETE**  
 delete traffic-group [name]

**DESCRIPTION**  
 You can use the traffic-group component to specify the failover behavior for devices in a failover device group.

**EXAMPLES**  
 create traffic-group my\_traffic\_group  
 Creates a traffic group named my\_traffic\_group.  
 create traffic-group my\_traffic\_group ha-order { my\_device }  
 Creates a traffic group named my\_traffic\_group with a preferred device named my\_device.

**OPTIONS**  
**app-service**  
 Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

**auto-failback-enabled**  
 Specifies whether the traffic group fails back to the default device.

**auto-failback-time**  
 Specifies the time required to fail back. The value must be within a valid range: 0 - 300 inclusive.

**details**  
 Only usable with the show command. Displays the active or next-active devices for this traffic group.

**failover-method**  
 Specifies the method used to decide if the current device needs to failover the traffic-group to another device. If the failover-method is set to ha-score, a score is calculated for each device in the monitoring HA group; and the highest score is the current active device while the next highest score will be the device that takes over if the current one fails. If the failover-method is set to ha-order, a list of devices and their respective HA load is used to decide the next one to take over if the current devices fails.

**failover-objects**

Only usable with the show command. Tells it to display all of the objects associated with that traffic group.

#### ha-group

Deprecated since v13.0.0. Use monitor and failover-method instead. This specifies a ha-group for the traffic group to decide the active device within the traffic group. The HA group must exist first. Note: This attribute is only specific to the local device i.e. not sync'ed to its peers in the traffic group. If you use this deprecated command attribute, it will also set the failover-method to ha-score.

#### ha-order

This list of devices specifies the order in which the devices will become active for the traffic group when a failure occurs. This list may contain zero, one or more entries up to the number of devices in the failover device group. If auto-failback enabled is set to true, this list must contain at least one entry for the auto-failback device.

#### ha-load-factor

Specifies a number for this traffic group that represents the load this traffic group presents to the system relative to other traffic groups. This allows the failover daemon to load balance the active traffic groups amongst the devices. The value is one by default. The value must be within a valid range: 1 - 1000 inclusive.

#### monitor { ha-group [string] }

This specifies a ha-group monitor for the traffic group to decide the active device within the traffic group. The HA group must exist first. Note: This attribute is only specific to the local device i.e. not sync'ed to its peers in the traffic group.

#### description

Specifies a user-defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### is-floating

Indicates whether the traffic group can fail over to other devices in the device group.

mac Specifies a MAC address for the traffic group.

#### partition

Displays the administrative partition within which the device group resides.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### recursive

Displays all objects of the specified type and the folder that contains the object.

#### unit\_id

Displays the unit ID for the traffic group. The unit ID is set automatically when you create a traffic group. The value is between 1 and 15.

#### SEE ALSO

create, delete, edit, glob, list, modify, regex, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2013, 2016. All rights reserved.

BIG-IP      2016-10-04      cm traffic-group(1)

---

## cm trust-domain

#### NAME

trust-domain - Manages a CM trust domain by providing control of object failover.

#### MODULE

cm

#### SYNTAX

Manage the trust-domain component within the cm module using the syntax

shown in the following sections. The trust-domain name 'Root' is optional beginning with version 13.0.0. The 'create cm trust-domain' command is not allowed beginning version 13.0.0.

```
MODIFY
modify trust-domain [Root]
options:
  add-device {
    [ ca-device [true | false] | non-ca-device [true | false] ]
    device-ip [string]
    device-port [port_number]
    device-name [string]
    username [string]
    password [string]
    sha1-fingerprint [string]
  }
  devices delete {
    [ device names ]
  }
  remove-device [string]

deprecated since v13.0.0:
  ca-devices [add | delete | modify | replace-all-with] {
    [ device_name | ip address ]
  }
  md5-fingerprint [string]
  name [string]
  non-ca-devices [add | delete | modify | replace-all-with] {
    [ device_name | ip address ]
  }
  password [string]
  serial [string]
  sha1-fingerprint [string]
  username [string]

DISPLAY
list trust-domain
list trust-domain [ [ [name] | [glob] | [regex] ] ... ]
show running-config trust-domain
show running-config trust-domain [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  ca-cert
  ca-cert-bundle
  ca-key
  ca-devices
  non-ca-devices
  non-default-properties
  one-line
  partition
  recursive
status
trust-group

DELETE/RESTART
restart trust-domain
delete trust-domain
options:
  keep-current-certificate-authority
  import-user-defined-cert [string]
  import-user-defined-key [string]
```

**DESCRIPTION**

You can use the trust-domain component to manage the behavior of objects during fail over.

**DELETE/RESTART operations**

When applied to a trust-domain these operations reset the trust and make this device standalone.

**EXAMPLES**

Adds a certificate authority:

```
modify trust-domain add-device { ca-device true device-ip 192.168.1.245
device-name myDevice1 device-port 1234 username admin password admin }
```

Adds a non-authoritative certificate:

```
modify trust-domain add-device { ca-device false ip 192.168.1.248
device-name myDevice2 username admin password admin sha1-fingerprint
ab7012e8d834e639f497b2b1c9f1e855a4dbe232}
```

Removes a device from the trust domain:

```
modify trust-domain devices delete { myDevice1 myDevice2}
```

Resets the trust and makes this device standalone:

```
restart cm trust-domain
```

or

```
delete cm trust-domain
```

**EXAMPLES (deprecated since V13.0.0)**

Adds a certificate authority:

```
modify trust-domain Root ca-devices add { 192.168.1.245 } name
myDevice1 username admin password admin
```

Adds a non-authoritative certificate:

```
modify trust-domain Root non-ca-devices add { 192.168.1.245 } name
```

myDevice1 username admin password admin

Removes a device from the trust domain:

modify trust-domain Root ca-devices delete { myDevice1 }

#### OPTIONS

add-device

Adds a device to the trust domain.

device-ip

Device IP address when adding new device.

device-port

Device port number if other than 443 when adding new device.  
This parameter is optional.

device-name

Device name when adding new device.

username

Specifies the user name required to log on to a device when adding the device to the trust domain.

password

Specifies the password corresponding to the username required to log on to a device when adding the device to the trust domain.

sha1-fingerprint

Specifies the SSL certificate (DER format) sha1 fingerprint when verifying the identity of a new device. This field is optional.

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

ca-cert

Displays the certificate authority device trust certificate.

ca-cert-bundle

Displays the bundled certificate authority device trust certificates used to authenticate incoming connections.

ca-devices

Create and modify operations are deprecated since v13.0.0. List operation is still supported. Set of certificate authority devices in the trust domain.

ca-key

Displays the certificate authority device trust key. This key only displays for certificate authorities.

devices

Removes one or more devices from the trust domain. It takes the name of the device as the identifier.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

import-user-defined-cert

Specifies the certificate to import and use as the trust domain's new certificate authority. You must also use the import-user-defined-key option to specify the corresponding key. This option cannot be specified alongside keep-current-certificate-authority.

import-user-defined-key

Specifies the key to import and use as the trust domain's new certificate authority key. You must also use the import-user-defined-cert option to specify the corresponding certificate. This option cannot be specified alongside keep-current-certificate-authority.

keep-current-certificate-authority

By default, resetting trust will generate a new certificate authority. Adding this option to the delete command will instead keep the current certificate authority. This option cannot be specified alongside import-user-defined-cert or import-user-defined-key.

md5-fingerprint

Deprecated since v13.0.0. Specifies the SSL certificate fingerprint when verifying the identity of a new device.

name Deprecated since v13.0.0. Option used to specify the name of a new device.

non-ca-devices

Create and modify operations are deprecated since v13.0.0. List operation is still supported. Set of subordinate devices in the trust domain.

password

Deprecated since v13.0.0. Specifies the password for a new device.

recursive

Displays all objects of the specified type and the folder that contains the object.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### remove-device

Removes a single device from the trust domain. It takes the name of the device as the identifier.

#### serial

Deprecated since v13.0.0. Specifies the SSL certificate serial number when verifying the identity of a new device.

#### sha1-fingerprint

Deprecated since v13.0.0. Specifies the SSL certificate fingerprint when verifying the identity of a new device.

#### signature

Deprecated since v13.0.0. Specifies the SSL certificate signature, when verifying the identity of a new device.

#### status

Displays the status of the trust domain.

#### trust-group

Displays the device group associated with the trust domain.

#### username

Deprecated since v13.0.0. Specifies the user name required to log on to a device when adding the device to the trust domain.

#### SEE ALSO

delete, edit, glob, list, modify, regex, restart, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2016. All rights reserved.

## cm watch-devicegroup-device

#### NAME

watch-devicegroup-device - Displays information about the devices in the device group to which the local device belongs.

#### MODULE

cm

#### SYNTAX

Run the watch-devicegroup-device program within the cm module using the syntax shown in the following sections.

#### RUN

run watch-devicegroup-device

#### DESCRIPTION

You can use the watch-devicegroup-device program to view dynamic information about the synchronization of the devices in the device group to which the local device belongs. You can use this information to monitor or troubleshoot the devices.

By default, multiple devices with identical information are collapsed into a single row that displays in green. The devices column identifies the devices by the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16. Use the c (collapse) command to deactivate/activate this behavior.

For example, when you make a change to a device, the change is identified by a commit ID (cid.id) that displays when you run the watch-devicegroup-device program.

Within the program, you can use the following keys:

Press h to see a list of available commands.

Press the back tick key (`) to exit the help page.

Press c to toggle the view from a collapsed view to a full view. The command gathers information from every device in the trust group. When all devices in the trust group report the same information the view is collapsed and one line, highlighted in green, displays the information. The devices included in the line are shown in the devices column. You can press c to see the full view, which displays each device on a separate line.

Press Ctrl-C to exit the program.

Press the arrow keys to navigate across the columns or down the rows.

The content in the columns includes:

devices

Displays the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the config-sync IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16.

devgroup

Displays the name of the device group to which the device belongs. Note: This can be a sync-only, failover, or trust device group.

device

Displays the device object name.

cid.id

Displays the commit ID, which is a configuration change identifier.

cid-orig

Displays the name of the device on which the configuration change was made.

cid.time

Displays the time the configuration change was made.

last\_sync

Displays the time the device configuration was last synchronized with the device group.

The devices in the to-group of a configuration synchronization display the same time in this column. The local device that pushes the configuration to the other devices in the device group (to-group) has a different value in this column.

The devices in the from-group of a configuration synchronization display the same time in this column. The local device that receives the configuration from the other devices has a different value in this column. You can use this information to determine a rollback strategy.

## cm watch-sys-device

NAME

watch-sys-device - Displays information about the local device.

MODULE

cm

SYNTAX

Run the watch-sys-device program within the cm module using the syntax shown in the following sections.

RUN

run watch-sys-device

DESCRIPTION

You can use the watch-sys-device program to view dynamic information about the local device.

By default, multiple devices with identical information are collapsed into a single row that displays in green. The devices column identifies the devices by the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16. Use the c (collapse) command to deactivate/activate this behavior.

Within the program, you can use the following keys:

Press h to see a list of available commands.

Press the back tick key (`) to exit the help page.

Press c to toggle the view from a collapsed view to a full view. The command gathers information from every device in the trust group. When

all devices in the trust group report the same information the view is collapsed and one line, highlighted in green, displays the information. The devices included in the line are shown in the devices column. You can press c to see the full view, which displays each device on a separate line.  
Press Ctrl-C to exit the program.  
Press the arrow keys to navigate across the columns or down the rows.

The content in the columns includes:

devices

Displays the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16.

name Displays the device object name.

platform

Displays the device platform.

build

Displays the software build installed on the device.

failover\_state

Displays the high availability state (active or standby) of the device.

mgmt\_ip

Displays the IP address of the management port on the device.

configsnc\_ip

Displays the IP address on the device that is used for configuration synchronization.

unicast\_ip

Displays the unicast IP address of the device.

multicast\_ip

Displays the multicast IP address of the device.

mirror\_ip

Displays the IP address used for configuration mirroring for the device.

mirror\_secondary\_ip

Displays the secondary IP address used for configuration mirroring for the device.

desc Displays a description of the device.

## cm watch-trafficgroup-device

NAME

watch-trafficgroup-device - Displays information about the traffic groups associated with devices in a device group.

MODULE

cm

SYNTAX

Run the watch-trafficgroup-device program within the cm module using the syntax shown in the following sections.

RUN

run watch-trafficgroup-device

DESCRIPTION

You can use the watch-trafficgroup-device program to view dynamic information about the failover status of the devices in a device group to which the local device belongs. You can use this information to monitor or troubleshoot the devices in the device group.

By default, multiple devices with identical information are collapsed into a single row that displays in green. The devices column identifies the devices by the suffix of the configuration synchronization IP

address configured on the device. For example, if the devices in a device group have the IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16. Use the `c (collapse)` command to deactivate/activate this behavior.

Within the program, you can use the following keys:

Press `h` to see a list of available commands.  
Press the back tick key (```) to exit the help page.  
Press `c` to toggle the view from a collapsed view to a full view. The command gathers information from every device in the device group. When all devices in the device group report the same information the view is collapsed and one line, highlighted in green, displays the information. The devices included in the line are shown in the devices column. You can press `c` to see the full view, which displays each device on a separate line.  
Press `Ctrl-C` to exit the program.  
Press the arrow keys to navigate across the columns or down the rows.

The content in the columns includes:

`devices`

Displays the suffix of the configuration synchronization IP address configured on the device. For example, if the devices in a device group have the IP addresses 10.0.0.15 and 10.0.0.16, the IDs in this column will be 15 and 16.

`traffic_group`

Displays the name of the traffic group associated with the device.

`device_name`

Displays the device object name.

`failover state`

Displays the high availability state (active or standby) of the device.

`next_active`

Displays True for the device that becomes active if the active traffic group fails over.

`score`

Displays a system-generated high availability score used to select the next active device.

SEE ALSO

`run`, `tmsh`, `watch-sys-device`, `watch-devicegroup-device`

## gtm

### gtm datacenter

NAME

datacenter - Configures a Global Traffic Manager(tm) data center.

MODULE

gtm

SYNTAX

Configure the datacenter component within the gtm module using the syntax in the following sections.

CREATE/MODIFY

create datacenter [name]

modify datacenter [name]

options:

app-service [[string] | none]

contact [ [name] | none]

description [string]

[disabled | enabled]

location [none | [physical location] ]

prober-fallback [ any-available | inside-datacenter | outside-datacenter | pool | none ]

prober-pool [none | name]

prober-preference [ inside-datacenter | outside-datacenter | pool ]

metadata

[add | delete | modify] {

[metadata\_name ... ] {

value [ "value content" ]

persist [ true | false ]

```

}
}

edit datacenter [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

reset-stats datacenter
reset-stats datacenter [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list datacenter
list datacenter [ [ [name] | [glob] | [regex] ] ... ]
show running-config datacenter
show running-config datacenter [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

show datacenter
show datacenter [name]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  detail
  field-fmt

DELETE
delete datacenter [name]

DESCRIPTION
  You can use the datacenter component to create, modify, display, or
  delete a data center.

EXAMPLES
  create datacenter DC1

  Creates a data center named DC1 with options set to the default values.

  list datacenter DC1 all-properties

  Displays all properties of the data center named DC1.

OPTIONS
  app-service
  Specifies the name of the application service to which the data
  center belongs. The default value is none. Note: If the strict-
  updates option is enabled on the application service that owns the
  object, you cannot modify or delete the data center. Only the
  application service can modify or delete the data center.

  contact
  Specifies the name of the administrator or the name of the
  department that manages the data center. The default value is
  none.

  description
  User defined description.

  [disabled | enabled]
  Specifies whether the data center and its resources are available
  for load balancing. The default value is enabled.

  glob
  Displays the items that match the glob expression. See help glob
  for a description of glob expression syntax.

  location
  Specifies the physical location of the data center. The default
  value is none.

  metadata
  Specifies user-defined data to associate with a server. By default
  the persist attribute is set to true. This means the data is saved
  into the configuration file.

  name
  Specifies a unique name for the component. This option is required
  for the commands create and modify.

  prober-fallback
  Specifies the type of prober to use to monitor servers defined in
  this data center when the preferred type is not available. The
  default value is any-available.

  prober-pool
  Specifies a prober pool to use to monitor servers defined in this
  data center when either the prober-preference or prober-fallback
  value is pool. If neither the prober-preference or prober-fallback
  value is pool, the prober-preference and prober-fallback values
  are set to pool and any-available.

  prober-preference
  Specifies the type of prober to use to monitor servers defined in
  this data center. The default value is inside-datacenter.

  regex
  Displays the items that match the regular expression. The regular
  expression must be preceded by an at sign (@[regular expression])
  to indicate that the identifier is a regular expression. See help
  regex for a description of regular expression syntax.

SEE ALSO
  create, delete, glob, gtm link, gtm prober-pool, gtm server, list,
  modify, regex, reset-stats, show, tmsh

```

## gtm distributed-app

#### NAME

distributed-app - Configures a Global Traffic Manager(tm) distributed application.

#### MODULE

gtm

#### SYNTAX

Configure the distributed-app component within the gtm module using the syntax in the following sections.

##### CREATE/MODIFY

```
create distributed-app [name]
modify distributed-app [name]
options:
  app-service [[string] | none]
  dependency-level [datacenter | link | none | server | wideip]
  description [string]
  disabled-contexts
    [add | delete | modify | replace-all-with] {
      [datacenter | link | server] [name] ...
    }
  disabled-contexts none
  persistence [enabled | disabled]
  persist-cidr-ipv4 [integer]
  persist-cidr-ipv6 [integer]
  ttl-persistence [integer]
  wideips
    [add | delete | replace-all-with] {
      [name] ...
    }
  wideips [default | none]
```

##### edit distributed-app

```
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

##### reset-stats distributed-app

```
reset-stats distributed-app
[ [ [name] | [glob] | [regex] ] ... ]
```

##### DISPLAY

```
list distributed-app
list distributed-app [ [ [name] | [glob] | [regex] ] ... ]
show running-config distributed-app
show running-config distributed-app
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition
```

##### show distributed-app

```
show distributed-app [name]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  detail
  field-fmt
```

##### DELETE

```
delete distributed-app [name]
```

#### DESCRIPTION

You can use the distributed-app component to create, modify, display, or delete a distributed application.

#### EXAMPLES

```
create distributed-app DA1
```

Creates a distributed application named DA1 with options set to the default values.

```
list distributed-app DA1 all-properties
```

Displays all properties of the distributed application named DA1.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the distributed application belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the distributed application. Only the application service can modify or delete the distributed application.

##### dependency-level

Specifies the resources that must be in the available state before this distributed application is considered available. The options are:

##### datacenter

All of the data centers on the member list of this distributed application must be in an available state before the system considers the distributed application available.

link All of the links on the member list of this distributed application must be in an available state before the system considers the distributed application available.

none The distributed application has no dependencies. This value effectively disables this option. This is the default value.

##### server

All of the servers on the member list of this distributed application must be in an available state before the system considers the distributed application available.

##### wideip

All of the Wide IPs on the member list of this distributed application must be in an available state before the system considers the distributed application available.

##### description

User defined description.

##### disabled-contexts

Specifies the components that you want to add to or delete from this distributed application as disabled-contexts. You can also replace all of the components that are currently listed as disabled-contexts for this distributed application with other components. The default value is none.

The possible values are:

##### datacenter

Specifies the datacenters, by name, to which the system does not send traffic from this distributed application.

link Specifies the links, by name, to which the system does not send traffic from this distributed application.

none There are no components to which the system does not send traffic from this distributed application. This value effectively disables this option.

##### server

Specifies the servers, by name, to which the system does not send traffic from this distributed application.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

##### partition

Displays the administrative partition within which this object resides.

##### persistence

When enabled, if a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

##### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

##### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

##### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

##### ttl-persistence

Specifies, in seconds, the length of time for which the persistence entry is valid. The default value is 3600.

##### wideips

Specifies the Wide IPs, by name, that you want to add to or delete from this distributed application. You can also replace all of the Wide IPs that are currently associated with this distributed

application with other Wide IPs. The default value is none.

A Wide IP is a collection of one or more domain names that maps to one or more groups of virtual servers managed either by BIG-IP(r) systems, or by host servers. The Global Traffic Manager load balances name resolution requests across the virtual servers that are defined in the Wide IP that is associated with the requested domain name.

#### SEE ALSO

create, delete, glob, gtm link, gtm server, create, list, modify, regex, reset-stats, show, tmsh

options:

all-properties  
non-default-properties  
one-line

#### DISPLAY

list

list general

show running-config general

show running-config general [option name]

options:

all-properties  
non-default-properties

#### DESCRIPTION

You can use the general component to modify or display the General Traffic Manager settings.

#### EXAMPLES

modify general auto-discovery no

Turns off auto-discovery for the Global Traffic Manager.

list general all-properties

Displays all properties of the general settings for the Global Traffic Manager.

#### OPTIONS

automatic-configuration-save-timeout

Sets the timeout, in seconds, indicating how long to wait after a GTM configuration change before automatically saving the GTM configuration to the bigip\_gtm.conf. A timeout of -1 will cause the GTM configuration to NEVER be saved. A value of 0 will cause the GTM configuration to be saved immediately. The default value is 15 seconds.

auto-discovery

Specifies whether the auto-discovery process is activated for this system. The default value is no.

auto-discovery-interval

Specifies the frequency, in seconds, between system attempts to discover network components. The default value is 30.

cache-ldns-servers

Specifies whether the system retains, in cache, all local DNS servers that make requests. The default value is yes.

You must enable this option if you want the system to store and use the LDNS path information.

domain-name-check

Specifies the parameters for the Global Traffic Manager to use when performing domain name checking. The default value is allow-underscore.

The possible values are:

allow-underscore

The Global Traffic Manager checks domain names according to the specifications in RFC 1123 Requirements for Internet Hosts - Application and Support, except that underscores are allowed.

none

No validation is performed. Anything is allowed.

idn-compatible

Deprecated since v12.1.0. Equivalent to allow-underscore. Value of idn-compatible will be saved as allow-underscore.

strict

Deprecated since v12.1.0. Equivalent to allow-underscore. Value of strict will be saved as allow-underscore.

drain-persistent-requests

Specifies, when set to yes, that when you disable a pool, load-balanced, persistent connections remain connected until the TTL expires. The default value is yes. If you set this option to no, any persistent connections terminate immediately when a pool is disabled.

forward-status

Specifies, when set to enabled, that the availability status change for GTM objects will be shared with subscribers. This option will enable iControl clients to receive event notifications when a change occurs.

gtm-sets-recursion

Specifies, when set to yes, that the system enables recursive DNS queries, regardless of whether the requesting local DNS enabled recursive queries. The default value is no.

heartbeat-interval

Specifies the frequency at which the Global Traffic Manager queries other BIG-IP(r) systems for updated data. When configuring monitors for BIG-IP systems, F5 Networks recommends that the probe-interval option for the monitor be equal to or greater than the this option. The default value is 10.

iquery-cipher-list

This is a ":" separated list of cipher specifications as accepted by the "openssl ciphers" command. OpenSSL will use the cipher list to negotiate a mutually acceptable cipher with the server during iQuery connection setup.

iquery-minimum-tls-version

This is a string to specify the minimum TLS version that will be offered by the client (GTM) during iQuery connection negotiation.

monitor-disabled-objects

Specifies, when set to yes, that the system will continue to monitor objects even if the objects are disabled. The default value is no.

nethsm-timeout

Time to wait on a NetHSM key creation operation for DNSSEC before retry. Default is 20 seconds.

nsec3-types-bitmap-strict

When the nsec3-types-bitmap-strict setting has a default value of disabled the BIG-IP responds permissively to DS record queries when authenticating denial of existence. That is to say, the NSEC3 types bitmap will contain NS, even if we cannot be sure such a

record exists.

When the setting is set to non-default value enabled (ie strict), the BIG-IP will only confirm the existence of the NS record (via the types bitmap of the NSEC3) when the zone is configured as an unsecured delegation on the DNSSEC Zone. If it is not configured, the BIG-IP will respond with TXT in the types bitmap.

#### peer-leader

Specifies the name of a GTM server to be used for executing certain features, such as creating DNSSEC keys.

#### send-wildcard-rrs

Specifies, when set to enable, that WideIPs or WideIP aliases that contain wildcards will autogenerate Resource Records in the BIND database. The default value is disable.

#### static-persist-cidr-ipv4

Specifies the number of bits of the IPv4 address that the system considers when using the Static Persist load balancing mode. The default value is 32.

#### static-persist-cidr-ipv6

Specifies the number of bits of the IPv6 address that the system considers when using the Static Persist load balancing mode. The default value is 128.

#### synchronization

Specifies whether this system is a member of a synchronization group. The default value is no.

Members of the synchronization group continuously share configuration and metrics collection information. The synchronization group can contain Global Traffic Managers and Link Controllers.

#### synchronization-group-name

Specifies the name of the synchronization group to which the system belongs. The default name is default.

#### synchronization-time-tolerance

Specifies the number of seconds that one system clock can be out of sync with another system clock, in the synchronization group. If the variance between the clock times is higher than the time tolerance setting, the system logs the time difference once per hour.

Possible values are 0 (zero), and 5 - 600. (Values 1 through 4 are automatically set to 5, and 0 (zero) turns time synchronization off.) The default value is 10 seconds.

Note: If you are using NTP to synchronize the clock with a time server, select a time tolerance other than 0 (zero). When you do this, the system uses the synchronization-time-tolerance option as a fail-over mechanism if NTP is disabled for any reason.

#### synchronization-timeout

Specifies the number of seconds that the system attempts to synchronize the Global Traffic Manager configuration with a synchronization group member. If the synchronization times out, the system tries again. The default value is 180.

#### synchronize-zone-files

Specifies whether the system synchronizes zone files among the synchronization group members. The default value is no.

#### synchronize-zone-files-timeout

Specifies the number of seconds that a synchronization group member attempts to synchronize its zone files with a synchronization group member. If the synchronization times out, the system tries again. The default value is 300.

#### topology-allow-zero-scores

Specifies if topology load-balancing or QoS load-balancing with topology enabled will return pool members with zero topology scores. The default value is yes.

#### virtuals-depend-on-server-state

Specifies whether the system marks a virtual server down when the server on which the virtual server is configured can no longer be reached via iQuery. The default value is yes.

#### wideip-zone-nameserver

Specifies the DNS Nameserver to use for all NS records for automatically generated DNS Zones created for all Wide IPs. It should be set to a registered DNS Nameserver for the Wide IPs.

## gtm global-settings load-balancing

**NAME**

load-balancing - Configures the load balancing settings for the Global Traffic Manager(tm).

**MODULE**

gtm global-settings

**SYNTAX**

Modify or display the load-balancing component within the gtm global-settings module using the syntax in the following sections.

**MODIFY**

```
modify load-balancing
options:
  failure-rcode [noerror | formerr | servfail | nxdomain | notimpl | refused]
  failure-rcode-ttl [integer]
  failure-rcode-response [disabled | enabled]
  ignore-path-ttl [no | yes]
  respect-fallback-dependency [no | yes]
  topology-longest-match [no | yes]
  topology-prefer-edns0-client-subnet [disabled | enabled]
  verify-vs-availability [no | yes]
```

**edit load-balancing**

```
options:
  all-properties
  non-default-properties
```

**DISPLAY**

```
list
list load-balancing
show running-config load-balancing
show running-config load-balancing [option]
options:
  all-properties
  non-default-properties
  one-line
```

**DESCRIPTION**

You can use the load-balancing component to modify or display the load balancing settings for the Global Traffic Manager.

**EXAMPLES**

```
modify load-balancing ignore-path-ttl yes
```

Specifies that dynamic load balancing methods can use path data, even after the time-to-live (TTL) for the path data expires.

```
list load-balancing all-properties
```

Displays all properties of the load balancing settings for the Global Traffic Manager.

**OPTIONS**

**failure-rcode**

Specifies the DNS RCODE used when failure-rcode-response is enabled. Default is noerror. Options include noerror (no type exists at this name), formerr (format error in query), servfail (unable to process query), nxdomain (name does not exist), notimpl (no support for this kind of query), and refused (refuse to process based on policy). If failure-rcode-ttl is non-zero, only the Authority section of the noerror or nxdomain response will include a SOA record.

**failure-rcode-response**

When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This affects all Wide IPs and may only be overridden by a more specific enabled configuration of a Wide IP. This response is an authoritative empty answer from the system for record requests. With this option enabled, the system responds faster to requests for which it does not have viable answers configured. The default value is disabled.

**failure-rcode-ttl**

Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

**ignore-path-ttl**

Specifies, when set to yes, that dynamic load balancing methods can use path data, even after the time-to-live (TTL) for the path data expires. The default value is no.

**respect-fallback-dependency**

Specifies, when set to yes, that the system accepts virtual server status when the load balancing mode changes to the mode specified by the fallback-mode option of the pool. The default value is no.

**topology-longest-match**

Specifies, when set to yes, that the system evaluates all topology

records in the topology statement, and then selects the topology record that most specifically matches the IP address in an LDNS request (in other words, has the longest match). When this option is set to no, the system selects the first record in the topology statement that matches the request.

**topology-prefer-edns0-client-subnet**  
Specifies, when set to enabled, that the system should use the edns0 client subnet option (if one exists) instead of the source address when using topology load balancing. When this option is set to disabled or if the query did not contain a client subnet option, the system will fall back to the source address.

When disabled this option can be overridden by a per wide IP setting, gtm wideip [wideip type] [wideip name]  
**topology-prefer-edns0-client-subnet** [disabled | enabled].

**verify-vs-availability**  
Specifies, when set to yes, that the system checks the availability of virtual servers before sending a connection to those virtual servers. The default value is no.

## gtm global-settings metrics-exclusions

NAME

metrics-exclusions - Configures the IP addresses that you want to exclude from the Global Traffic Manager(tm) metrics.

MODULE

gtm global-settings

SYNTAX

Modify or display the metrics-exclusions within the gtm global-settings module using the syntax in the following sections.

MODIFY

```
modify metrics-exclusions
options:
  addresses [add | delete | none | replace-all-with] {
    [ip address]...
  }
```

edit metrics-exclusions

```
options:
  all-properties
```

DISPLAY

```
list
list metrics-exclusions
show running-config metrics-exclusions
  addresses
options:
  all-properties
  one-line
```

DESCRIPTION

You can use the metrics-exclusions component to exclude IP addresses from the Global Traffic Manager metrics.

EXAMPLES

```
modify metrics-exclusions addresses add {10.10.10.1}
```

Excludes the IP address 10.10.10.1 from inclusion in the Global Traffic Manager metrics.

```
list metrics-exclusions
```

Displays the IP addresses that are excluded from the Global Traffic Manager metrics.

OPTIONS

**ip address**  
Specifies the IP addresses that you want to add to or delete from the exclusion list, or with which you want to replace all existing IP addresses that are currently on the exclusion list.

## gtm global-settings metrics

#### NAME

metrics - Configures metrics for the Global Traffic Manager(tm).

#### MODULE

gtm global-settings

#### SYNTAX

Modify or display the metrics component within the gtm global-settings module using the syntax in the following sections.

##### MODIFY

modify metrics

options:

```
default-probe-limit [integer]
hops-ttl [integer]
hops-packet-length [integer]
hops-sample-count [integer]
hops-timeout [integer]
inactive-ldns-ttl [integer]
ldns-update-interval [integer]
inactive-paths-ttl [integer]
max-synchronous-monitor-requests [integer]
metrics-caching [integer]
metrics-collection-protocols none
metrics-collection-protocols
    [add | delete | replace-all-with] {
[ dns-dot | dns-rev | icmp | tcp | udp] ...
    }
path-ttl [integer]
paths-retry [integer]
```

edit metrics

options:

```
all-properties
non-default-properties
one-line
```

##### DISPLAY

list

list metrics

show running-config metrics

show running-config metrics [option]

options:

```
all-properties
non-default-properties
```

#### DESCRIPTION

You can use the metrics component to modify or display the Global Traffic Manager metrics settings.

#### EXAMPLES

```
modify metrics default-probe-limit 10
```

Sets the default probe limit for the Global Traffic Manager to 10.

```
list metrics all-properties
```

Displays all properties of the metrics settings for the Global Traffic Manager.

#### OPTIONS

default-probe-limit

Specifies the number of probe attempts that the system performs before removing the path from the metrics. The default value is 12.

hops-ttl

Specifies the number of seconds that the system considers traceroute utility data to be valid for name resolution and load balancing. The default value is 604800. Note that this option must be greater than the hops-timeout option.

**hops-packet-length**  
Specifies the length of packets, in bytes, that the system sends to a local DNS server to determine the path information between the two systems. Valid values are 64 - 500. The default value is 64.

**hops-sample-count**  
Specifies the number of packets that the system sends to a local DNS server to determine the path information between those two systems. Valid values are 1 - 10. The default value is 3.

**hops-timeout**  
Specifies the number of seconds that the big3d daemon waits for a probe. Valid values are 1 - 10. The default value is 3.

**inactive-ldns-ttl**  
Specifies the number of seconds that an inactive LDNS remains in the cache. Each time an LDNS makes a request, the clock starts again. Valid values are 60 - 31536000 (1 year). The default value is 2419200 (28 days).

**ldns-update-interval**  
Specifies the number of seconds that a tmm will wait before sending an update for a LDNS which has been accessed. The default value is 20 seconds.

**inactive-paths-ttl**  
Specifies the number of seconds that a path remains in the cache after its last access. Valid values are 60 - 31536000 (1 year). The default value is 604800 (7 days).

**max-synchronous-monitor-requests**  
Specifies how many monitors can attempt to verify the availability of a given resource at the same time. The default value is 20.

**metrics-caching**  
Specifies the interval (in seconds) at which the system dumps path and other metrics data. Valid values are 0 through 604800. The default value is 3600; 0 (zero) turns this feature off.

**metrics-collection-protocols**  
Specifies the protocols that the system uses to collect metrics information relevant to LDNS servers.

**path-ttl**  
Specifies the number of seconds that the system considers path data to be valid for name resolution and load balancing purposes. The default value is 2400. Note that this option must be greater than the paths-retry option and less than or equal to 2419200 (28 days).

**paths-retry**  
Specifies the interval (in seconds) at which the system retries the path data. Valid values are 1 - 600 (10 minutes). The default value is 120.

## gtm iquery

**NAME**  
iquery - Displays information about iQuery.

**MODULE**  
gtm

**SYNTAX**  
Display the iquery component within the gtm module using the syntax in the following sections.

**DISPLAY**  
show iquery  
options:  
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)  
field-fmt  
global

#### DESCRIPTION

You can use the iquery component to display iQuery statistics.

#### EXAMPLES

```
show iquery
```

Displays iQuery statistics in the system default units.

```
show iquery field-fmt
```

Displays iQuery statistics in field format.

#### OPTIONS

For information about options for the command show, see show.

#### SEE ALSO

show, tmsh

#### COPYRIGHT

## gtm ldns

#### NAME

ldns - Displays local domain name system (LDNS) statistics for the Global Traffic Manager(tm).

#### MODULE

gtm

#### SYNTAX

Display the ldns component within the gtm module using the syntax in the following section.

##### DISPLAY

```
show ldns
```

```
options:
```

```
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)  
field-fmt
```

#### DESCRIPTION

You can use the ldns component to display LDNS statistics.

#### EXAMPLES

```
show ldns
```

Displays LDNS statistics in the system default units.

```
show ldns field-fmt
```

Displays LDNS statistics in field format.

#### SEE ALSO

show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## gtm link

#### NAME

link - Configures Global Traffic Manager(tm) links.

#### MODULE

gtm

#### SYNTAX

Configure the link component within the gtm module using the syntax in the following sections.

##### CREATE/MODIFY

```
create link [name]
modify link [name]
options:
  app-service [[string] | none]
  cost-segments {
    { [up-to-bps [integer] ] [dollars-per-mbps [integer] ] }...
  }
  datacenter [string]
  description [string]
  [disabled | enabled]
  duplex-billing [disabled | enabled]
  limit-max-inbound-bps [integer]
  limit-max-inbound-bps-status [disabled | enabled]
  limit-max-outbound-bps [integer]
  limit-max-outbound-bps-status [disabled | enabled]
  limit-max-total-bps [integer]
  limit-max-total-bps-status [disabled | enabled]
  link-ratio [integer]
  monitor [none | [name] [and [name] ]... ]
  monitor min [integer] of { [name]... }
  prepaid-segment [integer]
  router-addresses
    [add | delete | modify | replace-all-with] {
[ip address] {
  app-service [[string] | none]
  description [string]
  device-name [[string] | none]
  translation [disabled | enabled]
}
}
  service-provider [name]
  uplink-address [ip address]
  weighting [price | ratio]
```

```
edit link [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
  one-line
```

```
reset-stats link
```

```
reset-stats link [ [ [name] | [glob] | [regex] ] ... ]
```

##### DISPLAY

```
list link
```

```
list link [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config link
```

```
show running-config link [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
```

```
show link
```

```
show link [name]
```

```
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  detail
  field-fmt
```

##### DELETE

```
delete link [name]
```

#### DESCRIPTION

You can use the link component to create, display, modify, or delete a link.

A link is a physical device that connects the network to the rest of the Internet. You can logically attach links to a collection of servers in order to manage access to the data sources on the network.

#### EXAMPLES

```
create link my_link datacenter DC1 router-addresses add {10.10.1.1}
```

Creates a link named my\_link in the DC1 data center and adds the IP address of the router that uses this link.

```
list link non-default-properties
```

Displays all non-default properties for all links.

```
delete link my_link
```

Deletes the link named my\_link.

```
show link my_link detail
```

Show the servers and virtual servers associated with my\_link.

```
show link all detail
```

Show the servers and virtual servers associated with each respective link in the system.

#### OPTIONS

#### app-service

Specifies the name of the application service to which the link belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the link. Only the application service can modify or delete the link.

#### cost-segments

Specifies the cost of each incremental segment of bandwidth. This option is valid only when the weighting option is set to price. Note that you cannot modify the list, only replace all of the options in the list.

By default, the list is empty. The options are:

#### dollars-per-mps

Specifies the cost in dollars per megabytes per second. By default this value is not specified.

#### up-to-bps

Specifies the cost in dollars per bytes per second. By default this value is not specified.

#### datacenter

Specifies the data center to which the link belongs.

#### description

User defined description.

#### detail

The detail option is used with the show display command. This shows the server IP addresses and virtual servers associated with this link. A server can have multiple server IP addresses, however, only the server IP addresses that use this link will be displayed. Assignment information for servers and virtuals will not be displayed if there are not any servers or virtuals that use this link. By default, links are automatically matched to server IP addresses and virtual servers according to their IP addresses. Explicit links may also be defined. How this link was assigned is displayed under the Link Assignment column: auto means that the system automatically assigned this link, and explicit means that the link was explicitly set by the user.

#### [disabled | enabled]

Specifies whether the link and its resources are available for load balancing. The default value is enabled.

#### duplex-billing

Enables or disables duplex billing for this link. The default value is enabled. This option is valid only when the weighting option is set to price.

#### disabled

The internet service provider (ISP) that supplies this link bills for bandwidth usage based on the total amount of inbound plus outbound traffic on the link.

#### enabled

The ISP that supplies this link bills for bandwidth usage based on the maximum amount of either inbound or outbound traffic on the link (whichever is higher), rather than billing for bandwidth usage based on the total amount of inbound plus outbound traffic on the link.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### limit-max-inbound-bps

Specifies the threshold for inbound traffic on the link. The default value is 0 (zero).

#### limit-max-inbound-bps-status

Enables or disables the limit-max-inbound-bps option for this link. The default value is disabled.

#### limit-max-outbound-bps

Specifies the threshold for inbound traffic on the link. The default value is 0 (zero).

#### limit-max-outbound-bps-status

Enables or disables the limit-max-outbound-bps option for this link. The default value is disabled.

#### limit-max-total-bps

Specifies the threshold as a sum of inbound and outbound traffic on the link. The default value is 0 (zero).

#### limit-max-total-bps-status

Enables or disables the limit-max-total-bps option for this link. The default value is disabled.

#### link-ratio

Specifies the frequency at which the system sends traffic through the link. The default value is 1.

Important: When you set this option, you must also set the weighting option to ratio.

#### monitor

Specifies the health monitors that the system uses to determine whether this link is available for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this link to be declared up. The default value is none.

name Specifies a unique name for the component. This option is required for the commands create and modify.

prepaid-segment  
Specifies the amount of bandwidth for which the system is prepaid. This option is valid only when the weighting option is set to price. The default value is 0 (zero).

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

router-addresses  
Specifies the IP addresses of the routers that use this link. A router address can be associated with only one link. You can use the following options:

app-service  
Specifies the name of the application service to which the link belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the link. Only the application service can modify or delete the link.

description  
User defined description.

device-name  
Deprecated in v13.0.0 Specifies the name of the device associated with this link. Defaults to none.

translation  
Specifies the address that the link uses for translation when communicating between the network and the Internet. The default value is any6.

service-provider  
Specifies the Internet Service Provider (ISP) or vendor that supplies this link. This allows you to provide a name or description that helps identify this link out of your data center. This is an optional field.

uplink-address  
Specifies the IP address the system uses to gather Simple Network Management Protocol (SNMP) metrics from the router interface. When you configure an uplink address, the system sends SNMP requests to the IP addresses configured using the router-addresses option for this link.

weighting  
Specifies the weighting methodology the system uses to select a link to which to send traffic. The default value is ratio. The options are:

price  
The system continuously checks the performance of each link, and sends traffic through the link with the best performance data.

ratio  
The system uses the value that you set in the link-ratio option to determine the link to which to send traffic.

show listener
show listener [name]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete listener [name]
```

#### DESCRIPTION

You can use the listener component to create, display, modify, or delete a listener.

A listener is an object that listens for DNS queries. Listeners are defined for specific IP addresses, and are always associated with port 53.

**Important:** When you create, modify, or delete a listener, the system saves the running configuration in the stored configuration files.

#### EXAMPLES

```
create listener my_listener address 10.10.1.1 persist replace-all-with
{ source_addr }
```

Creates a listener named `my_listener` with an IP address of 10.10.1.1, which uses the source address persistence method.

```
modify listener my_listener profiles replace-all-with { dns }
```

Replaces the profiles associated with the listener `my_listener`.

**Note:** To replace the profile associated with a listener, you must enclose the name of the new profile in curly brackets.

```
list listener non-default-properties
```

Displays all non-default properties for all listeners.

```
delete listener my_listener
```

Deletes the listener named my\_listener.

#### OPTIONS

##### address

Specifies the IP address on which the system listens. The system receives traffic sent to this IP address and processes it as needed. This option is required.

##### advertise

Specifies whether to advertise the listener address to surrounding routers. The options are yes or no. The default value is no.

##### app-service

Specifies the name of the application service to which the listener belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the listener. Only the application service can modify or delete the listener.

##### context

Specifies that the protocol profile is either a clientside or serverside profile. If not specified, the default value is all for both sides.

##### description

User defined description.

##### (enabled | disabled)

Specifies the state of the listener. The default value is enabled.

Note: When you disable a listener, the listener no longer accepts new connection requests. However, it allows current connections to finish processing before going to a down state.

##### fallback-persistence

Specifies a fallback persistence profile for the listener to use when the default persistence profile is not available. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### ip-protocol

Specifies the protocol on which this listener receives network traffic. The options are udp or tcp. The default value is udp.

##### last-hop-pool

Specifies the name of the last hop pool that you want the listener to use to direct reply traffic to the last hop router. The default value is none.

mask Specifies the netmask for a network listener only. This setting is required for a network listener.

The netmask clarifies whether the host bit is an actual zero or a wildcard representation. The default value is 255.255.255.255 for IPv4 or ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff for IPv6.

name Specifies a unique name for the component. This option is required for the commands create and modify.

##### partition

Displays the administrative partition within which the listener resides.

##### persist

Specifies a list of profiles separated by spaces that the listener uses to manage connection persistence. The default value is none.

To enable persistence, typically you specify a single profile. However, you can specify multiple profiles in conjunction with iRules(r) that define a persistence strategy based on incoming traffic. In the case of multiple profiles, the default option specifies which profile you want the listener to use if an iRule does not specify a persistence method. When you specify multiple profiles, the default value of the default property is no. You can set the value of the default property to yes for only one of the profiles.

pool Specifies a default pool to which you want the listener to automatically direct traffic. The default value is none.

port Specifies the service port on which the listener listens for connections. When you create a listener, the default value is 53 if no port number is specified.

##### profiles

Specifies the DNS, statistics and protocol profiles to use for this listener. When a listener is created, if a DNS profile is not specified, the generic "dns" profile is added. If a protocol profile is not specified, then the generic "tcp" profile is added for TCP and the "udp\_gtm\_dns" profile is added for UDP. A listener always has DNS and protocol profiles once it is created. Only a statistics profile can be added to or deleted from a listener.

The replace-all-with command replaces the profiles with the specified ones. The unspecified DNS and protocol profiles are not changed. If statistics profiles are not specified, the replace-all-with command removes the existing statistics profile from the listener. When the protocol is modified, if profiles are not specified, a default protocol profile is used. DNS and statistics profiles will not change.

##### rules

Specifies a list of iRules, separated by spaces, that customize the listener to direct and manage traffic. The default value is none.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### source-address-translation

Specifies the type of source address translation enabled for the listener as well as the pool that the source address translation will use.

pool Specifies the name of a SNAT pool used by the specified listener.

type Specifies the type of source address translation associated with the specified listener.

The options are:

#### automap

Specifies the use of self IP addresses for listener source address translation.

none Specifies no source address translation to be used by the listener.

snat Specifies the use of a SNAT pool of translation addresses for listener source address translation.

#### source-port

Specifies whether the system preserves the source port of the connection. The default value is preserve.

The options are:

#### change

Obfuscates internal network addresses.

#### preserve

Preserves the source port of the connection.

#### preserve-strict

Use this value only for UDP under very special circumstances, such as nPath or transparent (that is, no translation of any other L3/L4 field), where there is a 1:1 relationship between virtual IP addresses and node addresses, or when clustered multi-processing (CMP) is disabled.

#### translate-address

Enables or disables address translation for the listener. Disable address translation for a listener if you want to use the listener to load balance connections to any address. This option is useful when the system is load balancing devices that have the same IP address. The default value is disabled.

#### translate-port

Enables or disables port translation. Disable port translation for a listener, if you want to use the listener to load balance connections to any service. The default value is disabled.

#### vlan

Specifies a list of VLANs on which traffic is either disabled or enabled, based on whether the vlans-disabled or vlans-enabled option is specified.

#### vlans-disabled

Specifies that traffic is not accepted by this listener on the VLANs specified in the vlans option. This option is mutually exclusive with the vlans-enabled option.

#### vlans-enabled

Specifies that traffic is accepted by this listener on only the VLANs specified in the vlans option. This option is mutually exclusive with the vlans-disabled option.

#### SEE ALSO

create, delete, edit, glob, list, modify, net vlan, net vlan-group, regex, reset-stats, show, tmsh

# gtm monitor bigip-link

**NAME**  
bigip-link - Configures a BIG-IP(r) Link monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the bigip-link component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create bigip-link [name]  
modify bigip-link [name]  
options:  
app-service [[string] | none]  
defaults-from [name]  
description [string]  
destination [ip address]  
ignore-down-response [enabled | disabled]  
interval [integer]  
timeout [integer]

edit bigip-link [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

**DISPLAY**  
list bigip-link  
list bigip-link [ [ [name] | [glob] | [regex] ] ... ]  
show running-config bigip-link  
show running-config bigip-link [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

**DELETE**  
delete bigip-link [name]

Note: You cannot delete default monitors.

**DESCRIPTION**  
You can use the bigip-link component to configure a custom monitor, or you can use the default BIG-IP Link monitor that the Global Traffic Manager provides. This type of monitor acquires data captured through monitors managed by a BIG-IP Link Controller.

**EXAMPLES**  
create bigip-link my\_bigip-link defaults-from bigip\_link

Creates a monitor named my\_bigip-link that inherits properties from the default BIG-IP Link monitor.

list bigip-link

Displays the properties of all of the BIG-IP Link monitors.

**OPTIONS**

**app-service**  
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

**defaults-from**  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is bigip\_link.

**description**  
User defined description.

**destination**  
Specifies the IP address of the resource that is the destination of this monitor. The default value is \*.

Possible values are:

- \* Specifies to perform a health check on the IP address of the node.

**IP address**  
Specifies to perform a health check on the IP address that you specify, route the check through the IP address of the associated node, and mark the IP address of the associated node up or down accordingly.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

## gtm monitor bigip

#### NAME

bigip - Configures a BIG-IP(r) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the bigip component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create bigip [name]
modify bigip [name]
options:
  aggregate-dynamic-ratios [average-members | average-nodes | none |
    sum-members | sum-nodes]
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  timeout [integer]
```

```
edit bigip [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default properties
```

##### DISPLAY

```
list bigip
list bigip [ [name] | [glob] | [regex] ] ... ]
show running-config bigip
show running-config bigip [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete bigip [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the bigip component in the gtm monitor module to configure a custom monitor, or you can use the default BIG-IP(r) monitor that the Global Traffic Manager(tm) provides. The BIG-IP monitor is both a

health and performance monitor. This type of monitor acquires data captured through monitors managed by a BIG-IP Local Traffic Manager(tm).

You can monitor only the following components with a BIG-IP monitor:

- Global Traffic Manager server
- Global Traffic Manager virtual server
- Local Traffic Manager server
- Local Traffic Manager virtual server

#### EXAMPLES

```
create bigip my_bigip defaults-from bigip
```

Creates a monitor named my\_bigip that inherits properties from the default BIG-IP monitor.

```
list bigip
```

Displays the properties of all of the BIG-IP monitors.

#### OPTIONS

aggregate-dynamic-ratios

Specifies the monitor's response to a query. By default, the BIG-IP monitor uses the gtm\_score value as the vs\_score for a Local Traffic Manager virtual server.

You can use this option to override the default behavior using the following values:

average-members

Specifies that the monitor uses the average of the dynamic ratio values of the pool members associated with the pools that are associated with the virtual server as a response to a query.

average-nodes

Specifies that the monitor uses the average value of all of the nodes associated with the pool members that are associated with the pools that are associated with the virtual server as a response to a query.

none This is the default value.

sum-members

Specifies that the monitor uses the sum of the pool members as a response to a query.

sum-nodes

Specifies that the monitor uses the sum of the dynamic ratios of all of the nodes as a response to a query.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is bigip.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*:\*.

Possible values are:

\*:\* Specifies to perform a health check on the address and port supplied by a virtual server.

\*:port

Specifies to perform a health check on the virtual server with the IP address supplied by the virtual server and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the virtual server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 90 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### SEE ALSO

create, delete, edit, glob, gtm pool, gtm server, list, modify, regex, show, tmsh

## gtm monitor external

#### NAME

external - Configures an external monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the external component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create external [name]
modify external [name]
options:
  args [ [arguments] | none]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-timeout [integer]
  run [none | [external monitor] ]
  timeout [integer]
  user-defined [ [name] [value] | [name] none ]
```

```
edit external [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list external
list external [ [ [name] | [glob] | [regex] ] ... ]
show running-config external
show running-config external [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete external [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the external component to configure a custom monitor, or you can use the default external monitor that the Global Traffic Manager provides. You can use this type of monitor to monitor services using your own programs.

#### EXAMPLES

```
create external my_external defaults-from external
```

Creates a monitor named my\_external that inherits properties from the default external monitor.

list external

Displays the properties of all of the external monitors.

#### OPTIONS

args Specifies any command-line arguments that the external program requires. The default value is none.

defaults-from  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is external.

description  
User defined description.

destination  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

probe-timeout  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

run Specifies the external monitor file to be executed by the external monitor. The default value is none.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

user-defined  
Specifies any user-defined command-line arguments and variables that the external program requires. Use the following syntax to specify a user defined parameter.

```
modify external my_external user-defined my_param_name  
my_param_value
```

Use the following syntax to remove a user defined parameter.

```
modify external my_external user-defined my_param_name none
```

#### SEE ALSO

## gtm monitor firepass

**NAME**

firepass - Configures a FirePass(r) monitor.

**MODULE**

gtm monitor

**SYNTAX**

Configure the firepass component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**

```
create firepass [name]
modify firepass [name]
options:
  app-service [[string] | none]
  cipherlist [list]
  concurrency-limit [integer]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  max-load-average [floating point value]
  password [none | [password] ]
  probe-timeout [integer]
  timeout [integer]
  username [name]
```

**edit firepass** [ [ [name] | [glob] | [regex] ] ... ]

**options:**

- all-properties
- non-default-properties

**DISPLAY**

**list firepass**

**list firepass** [ [ [name] | [glob] | [regex] ] ... ]

**show running-config firepass**

**show running-config firepass** [ [ [name] | [glob] | [regex] ] ... ]

**options:**

- all-properties
- non-default-properties
- one-line
- partition

**DELETE**

**delete firepass** [name]

Note: You cannot delete default monitors.

**DESCRIPTION**

You can use the firepass component to configure a custom monitor, or you can use the default FirePass monitor that the BIG-IP(r) Global Traffic Manager(tm) provides. The FirePass monitor is both a health and performance monitor.

For more information about configuring monitors, refer to the Configuration Guide for BIG-IP(r) Global Traffic Management.

**EXAMPLES**

```
create firepass my_firepass defaults-from firepass_gtm
```

Creates a monitor named my\_firepass that inherits properties from the default FirePass monitor.

```
list firepass
```

Displays the properties of all of the FirePass monitors.

**OPTIONS**

**app-service**

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

**cipherlist**

Specifies the list of ciphers for this monitor. The default value is HIGH:!ADH.

**concurrency-limit**

Specifies the maximum percentage of licensed connections currently in use under which the monitor marks the FirePass system up. The default value is 95.

For example, a value of 95 percent means that the monitor marks the FirePass system up until 95 percent of licensed connections are in use. When the number of in-use licensed connections exceeds 95 percent, the monitor marks the FirePass system down.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `firepass_gtm`.

`description`  
User defined description.

`destination`  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the address and port supplied by a pool member.

`*:port`  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`  
Specifies to mark a pool member up or down based on the response of the server at the address you supply.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`ignore-down-response`  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

`interval`  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

`max-load-average`  
Specifies the number that the monitor uses to mark the FirePass system up or down. The system compares value of this option against a one-minute average of the FirePass system load. When the FirePass system-load average falls within the specified value, the monitor marks the FirePass system up. When the average exceeds the setting, the monitor marks the system down.

The default value is 12.0.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`  
Displays the administrative partition within which the component resides.

`password`  
Specifies the password, if the monitored target requires authentication. The default value is none.

`probe-timeout`  
Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

`regex`  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`timeout`  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 90 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

`username`  
Specifies the username, if the monitored target requires authentication. The default value is `gtmuser`.

#### SEE ALSO

`create`, `delete`, `edit`, `glob`, `gtm pool`, `list`, `modify`, `regex`, `show`, `tmsh`

#### COPYRIGHT

# gtm monitor ftp

**NAME**

ftp - Configures a File Transfer Protocol (FTP) monitor.

**MODULE**

gtm monitor

**SYNTAX**

Configure the ftp component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**

```
create ftp [name]
modify ftp [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  filename [ [filename] | none]
  ignore-down-response [enabled | disabled]
  interval [integer]
  mode [passive | port]
  password [none | [password] ]
  probe-timeout [integer]
  timeout [integer]
  username [name]
```

```
edit ftp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

**DISPLAY**

```
list ftp
list ftp [ [ [name] | [glob] | [regex] ] ... ]
show running-config ftp
show running-config ftp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

**DELETE**

```
delete ftp [name]
```

Note: You cannot delete default monitors.

**DESCRIPTION**

You can use the ftp component to configure a custom monitor, or you can use the default FTP monitor that the Global Traffic Manager provides. This type of monitor verifies the FTP service by attempting to download a specific file to the /var/tmp directory on the system. Once downloaded successfully, the file is not saved.

**EXAMPLES**

```
create ftp my_ftp defaults-from ftp
```

Creates a monitor named my\_ftp that inherits properties from the default FTP monitor.

```
list ftp
```

Displays the properties of all of the FTP monitors.

**OPTIONS**

**debug**  
Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

**defaults-from**  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is ftp.

**description**  
User defined description.

**destination**  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*.\*** Specifies to perform a health check on the address and port supplied by a pool member.

**\*:port**  
Specifies to perform a health check on the server with the IP

address supplied by the pool member and the port you specify.

**IP address:port**  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**filename**  
Specifies the full path and file name of the file that the system attempts to download. The health check is successful if the system can download the file. The default value is none.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

**mode** Specifies the data transfer process (DTP) mode. The default value is passive. The options are:

**passive**  
Specifies that the monitor sends a data transfer request to the FTP server. When the FTP server receives the request, the FTP server then starts and establishes the data connection.

**port** Specifies that the monitor starts and establishes the data connection with the FTP server.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**password**  
Specifies the password, if the monitored target requires authentication. The default value is none.

**partition**  
Displays the administrative partition within which the component resides.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor gateway-icmp

#### NAME

gateway-icmp - Configures a Gateway Internet Control Message Protocol (ICMP) monitor.

## MODULE

gtm monitor

## SYNTAX

Configure the gateway-icmp component within the gtm monitor module using the syntax in the following sections.

### CREATE/MODIFY

```
create gateway-icmp [name]
modify gateway-icmp [name]
options:
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-attempts [integer]
  probe-interval [integer]
  probe-timeout [integer]
  timeout [integer]
  transparent [enabled | disabled]

edit gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

### DISPLAY

```
list gateway-icmp
list gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
show running-config gateway-icmp
show running-config gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete gateway-icmp [name]
```

Note: You cannot delete default monitors.

## DESCRIPTION

You can use the gateway-icmp component to configure a custom monitor, or you can use the default Gateway ICMP monitor that the Global Traffic Manager provides. You can use a Gateway ICMP type of monitor for a virtual server, a server (that is, all of the virtuals on a specified server), a pool member, a pool (that is, all of the pool members of a specified pool), or a link.

## EXAMPLES

```
create gateway-icmp my_icmp defaults-from gateway_icmp
```

Creates a monitor named `my_icmp` that inherits properties from the default Gateway ICMP monitor.

```
list gateway-icmp
```

Displays the properties of all of the Gateway ICMP monitors.

## OPTIONS

### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `gateway_icmp`.

### description

User defined description.

### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)  
Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

### interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

probe-attempts  
Specifies the number of times the BIG-IP(r) system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 3 attempts.

probe-interval  
Specifies the frequency at which the BIG-IP system probes the host server. The default value is 1 second.

probe-timeout  
Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent  
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

## gtm monitor gtp

#### NAME

gtp - Configures a GPRS Tunneling Protocol (GTP) monitor. This monitor operates over UDP.

#### MODULE

gtm monitor

#### SYNTAX

Configure the gtp component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create gtp [name]
modify gtp [name]
options:
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-attempts [integer]
  probe-interval [integer]
  probe-timeout [integer]
  protocol-version [integer]
  timeout [integer]
```

```
edit gtp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```

DISPLAY
list gtp
list gtp [ [name] | [glob] | [regex] ] ... ]
show running-config gtp
show running-config gtp [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete gtp [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the gtp component to configure a custom monitor, or you can use the default GTP monitor that the Global Traffic Manager provides. This type of monitor verifies the GPRS tunneling service by attempting to send GTP Echo Requests to a pool, pool member, or virtual server, and verifying the receipt of a well-formed Echo Response packet. This monitor supports GTP version 1 and version 2 over UDP.

For more information about configuring monitors, refer to the Configuration Guide for BIG-IP(r) Global Traffic Management.

#### EXAMPLES

```
create gtp my_gtp defaults-from gtp
```

Creates a monitor named my\_gtp that inherits properties from the default GTP monitor.

```
list gtp
```

Displays the properties of all of the GTP monitors.

#### OPTIONS

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is gtp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

probe-attempts

Specifies the number of times the BIG-IP system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 3.

probe-interval

Specifies the frequency at which the BIG-IP system probes the host server. The default value is 1.

probe-timeout

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

protocol-version

Specifies the GTP protocol version used to perform the exchange. GTP version 1 and GTP version 2 are supported. The default is version 1.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a non-conforming Echo Reply, the system immediately flags the target as down without waiting for the timeout interval to expire.

## gtm monitor http

NAME

http - Configures a Hypertext Transfer Protocol (HTTP) monitor.

MODULE

gtm monitor

SYNTAX

Configure the http component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create http [name]
modify http [name]
options:
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  password [none | [password] ]
  probe-timeout [integer]
  recv [none | [string] ]
  reverse [enabled | disabled]
  send [none | [string] ]
  timeout [integer]
  transparent [enabled | disabled]
  username [ [name] | none]
```

```
edit http [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list http
list http [ [ [name] | [glob] | [regex] ] ... ]
show running-config http
show running-config http [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete http [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the http component to configure a custom monitor, or you can use the default HTTP monitor that the Global Traffic Manager provides. This type of monitor verifies the HTTP service by attempting to receive specific content from a Web page.

EXAMPLES

```
create http my_http defaults-from http
```

Creates a monitor named my\_http that inherits properties from the default HTTP monitor.

```
list http
```

Displays the properties of all of the HTTP monitors.

## OPTIONS

### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is http.

### description

User defined description.

### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

### IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

### interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

### partition

Displays the administrative partition within which the component resides.

### password

Specifies the password if the monitored target requires authentication. The default value is none.

### probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

### reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object.

The default setting is GET /, which retrieves a default HTML file for a web site. To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html.

Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

### timeout

Specifies the number of seconds the target has in which to respond

to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

SEE ALSO

create, delete, gtm pool, gtm server, list, modify, show, tmsh

## gtm monitor https

NAME

https - Configures a Hypertext Transfer Protocol over Secure Socket Layer (HTTPS) monitor.

MODULE

gtm monitor

SYNTAX

Configure the https component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create https [name]
modify https [name]
options:
  cert [ [cert list] | none]
  cipherlist [string]
  compatibility [enabled | disabled]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  key [ [key] | none]
  password [none | [password] ]
  probe-timeout [integer]
  recv [none | [string] ]
  reverse [enabled | disabled]
  send [none | [string] ]
  timeout [integer]
  transparent [enabled | disabled]
  username [ [name] | none]
```

```
edit https [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list https
list https [ [ [name] | [glob] | [regex] ] ... ]
show running-config https
show running-config https [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete https [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the http component to configure a custom monitor, or you can use the default HTTPS monitor that the Global Traffic Manager

provides. This type of monitor verifies the HTTPS service by attempting to receive specific content from a Web page protected by Secure Socket Layer (SSL) security.

#### EXAMPLES

```
create https my_https defaults-from https
```

Creates a monitor named `my_https` that inherits properties from the default HTTPS monitor.

```
list https
```

Displays the properties of all of the HTTPS monitors.

#### OPTIONS

`cert` Specifies a fully-qualified path for a client certificate that the monitor sends to the target SSL server. The default value is none.

`cipherlist`

Specifies the list of ciphers for this monitor. The default list `DEFAULT:+SHA:+3DES:+kEDH:!EXPORT` is located in the file `gtm_base_monitors.conf`.

`compatibility`

Specifies, when enabled, that the SSL options setting (in OpenSSL) is set to ALL. The default value is enabled.

`defaults-from`

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `https`.

`description`

User defined description.

`destination`

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

`*:port`

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

`IP address:port (with the transparent option enabled)`

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`ignore-down-response`

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

`interval`

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

`key` Specifies the RSA private key if the monitored target requires authentication. The key must be surrounded by quotation marks, for

example, `key \"client.key\"`. Note that if you specify a key, you must also specify a value for the `cert` option. The default value is none.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`

Displays the administrative partition within which the component resides.

`password`

Specifies the password if the monitored target requires authentication. The default value is none.

`probe-timeout`

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

`recv` Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for both the `send` and `recv` options, the monitor performs a simple service check and connect only.

`regex`

Displays the items that match the regular expression. The regular

expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object. The default value is GET /, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

#### username

Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

create, delete, edit, glob, gtm pool, list, modify, regex, show, tmsh

#### COPYRIGHT

## gtm monitor imap

#### NAME

imap - Configures an Internet Message Access Protocol (IMAP) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the imap component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create imap [name]
modify imap [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  folder [ [name] | none]
  ignore-down-response [enabled | disabled]
  interval [integer]
  password [none | [password] ]
  probe-timeout [integer]
  timeout [integer]
  transparent [enabled | disabled]
  username [ [name] | none]
```

```
edit imap [ [ [name] | [glob] | [regex] ] ... ]
```

```

options:
  all-properties
  non-default-properties

DISPLAY
list imap
list imap [ [ [name] | [glob] | [regex] ] ... ]
show running-config imap
show running-config imap [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition

DELETE
delete imap [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the imap component to configure a custom monitor, or you can use the default IMAP monitor that the Global Traffic Manager provides. This type of monitor verifies IMAP by attempting to open a specified mail folder on a server. This monitor is similar to the POP3 monitor.

#### EXAMPLES

```
create imap my_imap defaults-from imap
```

Creates a monitor named my\_imap that inherits properties from the default IMAP monitor.

```
list imap
```

Displays the properties of all of the IMAP monitors.

#### OPTIONS

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is imap.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*.\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

folder

Specifies the name of the folder on the IMAP server that the monitor tries to open. The default value is INBOX.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**transparent**  
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

SEE ALSO

## gtm monitor ldap

NAME

ldap - Configures a Lightweight Directory Access Protocol (LDAP) monitor.

MODULE

gtm monitor

SYNTAX

Configure the ldap component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create ldap [name]
modify ldap [name]
options:
  base [none | [string] ]
  chase-referrals [ no | yes ]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  filter [ [LDAP key] | none]
  ignore-down-response [enabled | disabled]
  interval [integer]
  mandatory-attributes [no | yes]
  password [none | [password] ]
  probe-timeout [integer]
  security [none | ssl | tls]
  timeout [integer]
  username [ [name] | none]
```

```
edit ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list ldap
list ldap [ [ [name] | [glob] | [regex] ] ... ]
show running-config ldap
show running-config ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

one-line  
partition

DELETE  
delete ldap [name]

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the ldap component to configure a custom monitor, or you can use the default LDAP monitor that the Global Traffic Manager provides. This type of monitor verifies the LDAP service by attempting to authenticate the specified user.

#### EXAMPLES

create ldap my\_ldap defaults-from ldap

Creates a monitor named my\_ldap that inherits properties from the default LDAP monitor.

list ldap

Displays the properties of all of the LDAP monitors.

#### OPTIONS

base Specifies the location in the LDAP tree from which the monitor starts the health check. A sample value is dc=bigip-test,dc=net. The default value is none.

chase-referrals  
Specifies whether the monitor upon receipt of an LDAP referral entry chases that referral. The default value is yes.

The options are:

no Specifies that the system will treat a referral entry as a normal entry and refrain from querying the remote LDAP server(s) pointed to by the referral entry.

yes Specifies that the system upon receiving any referral entry from the monitored LDAP server query, the system will then query the corresponding LDAP server(s) pointed to by the LDAP query. If the query for the referral is unsuccessful the system will mark the monitored LDAP server down.

debug  
Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is ldap.

description  
User defined description.

destination  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the address and port supplied by a pool member.

\*:port  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

filter  
Specifies an LDAP key for which the monitor searches. A sample value is objectclass=\*. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax

ignore-down-response  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval  
Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

mandatory-attributes  
Specifies whether the target must include attributes in its response to be considered up. The default value is no. The options are:

no Specifies that the system performs only a one-level search (based on the value of the filter option), and does not require that the target returns any attributes.

yes Specifies that the system performs a sub-tree search, and if the target returns no attributes, the target is considered down.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

password  
Specifies the password if the monitored target requires authentication. The default value is none.

probe-timeout  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

security  
Specifies the secure communications protocol that the monitor uses to communicate with the target. The default value is none.

The options are:

none Specifies that the system does not use a security protocol for communications with the target.

ssl Specifies that the system uses the SSL protocol for communications with the target.

tls Specifies that the system uses the TLS protocol for communications with the target.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

username  
Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor mssql

NAME  
mssql - Configures a Microsoft(r) Windows(r) Structured Query Language (MSSQL) monitor.

MODULE  
gtm monitor

SYNTAX  
Configure the mssql component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY  
create mssql [name]  
modify mssql [name]

```

options:
  count [0 | 1]
  database [ [name] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  password [none | [password] ]
  probe-timeout [integer]
  recv [none | [string] ]
  recv-column [none | [string] ]
  recv-row [none | [string] ]
  send [none | [string] ]
  timeout [integer]
  username [ [name] | none]

edit mssql [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

DISPLAY
list mssql
list mssql [ [ [name] | [glob] | [regex] ] ... ]
show running-config mssql
show running-config mssql [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition

DELETE
delete mssql [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the mssql component to configure a custom monitor, or you can use the default MSSQL monitor that the Global Traffic Manager provides. This type of monitor verifies Microsoft Windows SQL-based services.

#### EXAMPLES

```
create mssql my_mssql defaults-from mssql
```

Creates a monitor named my\_mssql that inherits properties from the default MSSQL monitor.

```
list mssql
```

Displays the properties of all of the MSSQL monitors.

#### OPTIONS

##### count

Specifies the number of instances for which the system keeps a connection open. By default, when you assign instances of this monitor to a resource, the system keeps the connection to the database open. With this option you can assign multiple instances to the database while reducing the overhead that multiple open connections can cause.

A value of 0 (zero), the default, keeps the connection open for all instances. A value of 1 opens a new connection for each instance. Any other positive value keeps the connection open for that many instances; for example, a value of 5 keeps the connection open for five instances of this monitor.

##### database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

##### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mssql.

##### description

User defined description.

##### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*.\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**

Displays the administrative partition within which the component resides.

**password**

Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

**recv-column**

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**recv-row**

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**send** Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(\*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**

Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor mysql

**NAME**

mysql - Configures a MySQL(r) monitor.

**MODULE**

gtm monitor

**SYNTAX**

Configure the mysql component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**

```
create mysql [name]
modify mysql [name]
options:
    count [0 | 1]
    database [ [name] | none]
    debug [no | yes]
    defaults-from [name]
    description [string]
    destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
    ignore-down-response [enabled | disabled]
    interval [integer]
    password [none | [password] ]
    probe-timeout [integer]
    recv [none | [string] ]
    recv-column [none | [string] ]
    recv-row [none | [string] ]
    send [none | [string] ]
    timeout [integer]
    username [ [name] | none]

edit mysql [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list mysql
list mysql [ [ [name] | [glob] | [regex] ] ... ]
show running-config mysql
show running-config mysql [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
    partition

DELETE
delete mysql [name]
```

Note: You cannot delete default monitors.

**DESCRIPTION**

You can use the mysql component to configure a custom monitor, or you can use the default MySQL monitor that the Global Traffic Manager provides. This type of monitor verifies Microsoft(r) Windows(r) SQL-based services.

**EXAMPLES**

```
create mysql my_mysql defaults-from mysql

Creates a monitor named my_mysql that inherits properties from the
default MySQL monitor.

list mysql

Displays the properties of all of the MySQL monitors.
```

**OPTIONS**

**count**

Specifies the number of instances for which the system keeps a connection open. By default, when you assign instances of this monitor to a resource, the system keeps the connection to the database open. With this option you can assign multiple instances to the database while reducing the overhead that multiple open connections can cause.

A value of 0 (zero), the default, keeps the connection open for all instances. A value of 1 opens a new connection for each instance. Any other positive value keeps the connection open for that many instances; for example, a value of 5 keeps the connection open for five instances of this monitor.

**database**

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

**debug**

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages

and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

**defaults-from**  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mysql.

**description**  
User defined description.

**destination**  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**password**  
Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

**recv-column**  
Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**recv-row**  
Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**send** Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(\*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor nntp

NAME  
nntp - Configures a Network News Transfer Protocol (NNTP) monitor.

MODULE  
gtm monitor

SYNTAX  
Configure the nntp component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY  
create nntp [name]  
modify nntp [name]  
options:  
  debug [no | yes]  
  defaults-from [name]  
  description [string]  
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]  
  ignore-down-response [enabled | disabled]  
  interval [integer]  
  newsgroup [ [name] | none]  
  password [none | [password] ]  
  probe-timeout [integer]  
  timeout [integer]  
  username [ [name] | none]

edit nntp [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

DISPLAY  
list nntp  
list nntp [ [ [name] | [glob] | [regex] ] ... ]  
show running-config nntp  
show running-config nntp [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties  
  one-line  
  partition

DELETE  
delete nntp [name]

Note: You cannot delete default monitors.

DESCRIPTION  
You can use the nntp component to configure a custom monitor, or you can use the default NNTP monitor that the Global Traffic Manager provides. This type of monitor verifies the Usenet News protocol service by attempting to retrieve a newsgroup identification string from the server.

EXAMPLES  
create nntp my\_nntp defaults-from nntp  
  
Creates a monitor named my\_nntp that inherits properties from the default NNTP monitor.  
  
list nntp  
  
Displays the properties of all of the NNTP monitors.

OPTIONS  
debug  
Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.  
  
The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is nntp.

description  
User defined description.

destination  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

newsgroup  
Specifies the name of the newsgroup that you are monitoring, for example alt.car.mercedes. The default value is none.

partition  
Displays the administrative partition within which the component resides.

password  
Specifies the password if the monitored target requires authentication. The default value is none.

probe-timeout  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

username  
Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

create, delete, edit, glob, gtm pool, list, modify, regex, show, tmsh

## gtm monitor none

**NAME**

none - A base level NULL monitor used to indicate that no monitoring will be performed.

**MODULE**

gtm monitor

**SYNTAX**

The none component within the gtm monitor module can be used only with the syntax described in the following sections.

**DISPLAY**

```
list none
list none [ [ [name] | [glob] | [regex] ] ... ]
show running-config none
show running-config none [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

**CREATE/MODIFY/DELETE**

Note: You cannot create a custom monitor based off of the none monitor nor can you modify or delete the existing default none monitor.

**DESCRIPTION**

The none component is used to configure a GTM pool member that explicitly does not inherit its parent pool's monitor and remains unmonitored, regardless of the monitor setting on the parent pool.

**EXAMPLES**

```
create gtm pool a test_pool monitor http members add { test:vs_1 {
monitor none } test:vs_2 { } }
```

Creates a gtm pool with an http monitor that has two members, vs\_1 and vs\_2. The pool member vs\_1 is configured with the none monitor so it does not inherit http monitoring from its parent pool, whereas pool member vs\_2 will inherit and use its parent's http monitor.

**OPTIONS**

Note: While the following options are specified as part of the definition of the none monitor, they cannot be changed since the none monitor is used to define the absence of a monitor, not an actual monitor.

**app-service**

Displays the application service to which the object belongs. The permanent value is none. Note: Regardless if the strict-updates option is enabled, you cannot modify or delete the object; these are unavailable options for the none monitor.

**defaults-from**

Specifies the name of the monitor from which this monitor inherits settings. The default value is none.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*:6666, also shown as \*:ircu-2.

**ignore-down-response**

Specifies whether this monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**

Specifies the frequency at which the system issues the monitor check. The default value is 0 seconds.

**partition**

Displays the administrative partition within which the component resides. The default value is Common.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 0 seconds.

**time-until-up**

Specifies the amount of time in seconds after the first successful response before a node is marked up. A value of 0 causes a node to be marked up immediately after a valid response is received from the node. The default value is 86500.

**timeout**

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 0 seconds.

**up-interval**

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0, which specifies that the system uses the value of the interval option whether the resource is up or down.

**SEE ALSO**

gtm pool, list, show, tmsh

## gtm monitor oracle

#### NAME

oracle - Configures an Oracle(r) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the oracle component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create oracle [name]
modify oracle [name]
options:
  count [0 | 1]
  database [ [name] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  password [none | [password] ]
  probe-timeout [integer]
  recv [none | [string] ]
  recv-column [none | [string] ]
  recv-row [none | [string] ]
  send [none | [string] ]
  timeout [integer]
  username [ [name] | none]
```

```
edit oracle [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list oracle
list oracle [ [ [name] | [glob] | [regex] ] ... ]
show running-config oracle
show running-config oracle [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete oracle [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the oracle component to configure a custom monitor, or you can use the default Oracle monitor that the Global Traffic Manager provides. This type of monitor verifies services based on Oracle by attempting to perform an Oracle login to a service.

#### EXAMPLES

```
create oracle my_oracle defaults-from oracle
```

Creates a monitor named my\_oracle that inherits properties from the default Oracle monitor.

```
list oracle
```

Displays the properties of all of the Oracle monitors.

#### OPTIONS

**count**  
Specifies the number of instances for which the system keeps a connection open. By default, when you assign instances of this monitor to a resource, the system keeps the connection to the database open. With this option you can assign multiple instances to the database while reducing the overhead that multiple open connections can cause.

A value of 0 (zero), the default, keeps the connection open for all instances. A value of 1 opens a new connection for each instance. Any other positive value keeps the connection open for that many instances; for example, a value of 5 keeps the connection open for five instances of this monitor.

#### database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

#### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

#### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is oracle.

#### description

User defined description.

#### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*.\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

#### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

#### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

#### interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

#### partition

Displays the administrative partition within which the component resides.

#### password

Specifies the password if the monitored target requires authentication. The default value is none.

#### probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

#### recv-column

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

#### recv-row

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**send** Specifies the SQL query that the monitor sends to the target

database, for example, `SELECT count(*) FROM mytable.`

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the `recv` option and ignores the option even if not null.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### username

Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor pop3

#### NAME

`pop3` - Configures a Post Office Protocol version 3 (POP3) monitor.

#### MODULE

`gtm monitor`

#### SYNTAX

Configure the `pop3` component within the `gtm monitor` module using the syntax in the following sections.

##### CREATE/MODIFY

```
create pop3 [name]
modify pop3 [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  password [none | [password] ]
  probe-timeout [integer]
  timeout [integer]
  username [ [name] | none]
```

```
edit pop3 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list pop3
list pop3 [ [ [name] | [glob] | [regex] ] ... ]
show running-config pop3
show running-config pop3 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete pop3 [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the `pop3` component to configure a custom monitor, or you can use the default POP3 monitor that the Global Traffic Manager provides. This type of monitor verifies the POP3 service by attempting to connect to a pool, pool member, or virtual server, log on as the specified user, and log off.

#### EXAMPLES

create pop3 my\_pop3 defaults-from pop3

Creates a monitor named my\_pop3 that inherits properties from the default POP3 monitor.

list pop3

Displays the properties of all of the POP3 monitors.

#### OPTIONS

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is pop3.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*.\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor postgresql

**NAME**  
    postgresql - Configures a PostgreSQL(r) monitor.

**MODULE**  
    gtm monitor

**SYNTAX**  
    Configure the postgresql component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create postgresql [name]  
modify postgresql [name]  
    options:  
        count [0 | 1]  
        database [ [name] | none]  
        debug [no | yes]  
        defaults-from [name]  
        description [string]  
        destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]  
        ignore-down-response [enabled | disabled]  
        interval [integer]  
        password [none | [password] ]  
        probe-timeout [integer]  
        recv [none | [string] ]  
        recv-column [none | [string] ]  
        recv-row [none | [string] ]  
        send [none | [string] ]  
        timeout [integer]  
        username [ [name] | none]  
  
edit postgresql [ [ [name] | [glob] | [regex] ] ... ]  
    options:  
        all-properties  
        non-default-properties  
  
**DISPLAY**  
list postgresql  
list postgresql [ [ [name] | [glob] | [regex] ] ... ]  
show running-config postgresql  
show running-config postgresql [ [ [name] | [glob] | [regex] ] ... ]  
    options:  
        all-properties  
        non-default-properties  
        one-line  
        partition  
  
**DELETE**  
delete postgresql [name]

    Note: You cannot delete default monitors.

**DESCRIPTION**  
    You can use the postgresql component to configure a custom monitor, or you can use the default PostgreSQL monitor that the Global Traffic Manager provides. This type of monitor verifies Microsoft(r) Windows(r) SQL-based services.

**EXAMPLES**  
    create postgresql my\_postgresql defaults-from postgresql  
  
    Creates a monitor named my\_postgresql that inherits properties from the default PostgreSQL monitor.  
  
    list postgresql  
  
    Displays the properties of all of the PostgreSQL monitors.

**OPTIONS**  
    count  
    Specifies the number of instances for which the system keeps a connection open. By default, when you assign instances of this monitor to a resource, the system keeps the connection to the database open. With this option you can assign multiple instances to the database while reducing the overhead that multiple open connections can cause.  
  
    A value of 0 (zero), the default, keeps the connection open for all instances. A value of 1 opens a new connection for each instance. Any other positive value keeps the connection open for that many instances; for example, a value of 5 keeps the

connection open for five instances of this monitor.

**database**

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

**debug**

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the  
/var/log/monitors/--.log file.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is postgresql.

**description**

User defined description.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*.\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**

Displays the administrative partition within which the component resides.

**password**

Specifies the password if the monitored target requires authentication. The default value is none.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

**recv-column**

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**recv-row**

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**send** Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(\*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does

not need the recv option and ignores the option even if not null.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**username**  
Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor radius-accounting

NAME

radius-accounting - Configures a RADIUS accounting monitor for the BIG-IP(r) Global Traffic Manager.

MODULE

gtm monitor

SYNTAX

Configure the radius-accounting component within the gtm monitor module using the syntax shown in the following sections.

CREATE/MODIFY

```
create radius-accounting [name]
modify radius [name]
options:
  app-service [[string] | none]
  check-until-up [disabled | enabled]
  debug [no | yes]
  defaults-from [ [name] | none]
  description [string]
  destination [ip address]
  interval [integer]
  manual-resume [disabled | enabled]
  nas-ip-address [ip address]
  secret [string]
  time-until-up [integer]
  timeout [integer]
  username [none | [string] ]
```

```
edit radius-accounting [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list radius-accounting
list radius-accounting [ [ [name] | [glob] | [regex] ] ...]
show running-config radius
show running-config radius [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete radius-accounting [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the radius-accounting component to configure a custom monitor, or you can use the default RADIUS accounting monitor that the Global Traffic Manager provides. This type of monitor provides information about the usage of the RADIUS service for accounting purposes.

EXAMPLES

create radius-accounting my\_radius\_acct defaults-from radius\_accounting

Creates a monitor named my\_radius\_acct that inherits properties from the default RADIUS accounting monitor.

list radius-accounting

Displays the properties of all of the RADIUS accounting monitors.

#### OPTIONS

app-service

Specifies the name of the application service to which this monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this monitor. Only the application service can modify or delete this monitor.

check-until-up

When enabled, specifies that when an active and passive (inband) monitor are combined in an AND type of rule, the active monitor performs health checks only when the pool member is down, or until the pool member is marked as up. When the passive monitor marks the pool member down, the active monitor resumes health checks.

The default value is disabled.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is radius.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*.\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

nas-ip-address

Specifies the network access server IP address that the system uses to identify itself to the RADIUS server. Using this option, multiple BIG-IP(r) systems can appear as a single network access device to the RADIUS server. The default value is none.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Specifies the secret the monitor needs to communicate with the resource. The default value is none.

#### time-until-up

Specifies the amount of time in seconds after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### username

Specifies the username, if the monitored target requires authentication. The default value is none.

#### SEE ALSO

create, delete, edit, glob, gtm pool, list, modify, regex, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

## gtm monitor radius

#### NAME

radius - Configures a Remote Access Dial-in User Service (RADIUS) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the radius component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create radius [name]
modify radius [name]
options:
  app-service [[string] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  nas-ip-address [ [ip address] | none]
  password [none | [password] ]
  probe-timeout [integer]
  secret [none | [secret] ]
  timeout [integer]
  username [ [name] | none]
```

```
edit radius [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list radius
list radius [ [ [name] | [glob] | [regex] ] ... ]
show running-config radius
show running-config radius [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete radius [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the radius component to configure a custom monitor, or you can use the default RADIUS monitor that the Global Traffic Manager

provides. This type of monitor verifies the RADIUS service by attempting to authenticate the specified user.

#### EXAMPLES

```
create radius my_radius defaults-from radius
```

Creates a monitor named `my_radius` that inherits properties from the default RADIUS monitor.

```
list radius
```

Displays the properties of all of the RADIUS monitors.

#### OPTIONS

`app-service`

Specifies the name of the application service to which this monitor belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete this monitor. Only the application service can modify or delete this monitor.

`debug`

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

`no` Specifies that the system does not redirect error messages and additional information related to this monitor.

`yes` Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

`defaults-from`

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `radius`.

`description`

User defined description.

`destination`

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*.*`.

Possible values are:

`*.*` Specifies to perform a health check on the IP address and port supplied by a pool member.

`*:port`

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

`glob` Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

`ignore-down-response`

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

`interval`

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`nas-ip-address`

Specifies the network access server IP address that the system uses to identify itself to the RADIUS server. Using this option, multiple BIG-IP(r) systems can appear as a single network access device to the RADIUS server. The default value is none.

`partition`

Displays the administrative partition within which the component resides.

`password`

Specifies the password if the monitored target requires authentication. The default value is none.

`probe-timeout`

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`secret`

Specifies the secret the monitor needs to communicate with the resource. The default value is none.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

username  
Specifies the username, if the monitored target requires authentication. The default value is none.

## gtm monitor real-server

NAME  
real-server - Configures a RealServer(r) monitor.

MODULE  
gtm monitor

SYNTAX  
Configure the real-server component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY  
create real-server [name]  
modify real-server [name]  
options:  
  defaults-from [name]  
  description [string]  
  ignore-down-response [enabled | disabled]  
  interval [integer]  
  metrics [ [metrics] | none]  
  probe-timeout [integer]  
  timeout [integer]  
  
edit real-server [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  non-default-properties

DISPLAY  
list real-server  
list real-server [ [ [name] | [glob] | [regex] ] ... ]  
show running-config real-server  
show running-config real-server [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  agent  
  all-properties  
  command  
  method  
  non-default-properties  
  one-line  
  partition

DELETE  
delete real-server [name]

Note: You cannot delete default monitors.

DESCRIPTION

You can use the real-server component to configure a custom monitor, or you can use the default RealServer monitor that the Global Traffic Manager provides. This type of monitor checks the performance of a pool, pool member, or virtual server that is running the RealServer data collection agent, and then dynamically load balances traffic accordingly.

EXAMPLES

create real-server my\_real-server defaults-from real\_server

Creates a monitor named my\_real-server that inherits properties from the default RealServer monitor.

list real-server

Displays the properties of all of the RealServer monitors.

#### OPTIONS

agent

Displays the agent for the monitor. The default agent is Mozilla/4.0 (compatible: MSIE 5.0; Windows NT). You cannot modify the agent.

command

Displays the command that the system uses to obtain the metrics from the resource. See the documentation for this resource for information on available commands. You cannot modify the command.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is real\_server.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

method

Displays the GET method. You cannot modify the method.

metrics

Specifies the performance metrics that the commands collect from the target. The default value is ServerBandwidth:1.5, CPUPercentUsage, MemoryUsage, TotalClientCount.

partition

Displays the administrative partition within which the component resides.

probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### SEE ALSO

## gtm monitor scripted

#### NAME

scripted - Configures a Scripted monitor.

#### MODULE

gtm monitor

## SYNTAX

Configure the scripted component within the gtm monitor module using the syntax in the following sections.

### CREATE/MODIFY

```
create scripted [name]
modify scripted [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  filename [ [filename] | none]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-timeout [integer]
  timeout [integer]

edit scripted [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

### DISPLAY

```
list scripted
list scripted [ [ [name] | [glob] | [regex] ] ... ]
show running-config scripted
show running-config scripted [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

### DELETE

```
delete scripted [name]
```

Note: You cannot delete default monitors.

## DESCRIPTION

You can use the scripted component to configure a custom monitor, or you can use the default scripted monitor that the Global Traffic Manager provides.

## EXAMPLES

```
create scripted my_scripted defaults-from scripted
```

Creates a monitor named my\_scripted that inherits properties from the default Scripted monitor.

```
list scripted
```

Displays the properties of all of the scripted monitors.

## OPTIONS

### debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is scripted.

### description

User defined description.

### destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*.\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

### \*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

### IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

### filename

Specifies the name of a file in the /config/eav/ directory on the system. The user-created file contains the send and expect data that the monitor uses for the monitor check. The default value is none.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### SEE ALSO

BIG-IP          2017-08-15          gtm monitor scripted(1)

## gtm monitor sip

**NAME**  
sip - Configures a Session Initiation Protocol (SIP) monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the sip component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**  
create sip [name]  
modify sip [name]  
options:  
cert [ [cert list] | none]  
cipherlist [list]  
compatibility [enabled | disabled]  
debug [ no | yes]  
defaults-from [name]  
description [string]  
destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]  
filter [any | none | status]  
filter-neg [any | none | status]  
headers [ [new line separated headers] | none]  
ignore-down-response [enabled | disabled]  
interval [integer]  
key [ [key] | none]  
mode [sips | tcp | tls | udp]  
probe-timeout [integer]  
request [none | [string] ]  
username [ [name] | none]

edit sip [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

```

DISPLAY
list sip
list sip [ [name] | [glob] | [regex] ] ... ]
show running-config sip
show running-config sip [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete sip [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the sip component to configure a custom monitor, or you can use the default SIP monitor that the Global Traffic Manager provides. This type of monitor checks the status of SIP Call-ID services on a device. The SIP protocol enables real-time messaging, voice, data, and video.

#### EXAMPLES

```
create sip my_sip defaults-from sip
```

Creates a monitor named my\_sip that inherits properties from the default SIP monitor.

```
list sip
```

Displays the properties of all of the SIP monitors.

#### OPTIONS

**cert** Specifies a fully-qualified path for a client certificate that the monitor sends to the target SSL server. The default value is none.

**cipherlist**  
Specifies the list of ciphers for this monitor. The default value is none.

**compatibility**  
Specifies, when enabled, that the SSL options setting (in OpenSSL) is set to ALL. The default value is enabled.

**debug**  
Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

**defaults-from**  
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is sip.

**description**  
User defined description.

**destination**  
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**filter**  
Specifies the SIP status codes that the target can return to be considered up. By default the system always accepts status codes whose value is in the 100s, 200s, or 300s.

The options are:

**any** Specifies that the monitor accepts any SIP status codes.

**none** Specifies that the monitor does not accept any other SIP status codes. This is the default value.

**status**  
Specifies one or more status codes that you want to add to the monitor.

**filter-neg**  
Specifies the SIP status codes that the target can return to be considered down. By default the system always accepts status codes

according to sip-monitor.filter. After checking that, the status code is checked against this key. If a code is also in sip-monitor.filter, the node is marked up.

The options are:

any Specifies that the monitor rejects all SIP status codes that are not in sip-monitor.filter.

none Specifies that the monitor does not specifically reject any other SIP status codes. This is the default value.

status  
Specifies one or more status codes that you want to add to the monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

headers  
Specifies the set of SIP headers in the SIP message that is sent to the target. Separate each header with a new line. The default value is none.

ignore-down-response  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

key Specifies the key if the monitored target requires authentication. The default value is none.

mode Specifies the protocol that the monitor uses to communicate with the target. The options are:

sips Specifies that the monitor uses SIPS to communicate with the target.

tcp Specifies that the monitor uses TCP to communicate with the target.

tls Specifies that the monitor uses TLS to communicate with the target, and the SIP URI is SIPS.

udp Specifies that the monitor uses UDP to communicate with the target.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

probe-timeout  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

request  
Specifies the SIP request line in the SIP message that is sent to the target. The default value is none.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

## gtm monitor smtp

**NAME**

smtp - Configures a Simple Mail Transport Protocol (SMTP) monitor.

**MODULE**

gtm monitor

**SYNTAX**

Configure the smtp component within the gtm monitor module using the syntax in the following sections.

**CREATE/MODIFY**

```
create smtp [name]
modify smtp [name]
  options:
    debug [no | yes]
    defaults-from [name]
    description [string]
    destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
    domain [ [name] | none]
    ignore-down-response [enabled | disabled]
    interval [integer]
    probe-timeout [integer]
    timeout [integer]

edit smtp [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
```

**DISPLAY**

```
list smtp
list smtp [ [ [name] | [glob] | [regex] ] ... ]
show running-config smtp
show running-config smtp [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition
```

**DELETE**

```
delete smtp [name]
```

Note: You cannot delete default monitors.

**DESCRIPTION**

You can use the smtp component to configure a custom monitor, or you can use the default SMTP monitor that the Global Traffic Manager provides. This type of monitor checks the status of a pool, pool member, or virtual server by issuing standard SMTP commands.

**EXAMPLES**

```
create smtp my_smtp defaults-from smtp
```

Creates a monitor named my\_smtp that inherits properties from the default SMTP monitor.

```
list smtp
```

Displays the properties of all of the SMTP monitors.

**OPTIONS**

**debug**

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

**no** Specifies that the system does not redirect error messages and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is smtp.

**description**

User defined description.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

domain  
Specifies the domain name to check, for example, bigipinternal.com. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition  
Displays the administrative partition within which the component resides.

probe-timeout  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

## gtm monitor snmp-link

NAME  
snmp-link - Configures a Simple Network Management Protocol (SNMP) link monitor.

MODULE  
gtm monitor

SYNTAX  
Configure the snmp-link component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY  
create snmp-link [name]  
modify snmp-link [name]  
options:  
  app-service [[string] | none]  
  community [[name] | none]  
  defaults-from [name]  
  description [string]  
  destination [ip address]  
  ignore-down-response [enabled | disabled]  
  interval [integer]  
  port [ [integer] | none]  
  probe attempts [integer]  
  probe-interval [integer]

```

    probe-timeout [integer]
    timeout [integer]
    version [ [integer] | none]

edit snmp-link [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list snmp-link
list snmp-link [ [ [name] | [glob] | [regex] ] ... ]
show running-config snmp-link
show running-config snmp-link [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
    partition

DELETE
delete snmp-link [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the snmp-link component to configure a custom monitor, or you can use the default SNMP Link monitor that the Global Traffic Manager provides. This type of monitor checks the current CPU, memory, and disk usage of a pool, pool member, or virtual server that is running an SNMP data collection agent, and then dynamically load balances traffic accordingly.

#### EXAMPLES

```
create snmp-link my_snmp-link defaults-from snmp_link
```

Creates a monitor named my\_snmp-link that inherits properties from the default SNMP Link monitor.

```
list snmp-link
```

Displays the properties of all of the SNMP Link monitors.

#### OPTIONS

##### app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

##### community

Specifies the community name that the BIG-IP(r) system must use to authenticate with the host server through SNMP. The default value is public.

##### defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is snmp\_link.

##### description

User defined description.

##### destination

Specifies the IP address of the resource that is the destination of this monitor. The default value is \*.

Possible values are:

- \* Specifies to perform a health check on the IP address of the node.

##### IP address

Specifies to perform a health check on the IP address that you specify, route the check through the IP address of the associated node, and mark the IP address of the associated node up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

##### interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

##### partition

Displays the administrative partition within which the component resides.

port Specifies the port number to which this monitor sends SNMP traps. The default value is 161.

##### probe-attempts

Specifies the number of times the BIG-IP system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 3.

probe-interval  
Specifies the frequency at which the BIG-IP system probes the host server. The default value is 0.

probe-timeout  
Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

version  
Specifies the SNMP version the monitor uses. The default value is none.

SEE ALSO

## gtm monitor snmp

NAME  
snmp - Configures a Simple Network Management Protocol (SNMP) monitor.

MODULE  
gtm monitor

SYNTAX  
Configure the snmp component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY  
create snmp [name]  
modify snmp [name]  
options:  
app-service [[string] | none]  
community [ [name] | none]  
defaults-from [name]  
description [string]  
destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]  
ignore-down-response [enabled | disabled]  
interval [integer]  
port [integer]  
probe attempts [integer]  
probe-interval [integer]  
probe-timeout [integer]  
timeout [integer]  
version [ [integer] | none]

edit snmp [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties

DISPLAY  
list snmp  
list snmp [ [ [name] | [glob] | [regex] ] ... ]  
show running-config snmp  
show running-config snmp [ [ [name] | [glob] | [regex] ] ... ]  
options:  
all-properties  
non-default-properties  
one-line  
partition

DELETE

delete snmp [name]

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the snmp component to configure a custom monitor, or you can use the default SNMP monitor that the Global Traffic Manager provides. The SNMP monitor is both a health and performance monitor. This type of monitor checks the performance of a server running an SNMP agent such as UC Davis, for the purpose of load balancing traffic to that server.

#### EXAMPLES

```
create snmp my_snmp defaults-from snmp_gtm
```

Creates a monitor named my\_snmp that inherits properties from the default SNMP monitor.

```
list snmp
```

Displays the properties of all of the SNMP monitors.

#### OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

community

Specifies the community name that the BIG-IP(r) system must use to authenticate with the host server through SNMP. The default value is public.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is snmp\_gtm.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 90 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

port Specifies the port number to which this monitor sends SNMP traps. The default value is 161.

probe-attempts

Specifies the number of times the BIG-IP system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 1.

probe-interval

Specifies the frequency at which the BIG-IP system probes the host server. The default value is 1.

probe-timeout

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 180 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**version**  
Specifies the SNMP version the monitor uses. The default value is v1.

SEE ALSO

create, delete, edit, glob, gtm pool, list, modify, regex, show, tmsh

## gtm monitor soap

NAME

soap - Configures a Simple Object Access Protocol (SOAP) monitor.

MODULE

gtm monitor

SYNTAX

Configure the soap component within the gtm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create soap [name]
modify soap [name]
options:
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  expect-fault [no | yes]
  ignore-down-response [enabled | disabled]
  interval [integer]
  method [string]
  namespace [ [name] | none]
  parameter-name [ [name] | none]
  parameter-type [bool | int | long | [string] ]
  parameter-value [none | [integer] | [string] ]
  password [none | [password] ]
  probe-timeout [integer]
  protocol [[none] | [protocol] ]
  return-type [bool | char | double | int | long | short | [string] ]
  return-value [none | [integer] | [string]]
  soap-action [string]
  timeout [integer]
  url-path [none | [string] ]
  username [ [name] | none]

edit soap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list soap
list soap [ [ [name] | [glob] | [regex] ] ... ]
show running-config soap
show running-config soap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete soap [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the soap component to configure a custom monitor, or you can use the default SOAP monitor that the Global Traffic Manager provides. This type of monitor tests a Web service based on SOAP.

EXAMPLES

create soap my\_soap defaults-from soap

Creates a monitor named my\_soap that inherits values from the system default SOAP monitor.

list soap

Displays the properties of all of the SOAP monitors.

#### OPTIONS

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the type of monitor you want to use to create the new monitor. The default value is soap.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

\*: \* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*: port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address: port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

expect-fault

Specifies whether the value of the method option causes the monitor to expect a SOAP fault message. The default value is no.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

method

Specifies the method by which the monitor contacts the resource.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

namespace

Specifies the name space for the Web service you are monitoring, for example, http://example.com/. The default value is none.

parameter-name

If the method has a parameter, specifies the name of that parameter. The default value is bool.

parameter-type

Specifies the parameter type. The default value is none.

parameter-value

Specifies the value for the parameter. The default value is none.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

protocol

Specifies the protocol that the monitor uses to communicate with the target. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help

regex for a description of regular expression syntax.

**return-type**  
Specifies the type for the returned parameter. The default value is bool.

**return-value**  
Specifies the value for the returned parameter. The default value is none.

**soap-action**  
Specifies the value for the SOAPAction header. The default value is the empty string.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**url-path**  
Specifies the URL for the Web service that you are monitoring, for example, /services/myservice.aspx. The default value is none.

**username**  
Specifies the user name if the monitored target requires authentication. The default value is none.

## gtm monitor tcp-half-open

#### NAME

tcp-half-open - Configures a Transmission Control Protocol (TCP) Half Open monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the tcp-half-open component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create tcp-half-open [name]
modify tcp-half-open [name]
options:
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-attempts [integer]
  probe-interval [integer]
  probe-timeout [integer]
  timeout [integer]
  transparent [disabled | enabled]
```

```
edit tcp-half-open [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list tcp-half-open
list tcp-half-open [ [ [name] | [glob] | [regex] ] ... ]
show running-config tcp-half-open
show running-config tcp-half-open [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete tcp-half-open [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the tcp-half-open component to configure a custom monitor, or you can use the default TCP Half Open monitor that the Global Traffic Manager provides.

For more information about configuring monitors, refer to the Configuration Guide for BIG-IP(r) Global Traffic Management.

#### EXAMPLES

```
create tcp-half-open my_tcp-half-open defaults-from tcp_half_open
```

Creates a monitor named my\_tcp-half-open that inherits properties from the default TCP Half Open monitor.

```
list tcp-half-open
```

Displays the properties of all of the TCP Half Open monitors.

#### OPTIONS

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is tcp\_half\_open.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

probe-attempts

Specifies the number of times the BIG-IP system attempts to probe the host server, after which the BIG-IP system considers the host server down or unavailable. The default value is 3.

probe-interval

Specifies the frequency at which the BIG-IP system probes the host server. The default value is 1.

probe-timeout

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through

firewalls. The default value is disabled.

#### SEE ALSO

---

## gtm monitor tcp

#### NAME

tcp - Configures a Transmission Control Protocol (TCP) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the tcp component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create tcp [name]
modify tcp [name]
options:
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-timeout [integer]
  recv [none | [string] ]
  reverse [enabled | disabled]
  send [none | [string] ]
  timeout [integer]
  transparent [disabled | enabled]
```

```
edit tcp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list tcp
list tcp [ [ [name] | [glob] | [regex] ] ... ]
show running-config tcp
show running-config tcp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete tcp [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the tcp component to configure a custom monitor, or you can use the default TCP monitor that the Global Traffic Manager provides.

#### EXAMPLES

```
create tcp my_tcp defaults-from tcp
```

Creates a monitor named my\_tcp that inherits properties from the default TCP monitor.

```
list tcp
```

Displays the properties of all of the TCP monitors.

#### OPTIONS

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is tcp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**  
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**  
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**IP address:port (with the transparent option enabled)**  
Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**ignore-down-response**  
Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**  
Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

**partition**  
Displays the administrative partition within which the component resides.

**probe-timeout**  
Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**reverse**  
Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

**send** Specifies the text string that the monitor sends to the target object. The default setting is GET /, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

**timeout**  
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

**transparent**  
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

## gtm monitor udp

**NAME**  
udp - Configures a User Datagram Protocol (UDP) monitor.

**MODULE**  
gtm monitor

**SYNTAX**  
Configure the udp component within the gtm monitor module using the syntax in the following sections.

```
CREATE/MODIFY
create udp [name]
modify udp [name]
options:
    debug [no | yes]
    defaults-from [name]
    description [string]
    destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
    ignore-down-response [enabled | disabled]
    interval [integer]
    probe-attempts [integer]
    probe-interval [integer]
    probe-timeout [integer]
    recv [none | [string] ]
    reverse [enabled | disabled]
    send [none | [string] ]
    timeout [integer]
    transparent [disabled | enabled]

edit udp [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list udp
list udp [ [ [name] | [glob] | [regex] ] ... ]
show running-config udp
show running-config udp [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
    partition

DELETE
delete udp [name]
```

Note: You cannot delete default monitors.

**DESCRIPTION**  
You can use the udp component to configure a custom monitor, or you can use the default UDP monitor that the Global Traffic Manager provides. This type of monitor verifies the UDP service by attempting to send UDP packets to a pool, pool member, or virtual server, and receiving a reply.

For more information about configuring monitors, refer to the Configuration Guide for BIG-IP(r) Global Traffic Management.

**EXAMPLES**  
create udp my\_udp defaults-from udp  
  
Creates a monitor named my\_udp that inherits properties from the default UDP monitor.  
  
list udp  
  
Displays the properties of all of the UDP monitors.

**OPTIONS**  
debug  
Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.  
  
The options are:  
  
no Specifies that the system does not redirect error messages

and additional information related to this monitor.

**yes** Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

**defaults-from**

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `udp`.

**description**

User defined description.

**destination**

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

**\*:\*** Specifies to perform a health check on the IP address and port supplied by a pool member.

**\*:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

**IP address:port**

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

**IP address:port (with the transparent option enabled)**

Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

**glob** Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

**ignore-down-response**

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

**interval**

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

**name** Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

**partition**

Displays the administrative partition within which the component resides.

**probe-attempts**

Specifies the maximum number of times the BIG-IP system will attempt to probe an unresponsive host server before marking the server as down/unavailable. The default value is 3 attempts. This attribute requires the usage of a Receive String, otherwise only 1 probe attempt occurs.

**probe-interval**

Specifies the time between individual probe attempts sent by the BIG-IP to the host server. The default value is 1 second. This attribute requires the usage of a Receive String, otherwise only 1 probe attempt occurs.

**probe-timeout**

Specifies the number of seconds after which the BIG-IP system times out the probe request to the BIG-IP system. The default value is 5 seconds.

**recv** Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names. If you do not specify a value for both the `send` and `recv` options, the monitor performs a simple service check and connect only.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

**reverse**

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

**send** Specifies the text string that the monitor sends to the target object. The default value is "default send string".

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, `GET /www/company/index.html`. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to

determine that the service is up. In this case, the system does not need the value of the recv option and ignores the option even if not null.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

#### SEE ALSO

create, delete, edit, glob, gtm pool, gtm server, list, modify, regex, show, tmsh

#### COPYRIGHT

## gtm monitor wap

#### NAME

wap - Configures a Wireless Application Protocol (WAP) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the wap component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

```
create wap [name]
modify wap [name]
options:
  accounting-node [none | [RADIUS server name] ]
  accounting-port [ [integer] | none]
  call-id [none | [RADIUS server 11 digit phone number] ]
  check-until-up [enabled | disabled]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  framed-address [none | [RADIUS framed IP address] ]
  ignore-down-response [enabled | disabled]
  interval [integer]
  probe-timeout [integer]
  recv [none | [string] ]
  secret [none | [password] ]
  send [none | [string] ]
  server-id [none | [RADIUS NAS-ID] ]
  session-id [none | [RADIUS session ID] ]
  timeout [integer]
```

```
edit wap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

##### DISPLAY

```
list wap
list wap[ [ [name] | [glob] | [regex] ] ... ]
show running-config wap
show running-config wap[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

##### DELETE

```
delete wap [name]
```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the wap component to configure a custom monitor, or you can use the default WAP monitor that the Global Traffic Manager provides. This type of monitor requests the URL specified in the send option, and finds the string specified in the recv option somewhere in the data returned by the URL response.

#### EXAMPLES

```
create wap my_wap defaults-from wap
```

Creates a monitor named my\_wap that inherits properties from the default WAP monitor.

```
list wap
```

Displays the properties of all of the WAP monitors.

#### OPTIONS

accounting-node

Specifies the RADIUS server that provides authentication for the WAP target. Note that if you configure the accounting-port option, but you do not configure the this option, the system assumes that the RADIUS server and the WAP server are the same system.

accounting-port

Specifies the port that the monitor uses for RADIUS accounting. The default value is none. A value of 0 (zero) disables RADIUS accounting.

call-id

Specifies the 11-digit phone number for the RADIUS server. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is wap.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is \*.\*.

Possible values are:

\*:\* Specifies to perform a health check on the IP address and port supplied by a pool member.

\*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

framed-address

Specifies the RADIUS framed IP address. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

recv Specifies the text string that the monitor looks for in the returned resource. The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names. If you do not specify both a value for both the send and recv options, the monitor performs a simple service check and connect only. The

default value is none.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### secret

Specifies the password the monitor needs to communicate with the resource. The default value is none.

send Specifies the text string that the monitor sends to the target object. The default setting is GET /, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if it is not null. The default value is none.

#### server-id

Specifies the RADIUS NAS-ID for this system when configuring a RADIUS server. The default value is none.

#### session-id

Specifies the RADIUS session identification number when configuring a RADIUS server. The default value is none.

#### timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

#### SEE ALSO

create, delete, edit, glob, gtm pool, list, modify, regex, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2010, 2012-2014. All rights reserved.

## gtm monitor wmi

#### NAME

wmi - Configures a Windows(r) Management Instrumentation (WMI) monitor.

#### MODULE

gtm monitor

#### SYNTAX

Configure the wmi component within the gtm monitor module using the syntax in the following sections.

##### CREATE/MODIFY

create wmi [name]

modify wmi [name]

##### options:

command [[command] | none]

defaults-from [name]

description [string]

ignore-down-response [enabled | disabled]

interval [integer]

metrics [ [integer] | none]

password [none | [password] ]

probe-timeout [integer]

timeout [integer]

url [none | [URL]]

username [ [name] | none]

edit wmi [ [ [name] | [glob] | [regex] ] ... ]

##### options:

all-properties

non-default-properties

```

DISPLAY
list wmi
list wmi [ [ [name] | [glob] | [regex] ] ... ]
show running-config wmi
show running-config wmi [ [ [name] | [glob] | [regex] ] ... ]
options:
  agent
  all-properties
  method
  non-default-properties
  one-line
  partition
  post

DELETE
delete wmi [name]

```

Note: You cannot delete default monitors.

#### DESCRIPTION

You can use the wmi component to configure a custom monitor, or you can use the default WMI monitor that the Global Traffic Manager provides. This type of monitor checks the performance of a pool, pool member, or virtual server that is running the WMI data collection agent, and then dynamically load balances traffic accordingly.

#### EXAMPLES

```
create wmi my_wmi defaults-from wmi
```

Creates a monitor named my\_wmi that inherits properties from the default WMI monitor.

```
list wmi
```

Displays the properties of all of the WMI monitors.

#### OPTIONS

agent

Displays the agent for the monitor. The default agent is Mozilla/4.0 (compatible: MSIE 5.0; Windows NT). You cannot modify the agent.

command

Specifies the command that the system uses to obtain the metrics from the resource. See the documentation for this resource for information on available commands.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is wmi.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-down-response

Specifies whether the monitor ignores a down response from the system it is monitoring. The default value is disabled.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 30 seconds.

method

Displays the GET method. You cannot modify the method.

metrics

Specifies the performance metrics that the commands collect from the target. The default value is LoadPercentage, DiskUsage, PhysicalMemoryUsage:1.5, VirtualMemoryUsage:2.0.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

post Specifies the mechanism that the monitor uses for posting. The default value is RespFormat=HTML. You cannot change the post format for WMI monitors.

probe-timeout

Specifies the number of seconds after which the BIG-IP(r) system times out the probe request to the BIG-IP system. The default value is 5 seconds.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 120 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

url Specifies the URL that the monitor uses. The default value is /scripts/f5Isapi.dll.

username  
Specifies the user name if the monitored target requires authentication. The default value is none.

#### SEE ALSO

create, delete, edit, glob, gtm pool, list, ltm node, modify, regex, show, tmsh

#### COPYRIGHT

## gtm path

NAME  
path - Displays path statistics for the Global Traffic Manager(tm).

MODULE  
gtm

SYNTAX  
Show the path statistics using the syntax in the following section.

DISPLAY  
show path  
options:  
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)  
field-fmt

DESCRIPTION  
You can use the path component to display path statistics for the Global Traffic Manager.

SEE ALSO  
show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2010. All rights reserved.

BIG-IP 2017-04-05 gtm path(1)

---

## gtm persist

NAME  
persist - Displays persistence records for the Global Traffic Manager(tm).

MODULE  
gtm

SYNTAX  
Display statistics for the persist component within the gtm module using the syntax in the following section.

DISPLAY

```
show persist
options:
  destination [ [name] | none]
  key [ip address | string]
  level [application | wideip]
  max-results [integer]
  target-name [ [name] | none]
  target-type [datacenter | link | pool-member | server]
```

#### DESCRIPTION

You can use the persist component to display various persistence records based on the filtering options that you use.

#### EXAMPLES

```
show persist

Displays all Global Traffic Manager persistence records.

show persist level wideip

Displays persistence records only for wideip persistence.
```

#### OPTIONS

**destination**  
Displays persistence records for the specified destination.

**key** Displays persistence records for the specified LDNS address or generic key.

**level**  
Displays persistence records for the specified level (destination type), either wideip or application.

**max-results**  
Specifies the maximum number of persistence records that you want the system to return.

**target-name**  
Displays persistence records for the specified target name.

If target-type pool-member is specified, then a valid target-name filter for a terminal pool member is the full path virtual server name, for example /Common/vs-dns-1. Do not include the server name in the target-name filter field.

For a non-terminal member the valid target-name filter is the non-pathed DNS name, for example www.alt.example.com.

Please refer to the EXAMPLES section below for more info.

**target-type**  
Displays persistence records for the specified type of target.

#### EXAMPLES

```
All persistence records:
[root@bigip-1:Active:Standalone] config # tmsh show gtm persist

## gtm pool a

### NAME

a - Configures A load balancing pools for the Global Traffic Manager(tm).

### MODULE

gtm pool

### SYNTAX

Modify the Global Traffic Manager pool a component within the gtm module using the syntax shown in the following sections.

#### CREATE/MODIFY

```
create pool a [name]
modify pool a [name]
options:
  alternate-mode [drop-packet | fallback-ip | global-availability
    | none | packet-rate | ratio | return-to-dns | round-robin
    | static-persistence | topology | virtual-server-capacity
    | virtual-server-score]
  app-service [[string] | none]
  description [string]

```

```
DELETE
delete pool a [name]
```

Note: You must remove all references to a pool before you can delete the pool.

#### DESCRIPTION

You can use the pool component to configure the A pool definitions on the Global Traffic Manager. You use a pool to group member servers together to use a common load balancing algorithm.

#### EXAMPLES

```
create pool a mypool members add {
member myServer:myVs
}
monitor http
```

Creates a Global Traffic Manager A pool with one member myServer:myVs using the Round Robin load balancing method, and default HTTP monitor checks for member availability.

```
delete pool a my_pool
```

Deletes the pool my\_pool.

```
show pool a
```

Displays statistics for all A pools.

```
list pool a my_pool
```

Displays settings of pool my\_pool.

#### OPTIONS

##### alternate-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

##### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

##### fallback-ip

Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

##### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

none Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

##### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

##### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

##### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

##### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

**static-persistence**  
Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

**topology**  
Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

**virtual-server-capacity**  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

**virtual-server-score**  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

**app-service**  
Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

**description**  
User defined description.

[disabled | enabled]  
Specifies whether this pool is available for load balancing. The default value is enabled.

**dynamic-ratio**  
Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

**fallback-ip**  
Specifies the IPv6 address of the server to which the system directs requests in the event that the load balancing methods configured for this pool fail to return a valid virtual server. The default value is ::.

**fallback-mode**  
Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

**completion-rate**  
Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

**cpu** Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

**drop-packet**  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

**fallback-ip**  
Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

**fewest-hops**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

**global-availability**  
Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

**kilobytes-per-second**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

**least-connections**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

**lowest-round-trip-time**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

**none** Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

**packet-rate**  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

**quality-of-service**  
Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

**ratio**  
Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

**return-to-dns**  
Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

**round-robin**  
Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

**static-persistence**  
Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

**topology**  
Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

**virtual-server-capacity**  
Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

**virtual-server-score**  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**limit-max-bps**  
Specifies the maximum allowable data throughput rate, in bits per second, for the virtual servers in the pool. If the network traffic volume exceeds this value, the system marks the pool as unavailable. The default value is 0 (zero).

**limit-max-bps-status**  
Enables or disables the limit-max-bps option for this pool. The default value is disabled.

**limit-max-connections**  
Specifies the number of current connections allowed for the virtual servers in the pool. If the current connections exceed this value, the system marks the pool as unavailable. The default value is 0 (zero).

**limit-max-connections-status**  
Enables or disables the limit-max-connections option for this pool. The default value is disabled.

**limit-max-pps**  
Specifies the maximum allowable data transfer rate, in packets per second, for the virtual servers in the pool. If the network traffic volume exceeds this value, the system marks the pool as unavailable. The default value is 0 (zero).

**limit-max-pps-status**  
Enables or disables the limit-max-pps option for this pool. The default value is disabled.

**load-balancing-mode**  
Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

**completion-rate**  
Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data

center and the client LDNS.

**cpu** Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

**drop-packet**  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

**fallback-ip**  
Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

**fewest-hops**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

**global-availability**  
Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

**kilobytes-per-second**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

**least-connections**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

**lowest-round-trip-time**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

**packet-rate**  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

**quality-of-service**  
Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

**ratio**  
Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

**return-to-dns**  
Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

**round-robin**  
Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

**static-persistence**  
Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

**topology**  
Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

**virtual-server-capacity**  
Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

**virtual-server-score**  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

**manual-resume**

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

**max-answers-returned**

Specifies the maximum number of available virtual servers that the system lists in a response. The default value is 1.

**members**

Specifies the vs-name of the pool members. The default value is none.

You can also use the following options with pool members:

**app-service**

Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

**depends-on**

Specifies the name of the virtual server on which this pool member depends.

**description**

User defined description.

**[enabled | disabled]**

Specifies whether this pool member is available for load balancing. The default value is enabled.

**limit-max-bps**

Specifies the maximum allowable data throughput rate, in bits per second, for the pool member. If the network traffic volume exceeds this value, the system marks the pool member as unavailable.

**limit-max-bps-status**

Enables or disables the limit-max-bps option for this pool member. The default value is disabled.

**limit-max-connections**

Specifies the number of current connections allowed for this pool member. If the current connections exceed this value, the system marks this pool member as unavailable.

**limit-max-connections-status**

Enables or disables the limit-max-connection option for this pool member. The default value is disabled.

**limit-max-pps**

Specifies the maximum allowable data transfer rate, in packets per second, for this pool member. If the network traffic volume exceeds this value, the system marks this pool member as unavailable.

**limit-max-pps-status**

Enables or disables the limit-max-pps option for this pool member. The default value is disabled.

**member-order**

Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

**monitor**

Specifies the health monitors that the system uses to determine whether it can use this pool member for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this pool member to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probes that should be used. The default value is none.

**ratio**

Specifies the weight of the pool member for load balancing purposes.

**vs-name**

Displays the name of the corresponding virtual server.

**metadata**

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

**monitor**

Specifies the health monitors that the system uses to determine whether it can use this pool for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this pool to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probes that should be used. The default value is none.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**partition**

Displays the partition within which the component resides.

**qos-hit-ratio**

Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

**qos-hops**

Assigns a weight to the Hops performance factor when the value of the either the load-balancing-mode or fallback-mode options is

quality-of-service. The default value is 0 (zero).

#### qos-kilobytes-second

Assigns a weight to the Kilobytes per Second performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 3.

#### qos-lcs

Assigns a weight to the Link Capacity performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 30.

#### qos-packet-rate

Assigns a weight to the Packet Rate performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 1.

#### qos-rtt

Assigns a weight to the Round Trip Time performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 50.

#### qos-topology

Assigns a weight to the Topology performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-vs-capacity

Assigns a weight to the Virtual Server performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-vs-score

Assigns a weight to the Virtual Server Score performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**ttl** Specifies the number of seconds that the IP address, once found, is valid. Once the time-to-live (TTL) expires, the client has to request the IP address resolution again. The valid values are 0 through 4294967295; the default value is 30.

#### verify-member-availability

Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

Note: You must remove all references to a pool before you can delete the pool.

#### DESCRIPTION

You can use the pool component to configure the AAAA pool definitions on the Global Traffic Manager. You use a pool to group member servers together to use a common load balancing algorithm.

#### EXAMPLES

```
create pool aaaa mypool members add {  
  member myServer:myVs  
}  
monitor http
```

Creates a Global Traffic Manager AAAA pool with one member myServer:myVs using the Round Robin load balancing method, and default HTTP monitor checks for member availability.

```
delete pool aaaa my_pool
```

Deletes the pool my\_pool.

```
show pool aaaa
```

Displays statistics for all AAAA pools.

```
list pool aaaa my_pool
```

Displays settings of pool my\_pool.

#### OPTIONS

alternate-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

fallback-ip

Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

none Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

virtual-server-capacity

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

app-service

Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application

service can modify or delete this pool.

description  
User defined description.

[disabled | enabled]  
Specifies whether this pool is available for load balancing. The default value is enabled.

dynamic-ratio  
Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

fallback-ip  
Specifies the IPv6 address of the server to which the system directs requests in the event that the load balancing methods configured for this pool fail to return a valid virtual server. The default value is ::.

fallback-mode  
Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

completion-rate  
Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

drop-packet  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

fallback-ip  
Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

fewest-hops  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

global-availability  
Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

kilobytes-per-second  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

least-connections  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

lowest-round-trip-time  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

none Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

packet-rate  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

quality-of-service  
Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

`return-to-dns`

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

`round-robin`

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

`static-persistence`

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

`topology`

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

`virtual-server-capacity`

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

`virtual-server-score`

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

`glob` Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

`limit-max-bps`

Specifies the maximum allowable data throughput rate, in bits per second, for the virtual servers in the pool. If the network traffic volume exceeds this value, the system marks the pool as unavailable. The default value is 0 (zero).

`limit-max-bps-status`

Enables or disables the limit-max-bps option for this pool. The default value is disabled.

`limit-max-connections`

Specifies the number of current connections allowed for the virtual servers in the pool. If the current connections exceed this value, the system marks the pool as unavailable. The default value is 0 (zero).

`limit-max-connections-status`

Enables or disables the limit-max-connections option for this pool. The default value is disabled.

`limit-max-pps`

Specifies the maximum allowable data transfer rate, in packets per second, for the virtual servers in the pool. If the network traffic volume exceeds this value, the system marks the pool as unavailable. The default value is 0 (zero).

`limit-max-pps-status`

Enables or disables the limit-max-pps option for this pool. The default value is disabled.

`load-balancing-mode`

Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

`completion-rate`

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

`cpu` Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

`drop-packet`

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

`fallback-ip`

Specifies that the Global Traffic Manager returns the IP address that you specify as an answer to the query.

`fewest-hops`

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

`global-availability`

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

`kilobytes-per-second`

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

#### least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

#### lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### manual-resume

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

#### max-answers-returned

Specifies the maximum number of available virtual servers that the system lists in a response. The default value is 1.

#### members

Specifies the vs-name of the pool members. The default value is none.

You can also use the following options with pool members:

#### app-service

Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

#### depends-on

Specifies the name of the virtual server on which this pool member depends.

#### description

User defined description.

#### [enabled | disabled]

Specifies whether this pool member is available for load balancing. The default value is enabled.

#### limit-max-bps

Specifies the maximum allowable data throughput rate, in bits per second, for the pool member. If the network traffic

volume exceeds this value, the system marks the pool member as unavailable.

**limit-max-bps-status**  
Enables or disables the limit-max-bps option for this pool member. The default value is disabled.

**limit-max-connections**  
Specifies the number of current connections allowed for this pool member. If the current connections exceed this value, the system marks this pool member as unavailable.

**limit-max-connections-status**  
Enables or disables the limit-max-connection option for this pool member. The default value is disabled.

**limit-max-pps**  
Specifies the maximum allowable data transfer rate, in packets per second, for this pool member. If the network traffic volume exceeds this value, the system marks this pool member as unavailable.

**limit-max-pps-status**  
Enables or disables the limit-max-pps option for this pool member. The default value is disabled.

**member-order**  
Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

**monitor**  
Specifies the health monitors that the system uses to determine whether it can use this pool member for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this pool member to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probers that should be used. The default value is none.

**ratio**  
Specifies the weight of the pool member for load balancing purposes.

**vs-name**  
Displays the name of the corresponding virtual server.

**metadata**  
Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

**monitor**  
Specifies the health monitors that the system uses to determine whether it can use this pool for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this pool to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probers that should be used. The default value is none.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**partition**  
Displays the partition within which the component resides.

**qos-hit-ratio**  
Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

**qos-hops**  
Assigns a weight to the Hops performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-kilobytes-second**  
Assigns a weight to the Kilobytes per Second performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 3.

**qos-lcs**  
Assigns a weight to the Link Capacity performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 30.

**qos-packet-rate**  
Assigns a weight to the Packet Rate performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 1.

**qos-rtt**  
Assigns a weight to the Round Trip Time performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 50.

**qos-topology**  
Assigns a weight to the Topology performance factor when the value of the either the load-balancing-mode or fallback-mode options is

quality-of-service. The default value is 0 (zero).

#### qos-vs-capacity

Assigns a weight to the Virtual Server performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-vs-score

Assigns a weight to the Virtual Server Score performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ttl Specifies the number of seconds that the IP address, once found, is valid. Once the time-to-live (TTL) expires, the client has to request the IP address resolution again. The valid values are 0 through 4294967295; the default value is 30.

#### verify-member-availability

Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

## gtm pool cname

#### NAME

cname - Configures CNAME load balancing pools for the Global Traffic Manager(tm).

#### MODULE

gtm pool

#### SYNTAX

Modify the Global Traffic Manager pool cname component within the gtm module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create pool cname [name]
modify pool cname [name]
options:
  alternate-mode [drop-packet | global-availability
    | none | packet-rate | ratio | return-to-dns | round-robin
    | static-persistence | topology | virtual-server-capacity
    | virtual-server-score]
  app-service [[string] | none]
  description [string]
  [disabled | enabled]
  dynamic ratio [disabled | enabled]
  fallback-mode [completion-rate | cpu | drop-packet
    | fewest-hops | global-availability | kilobytes-per-second

DELETE
delete pool cname [name]

```

Note: You must remove all references to a pool before you can delete the pool.

#### DESCRIPTION

You can use the pool component to configure the CNAME pool definitions on the Global Traffic Manager. You use a pool to group member names together to use a common load balancing algorithm.

#### EXAMPLES

```

create pool cname mypool members add {
canonical.mydomain.com
}

```

Creates a Global Traffic Manager CNAME pool with one member canonical.mydomain.com using the Round Robin load balancing method.

```
delete pool cname my_pool
```

Deletes the pool my\_pool.

```
show pool cname
```

Displays statistics for all CNAME pools.

```
list pool cname my_pool
```

Displays settings of pool my\_pool.

#### OPTIONS

##### alternate-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

##### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

##### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

none Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified

in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### app-service

Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

#### description

User defined description.

#### [disabled | enabled]

Specifies whether this pool is available for load balancing. The default value is enabled.

#### dynamic-ratio

Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

#### fallback-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

#### completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

#### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

#### fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

**kilobytes-per-second**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

**least-connections**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

**lowest-round-trip-time**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

**none** Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

**packet-rate**  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

**quality-of-service**  
Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

**ratio**  
Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

**return-to-dns**  
Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

**round-robin**  
Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

**static-persistence**  
Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

**topology**  
Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

**virtual-server-capacity**  
Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

**virtual-server-score**  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**load-balancing-mode**  
Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

**completion-rate**  
Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

**cpu** Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

**drop-packet**  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

**fewest-hops**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

**global-availability**

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

**kilobytes-per-second**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

**least-connections**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

**lowest-round-trip-time**  
Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

**packet-rate**  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

**quality-of-service**  
Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

**ratio**  
Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

**return-to-dns**  
Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

**round-robin**  
Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

**static-persistence**  
Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

**topology**  
Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

**virtual-server-capacity**  
Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

**virtual-server-score**  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### **manual-resume**

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

#### **members**

Specifies the member-dname of the pool members. The default value is none.

You can also use the following options with pool members:

#### **app-service**

Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

#### **description**

User defined description.

[enabled | disabled]

Specifies whether this pool member is available for load balancing. The default value is enabled.

#### **member-order**

Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

ratio  
Specifies the weight of the pool member for load balancing purposes.

static-target  
Specifies the member's name specifies a static DNAME rather than a name linked to a Wide IP defined on the system. This may be required if the target DNAME is not owned by the organization or configured on GTM. One side-effect of using a static target is that the member is always considered available for load balancing. The default value is no.

member-dname  
Displays the member's DNAME.

metadata  
Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition  
Displays the partition within which the component resides.

qos-hit-ratio  
Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

qos-hops  
Assigns a weight to the Hops performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

qos-kilobytes-second  
Assigns a weight to the Kilobytes per Second performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 3.

qos-lcs  
Assigns a weight to the Link Capacity performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 30.

qos-packet-rate  
Assigns a weight to the Packet Rate performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 1.

qos-rtt  
Assigns a weight to the Round Trip Time performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 50.

qos-topology  
Assigns a weight to the Topology performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

qos-vs-capacity  
Assigns a weight to the Virtual Server performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

qos-vs-score  
Assigns a weight to the Virtual Server Score performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ttl Specifies the number of seconds that the answer, once found, is valid. Once the time-to-live (TTL) expires, the client has to request name resolution again. The valid values are 0 through 4294967295; the default value is 30.

verify-member-availability  
Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

## gtm pool mx

### NAME

mx - Configures MX load balancing pools for the Global Traffic Manager(tm).

### MODULE

gtm pool

### SYNTAX

Modify the Global Traffic Manager pool mx component within the gtm module using the syntax shown in the following sections.

```
CREATE/MODIFY
create pool mx [name]
modify pool mx [name]
options:
  alternate-mode [drop-packet | global-availability
    | none | packet-rate | ratio | return-to-dns | round-robin
    | static-persistence | topology | virtual-server-capacity
    | virtual-server-score]
  app-service [[string] | none]
  description [string]
  [disabled | enabled]
  dynamic ratio [disabled | enabled]
  fallback-mode [completion-rate | cpu | drop-packet
    | fewest-hops | global-availability | kilobytes-per-second
    | least-connections | lowest-round-trip-time | none
    | packet-rate | quality-of-service | ratio | return-to-dns
    | round-robin | static-persistence | topology
    | virtual-server-capacity | virtual-server-score]
  load-balancing-mode [completion-rate | cpu | drop-packet
    | fewest-hops | global-availability
    | kilobytes-per-second | least-connections
    | lowest-round-trip-time | packet-rate | quality-of-service
    | ratio | return-to-dns | round-robin | static-persistence
    | topology | virtual-server-capacity | virtual-server-score]
  manual-resume [disabled | enabled]
  max-answers-returned [integer]
  members none
  members
    [ add | delete | modify | replace-all-with ] {
      [member-dname] {
options:
  app-service [[string] | none]
  description [string]
  [disabled | enabled]
  member-order [integer]
  priority [integer]
  ratio [integer]
  }...
  }
  metadata none
  metadata
    [add | delete | modify | replace-all-with] {
      [metadata name ... ] {
app-service [[string] | none]
persist [ true | false ]
value [ "value content" ]
  }
  }
  qos-hit-ratio [integer]
  qos-hops [integer]
  qos-kilobytes-second [integer]
  qos-lcs [integer]
  qos-packet-rate [integer]
  qos-rtt [integer]
  qos-topology [integer]
  qos-vs-capacity [integer]
  qos-vs-score [integer]
  ttl [integer]
  verify-member-availability [disabled | enabled]

edit pool mx [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

reset-stats pool mx
reset-stats pool mx [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list pool mx
list pool mx [ [ [name] | [glob] | [regex] ] ... ]
show running-config pool mx
show running-config pool mx [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  members member-dname
  one-line
  partition
```

```
show pool mx
show pool mx [name]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
detail
field-fmt

DELETE
delete pool mx [name]
```

Note: You must remove all references to a pool before you can delete the pool.

#### DESCRIPTION

You can use the pool component to configure the MX pool definitions on the Global Traffic Manager. You use a pool to group member names together to use a common load balancing algorithm.

#### EXAMPLES

```
create pool mx mypool members add {
  mail1.mydomain.com {
    priority 20
  }
}
```

Creates a Global Traffic Manager MX pool with one member mail1.mydomain.com with priority 20 using the Round Robin load balancing method.

```
delete pool mx my_pool
```

Deletes the pool my\_pool.

```
show pool mx
```

Displays statistics for all MX pools.

```
list pool mx my_pool
```

Displays settings of pool my\_pool.

#### OPTIONS

**alternate-mode**  
Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

**drop-packet**  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

**global-availability**  
Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

**none** Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

**packet-rate**  
Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

**ratio**  
Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

**return-to-dns**  
Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

**round-robin**  
Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

**static-persistence**  
Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

**topology**  
Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

**virtual-server-capacity**  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

**virtual-server-score**  
Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking

system.

#### app-service

Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

#### description

User defined description.

[disabled | enabled]

Specifies whether this pool is available for load balancing. The default value is enabled.

#### dynamic-ratio

Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

#### fallback-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

#### completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

#### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

#### fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

#### kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

#### least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

#### lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

none Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### load-balancing-mode

Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

#### completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

**cpu** Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

#### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

#### fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

#### kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

#### least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

#### lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### manual-resume

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

#### max-answers-returned

Specifies the maximum number of available virtual servers that the system lists in a response. The default value is 1.

#### members

Specifies the member-dname of the pool members. The default value is none.

You can also use the following options with pool members:

#### app-service

Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

#### description

User defined description.

[enabled | disabled]

Specifies whether this pool member is available for load balancing. The default value is enabled.

#### member-order

Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

#### priority

Specifies the response resource record's priority RDATA field value when this member is picked. The default value is 10.

#### ratio

Specifies the weight of the pool member for load balancing purposes.

#### member-dname

Displays the member's DNAME.

#### metadata

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the partition within which the component resides.

#### qos-hit-ratio

Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

#### qos-hops

Assigns a weight to the Hops performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-kilobytes-second

Assigns a weight to the Kilobytes per Second performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 3.

#### qos-lcs

Assigns a weight to the Link Capacity performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 30.

#### qos-packet-rate

Assigns a weight to the Packet Rate performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 1.

#### qos-rtt

Assigns a weight to the Round Trip Time performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 50.

#### qos-topology

Assigns a weight to the Topology performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-vs-capacity

Assigns a weight to the Virtual Server performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-vs-score

Assigns a weight to the Virtual Server Score performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**ttl** Specifies the number of seconds that the answer, once found, is valid. Once the time-to-live (TTL) expires, the client has to request name resolution again. The valid values are 0 through 4294967295; the default value is 30.

#### verify-member-availability

Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

DELETE
delete pool naptr [name]

```

Note: You must remove all references to a pool before you can delete the pool.

#### DESCRIPTION

You can use the pool component to configure the NAPTR pool definitions on the Global Traffic Manager. You use a pool to group member names together to use a common load balancing algorithm.

#### EXAMPLES

```

create pool naptr mypool members add {
    _sip.udp.a.mydomain.com {
flags "s"
order 20
preference 100
service "sip+d2u"
    }
    _sip.udp.b.mydomain.com {
flags "s"
order 20
preference 110
service "sip+d2u"
    }
}

```

Creates a Global Traffic Manager NAPTR pool with two members using the Round Robin load balancing method.

```
delete pool naptr my_pool
```

Deletes the pool `my_pool`.

`show pool naptr`

Displays statistics for all NAPTR pools.

`list pool naptr my_pool`

Displays settings of pool `my_pool`.

#### OPTIONS

##### `alternate-mode`

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the `load-balancing-mode` option. The default value is `round-robin`.

The options are:

##### `drop-packet`

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

##### `global-availability`

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

`none` Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the `fallback-mode` option.

Note that if the value of the `fallback-mode` option is `none`, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

##### `packet-rate`

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

##### `ratio`

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

##### `return-to-dns`

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

##### `round-robin`

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

##### `static-persistence`

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

##### `topology`

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

##### `virtual-server-capacity`

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

##### `virtual-server-score`

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

##### `app-service`

Specifies the name of the application service to which this pool belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

##### `description`

User defined description.

[`disabled` | `enabled`]

Specifies whether this pool is available for load balancing. The default value is `enabled`.

##### `dynamic-ratio`

Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the `load-balancing-mode` option for the pool with one of these dynamic load balancing modes: `completion-rate`, `fewest-hops`, `kilobytes-per-second`, `least-connections`, `lowest-round-trip-times`, `quality-of-service`, `virtual-server-capacity`, or `virtual-server-score`.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When `dynamic-ratio` is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

#### fallback-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

#### completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

#### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

#### fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

#### kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

#### least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

#### lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

none Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

load-balancing-mode

Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

manual-resume

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option

is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

**max-answers-returned**  
Specifies the maximum number of available virtual servers that the system lists in a response. The default value is 1.

**members**  
Specifies the member-dname of the pool members. The default value is none.

You can also use the following options with pool members:

**app-service**  
Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

**description**  
User defined description.

**[enabled | disabled]**  
Specifies whether this pool member is available for load balancing. The default value is enabled.

**flags**  
Specifies the response resource record's flags RDATA field value when this member is picked. Either 'a' or 's' may be specified for this attribute as GTM supports only these record types.

**member-order**  
Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

**order**  
Specifies the response resource record's order RDATA field value when this member is picked. The default value is 10.

**preference**  
Specifies the response resource record's preference RDATA field value when this member is picked. The default value is 10.

**ratio**  
Specifies the weight of the pool member for load balancing purposes.

**service**  
Specifies the response resource record's service RDATA field value when this member is picked.

**member-dname**  
Displays the member's DNAME.

**metadata**  
Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**partition**  
Displays the partition within which the component resides.

**qos-hit-ratio**  
Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

**qos-hops**  
Assigns a weight to the Hops performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

**qos-kilobytes-second**  
Assigns a weight to the Kilobytes per Second performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 3.

**qos-lcs**  
Assigns a weight to the Link Capacity performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 30.

**qos-packet-rate**  
Assigns a weight to the Packet Rate performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 1.

**qos-rtt**  
Assigns a weight to the Round Trip Time performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 50.

**qos-topology**  
Assigns a weight to the Topology performance factor when the value

of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-vs-capacity

Assigns a weight to the Virtual Server performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### qos-vs-score

Assigns a weight to the Virtual Server Score performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**ttl** Specifies the number of seconds that the answer, once found, is valid. Once the time-to-live (TTL) expires, the client has to request name resolution again. The valid values are 0 through 4294967295; the default value is 30.

#### verify-member-availability

Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

delete pool srv [name]

    Note: You must remove all references to a pool before you can delete
    the pool.

```

**DESCRIPTION**

You can use the pool component to configure the SRV pool definitions on the Global Traffic Manager. You use a pool to group member names together to use a common load balancing algorithm.

**EXAMPLES**

```

    create pool srv mypool members add {
    imap.mydomain.com {
    port 143
    priority 20
    }
    }

```

Creates a Global Traffic Manager SRV pool with one member imap.mydomain.com with port 143 and priority 20 using the Round Robin load balancing method.

```
delete pool srv my_pool
```

Deletes the pool my\_pool.

```
show pool srv
```

Displays statistics for all SRV pools.

```
list pool srv my_pool
```

Displays settings of pool my\_pool.

**OPTIONS**

**alternate-mode**  
Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred method is unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option. The default value is round-robin.

The options are:

**drop-packet**  
Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

none Specifies that the system skips the alternate load balancing mode and immediately tries the load balancing mode specified in the fallback-mode option.

Note that if the value of the fallback-mode option is none, and you have multiple pools configured, the Global Traffic Manager uses the next available pool.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### app-service

Specifies the name of the application service to which this pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool. Only the application service can modify or delete this pool.

#### description

User defined description.

[disabled | enabled]

Specifies whether this pool is available for load balancing. The default value is enabled.

#### dynamic-ratio

Enables or disables a dynamic ratio load balancing algorithm for this pool. This option is applicable only when you also configure the load-balancing-mode option for the pool with one of these dynamic load balancing modes: completion-rate, fewest-hops, kilobytes-per-second, least-connections, lowest-round-trip-times, quality-of-service, virtual-server-capacity, or virtual-server-score.

When this option is disabled (the default), the system uses only the server or virtual server with the best metrics, or highest quality of service (QoS) score, for load balancing. When dynamic-ratio is enabled, the system treats QoS scores as ratios, and it uses each server or virtual server in proportion to the ratio determined by the QoS calculation.

#### fallback-mode

Specifies the load balancing mode that the system uses to load balance name resolution requests among the members of this pool, if the preferred and alternate modes are unsuccessful in picking a pool. You set the preferred mode using the load-balancing-mode option, and the alternate mode using the alternate-mode option. The default value is return-to-dns.

The options are:

#### completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

cpu Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

#### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

#### fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

#### kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

#### least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

#### lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

**none** Specifies that there is no fallback mode. If the system cannot use the preferred or alternate load balancing modes, it uses the next pool to resolve the request. If there are no more pools available, the result is the same as when the value for the fallback-mode option is return-to-dns.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### load-balancing-mode

Specifies the preferred load balancing mode that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

#### completion-rate

Specifies that the Global Traffic Manager selects the virtual server that currently maintains the least number of dropped or timed-out packets during a transaction between a data center and the client LDNS.

**cpu** Specifies that the Global Traffic Manager selects the virtual server that currently has the most CPU processing time available to handle name resolution requests.

#### drop-packet

Specifies that the Global Traffic Manager does nothing with the packet, and simply drops the request.

#### fewest-hops

Specifies that the Global Traffic Manager distributes connection requests to the virtual server in the data center that has the fewest router hops from the Local DNS.

#### global-availability

Specifies that the Global Traffic Manager distributes connection requests to virtual servers included in the pool in the order in which they are listed.

#### kilobytes-per-second

Specifies that the Global Traffic Manager distributes connection requests to the virtual server that is currently processing the fewest number of kilobytes per second.

#### least-connections

Specifies that the Global Traffic Manager distributes connection requests to the virtual server on the Local Traffic Manager that currently hosts the fewest connections.

#### lowest-round-trip-time

Specifies that the Global Traffic Manager distributes connection requests to the virtual server with the fastest measured round trip time between a data center and a client LDNS.

#### packet-rate

Specifies that the Global Traffic Manager assigns connection requests to the virtual server that is currently processing the fewest number of packets per second.

#### quality-of-service

Specifies that the Global Traffic Manager distributes connection requests using current performance information to calculate an overall score for each virtual server, and then distributes connections to the virtual servers based on these scores.

#### ratio

Specifies that the Global Traffic Manager distributes connection requests among a pool of virtual servers using a weighted Round Robin load balancing method.

#### return-to-dns

Specifies that the Global Traffic Manager immediately returns connection requests to the Local DNS for resolution.

#### round-robin

Specifies that the Global Traffic Manager distributes connection requests in a circular and sequential pattern among the virtual servers in a pool.

#### static-persistence

Specifies that the Global Traffic Manager consistently maps an LDNS IP address to the same available virtual server for the duration of a session.

#### topology

Specifies that the Global Traffic Manager uses proximity-based load balancing to distribute connection requests.

#### virtual-server-capacity

Specifies that the Global Traffic Manager distributes connection requests by creating a list of the virtual servers, weighted by capacity, then picks one of the virtual servers from the list. The virtual servers with the greatest capacity are picked most often, but over time all virtual servers are returned.

#### virtual-server-score

Specifies that the Global Traffic Manager assigns connection requests to virtual servers based on a user-defined ranking system.

#### manual-resume

Enables or disables the manual resume function for this pool. If you leave this option disabled (the default), then a member of this pool automatically becomes available for load balancing when its status changes from down to up. When the manual-resume option is enabled, if the status of a member of this pool changes from up to down, the pool member remains disabled indefinitely until you manually re-enable it.

#### max-answers-returned

Specifies the maximum number of available virtual servers that the system lists in a response. The default value is 1.

#### members

Specifies the member-dname of the pool members. The default value is none.

You can also use the following options with pool members:

#### app-service

Specifies the name of the application service to which this pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this pool member. Only the application service can modify or delete this pool member.

#### description

User defined description.

[enabled | disabled]

Specifies whether this pool member is available for load balancing. The default value is enabled.

member-order

Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members, such as the Ratio load balancing method.

port Specifies the response resource record's port RDATA field value when this member is picked.

priority

Specifies the response resource record's priority RDATA field value when this member is picked. The default value is 10.

ratio

Specifies the relative weight of the pool member for load balancing purposes.

weight

Specifies the response resource record's weight RDATA field value when this member is picked. The default value is 10.

member-dname

Displays the member's DNAME.

metadata

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the partition within which the component resides.

qos-hit-ratio

Assigns a weight to the Hit Ratio performance factor for the Quality of Service dynamic load balancing mode. The default value is 5.

qos-hops

Assigns a weight to the Hops performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

qos-kilobytes-second

Assigns a weight to the Kilobytes per Second performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 3.

qos-lcs

Assigns a weight to the Link Capacity performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 30.

qos-packet-rate

Assigns a weight to the Packet Rate performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 1.

qos-rtt

Assigns a weight to the Round Trip Time performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 50.

qos-topology

Assigns a weight to the Topology performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

qos-vs-capacity

Assigns a weight to the Virtual Server performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

qos-vs-score

Assigns a weight to the Virtual Server Score performance factor when the value of the either the load-balancing-mode or fallback-mode options is quality-of-service. The default value is 0 (zero).

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ttl Specifies the number of seconds that the answer, once found, is valid. Once the time-to-live (TTL) expires, the client has to request name resolution again. The valid values are 0 through 4294967295; the default value is 30.

verify-member-availability

Specifies that the system verifies the availability of the members before sending a connection to those resources. The default value is enabled.

## gtm prober-pool

#### NAME

prober-pool - Configures prober pools for the Global Traffic Manager(tm).

#### MODULE

gtm

#### SYNTAX

Modify the Global Traffic Manager prober-pool component within the gtm module using the syntax shown in the following sections.

##### CREATE/MODIFY

```
create prober-pool [name]
modify prober-pool [name]
options:
  app-service [[string] | none]
  description [string]
  [disabled | enabled]
  load-balancing-mode [global-availability | round-robin]
  members none
  members
    [ add | delete | modify | replace-all-with ] {
      [name] {
        options:
          app-service [[string] | none]
          description [string]
          [disabled | enabled]
          order [integer]
        }...
      }
  }
edit prober-pool [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
reset-stats prober-pool
reset-stats prober-pool [ [ [name] | [glob] | [regex] ] ... ]
```

##### DISPLAY

```
list prober-pool
list prober-pool [ [ [name] | [glob] | [regex] ] ... ]
show running-config prober-pool
show running-config prober-pool [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
show prober-pool
show prober-pool [name]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  detail
  field-fmt
```

##### DELETE

```
delete prober-pool [name]
```

Note: You must remove all references to a prober-pool before you can delete the prober-pool.

#### DESCRIPTION

You can use the prober-pool component to configure prober pool definitions on the Global Traffic Manager. You use prober pools to control which BIG-IP servers on your network are utilized by GTM to monitor the up/down state of GTM resources. Once defined, prober pools can be set to monitor whole data centers or individual servers.

#### EXAMPLES

```
create prober-pool my_pool members add {
  bigip-dallas
  bigip-london
}
```

Creates a Global Traffic Manager prober pool with two members bigip-dallas and bigip-london. Members are selected using the global-

availability load balancing method.

delete prober-pool my\_pool

Deletes the prober pool my\_pool.

show prober-pool

Displays statistics for all prober pools.

list prober-pool my\_pool

Displays settings of prober pool my\_pool.

#### OPTIONS

app-service

Specifies the name of the application service to which this prober pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this prober pool. Only the application service can modify or delete this prober pool.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

load-balancing-mode

Specifies the load balancing mode that the system uses to select members of this pool. The default value is global-availability.

The options are:

global-availability

Specifies that the Global Traffic Manager selects the first available pool member in the order in which they are listed.

round-robin

Specifies that the Global Traffic Manager selects members using a circular, sequential pattern among available pool members.

members

Specifies the BIG-IP server names of the pool members. The default value is none.

You can also use the following options with prober pool members:

app-service

Specifies the name of the application service to which this prober pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this prober pool member. Only the application service can modify or delete this prober pool member.

description

User defined description.

[enabled | disabled]

Specifies whether this pool member is available to issue probes. The default value is enabled.

order

Specifies the order number of the pool member. The system uses this number with load balancing methods that involve prioritizing pool members by listed order.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

## gtm region

**NAME**  
region - Configures a Global Traffic Manager(tm) region.

**MODULE**  
gtm

**SYNTAX**  
Configure the region component within the gtm module using the syntax shown in the following sections.

**CREATE/MODIFY**  
create region [name]  
modify region [name]  
options:  
  app-service [[string] | none]  
  description [string]  
  [name]  
  region-members  
  options:  
    app-service [[string] | none]  
    continent [Africa | Antarctica | Asia | Australia | Europe  
| North America | South America | unknown]  
    country [two-letter abbreviation of country name]  
    datacenter [name]  
    geoip-isp [name]  
    isp [AOL | BeijingCNC | CNC | ChinaTelecom | Comcast | Earthlink  
| ShanghaiCNC | ShanghaiTelecom]  
    not [continent | country | datacenter | isp | pool | region-name  
| subnet]  
    pool [name]  
    region-name [name]  
    state [name]  
    subnet

edit region [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties

**DISPLAY**  
list region  
list region [ [ [name] | [glob] | [regex] ] ... ]  
show running-config region  
show running-config region [ [ [name] | [glob] | [regex] ] ... ]  
options:  
  all-properties  
  one-line

**DELETE**  
delete region [name]

**DESCRIPTION**  
You can use the region component to create, display, modify, or delete a region. A region is a customized collection of topologies with which you can extend the topology functionality by defining specific geographical regions that have meaning for your network.

**EXAMPLES**  
create region my\_region continent Australia  
  
Creates a region named my\_region to populate with resources on the continent of Australia.  
  
list region  
  
Displays properties for all regions.  
  
delete region my\_region  
  
Deletes the region named my\_region.

**OPTIONS**  
app-service  
Specifies the name of the application service to which the region belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the region. Only the application service can modify or delete the region.  
  
description  
User defined description.  
  
glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.  
  
name Specifies a unique name for the component. This option is required for the commands create and modify.  
  
regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.  
  
region-members  
Specifies the members that you want to add to, delete from, replace-all-with, or modify for this region.  
  
You can specify the following options for region members:

**app-service**  
Specifies the name of the application service to which the region member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the region member. Only the application service can modify or delete the region member.

**continent**  
Specifies the name of a continent.

**country**  
Specifies the two-letter abbreviation of a country. Use the command completion feature to view the numerous options.

**datacenter**  
Specifies the name of an existing data center.

**geoip-isp**  
An ISP whose IP Address allocation range should be used in matching topologies. Any ISP string may be given as long as it matches the string in the GeoIP-ISP Database. Case is irrelevant.

**isp** Specifies the name of an Internet service provider.

**not** Specifies region-members to exclude from this region.

**pool** Specifies the name of an existing pool.

**region-name**  
Specifies the name of an existing region.

**state**  
Specifies the name of an existing state.

**subnet**  
Specifies an existing subnet.

SEE ALSO  
create, delete, edit, glob, list, modify, regex, show, tmsh

COPYRIGHT

BIG-IP 2015-01-28 gtm region(1)

---

## gtm rule

**NAME**  
rule - Opens an editor in which you can configure iRules(r) for traffic management system configuration.

**MODULE**  
gtm

**SYNTAX**  
Configure the rule component within the gtm module using the syntax shown in the following sections.

```
CREATE/MODIFY
create rule [name]
modify rule [name]
option:
  metadata
    [add | delete | modify] {
[metadata_name] {
  value [ "value content" ]
  persist [ true | false ]
}
}
edit rule [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list rule
list rule [ [ [name] | [glob] | [regex] ] ... ]
show running-config rule
show running-config rule [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

show rule
show rule [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

```
DELETE
delete rule [name]
```

Note: You can also delete metadata associated with an iRule. See the example section for detail.

#### DESCRIPTION

You can use iRules to direct traffic not only to specific pools, but also to individual pool members, including port numbers and URI paths, either to implement persistence or to meet specific load balancing requirements. The syntax that you use to write iRules is based on the Tools Command Language (Tcl) programming standard. Thus, you can use many of the standard Tcl commands, plus a robust set of extensions that the BIG-IP(r) local traffic management system provides to help you further increase load balancing efficiency.

For information about standard Tcl syntax, see <http://tmml.sourceforge.net/doc/tcl/index.html>. For a list of Tcl commands that have been disabled within the traffic management system and therefore cannot be used in the traffic management system, see the Configuration Guide for BIG-IP(r) Local Traffic Management(r). This guide is available at <https://support.f5.com>.

#### EXAMPLES

```
edit rule my_irule
```

Opens the vi editor in which you can edit the iRule named my\_irule. Note that after you close the editor, you must run the command sequence save config to save the configuration changes to the stored configuration files.

The following are example iRules for the Global Traffic Manager(tm).

```
when DNS_REQUEST {
  if {[IP::addr [IP::remote_addr]/24 equals 10.10.1.0/24] }
    {cname cname.siterequest.com } else { host 10.20.20.20}}
```

Specifies that requests from 10.10.1.0/24 be directed to cname.siterequest.com, and all other requests be directed to 10.20.20.20.

```
when DNS_REQUEST {
  if {[whereis [IP::remote_addr]] contains "Asia"}
    {pool asia_pool} else {pool general_pool}}
```

Specifies that requests that originate in Asia be directed to the pool named asia\_pool, and that all other requests be directed to the pool named general\_pool.

metadata is the user defined key/value pair

Adds new metadata to named my\_meta and modifies existing metadata named my\_meta2 for the iRule named my\_irule.

```
modify rule my_irule {
when DNS_REQUEST {
  metadata replace-all-with {
    my_meta {      persist false      value "hello"
  }
  my_meta2 {      persist false      value "hello
2"
  }
}
```

Deletes metadata named my\_meta from the iRule named my\_irule.

```
modify rule my_irule {
when RULE_INIT {}
definition-checksum 7c0dba9aa53e8959042c6cfe041d3d11
metadata delete { my_meta }
```

#### OPTIONS

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

metadata  
Specifies a user-defined key/value pair.

name Specifies a unique name for the component. This option is required.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### SEE ALSO

edit, glob, list, regex, show, tmsh

#### COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

DELETE
delete server [name]

DESCRIPTION
  You can use the server component to configure a Global Traffic Manager
  server.

EXAMPLES
  create server my_server devices add { my_device { addresses add {
    10.10.1.1 } } } datacenter my_datacenter

  Creates a server named my_server in my_datacenter with a self IP
  address of 10.10.1.1.

  modify server my_server virtual-servers add {myVs { address
    10.10.10.2:80 } }

  Adds the virtual server myVs with an IP address of 10.10.10.2:80 as a
  resource to the server named my_server.

  list server non-default-properties

  Displays all non-default properties for all servers.

  delete server my_server

  Deletes the server named my_server.

  show server my_server detail

  Shows the link associated with each server IP address for
  my_server.

  show server all detail

  Shows the link assignments for all servers in the system.

  show server my_server virtual-servers

  Shows the regular server information as well as any virtuals on
  my_server. The link associated with a virtual server is displayed,
  or --- is shown to indicate that the virtual is not using a
  configured link.

OPTIONS
  app-service
  Specifies the name of the application service to which the server
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the server. Only the application
  service can modify or delete the server.

  datacenter
  Specifies the data center to which the server belongs. This option
  is required for the command create.

  description
  User defined description.

  detail
  The detail option is used with the show display command. This
  shows device statistics, virtual server statistics, and links
  associated with the server. Only the device addresses that have an
  associated link are displayed. If this server is not using any
  links, no link assignment information is printed. By default,
  links are automatically matched to device addresses according to
  the smallest subnet match. Explicit links may also be defined. How
  this link was assigned is displayed in the Link Assignment column:

```

auto means that the system automatically assigned this link, and explicit means that the link was explicitly set by the user.

#### devices

Specifies the names of the devices that represent this server. Every device must have at least one address. The options are:

#### addresses

Specifies the IP addresses that represent the device. If GTM configuration synchronization is enabled and all existing addresses for a device are being replaced, new addresses should be added and synchronized before old addresses are removed, otherwise the changes may fail to synchronize. Alternatively, the address configuration changes can be performed on each GTM. The options are:

#### app-service

Specifies the name of the application service to which the address belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the address. Only the application service can modify or delete the address.

#### description

User defined description.

#### explicit-link-name

Specifies the explicit link name for the device. The default value is none.

#### translation

Specifies the internal IP address that corresponds to the external IP address of this device. The default value is ::.

#### app-service

Specifies the name of the application service to which the device belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the device. Only the application service can modify or delete the device.

#### description

User defined description.

[disabled | enabled]

Enables or disables the server. The default value is enabled.

#### expose-route-domains

Allow the GTM server to auto-discover LTM virtual servers from all route domains. The default value is no.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### iq-allow-path

Specifies whether the Global Traffic Manager uses this BIG-IP(r) system to conduct a path probe before delegating traffic to it. The default value is yes.

#### iq-allow-service-check

Specifies whether the Global Traffic Manager uses this BIG-IP system to conduct a service check probe before delegating traffic to it. The default value is yes.

#### iq-allow-snmp

Specifies whether the Global Traffic Manager uses this BIG-IP system to conduct an SNMP probe before delegating traffic to it. The default value is yes.

#### iquery-cipher-list

This is a ":" separated list of cipher specifications as accepted by the "openssl ciphers" command. OpenSSL will use the cipher list to negotiate a mutually acceptable cipher with the server during iQuery connection setup. Setting this value on the server will override the value inherited from the global settings.

#### iquery-minimum-tls-version

This is a string to specify the minimum TLS version that will be offered by the client (GTM) during iQuery connection negotiation. Setting this value on the server will override the value inherited from the global settings.

#### limit-cpu-usage

For a server configured as a generic host, specifies the percent of CPU usage, otherwise has no effect. If percent of CPU usage goes above the limit, the system marks the server as unavailable.

#### limit-cpu-usage-status

Enables or disables the limit-cpu-usage option for this server. Only has an effect on a server configured as a generic host. The default value is disabled.

#### limit-mem-avail

For a server configured as a generic host, specifies the available memory required by the virtual servers on the server. If available memory falls below this limit, the system marks the server as unavailable.

#### limit-mem-avail-status

Enables or disables the limit-mem-avail option for this server. Only used on a server configured as a generic host. The default value is disabled.

#### limit-max-bps

Specifies the maximum allowable data throughput rate, in bits per second, for this server. If the network traffic volume exceeds this limit, the system marks the server as unavailable.

#### limit-max-bps-status

Enables or disables the limit-max-bps option for this server. The default value is disabled.

#### limit-max-connections

Specifies the maximum number of concurrent connections, combined, for this server. If the connections exceed this limit, the system marks the server as unavailable.

#### limit-max-connections-status

Enables or disables the limit-max-connections option for this server. The default value is disabled.

#### limit-max-pps

Specifies the maximum allowable data transfer rate, in packets per second, for this server. If the network traffic volume exceeds this limit, the system marks the server as unavailable.

#### limit-max-pps-status

Enables or disables the limit-max-pps option for this server. The default value is disabled.

#### link-discovery

Specifies whether the system auto-discovers the links for this server. The default value is disabled. The options are:

##### disabled

Specifies that the system does not auto-discover the links that are available for the server.

##### enabled

Specifies that the system auto-discovers the links that are configured on the server. With this option, the system automatically adds, deletes, and modifies link settings in the configuration.

##### enabled-no-delete

Specifies that the system auto-discovers the links that are configured on the server. With this option, the system automatically adds and modifies link settings in the configuration, but does not delete them. This option is useful when you regularly take links in and out of service.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

#### monitor

Specifies the health monitors that the system uses to determine whether this server is available for load balancing. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this server to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probes that should be used.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the object resides.

#### prober-fallback

Specifies the type of prober to use to monitor this server's resources when the preferred type is not available. If this value is specified, it overrides the prober fallback value on this server's data center. The default value is inherit.

#### prober-pool

Specifies the name of a prober pool to use to monitor this server's resources when either the prober-preference or prober-fallback value is pool. If neither the prober-preference or prober-fallback value is pool, the prober-preference and prober-fallback values are set to pool and any-available. If this value is specified, it overrides any prober pool set on this server's data center. The default value is none.

#### prober-preference

Specifies the type of prober to use to monitor this server's resources. If this value is specified, it overrides the prober preference value on this server's data center. The default value is inherit.

#### product

Specifies the server type. The server type determines the metrics that the system can collect from the server. Use the command completion feature to view the types of servers that are available.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### virtual-server-discovery

Specifies whether the system auto-discovers the virtual servers for this server. The default value is disabled. The options are:

##### disabled

Specifies that the system does not auto-discover the virtual servers that are configured on the server. With this option, you must configure the virtual servers for this server.

##### enabled

Specifies that the system auto-discovers the virtual servers that are configured on the server. With this option, the system automatically adds, deletes, and modifies virtual server settings in the configuration.

##### enabled-no-delete

Specifies that the system auto-discovers the virtual servers that are configured on the server. With this option, the system automatically adds and modifies virtual server settings in the configuration, but does not delete them. This option is useful when you regularly take virtual servers in and out of service.

#### virtual-servers

Specifies the name of the virtual servers that are resources for this server. You can include the following options for virtual servers.

##### app-service

Specifies the name of the application service to which the virtual server belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the virtual server. Only the application service can modify or delete the virtual server.

##### depends-on

Specifies the vs-name of the server on which this virtual server depends.

##### description

User defined description.

##### destination

Specifies the IP address and port of the virtual server.

##### [disabled | enabled]

Specifies whether this virtual server is available for load balancing. The default value is enabled.

##### explicit-link-name

Specifies the explicit link name for the virtual server. The default value is none.

##### limit-max-bps

Specifies the maximum allowable data throughput rate, in bits per second, for this virtual server. If the network traffic volume exceeds this value, the system marks the virtual server as unavailable. The default value is 0 (zero).

##### limit-max-bps-status

Enables or disables the limit-max-bps option for this virtual server. The default value is disabled.

##### limit-max-connections

Specifies the number of current connections allowed for this virtual server. If the current connections exceed this value, the system marks this virtual server as unavailable. The default value is 0 (zero).

##### limit-max-connections-status

Enables or disables the limit-max-connections option for this virtual server. The default value is disabled.

##### limit-max-pps

Specifies the maximum allowable data transfer rate, in packets per second, for this virtual server. If the network traffic volume exceeds this limit, the system marks the virtual server as unavailable. The default value is 0 (zero).

##### limit-max-pps-status

Enables or disables the limit-max-pps option for this virtual server. The default value is disabled.

##### ltm-name

The virtual server name found on the LTM. Useful for differentiating between virtuals with same IP and port, but different protocols. The ltm-name used in probe requests.

##### monitor

Specifies the monitor you want to assign to this virtual server. Multiple monitors may be specified with the and keyword. The min keyword is used to specify the minimum number of monitors that must succeed for this server to be declared up. The require keyword is used to specify the minimum number of probes that must succeed for this server to be declared up and the number of probes that should be used. The default value is none.

##### translation-address

Specifies the public address that this virtual server translates into when the Global Traffic Manager communicates between the network and the Internet. The default value is ::.

translation-port  
Specifies the translation port number or service name for the virtual server, if necessary. The default value is 0.

## gtm topology

NAME

topology - Configures a topology statement.

MODULE

gtm

SYNTAX

Configure the topology component within the gtm module using the syntax shown in the following sections.

CREATE

create topology

options:

app-service [[string] | none]  
description [[string] | none]  
ldns: [continent | country | geoip-isp | isp | not | region | state | subnet]  
order [integer]  
score [integer]  
server: [continent | country | datacenter | geoip-isp | isp | not | pool | region | state | subnet]

MODIFY

modify topology [ [name] | [glob] | [regex] ] ... ]

options:

app-service [[string] | none]  
description [[string] | none]  
order [integer]  
score [integer]

EDIT

edit topology [ [name] | [glob] | [regex] ] ... ]

options:

all-properties  
non-default-properties

DISPLAY

list topology

show running-config topology [ [name] | [glob] | [regex] ] ... ]

options:

all-properties  
non-default-properties  
one-line

DELETE

delete topology all

delete topology

[ldns: [identifier] [value] server: [identifier] [value] ]

DESCRIPTION

You can use the topology component to configure a topology statement. A topology statement is a set of characteristics that identify the origin of a given name resolution request.

EXAMPLES

create topology ldns: country US server: datacenter DC1 score 30

Creates a topology statement that specifies that the Global Traffic Manager routes any traffic coming from the United States to the datacenter named DC1. Note that the weight of this topology item for load balancing is 30.

delete topology ldns: country US server: datacenter DC1

Deletes the topology statement mentioned in the previous example.

OPTIONS

#### app-service

Specifies the name of the application service to which the topology belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the topology. Only the application service can modify or delete the topology.

#### description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### ldns:

Specifies the criteria that the Global Traffic Manager uses when matching requests from LDNS servers.

#### continent

A continent whose IP address allocation range should be used in matching topologies

#### country

A country whose IP address allocation range should be used in matching topologies

#### datacenter

A data center to be used in matching topologies

#### geoip-isp

An ISP whose IP Address allocation range should be used in matching topologies. Any ISP string may be given as long as it matches the string in the GeoIP-ISP Database. Case is irrelevant.

isp An ISP whose IP address allocation range should be used in matching topologies

not Specify a region member to exclude from the region

pool A pool to be used in matching topologies

#### region

Another region to be used in matching topologies

#### state

A state whose IP address allocation range should be used in matching topologies

#### subnet

A subnet to be used in matching topologies

#### order

Specify the order number of this topology item. Should not be specified if the Longest Match option is selected. Must be a value between 1 and the number of topology items inclusive (including any new topology items). If an existing topology item specifies the same order number, the order numbers for that item and all subsequent items are incremented.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### score

Specifies the weight of the topology item.

#### server:

Specifies the server to which the Global Traffic Manager routes requests.

#### continent

A continent whose IP address allocation range should be used as an LDNS routing destination

#### country

A country whose IP address allocation range should be used as an LDNS routing destination

#### datacenter

A data center to be used as an LDNS routing destination

#### geoip-isp

An ISP whose IP Address allocation range should be used in matching topologies. Any ISP string may be given as long as it matches the string in the GeoIP-ISP Database. Case is irrelevant.

isp An ISP whose IP address allocation range should be used as an LDNS routing destination

not Specify an item to exclude from the group

pool A pool to be used as an LDNS routing destination

#### region

Another region to be used as an LDNS routing destination

#### state

A state whose IP address allocation range be used as an LDNS routing destination

#### subnet

A subnet to be used as an LDNS routing destination

        field-fmt

DELETE
delete wideip a [all | [name] ]

DESCRIPTION
You can use the wideip component to create, modify, display, or delete
a wide IP that responds to A queries. An A wide IP is a mapping of a
fully-qualified domain name (FQDN) to a set of IPv4 virtual servers
that host the domain's content, such as a web site or an e-commerce
site.

EXAMPLES
create wideip a www.my_wide_ip.com

Creates a wide IP named www.my_wide_ip.com.

delete wideip a www.my_wide_ip.com

Deletes the wide IP named www.my_wide_ip.

OPTIONS
aliases
Specifies alternate domain names for the web site content you are
load balancing. You can use two different wildcard characters,
asterisk (*) and question mark (?), to represent one or more
characters. The default value is none.

app-service
Specifies the name of the application service to which this wide
ip belongs. The default value is none. Note: If the strict-updates
option is enabled on the application service that owns the object,
you cannot modify or delete this wide ip. Only the application
service can modify or delete this wide ip.

description
User defined description. Note: Advanced search on the GUI's
Wideip list page can be turned on/off by modifying the DB variable
ui.advancedsearch via the tmsh command "modify sys db
ui.advancedsearch value true/false". This will result in a new
description column and the inclusion of that field in the search.

[disabled | enabled]
Specifies whether the wide IP and its resources are available for
load balancing.

failure-rcode

```

Specifies the DNS RCODE used when failure-rcode-response is enabled. Default is noerror. Options include noerror (no type exists at this name), formerr (format error in query), servfail (unable to process query), nxdomain (name does not exist), notimpl (no support for this kind of query), and refused (refuse to process based on policy). If failure-rcode-ttl is non-zero, only the Authority section of the noerror or nxdomain response will include a SOA record.

#### failure-rcode-response

When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This response is an authoritative empty answer from the system to A record requests. With this option enabled, the system responds faster to A requests for which it does not have A records configured. The default value is disabled.

#### failure-rcode-ttl

Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

#### last-resort-pool

Specifies a last resort pool to use when load balancing requests for this wide IP. Any A or CNAME pool type is allowed. The default value is none.

#### load-balancing-decision-log-verbosity

Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default value is none.

#### minimal-response

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the component resides.

#### persistence

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### pools

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pools-cname

Configures the CNAME pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pool-lb-mode

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

#### global-availability

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the

first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

**ratio**  
Specifies that the system selects a pool based on the ratio that you assign to the pool.

**round-robin**  
Specifies that the system selects pools sequentially.

**topology**  
Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

**regex**  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**rules**  
Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

**ttl-persistence**  
Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

**topology-prefer-edns0-client-subnet**  
Specifies, when set to enabled, that this wide IP should use the edns0 client subnet option (if one exists) instead of the source address when using topology load balancing. When this option is set to disabled or if the query did not contain a client subnet option, the system will fall back to the source address.

This setting has no effect when the global setting, configured under gtm global-settings load-balancing topology-prefer-edns0-client-subnet [disabled | enabled], is set to enabled. When either setting is enabled then this feature will be enabled.

    field-fmt

DELETE
delete wideip aaaa [all | [name] ]

DESCRIPTION
    You can use the wideip component to create, modify, display, or delete
    a wide IP that responds to AAAA queries. An AAAA wide IP is a mapping
    of a fully-qualified domain name (FQDN) to a set of IPv6 virtual
    servers that host the domain's content, such as a web site or an
    e-commerce site.

EXAMPLES
    create wideip aaaa www.my_wide_ip.com

    Creates a AAAA wide IP named www.my_wide_ip.com.

    delete wideip aaaa www.my_wide_ip.com

    Deletes the AAAA wide IP named www.my_wide_ip.

OPTIONS
    aliases
    Specifies alternate domain names for the web site content you are
    load balancing. You can use two different wildcard characters,
    asterisk (*) and question mark (?), to represent one or more
    characters. The default value is none.

    app-service
    Specifies the name of the application service to which this wide
    ip belongs. The default value is none. Note: If the strict-updates
    option is enabled on the application service that owns the object,
    you cannot modify or delete this wide ip. Only the application
    service can modify or delete this wide ip.

    description
    User defined description. Note: Advanced search on the GUI's
    Wideip list page can be turned on/off by modifying the DB variable
    ui.advancedsearch via the tmsh command "modify sys db
    ui.advancedsearch value true/false". This will result in a new
    description column and the inclusion of that field in the search.

    [disabled | enabled]
    Specifies whether the wide IP and its resources are available for
    load balancing.

    failure-rcode
    Specifies the DNS RCODE used when failure-rcode-response is
    enabled. Default is noerror. Options include noerror (no type
    exists at this name), formerr (format error in query), servfail
    (unable to process query), nxdomain (name does not exist), notimpl
    (no support for this kind of query), and refused (refuse to
    process based on policy). If failure-rcode-ttl is non-zero, only

```

the Authority section of the noerror or nxdomain response will include a SOA record.

#### failure-rcode-response

When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This response is an authoritative empty answer from the system to AAAA record requests. With this option enabled, the system responds faster to AAAA requests for which it does not have AAAA records configured. The default value is disabled.

#### failure-rcode-ttl

Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

last-resort-pool Specifies a last resort pool to use when load balancing requests for this wide IP. Any AAAA or CNAME pool type is allowed. The default value is none.

#### load-balancing-decision-log-verbosity

Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default value is none.

#### minimal-response

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the component resides.

#### persistence

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### pools

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pools-cname

Configures the CNAME pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pool-lb-mode

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

#### global-availability

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

#### ratio

Specifies that the system selects a pool based on the ratio that you assign to the pool.

round-robin  
Specifies that the system selects pools sequentially.

topology  
Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

regex  
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rules  
Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

ttl-persistence  
Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

topology-prefer-edns0-client-subnet  
Specifies, when set to enabled, that this wide IP should use the edns0 client subnet option (if one exists) instead of the source address when using topology load balancing. When this option is set to disabled or if the query did not contain a client subnet option, the system will fall back to the source address.

This setting has no effect when the global setting, configured under gtm global-settings load-balancing topology-prefer-edns0-client-subnet [disabled | enabled], is set to enabled. When either setting is enabled then this feature will be enabled.

DELETE
delete wideip cname [all | [name] ]

DESCRIPTION
    You can use the wideip component to create, modify, display, or delete
    a wide IP that responds to CNAME queries. A CNAME wide IP is a mapping
    of a fully-qualified domain name (FQDN) to its canonical name.

EXAMPLES
    create wideip cname www.my_wide_ip.com

    Creates a CNAME wide IP named www.my_wide_ip.com.

    delete wideip cname www.my_wide_ip.com

    Deletes the CNAME wide IP named www.my_wide_ip.

OPTIONS
    aliases
    Specifies alternate domain names for the web site content you are
    load balancing. You can use two different wildcard characters,
    asterisk (*) and question mark (?), to represent one or more
    characters. The default value is none.

    app-service
    Specifies the name of the application service to which this wide
    ip belongs. The default value is none. Note: If the strict-updates
    option is enabled on the application service that owns the object,
    you cannot modify or delete this wide ip. Only the application
    service can modify or delete this wide ip.

    description
    User defined description. Note: Advanced search on the GUI's
    Wideip list page can be turned on/off by modifying the DB variable
    ui.advancedsearch via the tmsh command "modify sys db
    ui.advancedsearch value true/false". This will result in a new
    description column and the inclusion of that field in the search.

    [disabled | enabled]
    Specifies whether the wide IP and its resources are available for
    load balancing.

    failure-rcode
    Specifies the DNS RCODE used when failure-rcode-response is
    enabled. Default is noerror. Options include noerror (no type
    exists at this name), formerr (format error in query), servfail
    (unable to process query), nxdomain (name does not exist), notimpl
    (no support for this kind of query), and refused (refuse to
    process based on policy). If failure-rcode-ttl is non-zero, only
    the Authority section of the noerror or nxdomain response will
    include a SOA record.

    failure-rcode-response
    When enabled, specifies that the system returns a RCODE response
    to Wide IP requests after exhausting all load-balancing methods.
    This response is an authoritative empty answer from the system to
    CNAME record requests. With this option enabled, the system
    responds faster to CNAME requests for which it does not have CNAME
    records configured. The default value is disabled.

    failure-rcode-ttl
    Specifies the negative caching TTL of the SOA for the RCODE
    response. The default is 0, meaning no SOA is included (i.e. no
    caching).
```

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**last-resort-pool**

Specifies a last resort pool to use when load balancing requests for this wide IP. Any CNAME pool type is allowed. The default value is none.

**load-balancing-decision-log-verbosity**

Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default value is none.

**minimal-response**

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

**metadata**

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

**partition**

Displays the administrative partition within which the component resides.

**persistence**

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

**persist-cidr-ipv4**

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

**persist-cidr-ipv6**

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

**pools**

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

**pool-lb-mode**

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

**global-availability**

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

**ratio**

Specifies that the system selects a pool based on the ratio that you assign to the pool.

**round-robin**

Specifies that the system selects pools sequentially.

**topology**

Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

**regex**

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

**rules**

Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

#### ttl-persistence

Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

#### topology-prefer-edns0-client-subnet

Specifies, when set to enabled, that this wide IP should use the edns0 client subnet option (if one exists) instead of the source address when using topology load balancing. When this option is set to disabled or if the query did not contain a client subnet option, the system will fall back to the source address.

This setting has no effect when the global setting, configured under gtm global-settings load-balancing topology-prefer-edns0-client-subnet [disabled | enabled], is set to enabled. When either setting is enabled then this feature will be enabled.

DELETE
delete wideip mx [all | [name] ]

DESCRIPTION
  You can use the wideip component to create, modify, display, or delete
  a wide IP that responds to MX queries. An MX wide IP maps a domain's
  mail address to a set of hosts acting as mail servers.

EXAMPLES
  create wideip mx mydomain.com

  Creates an MX wide IP named mydomain.com.

  delete wideip mx mydomain.com

  Deletes the MX wide IP named mydomain.com.

OPTIONS
  aliases
  Specifies alternate domain names for the web site content you are
  load balancing. You can use two different wildcard characters,
  asterisk (*) and question mark (?), to represent one or more
  characters. The default value is none.

  app-service
  Specifies the name of the application service to which this wide
  ip belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete this wide ip. Only the application
  service can modify or delete this wide ip.

  description
  User defined description. Note: Advanced search on the GUI's
  Wideip list page can be turned on/off by modifying the DB variable
  ui.advancedsearch via the tmsh command "modify sys db
  ui.advancedsearch value true/false". This will result in a new
  description column and the inclusion of that field in the search.

  [disabled | enabled]
  Specifies whether the wide IP and its resources are available for
  load balancing.

  glob
  Displays the items that match the glob expression. See help glob
  for a description of glob expression syntax.

  failure-rcode
  Specifies the DNS RCODE used when failure-rcode-response is
  enabled. Default is noerror. Options include noerror (no type
  exists at this name), formerr (format error in query), servfail
  (unable to process query), nxdomain (name does not exist), notimpl
  (no support for this kind of query), and refused (refuse to
  process based on policy). If failure-rcode-ttl is non-zero, only
  the Authority section of the noerror or nxdomain response will
  include a SOA record.

  failure-rcode-response
  When enabled, specifies that the system returns a RCODE response
  to Wide IP requests after exhausting all load-balancing methods.
  This response is an authoritative empty answer from the system to
  MX record requests. With this option enabled, the system responds
  faster to MX requests for which it does not have MX records
  configured. The default value is disabled.

  failure-rcode-ttl
  Specifies the negative caching TTL of the SOA for the RCODE
  response. The default is 0, meaning no SOA is included (i.e. no
  caching).

  last-resort-pool
  Specifies a last resort pool to use when load balancing requests
  for this wide IP. Any MX or CNAME pool type is allowed. The
  default value is none.

  load-balancing-decision-log-verbosity
  Specifies the amount of detail logged when making load balancing
  decisions. This is used for debugging purpose only. Performance

```

will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default value is none.

#### minimal-response

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

**name** Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the component resides.

#### persistence

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### pools

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pools-cname

Configures the CNAME pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pool-lb-mode

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

#### global-availability

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

#### ratio

Specifies that the system selects a pool based on the ratio that you assign to the pool.

#### round-robin

Specifies that the system selects pools sequentially.

#### topology

Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### rules

Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

#### ttl-persistence

Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295

seconds. The default value is 3600.

**topology-prefer-edns0-client-subnet**  
Specifies, when set to enabled, that this wide IP should use the edns0 client subnet option (if one exists) instead of the source address when using topology load balancing. When this option is set to disabled or if the query did not contain a client subnet option, the system will fall back to the source address.

This setting has no effect when the global setting, configured under gtm global-settings load-balancing topology-prefer-edns0-client-subnet [disabled | enabled], is set to enabled. When either setting is enabled then this feature will be enabled.

  field-fmt

```

```

DELETE
delete wideip naptr [all | [name] ]

```

#### DESCRIPTION

You can use the wideip component to create, modify, display, or delete a wide IP that responds to NAPTR queries. A NAPTR wide IP is a mapping of a fully-qualified domain name (FQDN) to a set of either services or hosts defined under that name.

#### EXAMPLES

```

create wideip naptr example.com

Creates a NAPTR wide IP named example.com.

delete wideip naptr example.com

Deletes the NAPTR wide IP named example.com.

```

#### OPTIONS

**aliases**  
Specifies alternate domain names for the web site content you are load balancing. You can use two different wildcard characters, asterisk (\*) and question mark (?), to represent one or more characters. The default value is none.

**app-service**  
Specifies the name of the application service to which this wide ip belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this wide ip. Only the application service can modify or delete this wide ip.

**description**  
User defined description. Note: Advanced search on the GUI's Wideip list page can be turned on/off by modifying the DB variable ui.advancedsearch via the tmsh command "modify sys db ui.advancedsearch value true/false". This will result in a new description column and the inclusion of that field in the search.

**[disabled | enabled]**  
Specifies whether the wide IP and its resources are available for load balancing.

**glob** Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

**failure-rcode**  
Specifies the DNS RCODE used when failure-rcode-response is enabled. Default is noerror. Options include noerror (no type exists at this name), formerr (format error in query), servfail (unable to process query), nxdomain (name does not exist), notimpl (no support for this kind of query), and refused (refuse to process based on policy). If failure-rcode-ttl is non-zero, only the Authority section of the noerror or nxdomain response will include a SOA record.

**failure-rcode-response**  
When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This response is an authoritative empty answer from the system to NAPTR record requests. With this option enabled, the system responds faster to NAPTR requests for which it does not have NAPTR records configured. The default value is disabled.

**failure-rcode-ttl**  
Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

**last-resort-pool**  
Specifies a last resort pool to use when load balancing requests for this wide IP. Any NAPTR or CNAME pool type is allowed. The default value is none.

**load-balancing-decision-log-verbosity**  
Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option

pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default value is none.

#### minimal-response

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

name Specifies a unique name for the component. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the component resides.

#### persistence

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### pools

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pools-cname

Configures the CNAME pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pool-lb-mode

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

#### global-availability

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

#### ratio

Specifies that the system selects a pool based on the ratio that you assign to the pool.

#### round-robin

Specifies that the system selects pools sequentially.

#### topology

Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### rules

Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

#### ttd-persistence

Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

#### topology-prefer-edns0-client-subnet

Specifies, when set to enabled, that this wide IP should use the edns0 client subnet option (if one exists) instead of the source address when using topology load balancing. When this option is set to disabled or if the query did not contain a client subnet

option, the system will fall back to the source address.

This setting has no effect when the global setting, configured under gtm global-settings load-balancing topology-prefer-edns0-client-subnet [disabled | enabled], is set to enabled. When either setting is enabled then this feature will be enabled.

DELETE
delete wideip srv [all | [name] ]

```

#### DESCRIPTION

You can use the wideip component to create, modify, display, or delete a wide IP that responds to SRV queries. An SRV wide IP is a mapping of a fully-qualified domain name (FQDN) specifying a particular service of a domain to a host and port that provides the service.

#### EXAMPLES

```

create wideip srv _imap._tcp.mydomain.com

Creates an SRV wide IP named _imap._tcp.mydomain.com.

delete wideip srv _imap._tcp.mydomain.com

Deletes the SRV wide IP named _imap._tcp.mydomain.com.

```

#### OPTIONS

##### aliases

Specifies alternate domain names for the web site content you are load balancing. You can use two different wildcard characters, asterisk (\*) and question mark (?), to represent one or more characters. The default value is none.

##### app-service

Specifies the name of the application service to which this wide ip belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this wide ip. Only the application service can modify or delete this wide ip.

##### description

User defined description. Note: Advanced search on the GUI's Wideip list page can be turned on/off by modifying the DB variable ui.advancedsearch via the tmsh command "modify sys db ui.advancedsearch value true/false". This will result in a new description column and the inclusion of that field in the search.

##### [disabled | enabled]

Specifies whether the wide IP and its resources are available for load balancing.

##### failure-rcode

Specifies the DNS RCODE used when failure-rcode-response is enabled. Default is noerror. Options include noerror (no type exists at this name), formerr (format error in query), servfail (unable to process query), nxdomain (name does not exist), notimpl (no support for this kind of query), and refused (refuse to process based on policy). If failure-rcode-ttl is non-zero, only the Authority section of the noerror or nxdomain response will include a SOA record.

##### failure-rcode-response

When enabled, specifies that the system returns a RCODE response to Wide IP requests after exhausting all load-balancing methods. This response is an authoritative empty answer from the system to SRV record requests. With this option enabled, the system responds faster to SRV requests for which it does not have SRV records configured. The default value is disabled.

##### failure-rcode-ttl

Specifies the negative caching TTL of the SOA for the RCODE response. The default is 0, meaning no SOA is included (i.e. no caching).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

##### last-resort-pool

Specifies a last resort pool to use when load balancing requests for this wide IP. Any SRV or CNAME pool type is allowed. The default value is none.

##### load-balancing-decision-log-verbosity

Specifies the amount of detail logged when making load balancing decisions. This is used for debugging purpose only. Performance will be affected if the value is not none. Please reset it back to none after done debugging. With the option pool-selection, the log will contain pool load balancing algorithm details. This includes common actions taken to a set of pools (for example, whether all pools reset the ratio counter during the algorithm) and the result of the load balancing algorithm (for example, whether a pool is finally selected and the reason if applicable). With the option pool-traversal, the log will contain details of all pools traversed during load balancing. With the option pool-member-selection, the log will contain pool member load balancing algorithm details. This includes common actions taken to a set of pool members and the result of the load balancing algorithm. With the option pool-member-traversal, the log will contain details of all pool members traversed during load balancing. The default

value is none.

#### minimal-response

Specifies GTM will form the smallest allowable DNS response to a query. Typically, this will be a single resource record in the answer section. When set to disabled, GTM will attempt to chase CNAME chains, if required, to obtain the ultimate answer, and it will attempt to add address resource records to the additional section of the response for each answer when needed. The default value is enabled.

#### metadata

Specifies user-defined data to associate with a server. By default the persist attribute is set to true. This means the data is saved into the configuration file.

**name** Specifies a unique name for the component. The format of an SRV wide IP name is governed by RFC. The general form is 'service.protocol.domain.labels'. This option is required for the commands create and modify.

#### partition

Displays the administrative partition within which the component resides.

#### persistence

When enabled, specifies that when a local DNS server makes repetitive requests on behalf of a client, the system reconnects the client to the same resource as previous requests. The default value is disabled.

#### persist-cidr-ipv4

Specifies a mask used to group IPv4 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### persist-cidr-ipv6

Specifies a mask used to group IPv6 LDNS addresses. This feature allows one persistence record to be shared by LDNS addresses that match within this mask.

#### pools

Configures the pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pools-cname

Configures the CNAME pools the system uses when load balancing requests for this wide IP. The default value is none.

#### pool-lb-mode

Specifies the load balancing method used to select a pool in this wide IP. This option is relevant only when multiple pools are configured for this wide IP. The default value is round-robin.

The available load balancing methods are:

#### global-availability

Specifies that the system selects a pool by following the order of the Pool list. The system repeatedly selects the first pool in the list for as long as its status is available. If the pool becomes unavailable for any reason, the system then repeatedly selects the next pool in the list, and so on.

#### ratio

Specifies that the system selects a pool based on the ratio that you assign to the pool.

#### round-robin

Specifies that the system selects pools sequentially.

#### topology

Specifies that the system selects a pool based on topology information in the incoming LDNS request. Note that this load balancing method works only if you have configured a topology statement.

#### regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

#### rules

Specifies the iRules(r) that this wide IP uses for load balancing decisions. 'when' clauses for each event are grouped across all iRules(r) on this wide IP. For each event, clauses are evaluated in the listed rules order. The default value is none.

#### ttl-persistence

Specifies, in seconds, the length of time for which a persistence entry is valid. This value can range from 0 through 4294967295 seconds. The default value is 3600.

#### topology-prefer-edns0-client-subnet

Specifies, when set to enabled, that this wide IP should use the edns0 client subnet option (if one exists) instead of the source address when using topology load balancing. When this option is set to disabled or if the query did not contain a client subnet option, the system will fall back to the source address.

This setting has no effect when the global setting, configured under gtm global-settings load-balancing topology-prefer-edns0-client-subnet [disabled | enabled], is set

to enabled. When either setting is enabled then this feature will be enabled.

## ilx

### ilx global-settings

#### NAME

global-settings - system-wide settings for iRules Language Extension (ILX) Plugin.

#### MODULE

ilx

#### SYNTAX

The global-settings can be displayed/modified with the following syntax:

##### MODIFY

```
modify global-settings [name]
options:
  debug-port-blacklist add/delete/replace-all-with { [port] }
  log-publisher [name]
```

##### DISPLAY

```
list global-settings [name]
options:
  debug-port-blacklist
```

#### DESCRIPTION

An iRules Language Extension (ILX) plugin global-settings profile a way to store system-wide settings.

#### EXAMPLES

```
list ilx global-settings
See the current settings
```

```
modify global-settings debug-port-blacklist add { 20001 }
Add port 20001 to the list of reserved ports that cannot be used
to attach node inspector.
```

#### OPTIONS

debug-port-blacklist  
Specifies the list of reserved ports that cannot be used to attach node inspector in case debugging is enabled.

log-publisher Specifies the log destination for messages generated by the ILXLogger nodejs object in an extension without a plugin or extension level log publisher.

#### SEE ALSO

ilx plugin, modify, list

#### COPYRIGHT

## ilx node-version

**NAME**  
node-version - Available Node.js versions for iRules Language Extension (ILX) Plugin and Workspace.

**MODULE**  
ilx

**SYNTAX**  
The node-version can be displayed with the following syntax:

**DISPLAY**  
list node-version [name]

**DESCRIPTION**  
Provides major and full version of available node.js versions available to an iRules Language Extension (ILX) Plugin and Workspace.

**EXAMPLES**  
list ilx node-version  
See the current available versions

**SEE ALSO**  
ilx plugin, ilx workspace, list

**COPYRIGHT**

  immediate
  stop-draining

```

DESCRIPTION

An iRules Language Extension (ILX) plugin provides the following functionality:

- An RPC interface that allows an iRule to communicate with an ILX Node.js(tm) process.
- A Streaming interface that allows an ILX Node.js(tm) process to manage Virtual Server connections and payload data.

A plugin is created from an ilx workspace. Files from the workspace are copied into a system area and run from the system area. iRule files contained in the workspace are read into the system as ltm rule configuration. The ltm rule configuration objects are created in a sys folder that has the same name as the plugin.

The system will start one or more Node.js(tm) process for each extension (see also concurrency-mode below). Node.js(tm) will look in the extension directory for the file package.json. Node.js(tm) will look in package.json for a main field that identifies the main entry point of the plugin. If the main field is not present node will look for the file index.js.

The status of plugin processes can be viewed with the show command.

```
show plugin my_plugin
```

A plugin can be started, stopped and restarted. When a plugin is initially created the system will start processes for each extension. When a plugin is stopped existing plugin processes associated with active tmm connections are allowed to drain. Draining processes continue to run until the connections are closed. There are several options that control how processes are stopped, drain-existing-connections, immediate and stop-draining, and are describe below.

There are several ILX commands that an iRule may use to communicate with a Node.js(tm) extension process: ILX::init, ILX::call and ILX::notify.

ILX::init [plugin name] [extension name] establishes a communication path from an iRule to the node process. It returns a handle that must be passed to ILX::call and ILX::notify.

ILX::call [ILX handle] [method] [optional arg 1] [optional arg 2] ..... invokes the specified node method in the extension associated with the ILX handle. If the node method returns a javascript array or dictionary then a Tcl list object is returned from ILX::call, otherwise a Tcl string object is returned.

ILX::notify [ILX handle] [method] [optional arg 1] [optional arg 2] ..... sends a message to the node method but does not wait for the method to complete before returning. TCL\_OK is returned if the message was successfully queued. Any other return value indicates the message could not be queued.

#### RPC

The RPC API consists of two primary components, Node.js and Tcl.

The Node.js API contains an ILXServer class. Methods are added to the server using ILXServer.addMethod("method name", function(req, res) {

... }). "req" is an ILXRequest object and "res" is an ILXResponse object. ILXServer.listen will start the server.

A Tcl iRule connects to the Node.js process using the Tcl command  
set plugin [ILX::init "plugin name" "extension name"]

The Javascript methods are invoked from a Tcl iRule using either  
ILX::call or ILX::notify. The args are user defined and passed to the  
Node.js method via the ILXRequest object.  
set response [ILX::call \$plugin "method name" args...]

ILX::notify is similar to ILX::call except that the iRule will not wait  
for a response from the Node.js process.  
ILX::call \$plugin "method name" args...]

Here is a Hello World Node.js script

```
var f5 = require('f5-nodejs');
var server = new f5.ILXServer();
server.addMethod("hello_world", function(req, res) {
console.log("request args: " + JSON.stringify(req));
res.reply('hello_world');
});
server.listen();
```

Here is the Hello World Tcl iRule that passes some data to the Node.js  
process, waits for a response and logs the response to /var/log/ltm.  
The iRule must be associated with an ltm virtual-server.

```
when CLIENT ACCEPTED {
set plugin [ILX::init rpc example]
set rv [ILX::call $plugin hello_world arg1 val1 arg2 val2]
log local0.debug $rv
}
```

Run the following tmsh commands to create the ilx workspace and ilx  
plugin configuration for the RPC example above. See also help ilx  
workspace for more examples describing how to manage a workspace.

create ilx workspace rpc

create ilx workspace rpc extension example

edit ilx workspace rpc extension example

A file named index.js will be created. Replace the content of  
index.js with the Node.js Hello World script above. If you  
have bash shell access you can directly edit the file  
/var/ilx/workspaces/Common/rpc/extensions/example/index.js.

edit ilx workspace rpc rule example

A file named rpc\_example.tcl will be created. Replace the  
content of rpc\_example.tcl with the Tcl iRule Hello World  
example above. If you have bash shell access you can directly  
edit the file  
/var/ilx/workspaces/Common/rpc/rules/hello\_world.tcl.

create ilx plugin rpc from-workspace rpc

modify ltm virtual [name] rules { rpc/example }

You must create a Virtual Server and associate the rpc\_example  
rule with the Virtual Server. When a client connects to the  
Virtual Server you should see the output from both the  
Node.js process and Tcl iRule in /var/log/ltm.

See also the BIG-IP iRulesLX User Guide located in the Programmability  
Wiki at devcentral.f5.com.

## Streaming

The Streaming API allows a Node.js Plugin process to act as a proxy for  
connections through a Virtual Server. When a client connects to a  
Virtual Server an ILXFlow object is created and passed to the plugin.  
The ILXFlow object contains two Node.js sockets. ILXFlow.client  
represents the connection from the client to the plugin. ILXFlow.server  
represents the connection from the plugin to a server. The plugin will  
use ILXFlow.client to receive or send data to the client. The plugin  
will use ILXFlow.server to send or receive data from the server. The  
plugin may inspect or modify any/all client or server data. The  
ILXFlow.client and ILXFlow.server objects behave as native Node.js  
sockets. The plugin can also be configured to act as a server and  
respond directly to the client without completing a connection to a  
server. The plugin can also be configured as a native Node.js HTTP  
server.

```
[Client] <-> [Virtual Server] <-> [TMM]
|
v
[ILXFlow.client]
[Plugin]
[ILXFlow.server]
|
v
[TMM] <-> [Server]
```

Note that the plugin sees TCP payload. TCP headers are stripped by the  
TMM and are not visible to the plugin.

The following is a brief overview of the Javascript classes that make  
up the Streaming API. These classes contain many more features and  
options as described in the BIG-IP iRulesLX User Guide located in the

Programmability Wiki at devcentral.f5.com.

**ILXPlugin** - Connects to the TMM to accept Virtual Server client connections. When a connection is made an ILXFlow object is passed to the plugin via the "connect" event: `plugin.on("connect", function(flow) { ... })`.

**ILXPluginOptions** - Options that configure the events and data that a plugin will received.

**ILXFlow** - An object that represents a client socket to Virtual Server and server socket to a server.

**ILXStream** - An object that represents the client side connection from a client to a Virtual Server (`ILXFlow.client`), the server side connection from a Virtual Server to a server (`ILXFlow.server`), or a plugin initiated connection to a server (created using `ILXStream.connect`).

**ILXLbOptions** - Options that allow the plugin to specify which server the client will connect to by calling `ILXFlow.lbSelect(ILXLbOptions)`.

**ILXTable** - Functions for reading and writing the TMM Session DB. Very similar interface to the Tcl `iRule` table command.

**ILXBufferUtil** - Functions for searching and modifying a Node.js Buffer object.

**ILXDatagroup** - Functions for accessing ltm data-group configuration. The set of data-groups available to a plugin must be specified using the `ILXPluginOptions` when the plugin is started.

**ILXTransaction** - If HTTP and ILX profiles are attached to a virtual server then all header and data inspection and modification are done in the context of request and response transaction. An `ILXTransaction` object is passed to the following events: `requestStart`, `requestComplete`, `responseStart` and `responseComplete`. The `ILXTransaction` object contains things like request headers, URI and method, and response headers and status.

The following is a sample streaming plugin that acts as a pass through. Data is read from the client and sent to the server. Data is read from the server and sent to the client. Note that it is important to handle "error" events as the Node.js plugin process will exit if they are not handled.

```
var f5 = require("f5-nodejs");
var plugin = new f5.ILXPlugin();
plugin.on("connect", function(flow) {
    flow.client.on("readable", function() {
        var buffer;
        while (true) {
            buffer = flow.client.read();
            if (buffer === null) {
                break;
            }
            console.log("Client Data");
            console.log(buffer.toString());
            flow.server.write(buffer);
        }
    });
    flow.client.on("error", function(err) {
        console.log("client socket error: " + err);
    });
    flow.server.on("readable", function() {
        var buffer;
        while (true) {
            buffer = flow.server.read();
            if (buffer === null) {
                break;
            }
            console.log("Server Data");
            console.log(buffer.toString());
            flow.client.write(buffer);
        }
    });
    flow.server.on("error", function(err) {
        console.log("server socket error: " + err);
    });
    flow.on("error", function(err) {
        console.log("flow error: " + err);
    });
});
var options = new f5.ILXPluginOptions(); // use defaults
plugin.start(options);
```

The following is a sample streaming HTTP plugin that acts as a pass through. Note that the example above can also be used to manage HTTP traffic. This example requires a Virtual Server with both HTTP and ILX profiles.

```
var f5 = require('f5-nodejs');
var plugin = new f5.ILXPlugin();
plugin.on("connect", function(flow) {
    {
        flow.client.on("requestStart", function(request) {
            // HTTP request URI, headers and more
            console.log(
                "requestStart: " + JSON.stringify(request.params));
        });
        flow.client.on("readable", function() {
            // HTTP request body, if present
            var buf;
            while (true) {
                buf = flow.client.read();
```

```

        if (buf !== null) {
            console.log("request body:" + buf.length + " bytes");
            console.log(buf.toString());
            flow.server.write(buf);
        }
        else {
            break;
        }
    }
});
flow.client.on("requestComplete", function(request) {
// Entire HTTP request received
console.log(
    "requestComplete: " + JSON.stringify(request.params));
request.complete();
});
flow.client.on("error", function(err) {
console.error("flow.client error:" + err);
});

    flow.server.on("responseStart", function(response) {
// HTTP response headers, status and more
console.log(
    "responseStart: " + JSON.stringify(response.params));
});
    flow.server.on("readable", function() {
// HTTP response body, if present
var buf;
while (true) {
    buf = flow.server.read();
    if (buf !== null) {
        console.log(
            "response body:" + buf.length + " bytes");
        console.log(buf.toString());
        flow.client.write(buf);
    }
    else {
        break;
    }
}
});
    flow.server.on("responseComplete", function(response) {
// Entire HTTP response received
console.log(
    "responseComplete: " + JSON.stringify(response.params));
response.complete();
});
    flow.server.on("error", function(err) {
console.error("flow.server error:" + err);
});
    flow.on("error", function(err) {
console.error("flow.error:" + err);
});
});
var options = new f5.ILXPluginOptions(); // use defaults
plugin.start(options);

```

Run the following tmsh commands to create ilx workspace and ilx plugin configuration for a streaming plugin using either of the sample plugins above.

```
create ilx workspace streaming
```

```
