/var/ilx/workspaces/Common//rules/...
/var/ilx/workspaces/Common//version

The extensions directory contains sub-directories. Each sub-directory contains files for a specific extension. /var/ilx/workspaces/Common//extensions//... Each extension directory must contain a package.json file. This is a standard npm package definition file. For more information see www.npmjs.org/doc/package.json.html. When an ilx plugin is started node will look in package.json for a main field that identifies the main entry point of the plugin. If the main field is not present node will look for the file index.js.

The rules directory contains zero or more files that contain iRules (see ltm rule). /var/ilx/workspaces/Common//rules/.tcl. ILX iRule commands are used to communicate with a Node.js(tm) process that is running as part of an ILX Plugin. When a new rule is created using either of the following commands a sample iRule file is opened with syntax examples for the ILX iRule commands.

create ilx workspace ilx rule test
edit ilx workspace ilx rule test

When a new extension is created using the following commands a sample index.js file will be created that contains Node.js(tm) and ILX iRule examples. The extension directory is also populated with the file package.json and locally installed Node.js(tm) modules.

tmsh create ilx workspace my_workspace
tmsh create ilx workspace my_workspace extension my_extension

The version file indicates the BIG-IP version used to create the workspace.

EXAMPLES

create workspace my_workspace

Creates a workspace named my_workspace in /var/ilx/workspaces/Common/my_workspace (assuming your current working folder is the default BIG-IP folder /Common).

create workspace my_workspace rule my_rule

Adds the iRule my_rule as the file my_rule.tcl to the workspace directory named /var/ilx/workspaces/Common/my_workspace/rules/.

edit workspace my_workspace rule my_rule

Adds or modifies the iRule my_rule as the file my_rule.tcl to the workspace directory named /var/ilx/workspaces/Common/my_workspace/rules/.

create workspace my_workspace extension my_extension

Adds a new extension directory in /var/ilx/workspaces/Common/my_workspace/extensions/my_extension and installs node_modules/f5-nodejs within the directory. my_extension must be a valid Linux directory name.

edit workspace my_workspace extension my_extension

If the extension does not exist a new extension directory is created in /var/ilx/workspaces/Common/my_workspace/extensions/my_extension, installs node_modules/f5-nodejs within the directory and opens the editor on the file within the directory named index.js. If the extension already exists the editor will open index.js.

edit workspace my_workspace file extensions/my_extension/my_file.js

If the extension does not exist a new extension directory is created in /var/ilx/workspaces/Common/my_workspace/extensions/my_extension, installs node_modules/f5-nodejs within the directory and opens the editor on my_file.js. If the extension already exists the editor will open my_file.js.

edit workspace my_workspace file extensions/my_extension/my_file.js

The editor is opened on /var/ilx/workspaces/Common/my_workspace/extensions/my_extension/my_file.js. The extension must already exist.

delete workspace my_workspace

Deletes the workspace named my_workspace. This removes all disk files associated with the workspace and cannot be undone. You will be prompted to confirm before the workspace is deleted.

delete workspace my_workspace extension my_extension

Deletes the extension named my_extension in my_workspace.

delete workspace my_workspace rule my_rule

Deletes the iRule file named my_rule in my_extension in my_workspace.

delete workspace my_workspace file extensions/my_extension/my_file

Deletes the file named my_file in my_extension in my_workspace.

list workspace my_workspace

List the content of my_workspace

list workspace recursive my_workspace

List all files and directories in my_workspace.

list workspace my_workspace rule

List the rules associated with my_workspace.

list workspace my_workspace rule my_rule

List the text content of the rule my_rule associated with my_workspace

list workspace my_workspace file rules/my_rule.tcl

List the text content of the file rules/my_rule.tcl associated with my_workspace

list workspace my_workspace extension

List the extensions associated with my_workspace.

list workspace my_workspace extension my_extension

List the content of the my_extension extension directory associated with my_workspace.

list workspace my_workspace file extensions/my_extension/my_file

List the text content of the file my_file in extension my_extension.

show workspace my_workspace

Show the top level files for the specified workspace. Show the group, last modify time, owner, permissions and size of the workspace.

show workspace

Show all workspaces.

OPTIONS

archive

Specifies the name of a workspace archive file. See the section below on archives.

all-files

Recursively list all directory and file names contained in a workspace.

all-properties

For a show command, show group, last modify time, owner, permissions, type and size of the file/directory.

detail

For a show command, show all the files in the workspace.

extension

Specifies the name of a workspace extension.

file For the edit and list commands the file option specifies the name of a file in a workspace to edit or list. For the delete command the file option specifies the name of a workspace file to delete.

from-archive

Specifies the name of a tar or gzipped tar archive file from which to create or update a workspace. See the section below on archives.

from-plugin

Specifies the name of an ilx plugin from which to create or modify a workspace. The files used to create the plugin are copied into the workspace.

from-uri

Specifies the name of a URI from which to create or update a workspace. The URI must refer to a tar or gzipped tar archive file.

from-workspace

Specifies the name of a workspace from which to create or modify a workspace. The files used to create the workspace specified by from-workspace are copied into the new workspace.

node-version

Specifies the version of Node.js that will be used to run an . When an is created or updated from a workspace the plugin inherits the node-version from the workspace. The node-version may be specified when an ilx workspace is created. The node-version may also be changed after the ilx workspace has been created.

When the node-version of a workspace is changed the workspace is archived. The following files and directories are replaced: The file

[workspace name]/extensions/[extension name]/node_modules/f5-nodejs/package.json

and the content of the directory

[workspace name]/extensions/[extension name]/node_modules/f5-nodejs/lib.

To update an existing ilx plugin to use the new workspace version issue the following command:

modify ilx plugin [plugin name] from-workspace [workspace name]

When a node process is started the BigIP sets the NODE_PATH environment variable. For Node.js version 0.12 plugins the NODE_PATH is set to /usr/local/node/v0.12/lib/node_modules. For Node.js version 6 the NODE_PATH is set to /usr/lib/node_modules:/usr/local/node/v6/lib/node_modules.

one-line

List the content of a workspace on a single line.

recursive

Recursively list all workspaces contained in the current BIG-IP system folder (see sys folder).

rule Specifies the name of a rule file to create, delete, edit or list.

staged-directory

The directory where the workspace and associated files reside. This is a read-only property.

name Specifies the name of a workspace. This option is required for the commands create, delete, edit and modify.

ACCESS CONTROL

Workspaces are stored under file system directory /var/ilx/workspaces.

A user with the role of admin can access all workspaces under /var/ilx/workspaces.

Users with the role of irule-manager, manager and resource-admin can manage workspaces under /var/ilx/workspaces/, where is the name of an existing sys folder that the user has permission to access, see also help sys folder and help pwd.

As a convenience workspaces are automatically created in the users' current folder relative to /var/ilx/workspaces. However, workspaces may be created in file system directories that do not correspond to BIG-IP system configuration folders. In this case the workspace must be referred to by full path.

The following creates two workspaces, the first in the file system location /var/ilx/workspaces/Common/my_workspace and the second in the filesystem location /var/ilx/workspaces/Common/my_folder/my_workspace.

```
(tmos)# pwd
/Common
(tmos)# create ilx workspace my_workspace
(tmos)# cd my_folder
(tmos)# pwd
/Common/my_folder
(tmos)# create ilx workspace my_workspace_2
(tmos)# list ilx workspace my_workspace_2

(tmos)# cd ..
(tmos)# pwd
/Common
(tmos)# list ilx workspace my_workspace
```

Full folder paths may be used to refer to a workspace.

```
(tmos)# create ilx workspace /Common/my_folder/my_workspace_2
(tmos)# list ilx workspace /Common/my_folder/my_workspace_2
```

If an auth partition is removed from the BIG-IP configuration the workspace files remain on disk and can be accessed by a user with the role of admin. If a sys folder is removed under an auth partition, such as removing the folder /Common/my_config, all workspaces under the file system directory /var/ilx/workspaces/Common/my_config remain accessible to all users that have access to the Common partition.

ARCHIVES

A workspace archive is a gzipped tar file of an existing workspace. The archive contains all files in the workspace.

There are two ways to refer to an archive: 1) 2) //.

Workspace archives are stored in /var/ilx/workspaces/archive/. The system looks for archives in /var/ilx/workspaces/archive.

If an auth partition is removed from the BIG-IP configuration, archive files remain on disk and can be accessed by a user with the role of admin. A user with the role of admin can also manage archives under /var/ilx/workspaces in directories that do not correspond to a BIG-IP auth partition.

```
create workspace my_workspace archive my_workspace.tgz
```

Save the workspace as a gzipped tar file. The workspace must have been previously created.

```
create workspace my_workspace archive /my_partition/my_workspace.tgz
```

Save the workspace as a gzipped tar file to the set of archives in /my_partition. The workspace must have been previously created.

```
list workspace my_workspace archive
```

List all archives in the current auth partition.

```
list workspace my_workspace archive my_workspace.tgz
```

List file details for the archive my_workspace.tgz.

```
list workspace my_workspace archive /my_partition/my_workspace.tgz
```

List file details for the archive my_workspace.tgz that is in my_partition.

```
list workspace my_workspace archive /my_partition
```

List all archives in /my_partition.

```
delete workspace archive my_archive.tgz
```

Delete the workspace archive my_archive.tgz.

```
delete workspace archive /my_partition/my_archive.tgz
```

Delete the workspace archive my_archive.tgz in /my_partition.

```
create workspace my_workspace from-archive my_workspace.tgz
```

Create a new workspace from the archive my_workspace.tgz.

modify workspace my_workspace from-archive my_workspace.tgz

Update my_workspace from the archive my_workspace.tgz.

CONFIGURATION FILES

Workspaces are not stored in system config files.

Workspaces are stored in UCS files and are rolled forward to the next product release.

In a bladed system workspaces are clustered among blades.

Workspaces are not synced across device groups.

non-default-properties
one-line

DELETE
delete alg-log-profile [name | all]

DESCRIPTION

A ALG log profile allows fine grain control of the logging for ALG events. When attached to an supported ALG profile - currently FTP, RTSP, SIP, you can control the events to log as well as optional elements in the log entry.

EXAMPLES

```
create ltm alg-log-profile my_alg_log_profile end-control-channel { action backup-allocation-only } end-data-channel { action backup-allocation-only }
```

Creates the ALG log profile `my_alg_log_profile` that generates log entries for both inbound and data-channel when translation is from backup members only.

```
delete alg-log-profile my_lsn_log_profile
```

Deletes the ALG log profile named `my_lsn_log_profile`.

OPTIONS

app-service

Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

csv-format

When enabled, use CSV log format for log entries. The default value is disabled.

events

The type of ALG events available for logging control.

start-control-channel

Event for start of control channel connection.

end-control-channel

Event for end of control channel connection.

start-data-channel

Event for start of data channel connection.

end-data-channel

Event for end of data channel connection.

inbound-transaction

Event for inbound transaction event to an ALG end-point. Inbound transaction log entry could contain both incoming and outgoing messages.

action

Specify the logging action to be taken when a particular event is encountered.

enabled

Logging is enable for the event, regardless of how the flow is created.

backup-allocation-only

Logging is enable for the event, when the ALG is proxy with a LSN, and translation is take from backup pool member only.

disabled

Logging is disable for the event.

elements

Optional elements that can be added to the log message.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ltm auth crldp-server

NAME

crldp-server - Creates a Certificate Revocation List Distribution Point (CRDLP) server for implementing a CRLDP authentication module.

MODULE

ltm auth

SYNTAX

Configure the crldp-server component within the ltm auth module using the syntax in the following sections.

CREATE/MODIFY

```
create crldp-server [name]
modify crldp-server [name]
options:
  app-service [[string] | none]
  base-dn [ [LDAP base directory name] | none]
  description [string]
  host [ [ip address] | none]
  port [ [name] | [number] ]
  reverse-dn [disabled | enabled]
```

```
edit crldp-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list crldp-server
list crldp-server [ [ [name] | [glob] | [regex] ] ... ]
show running-config crldp-server
show running-config crldp-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete crldp-server [name]
```

DESCRIPTION

CRLDP authentication is a mechanism for checking certificate revocation status for client connections passing through the BIG-IP(r) system. This module is useful when your authentication data is stored on a remote CRLDP server.

To implement a CRLDP authentication module and create a CRLDP server:

1. Use the crldp-server component in the ltm auth module to create a CRLDP server.
2. Use the ssl-crldp component in the ltm auth module to configure a CRLDP configuration object and associate it with the server you created in Step 1.
3. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:
 - a. For the configuration option, specify the SSL CRLDP configuration object that you created in Step 2.
 - b. For the defaults-from option, specify a parent profile (either the default profile named ssl_crldp or another custom profile that you created).

EXAMPLES

```
create crldp-server my_crldp_server
```

Creates a CRLDP server named my_crldp_server.

```
delete crldp-server my_crldp_server
```

Deletes a CRLDP server named my_crldp_server.

OPTIONS

app-service

Specifies the name of the application service to which the CRLDP server belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the CRLDP server. Only the application service can modify or delete the CRLDP server.

base-dn

Specifies the LDAP base directory name for certificates that specify the CRL distribution point in directory name format (dirName). The default value is none.

Use this option when the value of the X509v3 attribute crlDistributionPoints is of type dirName. In this case, the BIG-IP system attempts to match the value of the crlDistributionPoints attribute to the value of the base-dn option. An example of a base-dn value is cn=lx,dc=f5,dc=com.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

host Specifies an IP address for the CRLDP server. This option is required. The default value is none.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

port Specifies the port for CRLDP authentication traffic. The default value is 389.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse-dn
Specifies in which order the system attempts to match the value of the base-dn option to the value of the X509v3 attribute crlDistributionPoints. When enabled, the system matches the value of the base-dn option from left to right, or from the beginning of the DN string, to accommodate dirName strings in certificates such as C=US,ST=WA,L=SEA,OU=F5,CN=xxx. The default value is disabled.

 non-default-properties

reset-stats kerberos-delegation
reset-stats kerberos-delegation
[[[name] | [glob] | [regex]] ...]

DISPLAY

```
list kerberos-delegation
list kerberos-delegation [ [ [name] | [glob] | [regex] ] ... ]
show running-config kerberos-delegation
show running-config kerberos-delegation
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show kerberos-delegation
show kerberos-delegation [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

DELETE

```
delete kerberos-delegation [name]
```

DESCRIPTION

The Kerberos delegation configuration acts like a proxy for Kerberos credentials. When connecting to a server that is inside its domain, the browser client fetches Kerberos credentials known as delegated credentials. These credentials are passed on to the system. Once the system has these credentials, it retrieves credentials for the RealServer(r) that is on the back end, and passes those credentials back.

Each user is assigned a unique cookie that describes a session on the system. This cookie is encrypted in a cookie key.

To configure a Kerberos authentication module and create a Kerberos configuration object:

1. Use the kerberos-delegation component in the ltm auth module to create a Kerberos configuration object.
2. Use the profile component, in the ltm auth module, to create an authentication profile in which you specify the following options:
 - a. For the configuration option, specify the Kerberos configuration object that you created in Step 1.
 - b. For the defaults-from option, specify a parent profile (either the default Kerberos profile named krbdelegate or another custom Kerberos profile that you created).

EXAMPLES

```
create kerberos-delegation my_kerberos-delegation_config client-principal client.net server-principal
server.net
```

Creates a Kerberos delegation profile named my_kerberos-delegation_config.

```
list kerberos-delegation all-properties
```

Displays all properties for all Kerberos delegation profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

client-principal

Specifies the principal that the client sees. This is usually a value such as HTTP/. This principal may be in a different domain from the server principal. This option is required. There is no default value.

debug-logging

Specifies whether the system logs debugging actions. The default value is disabled.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which this profile resides.

protocol-transition

Specifies whether associated virtual should transition client certificate authentication into Kerberos credentials.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

server-principal

Specifies the principal of the back-end web server. This is usually a value such as HTTP/. This may be in a different domain from the server

no default value.

DESCRIPTION

LDAP authentication is a mechanism for authenticating or authorizing client connections passing through the system. LDAP authentication is useful when your authentication or authorization data is stored on a remote LDAP server or a Microsoft(r) Windows Active Directory(r) server, and you want the client credentials to be based on basic HTTP authentication (that is, user name and password).

To configure an LDAP authentication module and create an LDAP configuration object:

1. Use the ldap component in the ltm auth module to create an LDAP configuration object.
2. Use the profile component, in the ltm auth module, to create an authentication profile in which you specify the following options:
 - a. For the configuration option, specify the LDAP configuration object that you created in Step 1.
 - b. For the defaults-from option, specify a parent profile (either the default LDAP profile named ldap or another custom profile that you created).

EXAMPLES

```
create ldap my_auth_ldap servers add {my_ldap_auth_server}
```

Creates a configuration object named my_auth_ldap

```
delete ldap my_auth_ldap
```

Deletes the configuration object named my_auth_ldap.

OPTIONS

bind-dn

Specifies the distinguished name of an account to which to bind, to perform searches. This search account is a Read-only account used to do searches. You can use the admin account as the search account. If no admin DN is specified, then no bind is attempted. The default value is none.

This option is required only when a site does not allow anonymous searches. If the remote server is a Microsoft(r) Windows(r) Active Directory(r) server, the distinguished name must be in the form of an email address.

bind-pw

Specifies the password for the search account created on the LDAP server. This option is required if you specify a value for the bind-dn option. The default value is none.

bind-timeout

Specifies a bind timeout limit. The default value is 30 seconds.

check-host-attr

Confirms the password for the bind distinguished name. This option is optional. The default value is disabled.

debug

Enables or disables syslog-ng debugging information at LOG DEBUG level. The default value is disabled. F5 Networks does not recommend using this option for normal configuration.

description

User defined description.

filter

Specifies a filter. Use this option for authorizing client traffic. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

group-dn

Specifies the group distinguished name. The system uses this option for authorizing client traffic. The default value is none.

group-member-attribute

Specifies a group member attribute. The system uses this option for authorizing client traffic. The default value is none.

idle-timeout

Specifies the idle timeout, in seconds, for connections. The default value is 3600 seconds.

ignore-auth-info-unavail

Specifies whether the system ignores authentication information, if it is not available. The default value is no.

ignore-unknown-user

Specifies whether the system ignores a user that is unknown. The default value is disabled.

login-attribute

Specifies a logon attribute. Normally, the value for this option is uid; however, if the server is a Microsoft Windows Active Directory server, the value must be the account name samaccountname (not case-sensitive). The default value is none.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

port Specifies the port number or name for the LDAP service. Port 389 is typically used for non-SSL and port 636 is used for an SSL-enabled LDAP service. The default value is ldap.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

scope

Specifies the search scope. The default value is sub. The options are:

base Specifies the search scope is base object. The base value is almost never useful for nameservice lookups.

one Specifies the search scope is one level.

sub Specifies the search scope is subtree.

search-base-dn

Specifies the search base distinguished name. The default value is none.

search-timeout

Specifies the search timeout. The default value is 30 seconds.

servers

Specifies the LDAP servers that the system must use to obtain authentication information. You must specify a server when you create an LDAP configuration object.

ssl Enables or disables SSL functionality. The default is disabled.

Note that when you use the command line interface to enable SSL for an LDAP service, the system does not change the service port number from 389 to 636, as is required. To change the port number from the command line, use the service option of this command (see above), for example, ldap [name] ssl enabled service 636.

ssl-ca-cert-file

Specifies the name of an SSL CA certificate using the full path to the file. The default value is none.

ssl-check-peer

Specifies whether the system checks an SSL peer. The default value is disabled.

ssl-ciphers

Specifies SSL ciphers. The default value is none.

ssl-client-cert

Specifies the name of an SSL client certificate. The default value is none.

ssl-client-key

Specifies the name of an SSL client key. The default value is none.

user-template

Specifies a user template for the LDAP application to use for authentication. The default value is none.

version

Specifies the version number of the LDAP application. The default value is 3.

warnings

Enables or disables warning messages. The default value is enabled.

options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete ocsdp-responder [name]
```

DESCRIPTION

To implement the SSL OCSF authentication module, you must create the following objects: one or more OCSF responder objects, an SSL OCSF configuration object, and an SSL OCSF profile.

To implement an SSL OCSF authentication module and create an OCSF responder object:

1. Use the ocsdp-responder component in the ltm auth module to configure an OCSF responder object.
2. Use the ssl-ocsf component in the ltm auth module to configure an SSL OCSF configuration object to which you add the OCSF responder object that you created in Step 1.
3. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:
 - a. For the configuration option, specify the SSL OCSF configuration object that you created in Step 2.
 - b. For the defaults-from option, specify a parent profile (either the default OCSF Responder profile named ssl_ocsf or another custom profile that you created).

OPTIONS

allow-certs

Enables or disables the addition of certificates to an OCSF request. The default value is enabled.

app-service

Specifies the name of the application service to which the OCSF responder object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the OCSF responder object. Only the application service can modify or delete the OCSF responder object.

ca-file

Specifies the name of the file containing trusted CA certificates used to verify the signature on the OCSF response. The default value is none.

ca-path

Specifies the name of the path containing trusted CA certificates used to verify the signature on the OCSF response. The default value is none.

cert-id-digest

Specifies a specific algorithm identifier, either sha1 or md5. The default value is sha1. The options are:

sha1 is newer and provides more security with a 160-bit hash length.
md5 is older and has only a 128-bit hash length.

The cert ID is part of the OCSP protocol. The OCSP client (in this case, the BIG-IP system) calculates the cert ID using a hash of the Issuer and serial number for the certificate that it is trying to verify.

chain

Specifies whether the system constructs a chain from certificates in the OCSP response. The default value is enabled.

check-certs

Enables or disables verification of an OCSP response certificate. Use this option for debugging purposes only. The default value is enabled.

description

User defined description.

explicit

Specifies that the Local Traffic Manager explicitly trusts that the OCSP response signer's certificate is authorized for OCSP response signing. If the signer's certificate does not contain the OCSP signing extension, specification of this option causes a response to be untrusted. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-aia

Specifies whether the system ignores the URL contained in the certificate's AIA fields, and always uses the URL specified by the responder instead. The default value is disabled.

intern

Specifies whether the system ignores certificates contained in an OCSP response when searching for the signer's certificate. To use this option, the signer's certificate must be specified with either the verify-other or va-file option. The default value is enabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

nonce

Specifies whether the system verifies an OCSP response signature or the nonce values. The default value is enabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

sign-digest

Specifies the algorithm for signing the request, using the signing certificate and key. This parameter has no meaning, if request signing is not in effect (that is, both the request signing certificate and request signing key parameters are empty). This parameter is required only when request signing is in effect. The default value is sha1.

sign-key

Specifies the key that the system uses to sign an OCSP request. The default value is none.

sign-key-pass-phrase

Specifies the passphrase that the system uses to encrypt the sign key. The default value is none.

sign-other

Adds a list of additional certificates to an OCSP request. The default value is none.

signer

Specifies a certificate used to sign an OCSP request. If the certificate is specified, but the key is not specified, then the private key is read from the same file as the certificate. If neither the certificate nor the key is specified, then the request is not signed. If the certificate is not specified and the key is specified, then the configuration is considered to be invalid. The default value is none.

status-age

Specifies the age of the status of the OCSP responder. The default value is 0 (zero).

trust-other

Instructs the BIG-IP local traffic management system to trust the certificates specified with the verify-other option. The default is value disabled.

url Specifies the URL used to contact the OCSP service on the responder. This option is required. The default value is none.

va-file

Specifies the name of the file containing explicitly trusted responder certificates. This parameter is

needed in the event that the responder is not covered by the certificates already loaded into the responder's CA store. The default value is none.

validity-period

Specifies the number of seconds used to specify an acceptable error range. Use this option when the OCSF responder clock and a client clock are not synchronized, which can cause a certificate status check to fail. This value must be a positive number. The default value is 300 seconds.

verify

Enables or disables verification of an OCSF response signature or the nonce values. Used for debugging purposes only. The default value is enabled.

verify-cert

Specifies that the system makes additional checks to see if the signer's certificate is authorized to provide the necessary status information. Use this option for testing purposes only. The default value is enabled.

verify-other

Specifies the name of the file used to search for an OCSF response signing certificate when the certificate has been omitted from the response. The default value is none.

verify-sig

Specifies that the system checks the signature on the OCSF response. Use this option for testing purposes only. The default value is enabled.

ltm auth profile

NAME

profile - Configures an authentication profile.

MODULE

ltm auth

SYNTAX

Configure the profile component within the ltm auth module using the syntax shown in the following sections.

CREATE/MODIFY

create profile [name]

modify profile [name]

options:

app-service [[string] | none]

configuration [[name] | none]

cookie-key [string]

cookie-name [string]

credential-source [http-basic-auth]

defaults-from [name]

description [string]

enabled [yes | no]

idle-timeout [integer]

rule [iRule name]

edit profile [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

reset-stats profile

reset-stats profile [[[name] | [glob] | [regex]] ...]

DISPLAY

list profile

list profile [[[name] | [glob] | [regex]] ...]

show running-config profile

show running-config profile [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties
one-line
partition

show profile
show profile [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global

DELETE
delete profile [name]

Note: You cannot delete default profiles.

DESCRIPTION

You can use the profile component to configure a custom authentication profile, or you can use the default profile that the BIG-IP(r) Local Traffic Manager system provides for each type of authentication module.

An authentication profile requires one of the following configuration objects: Itm auth kerberos-delegation, Itm auth ldap, Itm auth radius, Itm auth ssl-cc-ldap, Itm auth ssl-crldp, Itm auth ssl-ocsp or Itm auth tacacs. The type of profile specified by the defaults-from option must match the type of configuration object.

EXAMPLES

```
create profile my_authentication_profile { configuration tacacs defaults-from tacacs credential-source http-  
basic-auth enabled yes idle-timeout 30 rule _sys_auth_tacacs }
```

Creates a profile named my_authentication_profile for TACACS+ authentication.

list profile

Displays the properties of all of the auth profile components.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

configuration

Specifies the name of an authentication configuration object. This option is required.

cookie-key

Specifies the key that the system uses to encrypt the session cookie assigned to each user using the cookie-name option. The default value is f5auth. This option applies only to KRB Delegate profiles.

cookie-name

Specifies a session cookie that the system assigns to each user. F5 Networks recommends that each virtual server use a different cookie name. The system encrypts the cookie using the value of the cookie-key option. The default value is abc123. This option applies only to KRB Delegate profiles.

credential-source

Specifies the credential source.

defaults-from

Specifies the name of the authentication profile from which you want your custom profile to inherit settings. This option is required.

description

User defined description.

enabled

Specifies whether this authentication profile is enabled. The default value is yes.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

idle-timeout

Specifies the idle timeout for the authentication profile. The default value is 300 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rule Specifies the name of the rule that corresponds to the authentication method you want to use.

ltm auth radius-server

NAME

radius-server - Configures a RADIUS server for implementing remote RADIUS-based client authentication.

MODULE

ltm auth

SYNTAX

Configure the radius-server component within the ltm auth module using the syntax shown in the following sections.

CREATE/MODIFY

create radius-server [name]

modify radius-server [name]

options:

description [string]

port [[name] | [number]]

secret [none | ["string"]]

server [[hostname] | [ip address] | none]

timeout [integer]

edit radius-server [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list radius-server

list radius-server [[[name] | [glob] | [regex]] ...]

show running-config radius-server

show running-config radius-server [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete radius-server [name]

DESCRIPTION

You use a RADIUS authentication module when your authentication data is stored on a remote RADIUS server. In this case, client credentials are based on basic HTTP authentication (that is, user name and password).

To configure a RADIUS authentication module and create a RADIUS server:

1. Use the radius-server component in the ltm auth module to configure a RADIUS server.
2. Use the radius component in the ltm auth module to create a RADIUS configuration object that references the RADIUS server you created in Step 1.
3. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:
 - a. For the configuration option, specify the radius component that you created in Step 2.
 - b. For the defaults-from option, specify a parent profile (either the default RADIUS profile named radius or another custom profile that you created).

EXAMPLES

create radius-server bigip_auth_radius_server secret "This is the secret." server 10.1.1.1

Creates a RADIUS server named my_radius_server.

delete radius-server my_radius_server

Deletes the RADIUS server named my_radius_server.

OPTIONS

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition in which the component resides.

port Specifies the port for RADIUS authentication traffic. The default value is 1812.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret
Specifies the secret key the system uses to encrypt and decrypt packets sent or received from the server. This option is required.

server
Specifies the host name or IP address of the RADIUS server. This option is required.

timeout
Specifies the timeout value. The default value is 3 seconds.

SEE ALSO

create, delete, edit, glob, list, ltm auth profile, ltm auth radius, ltm virtual, modify, regex, show, tmsh

DELETE

delete radius [name]

DESCRIPTION

You use a RADIUS authentication module when your authentication data is stored on a remote RADIUS server. In this case, client credentials are based on basic HTTP authentication (that is, username and password).

To implement a RADIUS authentication module and create a RADIUS configuration object:

1. Use the radius-server component in the ltm auth module to configure a RADIUS server.
2. Use the radius component in the ltm auth module to create a RADIUS configuration object that references the RADIUS server you created in Step 1.
3. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:
 - a. For the configuration option, specify the RADIUS configuration object that you created in Step 2.
 - b. For the defaults-from option, specify a parent profile (either the default RADIUS profile named radius or another custom profile that you created).

EXAMPLES

```
create radius my_radius_auth servers add { myradiusserver }
```

Creates a RADIUS configuration object named my_radius_auth.

```
delete radius my_radius_auth
```

Deletes the RADIUS configuration object named my_radius_auth.

OPTIONS

accounting-bug

Enables or disables validation of the accounting response vector. This option is necessary only on older servers. The default value is disabled.

client-id

Sends a NAS-Identifier RADIUS attribute with string bar. If you do not specify a value for the client-id option, the system uses the pluggable authentication module (PAM) service type. You can disable this feature by specifying a blank client ID.

debug

Enables or disables syslog-ng debugging information at LOG DEBUG level. F5 Networks does not recommend this option for normal use. The default value is disabled.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

retries

Specifies the number of authentication retries that the Local Traffic Manager allows before authentication fails. The default value is 3.

service-type

Specifies the type of service used for the RADIUS server. The default is default, which behaves as authenticate-only.

servers

Specifies the hostnames or IP addresses of the RADIUS servers that the BIG-IP Local Traffic Manager uses to obtain authentication data.

SEE ALSO

create, delete, edit, glob, list, ltm auth profile, ltm auth radius-server, ltm virtual, modify, regex, show, tmsh

  one-line
  partition
```

DELETE

```
delete ssl-cc-ldap [name]
```

DESCRIPTION

You can use the ssl-cc-ldap component to configure SSL client certificate-based remote LDAP authorization for client traffic passing through the traffic management system.

To configure this type of authentication module and create a configuration object:

1. Use the ssl-cc-ldap component in the itm auth module to create an SSL client certificate LDAP configuration object.
2. Use the profile component in the itm auth module to create an authentication profile in which you specify the following options:

- a. For the configuration option, specify the configuration object that you created in Step 1.
- b. For the defaults-from option, specify a parent profile (either the default profile named `ssl_cc_ldap` or another custom profile that you created).

OPTIONS

`admin-dn`

Specifies the distinguished name of an account to which to bind to perform searches. This search account is a read-only account used to do searches. The admin account can also be used as the search account. If no admin DN is specified, then no bind is attempted.

This option is required only when an LDAP database does not allow anonymous searches. The default value is none.

`admin-password`

Specifies the password for the admin account. See `admin-dn` above. The default value is none.

`cache-size`

Specifies the maximum size, in bytes, allowed for the SSL session cache. Setting this option to 0 (zero) disallows SSL session caching. The default value is 20000 bytes (20KB).

`cache-timeout`

Specifies the number of usable lifetime seconds of negotiable SSL session IDs. When this time expires, a client must negotiate a new session. The default value is 300 seconds.

`certmap-base`

Specifies the search base for the subtree used by the certmap search method. A typical search base is: `ou=people,dc=company,dc=com`. The default value is none.

`certmap-key`

Specifies the name of the certificate map that the certmap search method uses. This name is found in the LDAP database. The default value is none.

`certmap-user-serial`

Specifies whether the system uses the client certificate's subject or serial number (in conjunction with the certificate's issuer) when trying to match an entry in the certificate map subtree.

A value of yes uses the serial number. A value of no uses the subject. The default value is no.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`group-base`

Specifies the search base for the subtree used by group searches. Use this option only when specifying the `valid-groups` option. The typical search base is similar to: `ou=groups,dc=company,dc=com`. The default value is none.

`group-key`

Specifies the name of the attribute in the LDAP database that specifies the group name in the group subtree. An example of a typical key is `cn` (common name for the group). The default value is none.

`group-member-key`

Specifies the name of the attribute in the LDAP database that specifies members (DNs) of a group. A typical key is `member`. The default value is none.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`role-key`

Specifies the name of the attribute in the LDAP database that specifies a user's authorization roles. Use this option only when specifying the `valid-roles` option. A typical role key is `authorizationRole`. The default value is none.

`search`

Specifies the type of LDAP search that is performed based on the client's certificate. Possible values are:

`cert` Searches for the exact certificate.

`certmap`

Searches for a user by matching the certificate issuer and the certificate serial number or certificate.

`user` Searches for a user based on the common name found in the certificate. This is the default value.

`secure`

Specifies whether the system attempts to use secure LDAP (LDAP over SSL). The alternative to using secure

LDAP is to use insecure (clear text) LDAP. Secure LDAP is a consideration when the connection between the BIG-IP system and the LDAP server cannot be trusted. The default value is no.

servers

Specifies a list of LDAP servers you want to search. You must specify a server when you create an SSL client certificate configuration object.

user-base

Specifies the search base for the subtree used when you select for the search option either of the values user or cert. A typical search base is: ou=people,dc=company,dc=com. You must specify a user base when you create an SSL client certificate configuration object. The default value is none.

user-class

Specifies the object class in the LDAP database to which the user must belong to be authenticated. The default value is none.

user-key

Specifies the key that denotes a user ID in the LDAP database (for example, the common key for the user option is uid). You must specify a user key when you create an SSL client certificate configuration object.

valid-groups

Specifies a space-delimited list of the names of groups to which the client must belong in order to be authorized (matches against the group key in the group subtree). The client needs to be a member of only one of the groups in the list. The default value is none.

valid-roles

Specifies a space-delimited list of the valid roles that clients must have to be authorized. The default value is none.

ltm auth ssl-crl dp

NAME

ssl-crl dp - Configures a Secure Socket Layer (SSL) Certificate Revocation List Distribution Point (CRLDP) configuration object for implementing SSL CRLDP to manage certificate revocation.

MODULE

ltm auth

SYNTAX

Configure the ssl-crl dp component within the ltm auth module using the syntax shown in the following sections.

CREATE/MODIFY

create ssl-crl dp [name]

modify ssl-crl dp [name]

options:

cache-timeout [integer]

connection-timeout [integer]

description [string]

servers

[add | delete | replace-all-with] {
[ip address ...]
}

servers [default | none]

update-interval [integer]

use-issuer [disabled | enabled]

edit ssl-crl dp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list ssl-crl dp

list ssl-crl dp [[[name] | [glob] | [regex]] ...]

show running-config ssl-crl dp

show running-config ssl-crl dp

[[name] | [glob] | [regex]] ...]

options:

- all-properties
- non-default-properties
- one-line
- partition

DELETE

delete ssl-crl dp [name]

DESCRIPTION

CRLDP authentication is a mechanism for checking certificate revocation status for client connections passing through the system. This module is useful when your authentication data is stored on a remote CRLDP server.

To implement a CRLDP authentication module and create an SSL CRLDP configuration object:

1. Use the crldp-server component, in the ltm auth module, to create a CRLDP server.
2. Use the ssl-crl dp component in the ltm auth module to configure a CRLDP configuration object that references the server you created in Step 1.
3. Use the profile component in the ltm auth module to create an authentication profile in which you specify the following options:
 - a. For the configuration option, specify the SSL CRLDP configuration object that you created in Step 2.
 - b. For the defaults-from option, specify a parent profile (either the default profile named ssl_crl dp or another custom profile that you created).

EXAMPLES

create ssl-crl dp my_auth_ssl-crl dp

Creates an SSL CRLDP configuration object named my_auth_ssl-crl dp.

delete ssl-crl dp my_auth_ssl-crl dp

Deletes the SSL CRLDP configuration object named my_auth_ssl-crl dp.

OPTIONS

cache-timeout

Specifies the number of seconds that CRLs are cached. The default value is 86400 (24 hours).

connection-timeout

Specifies the number of seconds before the connection times out. The default value is 15.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

servers

Specifies a host name or IP address for the secure CRLDP server. This option is required. The default value is none.

update-interval

Specifies an update interval for CRL distribution points that ensures that CRL status is checked at regular intervals, regardless of the CRL timeout value. This helps to prevent CRL information from becoming outdated before the BIG-IP system checks the status of a certificate. The default value is 0 (zero), which indicates an internal default value is active.

use-issuer

Specifies whether the system extracts the CRL distribution point from the client certificate. The default value is disabled.

SEE ALSO

Itm auth ssl-ocsp

NAME

ssl-ocsp - Configures OCSP authentication for client traffic passing through the traffic management system.

MODULE

Itm auth

SYNTAX

Configure the ssl-ocsp component within the Itm auth module using the syntax shown in the following sections.

CREATE/MODIFY

```
create ssl-ocsp [name]
modify ssl-ocsp [name]
options:
  description [string]
  responders
    [add | delete | replace-all-with] {
[name]...
}
  responders [default | none]
```

```
edit ssl-ocsp [ [ [name] | [glob] | [regex] ] ... ]
```

options:

all-properties
non-default-properties

DISPLAY

```
list ssl-ocsp
list ssl-ocsp [ [ [name] | [glob] | [regex] ] ... ]
show running-config ssl-ocsp
show running-config ssl-ocsp
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete ssl-ocsp [name]
```

DESCRIPTION

Online Certificate Status Protocol (OCSP) is an industry-standard protocol that offers an alternative to a certificate revocation list when using public-key technology. To implement an SSL OCSP authentication module, you must create the following objects: one or more OCSP responder objects, an SSL OCSP configuration object, and an SSL OCSP profile.

To implement an SSL OCSP authentication module and create an SSL OCSP configuration object:

1. Use the ocspp-responder component in the Itm auth module to configure an OCSP responder object.
2. Use the ssl-ocsp component in the Itm auth module to configure an SSL OCSP configuration object to which you add the OCSP responder object that you created in Step 1.
3. Use the profile component in the Itm auth module to create an authentication profile in which you specify the following options:
 - a. For the configuration option, specify the SSL OCSP configuration object that you created in Step 2.
 - b. For the defaults-from option, specify a parent profile (either the default OCSP Responder profile named ssl_ocsp or another custom profile that you created).

EXAMPLES

```
create ssl-ocsp my_auth_ssl-ocsp
```

Creates an SSL OCSP configuration object named my_auth_ssl-ocsp.

```
delete ssl-ocsp my_auth_ssl-ocsp
```

Deletes the SSL OCSP configuration object named my_auth_ssl-ocsp.

OPTIONS

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

responders

Specifies a list of OSCP responders that you configured using the ocsf-responder component in the ltm auth module.

SEE ALSO

ltm auth tacacs

NAME

tacacs - Configures a TACACS+ configuration component for implementing remote TACACS+-based client authentication.

MODULE

ltm auth

SYNTAX

Configure the tacacs component within the ltm auth module using the syntax shown in the following sections.

CREATE/MODIFY

create tacacs [name]

modify tacacs [name]

options:

accounting [send-to-all-servers | send-to-first-server]

authentication [use-all-servers | use-first-server]

debug [disabled | enabled]

description [string]

encryption [disabled | enabled]

protocol [none | [protocol]]

secret ["[string]"]

servers

[add | delete | replace-all-with] {

[[[hostname[:port]] | [ip address[:port]]] ...]

}

service [[name] | none]

edit tacacs [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list tacacs

list tacacs [[[name] | [glob] | [regex]] ...]

show running-config tacacs

show running-config tacacs [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete tacacs [name]

DESCRIPTION

Using a TACACS+ configuration object and profile, you can implement the TACACS+ authentication module as the mechanism for authenticating client connections passing through the BIG-IP Local Traffic Manager system. You use this module when your authentication data is stored on a remote TACACS+ server. In this case, client credentials are based on basic HTTP authentication (that is, user name and password).

To implement a TACACS+ authentication module and create a TACACS configuration object:

1. Use the tacacs component in the ltm auth module to configure a TACACS+ configuration object.
2. Use the profile component in the ltm auth module to create an authentication profile in which you specify

the following options:

- a. For the configuration option, specify the TACACS+ configuration object that you created in Step 1.
- b. For the defaults-from option, specify a parent profile (either the default TACACS+ profile named tacacs or another custom profile that you created).

EXAMPLES

```
create tacacs my_tacacs_auth secret "This is the secret" servers add {my_tacacs_server} encryption enabled
```

Enables encryption for TACACS+ packets.

```
create tacacs my_tacacs_auth secret "This is the secret" servers add { my_tacacs_server1 my_tacacs_server2 }  
accounting send-to-all-servers
```

Provides the ability to send accounting start and stop packets to all servers

OPTIONS

accounting

If multiple TACACS+ servers are defined and pluggable authentication module (PAM) session accounting is available, specifies where the system sends accounting start and stop packets. Possible values are:

send-to-all-servers

Sends to all servers.

send-to-first-server

Sends to the first available server.

authentication

Specifies when to use the secret key supplied for the secret option. This option is required. The options are:

use-all-servers

Use the secret key with all servers.

use-first-server

Use the secret key with the first available server.

debug

Enables syslog-ng debugging information at LOG DEBUG level. F5 Networks does not recommend this option for normal use. The default value is disabled.

description

User defined description.

encryption

Enables or disables encryption of TACACS+ packets. F5 Networks recommends this option for normal use. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

protocol

Specifies the protocol associated with the value specified in the service option, which is a subset of the associated service being used for client authorization or system accounting.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Sets the secret key used to encrypt and decrypt packets sent or received from the server. This option is required.

servers

Specifies the host name or IPv4 address of the TACACS+ server. For each server, a port may optionally be specified in the format hostname:port or IPv4:port. If no port is specified, the default port 49 is used. This option is required.

service

Specifies the name of the service that the user is requesting to be authenticated to use. Identifying the service enables the TACACS+ server to behave differently for different types of authentication requests. This option is required.

SEE ALSO

create, delete, edit, glob, list, ltm auth profile, ltm virtual, modify, regex, show, tmsh,

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

Itm cipher group

NAME

group - Configures a cipher group.

MODULE

itm cipher

SYNTAX

Configure the group component within the cipher module using the syntax shown in the following sections.

CREATE/MODIFY

```
create group [name]
modify group [name]
options:
  allow { add rule1 [ rule2... ] }
  description [string]
  exclude { add rule3 [ rule4... ] }
  require { add rule5 [ rule6... ] }
```

```
edit group [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list group
list group [ [ [name] | [glob] | [regex] ] ... ]

show group [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete group [all | [name]]
options:
  recursive
```

DESCRIPTION

You can use the group component to create, modify, or delete a custom cipher group, or display a custom cipher group.

Cipher groups are contain sets of cipher rules and are attached to client-ssl or server-ssl profiles.

EXAMPLES

```
create group my_group { allow add { f5-default } }
```

Creates a group named my_group with a single allowed rule, f5-default.

OPTIONS

allow
Specifies a list of rules that are allowed in this group.

description
User defined description.

exclude
Specifies a list of rules that are excluded from this group.

require
Specifies a list of rules that are required for this group. The operation is the intersection of allow and require after all excluded rules have been removed.

SEE ALSO

create, delete, edit, glob, list, Itm virtual, modify, mv, regex, reset-stats, show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

Itm cipher rule

NAME

rule - Configures a cipher rule.

MODULE

itm cipher

SYNTAX

Configure the rule component within the cipher module using the syntax shown in the following sections.

CREATE/MODIFY

create rule [name]

modify rule [name]

options:

 cipher [string]

 description [string]

 dh-groups [string]

 signature-algorithms [string]

edit rule [[[name] | [glob] | [regex]] ...]

options:

 all-properties

 non-default-properties

DISPLAY

list rule

list rule [[[name] | [glob] | [regex]] ...]

show rule [[[name] | [glob] | [regex]] ...]

DELETE

delete rule [all | [name]]

options:

 recursive

DESCRIPTION

You can use the rule component to create, modify, or delete a custom cipher rule, or display a custom cipher rule.

Cipher rules are gathered into cipher groups and attached to client-ssl or server-ssl profiles.

EXAMPLES

create rule my_rule cipher "default"

Creates a rule named my_rule with a cipher string "default".

OPTIONS

 cipher rule

Specifies the OpenSSL compatible cipher string.

 description

User defined description.

 dh-groups groups

Specifies the allowed named groups, separated by ":". For example: "P256:X25519"

The available named groups are: P256, P384, X25519 A special keyword, DEFAULT, represents the recommended set of named groups.

 signature-algorithms signature algorithms

Specifies the allowed signatures algorithms, separated by ":". For example:

"RSA_PKCS1_SHA256:ECDSA_P256_SHA256"

The available signature algorithms are: DSA-SHA1, DSA-SHA256, DSA-SHA384, DSA-SHA512, ECDSA-SHA1, ECDSA-SHA256, ECDSA-SHA384, ECDSA-SHA512, RSA-PKCS1-SHA1, RSA-PKCS1-SHA256, RSA-PKCS1-SHA384, RSA-PKCS1-SHA512, RSA-PSS-SHA256, RSA-PSS-SHA384, RSA-PSS-SHA512

A special keyword, DEFAULT, represents the recommended set of signature algorithms.

SEE ALSO

Itm classification application

NAME

application - Configures a custom classification application.

MODULE

Itm classification

SYNTAX

Configure the application within the Itm classification module using the syntax shown in the following sections.

CREATE/MODIFY

create application [name]

options:

app-service [[string] | none]

description [string]

application-id [integer]

category [name]

modify application [name]

options:

app-service [[string] | none]

description [string]

category [name]

edit application [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list application

list application [[all] | [name]]

show running-config application

show running-config application [[all] | [name]]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete application [name]

Note: All referring classification-filters (to this application) need to be deleted first; otherwise an error will be reported. Predefined applications cannot be deleted.

DESCRIPTION

You can use the application component to create, modify, delete, and display classification application.

EXAMPLES

create application my_app { application-id 8192 category my_cat }

Creates a new application named my_app.

modify application my_app { category Web description "My description." }

Modify an application named my_app.

list application

Displays all created applications.

delete application my_app

Deletes the application named my_app.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

application-id

Identifies the application. This is set during creation and cannot be changed. Identifiers must be unique

across predefined and user-defined applications. Predefined application-ids must be in numeric range [0, 8192), and user defined application-ids must be in numeric range [8192, 16384).

category

Refers to classification category. The referred category [name] should exist already; otherwise an error will be reported.

SEE ALSO

create, modify, delete, list, show, tmsh, ltm classification

COPYRIGHT

ltm classification auto-update settings

NAME

settings - Configures settings for classification hitless upgrade.

MODULE

ltm classification classification auto-update settings

SYNTAX

MODIFY

modify ltm classification auto-update settings

options:

auto-update-interval [daily|monthly|weekly]

enabled [yes|no]

DISPLAY

list ltm classification auto-update settings

DESCRIPTION

Use this command to display existing scheduler configuration.

EXAMPLES

modify ltm classification auto-update settings auto-update-interval daily enabled yes

Enable hitless upgrade with update frequency set to daily.

modify ltm classification auto-update settings enabled no

Disable hitless upgrade.

list ltm classification auto-update

List the configured settings for auto-update settings configuration.

OPTIONS

enabled Specifies that the updates scheduler is enabled or disabled.

auto-update-interval

Specifies the auto-update frequency for classification signatures. This attribute will only apply in case auto update is enabled. The default value is weekly.

SEE ALSO

list, modify, load, tmsh

COPYRIGHT

BIG-IP 2018-03-16 ltm classification auto-update settings(1)

ltm classification auto-update status

NAME

status - Display the status for classification hitless upgrade.

MODULE

ltm classification classification auto-update status

SYNTAX

DISPLAY

list ltm classification auto-update status

options:

last-updated-time

message

progress-status

DESCRIPTION

Use this command to display current hitless upgrade status.

EXAMPLES

list ltm classification auto-update status

Display the status information for hitless upgrade.

OPTIONS

last-updated-time

Indicates the date and time of the last hitless upgrade attempt was made.

message

Indicates the success or error message after we attempt hitless upgrade.

progress-status

Indicates the progress status during hitless upgrade process.

SEE ALSO

list, ltm, tmsh

ltm classification category

NAME

category - Configures a custom classification category.

MODULE

ltm classification

SYNTAX

Configure the category within the ltm classification module using the syntax shown in the following sections.

CREATE/MODIFY

create category [name]

options:

app-service [[string] | none]

description [string]

modify category [name]

options:

app-service [[string] | none]

description [string]

edit category [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list category

list category [[all] | [name]]

show running-config category

show running-config category [[all] | [name]]

options:

all-properties

non-default-properties

one-line
partition

DELETE
delete category [name]

Note: All referring applications/classification-filters (to this category) need to be deleted first; otherwise an error will be reported. Predefined categories cannot be deleted.

DESCRIPTION
You can use the category component to create, modify, delete, and display classification category.

EXAMPLES
create category my_cat

Creates a new category named my_cat.

modify category my_cat { description "My description." }

Modify a category named my_cat.

list category

Displays all created categories.

delete category my_cat

Deletes the category named my_cat.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

Itm classification ce

NAME
CE - Classification Engine configuration.

MODULE
ltm classification

SYNTAX
Configure the Classification Engine settings (AKA preset) within the ltm classification module using the syntax shown in the following sections.

CREATE/MODIFY
create ce [name]
modify ce [name]
options:
app-service [[string] | none]
allow-reclassification [on | off]
analyze-dns [on | off]
analyze-ssl-serverside [on | off]
flow-bundling [on | off]
cache-results [on | off]
policies [add | delete | default | replace-all-with | none]

DISPLAY
list ce [name]
show running-config ce [name]
options:
all-properties

non-default-properties
one-line

DELETE
delete ce [name]

DESCRIPTION
Use this command to create, modify, display, or delete an Classification Engine configuration.

EXAMPLES
create ce my_ce { allow-reclassification on flow-bundling on cache-results off }

Creates a new Classification Engine configuration named my_ce.

modify ce my_ce { cache-results on allow-reclassification off }

Turn Cache Results on and turn flow reclassification off on my_ce preset

list ce

Displays all Classification Engines configurations.

delete ce my_ce

Deletes the Classification Engine configuration named my_ce.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

allow-reclassification
Specifies that connection ("flow") allowed to be reclassified, i.e. classification result could be changed.

analyze-dns
Allows classification engine to perform extended analysis of DNS traffic providing extended classification result.

analyze-ssl-serverside
Enables classification engine to process SSL Server Side Hello to inspect ALPN (mostly for HTTP2 / SPDY subclassification).

flow-bundling
Enables / disables flow correlation mechanism (e.g. FTP and FTP-data protocols).

cache-results
Enables / Disables classification result caching.

policies
Specifies a LTM policy that you have configured previously, if you want to configure custom signatures.

SEE ALSO
create, modify, delete, list, show, tmsh, ltm profile classification, ltm policy

Itm classification signature-definition

NAME
signature-definition - Configure status for classification signature updates.

MODULE
itm classification

SYNTAX
Configure the signature-definition component within the ltm classification module using the syntax in the following sections.

DISPLAY
list signature-definition
list signature-definition [[name] | [glob] | [regex]]
options:
all-properties
non-default-properties
one-line
recursive
last-attempt-automatic-mode [enabled | disabled]
last-attempt-datetime [date]
last-attempt-user [string]
last-update-automatic-mode [enabled | disabled]
last-update-datetime [date]
last-update-user [string]
message [string]
progress-status [none | success | failure | in-progress]

DESCRIPTION
You can use the signature-definition component to configure the status for classification signature updates.

EXAMPLES
list signature-definition

Displays classification signature update status configuration.

OPTIONS
last-attempt-automatic-mode
Indicates whether the last attempt to update the signature file was done manually or automatically by the system.

last-attempt-datetime
Indicates the date and time of the last attempt to update the signature file.

last-attempt-user
Indicates the user who is the last one to attempt to update the signature file.

last-update-automatic-mode
Indicates whether the last successful signature file update was done manually or automatically by the system. The value of the last-update-automatic-mode may be different from the value of the last-attempt-automatic-mode if the last update attempt fails.

last-update-datetime
Indicates the date and time of the last successful signature file update. The value of the last-update-datetime is different from the value of the last-attempt-datetime if the last update attempt fails.

last-update-user
Indicates the user who did the last successful signature file update. The value of the last-update-user may be different from the value of the last-attempt-user if the last update attempt fails.

message
Indicates the error message when it fails to attempt to update the signature file.

progress-status
Indicates the progress status when attempting to update the signature file. The options are none, success, failure, and in-progress.

SEE ALSO
list, tmsb

Itm classification signature-update-schedule

NAME
signature-update-schedule - Configure schedule for classification signature updates.

MODULE
Itm classification

SYNTAX
Configure the signature-update-schedule component within the Itm classification module using the syntax in the

following sections.

Updated Command

There has been a new implementation for this command. Please consider using the following command instead, `ltm classification auto-update`

MODIFY

```
modify signature-update-schedule [name]
options:
  [auto-update-enabled | auto-update-disabled]
  auto-update-interval [daily | weekly | monthly]
```

```
edit signature-update-schedule [name]
```

```
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list signature-update-schedule
list signature-update-schedule [ [name] | [glob] | [regex] ]
options:
  all-properties
  non-default-properties
  one-line
  recursive
```

DESCRIPTION

You can use the `signature-update-schedule` component to configure schedule for classification signature updates.

EXAMPLES

```
list signature-update-schedule
```

Displays classification signature update schedule configuration.

```
modify signature-update-schedule auto-update-enabled auto-update-interval daily
```

Updates the scheduler for classification signature updates to run once a day.

```
modify signature-update-schedule auto-update-disabled
```

Disables the scheduler and allows signatures to update via the browser-based Configuration utility only.

OPTIONS

`app-service`

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`auto-update-disabled`

Specifies that the updates scheduler is disabled. The user can update the classification signatures using the browser-based BIG-IP Configuration utility.

`auto-update-enabled`

Specifies that the updates scheduler is enabled.

`auto-update-interval`

Specifies the auto-update frequency for classification signatures. This attribute will only apply in case auto update is enabled. The default value is weekly.

ltm classification signature-version

NAME

`signature-version` - Display classification signature version.

MODULE

`ltm classification`

SYNTAX

Display the signature-version component within the ltm classification module using the syntax in the following sections.

DISPLAY

list signature-version

options:

all-properties

non-default-properties

one-line

recursive

DESCRIPTION

You can use the signature-version component to display versions in classification signature updates.

EXAMPLES

list signature-version

Displays classification signature version configuration.

OPTIONS

cec-filename

Indicates the cec library filename in the last updated classification signature.

cec-version

Indicates the cec library version in the last updated classification signature.

classification-version

Indicates the classification version in the last updated classification signature.

conf-filename

Indicates the configuration filename in the last updated classification signature.

conf-version

Indicates the configuration version in the last updated classification signature.

im-version

Indicates the im version in the last updated classification signature.

qm-protocols-filename

Indicates the qosmos protocols filename in the last updated classification signature.

qm-protocols-version

Indicates the qosmos protocols version in the last updated classification signature.

update-time

Indicates the update time in the last updated classification signature.

SEE ALSO

list, tmsh

BIG-IP 2013-11-06 ltm classification signature-version(1)

ltm classification signatures

NAME

signatures - Manages classification engine signatures.

MODULE

ltm classification

SYNTAX

load signatures file [filename]

Loads classification signatures from a signature update file.

load signatures default

Resets classification engine and signatures to the factory defaults.

DESCRIPTION

You can use the signatures component to load the classification signatures from a file. Only admins can run this command.

You can obtain the latest signature update file (*.im) (if one is available) from <http://downloads.f5.com>.

For the filename, if no absolute path is specified, the default path /var/libdata/dpi/im/ is used.

Use load signatures default to discard and remove any installed upgrades and reset the classification engine and signatures to factory defaults. No user-created signatures will be deleted. By keeping the *.im file, you will be able to re-apply the update any time later using the load signatures file command.

EXAMPLES

```
load signatures file my_sig_file.im
```

Loads signatures from file "my_sig_file.im" under the folder: /var/libdata/dpi/im/.

```
load signatures file /var/tmp/new_sig_file.im
```

Loads signatures from file "new_sig_file.im" under the folder: /var/tmp/.

ltm classification stats application

NAME

application - Displays and resets classified application statistics.

MODULE

ltm classification stats

SYNTAX

Display statistics for the application component within the ltm classification stats module using the syntax in the following section.

DISPLAY

```
show application
```

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the application component to display classification application statistics. The statistics details are described below:

Name Specifies the number of the classified application.

Count

Specifies a number of classified flows or transactions (in transaction mode) to specific application.

LTM Policy

Specifies the number of classification decisions by LTM Policy (cpm).

Classification Engine

Specifies the number of classification decisions by classification engine (CEC).

Qosmos iXengine

Specifies the number of classification decisions by Qosmos iXengine (ixe).

Cache

Specifies the number of classification decisions by Results Cache.

URI Parameter

Specifies the number of classification decisions by evaluating HTTP URI query string classification parameter.

HTTP Header

Specifies the number of classification decisions by using HTTP classification header.

iRule

Specifies the number of classification decisions by iRule.

Bytes in
Specifies the bytes in of the classified application.

Bytes out
Specifies the bytes out of the classified application.

Packets in
Specifies the packets in of the classified application.

Packets out
Specifies the packets out of the classified application.

You can reset the classification application statistics using reset-stats command.

EXAMPLES

show application

Displays the classified application statistics.

reset-stats application

Resets the classified application statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

reset-stats, show, tmsh

COPYRIGHT

BIG-IP 2016-03-14 Itm classification stats application(1)

Itm classification stats url-category

NAME

url-category - Displays and resets classified url-category statistics.

MODULE

Itm classification stats

SYNTAX

Display statistics for the url-category component within the Itm classification stats module using the syntax in the following section.

DISPLAY

show url-category
option:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the url-category component to display classification url-category statistics. The statistics details are described below:

Name Specifies the number of the classified url-category.

Count
Specifies a number of classified flows or transactions (in transaction mode) to specific url-category.

iRule
Specifies the number of url-categorization decision by iRule.

Customdb
Specifies the number of url-categorization decision by custom url database.

wrdb Specifies the number of url-categorization decision by webroot database.

Bytes in
Specifies the bytes in of the classified url-category.

Bytes out
Specifies the bytes out of the classified url-category.

Packets in
Specifies the packets in of the classified url-category.

Packets out
Specifies the packets out of the classified url-category.

You can reset the classification url-category statistics using reset-stats command.

EXAMPLES

show url-category

Displays the classified url-category statistics.

reset-stats url-category

Resets the classified url-category statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

reset-stats, show, tmsh

COPYRIGHT

BIG-IP 2016-03-14 ltm classification stats url-category(1)

Itm classification stats urlcat-cloud

NAME

urlcat-cloud - Displays and resets URL category cloud lookup statistics.

MODULE

ltm classification stats

SYNTAX

Display statistics for the url category lookup within the ltm classification stats module using the syntax in the following section.

DISPLAY

show urlcat-cloud

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the urlcat-cloud component to display URL category cloud lookup statistics. The statistics details are described below:

Lookups

Specifies the number of URL look-up happened in cloud cache.

Cloud Query

Specifies the number of queries sent to the cloud. This happens if the entry is not present in cloud cache.

Cloud Response

Specifies the number of responses received from the cloud lookup. Each TMM gets a response. Hence the total is multiplied by TMM count.

Unknown

Specifies the number of unknown responses from the cloud. This means the webroot cloud does not know about the queried URL.

Entries

Specifies the number of entries present in the cloud cache. Each TMM has a copy of the cache. This number is cumulative and reset-stats does not reset this number.

Add Specifies the number of entries added to the cloud cache. If the cache is not cleared "adds" and "entries" must be the same.

Delete

Specifies the number of entries cleared from the cloud cache.

Queue Full

Specifies the number of instances that tmm could not send out a URL query.

You can reset the URL category cloud lookup statistics using reset-stats command. Reset-stats does not reset the number of entries in the cache.

EXAMPLES

show urlcat-cloud

Displays the URL category cloud lookup statistics.

reset-stats urlcat-cloud

Resets the URL category cloud lookup statistics, except the number of entries in the cache.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

reset-stats, show, tmsh

Itm classification update-signatures

NAME

update-signatures - Run automatic update for classification signatures.

MODULE

Itm classification

SYNTAX

Run the update-signatures component within the Itm classification module using the syntax in the following sections:

Updated Command

There has been a new implementation for this command. Please consider using the following command instead, run Itm classification updates

RUN

run update-signatures

DESCRIPTION

You can use the update-signatures component to update the classification signatures from F5 download server. Only admins can run this command.

SEE ALSO

Itm classification signature-update-schedule, run, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2018-02-06 Itm classification update-signatures(1)

Itm classification updates

NAME

updates - Configures classification updates.

MODULE

Itm classification updates

SYNTAX

INSTALL
install ltm classification updates
options:
file [string]

LOAD
load ltm classification updates
options:
[string]

RUN
run ltm classification updates

DISPLAY
show ltm classification updates

DESCRIPTION

Use this command to install and see all available IM packages.

EXAMPLES

install ltm classification updates file file_name

Install new update from file "file_name".

load ltm classification updates file_name

Load new update from file "file_name".

run ltm classification updates

Downloads new classification update from staging or production download server.

show ltm classification updates

Show all available updates.

OPTIONS

file Specifies IM package file.

SEE ALSO

show, install, load, run, ltm, tmsh

COPYRIGHT

ltm classification url-cat-policy

NAME

url-cat-policy - Configures an ltm classification url-cat policy. It's comprised of list of urldb feed lists. This is deprecated since version 13.0.0. Instead of creating url-cat-policy and attaching a feedlist to it, enable the feedlist directly.

MODULE

ltm classification

SYNTAX

Configure the url-cat-policy component within the ltm classification module using the syntax in the following sections.

CREATE/MODIFY
create url-cat-policy [name]
modify url-cat-policy [name]
options:
app-service [name]
description [string]
feed-lists [add | delete] { [name] }

edit url-cat-policy
options:
all-properties
non-default-properties

DISPLAY
list url-cat-policy [[[name]]
show running-config url-cat-policy
show running-config url-cat-policy [[[name]]
options:
all-properties
non-default-properties
one-line
partition
recursive

DISPLAY
delete url-cat-policy [name]

DESCRIPTION
You can use the url-cat-policy component to configure a shareable and reusable url categorization database feed coming from local files or download feeds. The url-cat-policy can then be enforced on the configuration object of the type: ltm virtual.

EXAMPLES
create ltm classification url-cat-policy POL1
feed-lists add { FL1 }
description none }

Creates a url-cat-policy POL1 with urldb feeds from FL1 feed lists.

list url-cat-policy

Displays the current list of url-categorization policies contents.

OPTIONS
app-service
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description
User defined description.

partition
Displays the administrative partition within which the component resides.

feed-lists
Adds, deletes, or replaces a feed list. Specifies a list of feed lists (see ltm classification urldb-feed-list) against which the packet will be compared.

SEE ALSO
create, edit, list, modify, ltm classification urldb-feed-list, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008, 2012-2015. All rights reserved.

BIG-IP 2016-10-28 ltm classification url-cat-policy(1)

ltm classification url-category

NAME
url-category - Configures a custom URL category.

MODULE
ltm classification

SYNTAX
Configure the url-category within the ltm classification module using the syntax shown in the following sections.

CREATE/MODIFY
create url-category [name]
options:
app-service [[string] | none]
description [string]
url-category-id [integer]
irule-event [enabled | disabled]

modify url-category [name]

options:
app-service [[string] | none]
description [string]
irule-event [enabled | disabled]

edit url-category [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list url-category
list url-category [[all] | [name]]
show running-config url-category
show running-config url-category [[all] | [name]]
options:
all-properties
non-default-properties
one-line
partition

DELETE
delete url-category [name]

Note: All referring url-categorization-filters (to this url-category) need to be deleted first; otherwise an error will be reported. Predefined url-categories cannot be deleted.

DESCRIPTION

You can use the url-category component to create, modify, delete, and display classification url-category.

EXAMPLES

create url-category my_urlcat { url-category-id 28672 irule-event disabled }

Creates a new url-category named my_urlcat.

modify url-category my_urlcat { irule-event enabled description "My description." }

Modify a url-category named my_urlcat.

list url-category

Displays all created categories.

delete url-category my_urlcat

Deletes the url-category named my_urlcat.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

url-category-id

Identifies the url-category. This is set during creation and cannot be changed. Identifiers must be unique across predefined and user-defined categories. Predefined url-category-ids must be in numeric range [24576, 28671), and user defined url-category-ids must be in numeric range [28672-32768).

irule-event

Indicates if the irule is enabled or disabled in result of the classification engine.

SEE ALSO

create, modify, delete, list, show, tmsh, ltm classification, pem policy

COPYRIGHT

BIG-IP 2013-11-12 ltm classification url-category(1)

ltm classification urlldb-feed-list

NAME

urldb-feed-list - Configures a feed-list to be used for URLDB file loads. A urldb-feed-list is a list of URL feeds (including local file paths) from where URLDB files are downloaded. These files contain URL categorization information.

MODULE

ltm classification

SYNTAX

Configure the urldb-feed-list component within the ltm classification module using the syntax in the following sections.

CREATE/MODIFY

```
create urldb-feed-list [name]
modify urldb-feed-list [[name] | all]
options:
  default-url-category [name]
  url [string]
  poll-interval [integer]
  user [string]
  password [string]
  app-service [name]
  description [string]
```

```
load urldb-feed-list [[name] | all]
```

DISPLAY

```
list urldb-feed-list [[name] | all | [property]]
show running-config urldb-feed-list [[name] | all | [property]]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

DELETE

```
delete urldb-feed-list [[name] | all]
```

DESCRIPTION

You can use the urldb-feed-list component to define reusable lists of feeds. You can use a feed list in an ltm classification url-cat-policy.

EXAMPLES

```
create urldb-feed-list FL1 { url file:///shared/images/custom_urldb_1.txt }
```

Creates a new feed list, "FL1" with URL category information in the file specified by url.

OPTIONS

create
Creates a new feed list.

delete
Deletes the feed list that you specify next, in curly braces ({}).

file
DEPRECATED since version 11.7.0. Specifies the file object containing the URLDB information.

url Specifies the url to fetch the file containing the URLDB information.

default-url-category
The URL category to be used for all the URLs specified in the URLDB file.

poll-interval
Specifies the time interval in hours at which the url needs to be polled.

app-service
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description
User defined description for this feed list.

partition
Displays the administrative partition within which the component resides.

SEE ALSO

edit, list, modify, ltm classification, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

Itm classification urldb-file

NAME

urldb-file - Manages a custom URLDB file

MODULE

Itm classification

SYNTAX

List the urldb-file component within the Itm classification module using the syntax in the following sections.

CREATE

create urldb-file [name]

options:

source-path [string]

app-service [name]

DEPRECATED: create command is deprecated from version 12.0.0. Though this command is visible, this is not meant to be used by the users. The daemons use it internally.

DISPLAY

list urldb-file [[name] | all | [property]]

show running-config urldb-file [[name] | all | [property]]

options:

all-properties

one-line

partition

DELETE

delete urldb-file [[name] | all]

DEPRECATED: delete command is deprecated from version 12.0.0. Though this command is visible, this is not meant to be used by the users. The daemons use it internally.

DESCRIPTION

You can use the urldb-file component to create, the custom URLDB file in versions before 11.7.0. The urldb-file is created internally using the URI specified in Itm classification urldb-feed-list in later versions.

EXAMPLES

create urldb-file FILE1 { source-path file:/shared/images/custom_urldb_1.txt }

Creates a new urldb file object, "FILE1" from the source file /shared/images/custom_urldb_1.txt

Create works in versions before 11.7.0. Has been deprecated in later versions

list urldb-file [fileobj-name]

Lists the attributes of urldb file object, "FILE1" from the source file /shared/images/custom_urldb_1.txt

OPTIONS

create

Creates a new file object for custom urlcat db.

delete

Deletes the file object that you specify next, in curly braces ({}).

source-path

Specifies the location from where the URLDB file object sources the file.

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description for this feed list.

partition

Displays the administrative partition within which the component resides.

SEE ALSO

edit, list, Itm classification, tmsh

COPYRIGHT

ltm clientssl-proxy cached-certs

NAME

cached-certs - Displays and deletes SSL Forward Proxy cached certificates and OSCP responses on the BIG-IP(r) system.

MODULE

ltm clientssl-proxy

SYNTAX

Use the cached-certs component within the ltm.clientssl-proxy module to manage connections using the following syntax.

DISPLAY

show cached-certs

options:

virtual [name]

clientssl-profile [name]

DELETE

delete cached-certs

options:

virtual [name]

clientssl-profile [name]

DESCRIPTION

You can use the cached-certs component to display or delete SSL Forward Proxy cached certificates based on a specified clientssl profile.

OPTIONS

virtual

Specifies the name of the virtual server that you want to display or delete cached certificates from.

clientssl-profile

Specifies the name of the clientssl profile that belongs to the virtual selected.

SEE ALSO

delete, show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2012-2014. All rights reserved.

ltm clientssl ocsf-stapling-responses

NAME

ocsf-stapling-responses - Deletes the cached OSCP responses on the BIG-IP(r) system.

MODULE

ltm clientssl

SYNTAX

Use the ocsf-stapling-responses component within the ltm.clientssl module to manage connections using the following syntax.

DELETE

delete ocsf-stapling-responses

options:

virtual [name]

clientssl-profile [name]

DESCRIPTION

You can use the ocsf-stapling-responses component to delete the cached OSCP responses based on a specified clientssl profile.

OPTIONS

virtual

Specifies the name of the virtual server that you want to display or delete cached certificates from.

clientssl-profile

Specifies the name of the clientssl profile that belongs to the virtual selected.

SEE ALSO

delete, tmsh

ltm data-group external

NAME

external - Configures an external class.

MODULE

ltm data-group

SYNTAX

Configure the external data-group within the ltm data-group module using the syntax shown in the following sections.

CREATE/MODIFY

create external [name]

modify external [name]

options:

app-service [[string] | none]

description [string]

external-file-name [[file name] | none]

separator [string]

source-path [URL]

type [integer | ip | string]

edit external [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list external

list external [[[name] | [glob] | [regex]] ...]

show [name] external-records

show running-config external

show running-config external [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete external [name]

DESCRIPTION

Data groups are lists of data that you define and use with iRules(r) operators. External data group records are stored in external files that you manage through the sys file data-group component. Note that external data groups can be very large, which is one reason why the groups are saved to external files. For example, a phone company may store a list of thousands of phone numbers in an external data group.

You should consider using an internal data group when the number of records is expected to be small.

An external data group acquires its type from the associated data-group file, which can be a list of IP addresses, strings, or integers.

External data groups are lists that specify:

• A data-group file where records are stored

• A description of the class

There are two ways to configure the external data-group object:

• Create external data-group object, and then specify the source-path and type of the external-file. In one step the external-file will be created within the sys file data-group module and external data-group within the ltm data-group module.

• Create an external-file within the sys file data-group module, and then create external data-group within the ltm data-group module. See help sys file data-group for information on creating the data-group file.

EXAMPLES

`create external ext-dg1 external-file-name string.dat description "created for rule xyz"`

Creates an external data group named ext-dg1, with the given description. The records for the data group are loaded from the data-group file string.dat previously created in the sys file data-group component.

`create external ext-dg1 description "created for rule xyz" source-path http://file-server/data-groups/ip.class type ip`

Downloads the data-group file from the given URL into file-store and creates a data-group file named ext-dg1 within the sys file data-group module. Creates an external data group named ext-dg1, with the given description. The records for the data group are loaded from the data-group file ext-dg1.

`create external ext-dg2 source-path file:/shared/save/Test.dat type string`

Creates a data-group file named ext-dg2 within the sys file data-group module. Creates an external data group named ext-dg2. The records for the data group are loaded from the data-group file ext-dg2.

`modify external ext-dg2 description "created for rule abc" source-path file:/shared/save/Test2.dat`

Downloads the file from the given URL into file-store and updates the source-path of data-group file referenced by external data group ext-dg2. Modifies the description of external data group ext-dg2.

`delete external ext-dg1`

Deletes the external data group named ext-dg1. Note: the data-group file referenced by ext-dg1 is not deleted at this time. If needed, it should be deleted under sys file data-group component.

`show external ext-dg1 external-records` Shows a sorted list of external data group records. Note: We recommend against displaying data-groups of over two million records due to control-plane resource constraints.

OPTIONS

`app-service`

Specifies the name of the application service to which the data group belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the data group. Only the application service can modify or delete the data group.

`description`

User defined description.

`external-file-name`

Specifies the data-group file where the records are stored.

Note: Only source-path or external-file-name may be specified for external data-group configuration item.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

`separator`

Specifies a separator to use when defining the data group. The default value is :.=.

`source-path [URL]`

This optional attribute takes a URL.

Note: Only source-path or external-file-name may be specified for external data-group configuration item, for example:

`source-path http://file-server/data-groups/AUL_1.cls`

`source-path https://file-server/data-groups/CNN.x`

`source-path ftp://username:password@server/data-groups/latest.class`

`source-path file:/shared/save/Test.dat`

`type` Specifies the kind of data in the group. This option is acquired from the data group file. If the external data group is created with external-file that was previously created within the sys file data-group module, then type option cannot be modified. If the external data group is created with source-path option, then type should be specified. The value for type could be integer or ip or string.

ltm data-group internal

NAME

internal - Configures an internal class.

MODULE

ltm data-group

SYNTAX

Configure the internal data-group within the ltm data-group module using the syntax shown in the following sections.

CREATE/MODIFY

```
create internal [name]
options:
  app-service [[string] | none]
  description [string]
  records [add | delete | modify | replace-all-with] {
    [record key] {
      data [value]
    }
  }
  records none
  type [integer | ip | [string] ]
```

```
modify internal [name]
options:
  app-service [[string] | none]
  description [string]
  records [add | delete | modify | replace-all-with] {
    [record key] {
      data [value]
    }
  }
  records none
```

```
edit internal [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list internal
list internal [ [ [name] | [glob] | [regex] ] ... ]
show running-config internal
show running-config internal [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DESCRIPTION

Data groups are lists of data that you define and use with iRules(r) operators. Consider using an external data group if the number of records is expected to be large.

The BIG-IP(r) system includes a number of predefined lists that you can use. They are:

- aol
- default_accept_language
- images
- private_net

The above lists are located in the file /config/profile_base.conf. When you run the load command, the system loads these lists; however, unless you have modified the lists, the system does not save the lists to the bigip.conf file.

The internal data groups are stored in the bigip.conf file.

Internal data groups can be one of three types:

- A list of IP addresses
- A list of strings

Â· A list of integers

Strings must be surrounded by quotation marks. Numbers can be either positive or negative. These groups define the type of data in the class, which can be IP addresses, strings, or integers>

EXAMPLES

```
create internal MyDG records add { 10.0.0.0 } type ip
```

Creates an internal data group named MyDG that contains a single IP address.

```
create internal DG2 records add { 192.1.1.255 192.2.1.255 192.3.1.255 } type ip
```

Creates an internal data group named DG2 that contains a list of three network addresses: 192.1.1.0/24, 192.2.1.1/24, and 192.3.1.1/24.

```
create internal MyDG records add { my_key { data my_value } } type string
```

Creates an internal data group named MyDG that contains a single name/value pair.

OPTIONS

app-service

Specifies the name of the application service to which the data group belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the data group. Only the application service can modify or delete the data group.

description

User defined description.

records

Configures the data in the group.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

type Specifies the kind of data in the group. The default value is ip. This option is required by the command create.

ltm default-node-monitor

NAME

default-node-monitor - Configures the default node monitor for the Local Traffic Manager.

MODULE

ltm

SYNTAX

Configure the default-node-monitor component within the ltm module using the syntax shown in the following sections.

CREATE/MODIFY

```
modify default-node-monitor
```

options:

rule [rule syntax]

```
edit default-node-monitor
```

options:

all-properties

DISPLAY

```
list default-node-monitor
```

```
show running-config default-node-monitor
```

options:

one-line

all-properties

DESCRIPTION

You can use the default-node-monitor component to modify the default monitor that the system applies to any node address to which a monitor is not explicitly assigned.

EXAMPLES

modify default-node-monitor rule icmp

Modifies the global default node monitor to use the rule ICMP.

list default-node-monitor

Displays the properties of the global default node monitor.

OPTIONS

rule Specifies the rule that the system applies to any node that has not been assigned a monitor rule. The default value is none.

You can specify:

• A single monitor, for example, modify default-node-monitor rule icmp.

• Multiple monitors, for example, modify default-node-monitor rule icmp and tcp_echo.

• A minimum number of monitors, for example, modify default-node-monitor rule min 1 of { icmp and tcp_echo }.

SEE ALSO

ltm dns analytics global-settings

NAME

global-settings - Configures the global settings of all DNS listeners on the BIG-IP(r) system.

MODULE

ltm dns analytics

SYNTAX

Configure the global-settings DNS listeners within the ltm dns analytics module using the syntax in the following sections.

MODIFY

modify global-settings

options:

collect-client-ip [enabled | disabled]

collect-query-name [enabled | disabled]

DISPLAY

list global-settings

list global-settings

options:

all-properties

non-default-properties

one-line

DESCRIPTION

You can use the global-settings component to configure and view information about the global settings of all DNS listeners.

EXAMPLES

list global-settings all-properties

Displays the global settings for the DNS listeners on the BIG-IP system.

OPTIONS

collect-client-ip

When enabled, the client IP addresses of DNS queries will be collected and stored in analytics database. The default value is enabled.

collect-query-name

When enabled, the domain names of DNS queries will be collected and stored in analytics database. The default value is enabled.

SEE ALSO

list, modify, tmsh

COPYRIGHT

ltm dns cache global-settings

NAME

global-settings - Configures the global settings of all DNS caches on the BIG-IP(r) system.

MODULE

ltm dns cache

SYNTAX

Configure the global-settings DNS cache component within the ltm dns cache module using the syntax in the following sections.

CREATE/MODIFY

modify global-settings [name]

options:

cache-maximum-ttl [integer]

cache-minimum-ttl [integer]

resolver-edns-buffer-size [integer]

edit global-settings [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list global-settings

list global-settings [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DESCRIPTION

You can use the global-settings component to configure and view information about the global settings of all DNS caches.

EXAMPLES

list global-settings all-properties

Displays the global settings for the DNS caches on the BIG-IP system.

OPTIONS

cache-maximum-ttl

Specifies the number of seconds after which you want the BIG-IP system to re-query for resource records. This setting allows the BIG-IP system to re-query for resource records sooner than the owner of the records intended.

cache-minimum-ttl

Specifies the minimum number of seconds you want the BIG-IP system to cache DNS resource records. This setting allows the BIG-IP system to cache resource records longer than the owner of the records intended.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

resolver-edns-buffer-size [integer]

Specifies the number of bytes you want the BIG-IP system to advertise as the EDNS buffer size in UDP queries.

SEE ALSO

edit, glob, list, modify, regex, tmsh

BIG-IP 2012-03-21 Itm dns cache global-settings(1)

Itm dns cache records all

NAME

all - Simultaneously manages all subcache types in DNS cache resolvers on the BIG-IP(r) system.

MODULE

Itm dns cache records

SYNTAX

Configure all cache components within the Itm dns cache records module using the syntax in the following sections.

DELETE

delete all cache [cache name]

DESCRIPTION

This all cache option clears all subcaches at once and resizes them to their initial sizes.

EXAMPLES

delete Itm dns cache records all cache my_dns_cache_resolver

Deletes all entries of all subcaches in my_dns_cache_resolver.

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc. BIG-IP 2019-04-17 Itm dns cache records all(1)

Itm dns cache records key

NAME

key - Manages the DNSKEY records in the DNS caches on the BIG-IP(r) system.

MODULE

Itm dns cache records

SYNTAX

Configure the key component within the Itm dns cache records module using the following syntax.

DISPLAY

show key cache [cache name]

options:

count-only

owner [domain name]

slot [integer]

tmm [integer]

DELETE

delete key cache [cache name]

options:

owner [domain name]

EXAMPLES

show key cache resolver_cache

Displays the DNSKEY records in the cache named resolver_cache.

delete key cache v_resolver_cache

Deletes the DNSKEY records from the cache named v_resolver_cache.

DESCRIPTION

You can use the following options with the key component.

OPTIONS

cache name

Specifies a DNS cache name from which to display or delete DNSKEY records. This is a required field.

count-only

For a show command, return only a count of the number of matched records.

owner

Specifies a domain name on which to filter the DNSKEY records in the specified DNS cache for a query or deletion.

slot Specifies a slot number on a chassis that contains the specified DNS cache. This is a 1 based index.

tmm Deprecated in v15.0.0 Use tmm-process instead. All records across all TMM processes and slots will be returned.

tmm-process

Specifies which individual TMM process's key records you want to view. This is a 0 based index. On a chassis, this filter also requires a slot to be specified. If not specified, all records will be returned unless the slot filter is in use.

SEE ALSO

delete, show, tmsh

COPYRIGHT

ltm dns cache records msg

NAME

msg - Manages message records in the DNS caches on the BIG-IP(r) system.

MODULE

ltm dns cache records

SYNTAX

Configure the msg component within the ltm dns cache records module using the following syntax.

DISPLAY

show msg cache [cache name]

options:

count-only

qname [domain name]

rcode [integer]

slot [integer]

tmm [integer]

DELETE

delete msg cache [cache name]

options:

qname [domain name]

rcode [integer]

DESCRIPTION

The msg component contains full DNS messages. You can display and delete these messages.

EXAMPLES

show msg cache resolver_cache

Displays the message records in the DNS cache named resolver_cache.

delete msg cache v_resolver_cache

Deletes the message records from the DNS cache named v_resolver_cache.

OPTIONS

cache name

Specifies a DNS cache name. This is a required field.

count-only

For a show command, return only a count of the number of matched records.

qname

Specifies a domain name on which to filter the DNS messages in the specified DNS cache for a query or deletion.

rcode

Specifies the DNS return code on which to filter DNS messages in the specified DNS cache for a query or deletion.

slot Specifies a slot number on a chassis that contains the specified DNS cache. This is a 1 based index.

tmm Deprecated in v15.0.0 Use tmm-process instead. All records across all TMM processes and slots will be returned.

tmm-process

Specifies which individual TMM process's msg records you want to view. This is a 0 based index. On a chassis, this filter also requires a slot to be specified. If not specified, all records will be returned unless the slot filter is in use.

SEE ALSO

delete, show, tmsh

COPYRIGHT

BIG-IP 2019-04-17 ltm dns cache records msg(1)

ltm dns cache records nameserver

NAME

nameserver - Manages the nameserver records in the DNS cache resolvers on the BIG-IP(r) system.

MODULE

ltm dns cache records

SYNTAX

Configure the nameserver component within the ltm dns cache records

DISPLAY

show cache [cache name]

options:

address [ip address]

count-only

has-edns [yes | no]

has-lame [yes | no]

rtt-range [min:max]

slot [integer]

tmm [integer]

ttl-range [min:max]

zone-name [name]

DELETE

delete cache [cache name]

options:

address [ip address]

has-edns [yes | no]

has-lame [yes | no]

rtt-range [min:max]

ttl-range [min:max]

zone-name [name]

DESCRIPTION

You can use the nameserver component to display or delete nameserver records from a DNS cache. The maximum number of records returned is 1000; therefore, broad searches may not show all records in the cache.

EXAMPLES

show cache my_cache zone-name com ttl-range 50:500

Displays the nameserver records, in the DNS cache named my_cache, with the zone name com, where the TTLs of the records are between 50 and 500.

OPTIONS

address

Specifies the nameserver records, in the specified DNS cache, to select based on the IP address of the nameserver.

cache name

Specifies a DNS cache name. This is a required field.

count-only

For a show command, return only a count of the matched records.

has-edns

Specifies the nameserver records to select from the specified DNS cache, based on whether the nameserver is EDNS lame. An EDNS lame nameserver does not reply to EDNS queries.

has-lame

Specifies the nameserver records to select from the specified DNS cache, based on whether the nameserver is lame for one or more items.

rtt-range

Specifies the nameserver records to select from the specified DNS cache, based on RTTs within the specified range (inclusive). A missing value (:500 or 50:) defaults to the minimum or maximum, respectively.

slot Specifies a slot number on a chassis that contains the specified DNS cache. This is a 1 based index.

tmm Deprecated in v15.0.0 Use tmm-process instead. All records across all TMM processes and slots will be returned.

tmm-process

Specifies which individual TMM process's nameserver records you want to view. This is a 0 based index. On a chassis, this filter also requires a slot to be specified. If not specified, all records will be returned unless the slot filter is in use.

ttl-range

Specifies the nameserver records to select from the specified DNS cache, based on TTLs within the specified range (inclusive). A missing value (:500 or 50:) defaults to the minimum or maximum, respectively.

zone-name

Specifies the nameserver records to select from the specified DNS cache, based on the specified zone name.

SEE ALSO

delete, show, tmsh

COPYRIGHT

BIG-IP 2019-04-17 Itm dns cache records nameserver(1)

Itm dns cache records rrset

NAME

rrset - Manages the RRset records in the DNS cache resolvers on the BIG-IP(r) system.

MODULE

Itm dns cache records

SYNTAX

Configure the rrset component within the Itm dns cache records module using the syntax in the following sections.

DISPLAY

show cache [cache name]

options:

class [IN | CH | HS | ANY]

count-only

owner [DNS name]

slot [integer]

tmm [integer]

ttl-range [integer:integer]

type [A | AAAA | CNAME | NS | PTR | RRSIG | DNSKEY | SOA | TXT | ANY | ...]

DELETE

delete cache [cache name]

options:

class [IN | CH | HS| ANY]

owner [DNS name]

ttl-range [integer:integer]

type [A | AAAA | CNAME | NS | PTR | RRSIG | DNSKEY | SOA | TXT | ANY | ...]

DESCRIPTION

You can use the rrset component to display or delete records in the specified DNS cache. The maximum number of records returned is 1000. Broad searches might not show all records in the cache.

EXAMPLES

show cache resCache2 class IN type A ttl-range 20:5000 owner .com

Displays RRset records of type A, class IN, with TTLs between 20 and 5000, and an owner of .com.

OPTIONS

cache name

Specifies a DNS cache name. This is a required field.

class

Specifies the class of RRset records to select from the specified DNS cache.

count-only

For a show command, return only a count of the matched records.

owner

Specifies the node on which to filter the RRset records in the specified DNS cache for a query or deletion.

slot Specifies a slot number on a chassis that contains the specified DNS cache. This is a 1 based index.

tmm Deprecated in v15.0.0 Use tmm-process instead. All records across all TMM processes and slots will be returned.

tmm-process

Specifies which individual TMM process's rrset records you want to view. This is a 0 based index. On a chassis, this filter also requires a slot to be specified. If not specified, all records will be returned unless the slot filter is in use.

ttl-range

Specifies the RRset records to select from the specified DNS cache, based on TTLs within the specified range (inclusive). A missing value (:500 or 50:) defaults to the minimum or maximum, respectively.

type Specifies the RRset records to select from the specified DNS cache, based on the specified type. Most record types are supported.

SEE ALSO

options:
  all-properties
  non-default-properties
  one-line
show resolver
show resolver [name]

```

DELETE

```

delete resolver [name]

```

DESCRIPTION

You can use the resolver component to configure and view information about a recursive-resolving DNS cache. A resolver cache performs recursive resolution to fill its cache.

Important: When sizing caches, consider the total amount of memory available and how you wish to allocate memory for DNS caching. Note that cache sizing values are per-TMM process; therefore, a platform with eight TMMs consumes the amount of memory set for the RRset cache times eight.

EXAMPLES

```

list resolver myCache

```

Displays the properties of the recursive-resolving DNS cache myCache.

```

modify resolver myCache local-zones { { name lz.example.net records add { "lz.example.net 60 IN A 127.0.0.1"
"www.lz.example.net 300 IN A 127.0.0.2" } } }

```

Modifies DNS cache myCache by adding a local-zone lz.example.net with 2 resource records.

OPTIONS

allowed-query-time

Specifies the time allowed for a query to stay in the queue before it is replaced by a new query when the number of concurrent distinct queries exceeds the limit. The default value is 200 milliseconds.

answer-default-zones

Specifies whether the resolver cache answers queries for default zones: localhost, reverse 127.0.0.1 and ::1, and AS112 zones. The default value is no.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

forward-zones

Adds, deletes, modifies, or replaces a set of forward zones on a DNS Cache, by specifying zone name(s). A given zone name should only use the symbols allowed for a fully qualified domain name (FQDN), namely ASCII letters a through z, digits 0 through 9, hyphen -, and period .. For example site.example.com would be a valid zone name.

A DNS Cache configured with a forward zone will forward any queries that result in a cache-miss (the answer was not available in the cache) and match a configured zone name, to the nameserver specified on the zone. If no nameservers are specified on the zone, an automatic SERVFAIL is returned. When a forward zone's nameserver returns a valid response to the DNS Cache, that response is cached and then returned to the requester.

nameservers

Adds, deletes, modifies, or replaces a set of nameservers in a forward zone on a DNS Cache. A nameserver is represented by an IP address and port in the format [IPv4:port] or [IPv6.port], for example 10.10.10.10:53 or 2001::1:ff.53, respectively.

If more than one nameserver is listed for a given forward zone, a matching query will be sent to the nameserver that is currently deemed the most responsive (based on RTTs). If no response is received within a certain window of time, the DNS Cache will resend the query to another nameserver with an increased wait window until a response is received.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

local-zones

Zones and associated resource records for which the cache will provide Authoritative responses. Default is empty. This is intended for small, simple authoritative data configurations.

The local-zone name must be fully qualified and should be the apex of the zone. The local-zone type may be one of the following: deny, refuse, static, transparent, type-transparent, or redirect. Zero or more resource records must be fully specified: name, ttl, class, type, and record data, separated by spaces, and within double quotes. For example, "www.example.net. 300 IN A 1.2.3.4".

For all local-zones types, if the DNS query matches, it is answered Authoritatively. How a non-matching query is handled depends on the local-zone type.

deny drops the query.

refuse sends a REFUSED response.

static sends either a NoData or NXDOMAIN response (includes SOA if present in local-zone).

transparent performs regular cache operation (i.e. transparent pass-through or iterative resolution) except for those query names which would result in NoData. This is the default local-zone type.

type-transparent Same as transparent but does not return NoData.

redirect returns responses with zone suffix record(s) for queries beneath that suffix. For example, a local-zone for example.com and a single A record for that name; queries for www.example.com or abc.www.example.com would return the single A record (both have the same suffix).

max-concurrent-queries

Specifies the maximum number of concurrent distinct queries used by the resolver. A query is identified by query name, type and class. If the number of distinct queries exceeds this limit, the resolver replaces the earliest query in the queue with the new query if it has been in the queue longer than the allowed time. The default value is 1024.

max-concurrent-tcp

Specifies the maximum number of concurrent TCP flows used by the resolver. The default value is 20.

max-concurrent-udp

Specifies the maximum number of concurrent UDP flows used by the resolver. The default value is 8192.

msg-cache-size

Specifies the maximum size in bytes of the DNS message cache. The default value is 1048576.

The BIG-IP system caches the messages in a DNS response in the message cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

nameserver-cache-count

Specifies the maximum number of DNS nameservers for which the BIG-IP system caches connection and capability data. The default value is 16536 entries.

randomize-query-name-case

When enabled, the resolver randomizes the case of query names. The default value is yes.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

response-policy-zones

Adds, deletes or modifies the response policy zone to be used by this DNS Cache. Only a DNS Express zone configured as a response policy zone can be added.

The query name of a recursive DNS request without DNSSEC enabled is queried against the data in the response policy zone. If a match is found, the configured response policy action is taken.

action

The action to take upon a match. `nxdomain` results in an `NXDOMAIN` response given to the client. `walled-garden` results in a response with a `CNAME` to the `walled-garden` zone and an `A` or `AAAA` response matching the DNS query type. The default action is `nxdomain`.

walled-garden

A local zone configured in this cache that contains an `A` and/or `AAAA` record. This is typically used to redirect a user that requests resolution of a name contained in the RPZ database to a local server. This local server can display a message to the user and/or record the connection. Only `A/AAAA/ANY` requests are redirected, a request for any other type is answered with a `NoData` response. If a request is received for type `A` or `AAAA` but there are no records of that type configured, a `NoData` response is returned instead.

root-hints

Specifies the IP addresses of DNS servers that the BIG-IP system considers authoritative for the DNS root nameservers.

Important:By default, the BIG-IP system uses the DNS root nameservers published by InterNIC.

Caution:When you add DNS root nameservers, the BIG-IP system no longer uses the default nameservers published by InterNIC, but instead uses the nameservers you add as authoritative for the DNS root nameservers.

route-domain

Specifies the route domain the resolver uses for outbound traffic. The default value is the default route domain.

rrset-cache-size

Specifies the maximum size in bytes of the resource records set cache. The default value is 10485760.

The BIG-IP system caches the supporting records in a DNS response in the resource record cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

rrset-rotate

Specifies the resource record rotation method used within cached responses. The default value is `none`.

`none` Resource record order is not modified.

`query-id` Resource record order is a function of the client's query id.

unwanted-query-reply-threshold

The system always rejects unsolicited replies. The default value of 0 (off) indicates the system does not generate SNMP traps or log messages when rejecting unsolicited replies.

Change the default value to monitor for unsolicited replies. This alerts you to a potential security attack, such as cache poisoning or DOS. For example, if you specify a value of 1,000,000, each time the system receives 1,000,000 unsolicited replies, it generates an SNMP trap and log message. The default value is 0 (off).

use-ipv4

When enabled, the resolver sends DNS queries to IPv4 addresses. The default value is `yes`.

use-ipv6

When enabled, the resolver sends DNS queries to IPv6 addresses. The default value is `yes`.

use-tcp

When enabled, the resolver can send queries over the TCP protocol. The default value is `yes`.

use-udp

When enabled, the resolver can send queries over the UDP protocol. The default value is `yes`.

ltm dns cache transparent

NAME

transparent - Configures a DNS cache without a resolver on the BIG-IP(r) system.

MODULE

ltm dns cache

SYNTAX

Configure the transparent DNS cache component within the ltm dns cache module using the syntax in the following sections.

CREATE/MODIFY

```
create transparent [name]
modify transparent [name]
options:
  answer-default-zones [yes | no]
  app-service [[string] | none]
  description [[string] | none]
  local-zones [ [none] |
  [ { { name [dname] type [type] records [none | add { [RR string] ... } ] } ... } ] ]
  msg-cache-size [integer]
  response-policy-zones [add | delete | modify] {
    [zone-name] {
  action [nxdomain | walled-garden]
  walled-garden [local-zone]
    }
  }
  response-policy-zones none
  rrset-cache-size [integer]
  rrset-rotate [none | query-id]
```

DISPLAY

```
list transparent
list transparent [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
show transparent
show transparent [name]
```

DELETE

```
delete transparent [name]
```

DESCRIPTION

You can use the transparent component to configure and view information about a transparent DNS cache. A transparent cache does not perform recursive resolution, but instead relies on another DNS resource for this functionality.

Important: When sizing caches, consider the total amount of memory available and how you wish to allocate memory for DNS caching. Note that cache sizing values are per-TMM process; therefore, a platform with eight TMMs consumes the amount of memory set for the RRset cache times eight.

EXAMPLES

```
list transparent myCache
```

Displays the properties of the transparent DNS cache myCache.

```
modify transparent myCache local-zones { { name lz.example.net records add { "lz.example.net 60 IN A
127.0.0.1" "www.lz.example.net 300 IN A 127.0.0.2" } } }
```

Modifies DNS cache myCache by adding a local-zone lz.example.net with 2 resource records.

OPTIONS

answer-default-zones

Specifies whether the resolver cache answers queries for default zones: localhost, reverse 127.0.0.1 and ::1, and AS112 zones. The default value is no.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

local-zones

Zones and associated resource records for which the cache will provide Authoritative responses. Default is empty. This is intended for small, simple authoritative data configurations.

The local-zone name must be fully qualified and should be the apex of the zone. The local-zone type may be one of the following: deny, refuse, static, transparent, type-transparent, or redirect. Zero or more

resource records must be fully specified: name, ttl, class, type, and record data, separated by spaces, and within double quotes. For example, "www.example.net. 300 IN A 1.2.3.4".

For all local-zones types, if the DNS query matches, it is answered Authoritatively. How a non-matching query is handled depends on the local-zone type.

deny drops the query.

refuse sends a REFUSED response.

static sends either a NoData or NXDOMAIN response (includes SOA if present in local-zone).

transparent performs regular cache operation (i.e. transparent pass-through or iterative resolution) except for those query names which would result in NoData. This is the default local-zone type.

type-transparent Same as transparent but does not return NoData.

redirect returns responses with zone suffix record(s) for queries beneath that suffix. For example, a local-zone for example.com and a single A record for that name; queries for www.example.com or abc.www.example.com would return the single A record (both have the same suffix).

msg-cache-size
Specifies the maximum size in bytes of the DNS message cache. The default value is 1048576.

The BIG-IP system caches the messages in a DNS response in the message cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

response-policy-zones
Adds, deletes or modifies the response policy zone to be used by this DNS Cache. Only a DNS Express zone configured as a response policy zone can be added.

The query name of a recursive DNS request without DNSSEC enabled is queried against the data in the response policy zone. If a match is found, the configured response policy action is taken.

action
The action to take upon a match. nxdomain results in an NXDOMAIN response given to the client. walled-garden results in a response with a CNAME to the walled-garden zone and an A or AAAA response matching the DNS query type. The default action is nxdomain.

walled-garden
A local zone configured in this cache that contains an A and/or AAAA record. This is typically used to redirect a user that requests resolution of a name contained in the RPZ database to a local server. This local server can display a message to the user and/or record the connection. Only A/AAAA/ANY requests are redirected, a request for any other type is answered with a NoData response. If a request is received for type A or AAAA but there are no records of that type configured, a NoData response is returned instead.

rrset-cache-size
Specifies the maximum size in bytes of the resource records set cache. The default value is 10485760.

The BIG-IP system caches the supporting records in a DNS response in the resource record cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

rrset-rotate
Specifies the resource record rotation method used within cached responses. The default value is none.

none Resource record order is not modified.

query-id Resource record order is a function of the client's query id.

options:
  all-properties
  non-default-properties
  one-line
show validating-resolver [name]
```

DELETE

```
delete validating-resolver [name]
```

DESCRIPTION

You can use the validating-resolver component to configure and view information about a validating recursive-

resolving DNS cache. A resolving and validating cache performs recursive resolution to fill its cache and uses DNSSEC to ensure the integrity of the data.

Important: When sizing caches, consider the total amount of memory available and how you wish to allocate memory for DNS caching. Note that cache sizing values are per-TMM process; therefore, a platform with eight TMMs consumes the amount of memory set for the resource record set cache times eight.

EXAMPLES

list validating-resolver myCache

Displays the properties of the validating recursive-resolving DNS cache myCache.

modify validating-resolver myCache local-zones { { name lz.example.net records add { "lz.example.net 60 IN A 127.0.0.1" "www.lz.example.net 300 IN A 127.0.0.2" } } }

Modifies DNS cache myCache by adding a local-zone lz.example.net with 2 resource records.

OPTIONS

allowed-query-time

Specifies the time allowed for a query to stay in the queue before it is replaced by a new query when the number of concurrent distinct queries exceeds the limit. The default value is 200 milliseconds.

answer-default-zones

Specifies whether the validating resolver cache answers queries for default zones: localhost, reverse 127.0.0.1 and ::1, and AS112 zones. The default value is no.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

dlv-anchors

Specifies the DNSKEY or DS resource records the BIG-IP system uses to establish DNSSEC trust with a DLV registry. The resource records must be specified in string format, for example, dig or drill format. The default is none.

forward-zones

Adds, deletes, modifies, or replaces a set of forward zones on a DNS Cache, by specifying zone name(s). A given zone name should only use the symbols allowed for a fully qualified domain name (FQDN), namely ASCII letters a through z, digits 0 through 9, hyphen -, and period .. For example site.example.com would be a valid zone name.

A DNS Cache configured with a forward zone will forward any queries that result in a cache-miss (the answer was not available in the cache) and match a configured zone name, to the nameserver specified on the zone. If no nameservers are specified on the zone, an automatic SERVFAIL is returned. When a forward zone's nameserver returns a valid response to the DNS Cache, that response is cached and then returned to the requester.

nameservers

Adds, deletes, or replaces a set of nameservers in a forward zone on a DNS Cache. A nameserver is represented by an IP address and port in the format [IPv4:port] or [IPv6.port], for example 10.10.10.10:53 or 2001::1:ff:53, respectively.

If more than one nameserver is listed for a given forward zone, a matching query will be sent to the nameserver that is currently deemed the most responsive (based on RTTs). If no response is received within a certain window of time, the DNS Cache will resend the query to another nameserver with an increased wait window until a response is received.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ignore-cd

When enabled, the system ignores the Checking Disabled setting on client queries, performs validation, and returns only secure answers. The default value is no.

key-cache-size

Specifies the maximum size in bytes of the DNSKEY cache. The default value is 1048576.

local-zones

Zones and associated resource records for which the cache will provide Authoritative responses. Default is empty. This is intended for small, simple authoritative data configurations.

The local-zone name must be fully qualified and should be the apex of the zone. The local-zone type may be one of the following: deny, refuse, static, transparent, type-transparent, or redirect. Zero or more resource records must be fully specified: name, ttl, class, type, and record data, separated by spaces, and within double quotes. For example, "www.example.net. 300 IN A 1.2.3.4".

For all local-zones types, if the DNS query matches, it is answered Authoritatively. How a non-matching query is handled depends on the local-zone type.

deny drops the query.

refuse sends a REFUSED response.

static sends either a NoData or NXDOMAIN response (includes SOA if present in local-zone).

transparent performs regular cache operation (i.e. transparent pass-through or iterative resolution) except for those query names which would result in NoData. This is the default local-zone type.

type-transparent Same as transparent but does not return NoData.

redirect returns responses with zone suffix record(s) for queries beneath that suffix. For example, a local-zone for example.com and a single A record for that name; queries for www.example.com or abc.www.example.com would return the single A record (both have the same suffix).

max-concurrent-queries

Specifies the maximum number of concurrent distinct queries used by the resolver. A query is identified by query name, type and class. If the number of distinct queries exceeds this limit, the resolver replaces the earliest query in the queue with the new query if it has been in the queue longer than the allowed time. The default value is 1024.

max-concurrent-tcp

Specifies the maximum number of concurrent TCP flows used by the resolver. The default value is 20.

max-concurrent-udp

Specifies the maximum number of concurrent UDP flows used by the resolver. The default value is 8192.

msg-cache-size

Specifies the maximum size in bytes of the DNS message cache. The default value is 1048576.

The BIG-IP system caches the messages in a DNS response in the message cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

nameserver-cache-count

Specifies the maximum number of DNS nameservers for which the BIG-IP system caches connection and capability data. The default value is 16536 entries.

prefetch-key

When enabled, the validating resolver fetches the DNSKEY early in the validation process. Disable this setting when you want to reduce resolver traffic, but understand that a client may have to wait for the validating resolver to perform a key lookup. The default value is yes.

randomize-query-name-case

When enabled, the resolver randomizes the case of query names. The default value is yes.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

response-policy-zones

Adds, deletes or modifies the response policy zone to be used by this DNS Cache. Only a DNS Express zone configured as a response policy zone can be added.

The query name of a recursive DNS request without DNSSEC enabled is queried against the data in the response policy zone. If a match is found, the configured response policy action is taken.

action

The action to take upon a match. nxdomain results in an NXDOMAIN response given to the client. walled-garden results in a response with a CNAME to the walled-garden zone and an A or AAAA response matching the DNS query type. The default action is nxdomain.

walled-garden

A local zone configured in this cache that contains an A and/or AAAA record. This is typically used to redirect a user that requests resolution of a name contained in the RPZ database to a local server. This local server can display a message to the user and/or record the connection. Only A/AAAA/ANY requests are redirected, a request for any other type is answered with a NoData response. If a request is received for type A or AAAA but there are no records of that type configured, a NoData response is returned instead.

root-hints

Specifies the IP addresses of DNS servers that the BIG-IP system considers authoritative for the DNS root nameservers.

Important:By default, the BIG-IP system uses the DNS root nameservers published by InterNIC.

Caution:When you add DNS root nameservers, the BIG-IP system no longer uses the default nameservers published by InterNIC, but instead uses the nameservers you add as authoritative for the DNS root nameservers.

route-domain

Specifies the route domain the resolver uses for outbound traffic. The default value is the default route domain.

rrset-cache-size

Specifies the maximum size in bytes of the resource records set cache. The default value is 10485760.

The BIG-IP system caches the supporting records in a DNS response in the resource record cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

rrset-rotate

Specifies the resource record rotation method used within cached responses. The default value is none.

none Resource record order is not modified.

query-id Resource record order is a function of the client's query id.

trust-anchors

Specifies the DNSKEY or DS resource records the BIG-IP system uses to establish DNSSEC trust with a specific DNS zone. The resource records must be specified in string format, for example, dig or drill format. The default value is none.

unwanted-query-reply-threshold

The system always rejects unsolicited replies. The default value of 0 (off) indicates the system does not generate SNMP traps or log messages when rejecting unsolicited replies.

Change the default value to monitor for unsolicited DNS replies. This alerts you to a potential security attack, such as cache poisoning or DOS. For example, if you specify a value of 1,000,000, each time the system receives 1,000,000 unsolicited replies, it generates an SNMP trap and log message. The default value is 0 (off).

use-ipv4

When enabled, the resolver sends DNS queries to IPv4 addresses. The default value is yes.

use-ipv6

When enabled, the resolver sends DNS queries to IPv6 addresses. The default value is yes.

use-tcp

When enabled, the resolver can send queries over the TCP protocol. The default value is yes.

use-udp

When enabled, the resolver can send queries over the UDP protocol. The default value is yes.

one-line

DELETE

delete key [name]

DESCRIPTION

You can use the key component to configure DNSSEC zone signing and key signing keys, and to view information about the keys.

EXAMPLES

create key ksk1

Creates the key signing key, ksk1, using the system default values.

create key zsk1

Creates the zone signing key, zsk1, using the system default values.

list key my_key

Displays the properties of the DNS security key my_key.

OPTIONS

algorithm

Specifies the algorithm to use to generate the key. The default value is RSASHA1.

app-service

Specifies the name of the application service to which the key belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the key. Only the application service can modify or delete the key.

bitwidth

Specifies the length of the key you want to generate. The default value is 1024. If a key is manually managed, MCPD will derive this value from the file and override any user defined value.

certificate-file

Specifies the file containing the public key. Fields certificate-file and key-file are required for manual DNSSEC key import.

description

User defined description.

[enabled | disabled]

Specifies whether the key is enabled or disabled.

expiration-period

Specifies the life of the key in d:h:m:s, h:m:s, m:s, or seconds. At the end of the period, the system deletes the expired generation of the key. This value must be greater than the value of the rollover-period option. The difference between the two periods must be more than the value of the ttl option.

The default value is 0 (zero), which indicates unset, and thus the key does not expire.

generation

Displays the generation of the key, including the following:

creator

Hostname of BIG-IP system that created this generation.

expiration

The date and time that this generation of the key expires. This can be modified and is in the following format: yyyy-mm-dd:hh:mm:ss.

handle

The handle of a generation of a key that is used for internal interactions with the key subsystem (for example, HSM for FIPS).

key-tag

The hash identifier of the DNSKEY. This can be used to identify which DNSKEY was used to generate a given RRSIG.

pub-text

The text of the public portion of the DNSSEC Key Generation.

rollover

The date and time that the generation of the key rolls over to a new key. This can be modified and is in the following format: yyyy-mm-dd:hh:mm:ss.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

key-file

Specifies the file containing the private key. Fields certificate-file and key-file are required for manual DNSSEC key import.

key-type

Specifies whether the key is of type ksk or zsk. The default value is zsk.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rollover-period

Specifies the amount of time, in d:h:m:s, h:m:s, m:s, or seconds, before the system generates another generation of the key. At the end of the period, the system creates a new generation of the key. Two generations of the key exist during the time between the end of the rollover period and the end of the expiration period.

This value must be greater than or equal to one third of the value of the expiration-period option, and less than the value of the expiration period option. The difference between the two periods must be more than the value of the ttl option.

The default value is 0 (zero), which indicates unset, and thus the key does not roll over.

signature-pub-period

Specifies the amount of time, in d:h:m:s, h:m:s, m:s, or seconds, before the system publishes another generation of the signature. At the end of the period, the system creates a new signature.

This value must be less than the value of the signature-valid-period option. The default value is 403200 seconds.

signature-valid-period

Specifies the amount of time, in d:h:m:s, h:m:s, m:s, or seconds, that the signature is valid. The validity period will begin when the signature is generated but the inception time of the signature will be back-dated by one hour, to allow for clock skew on the validator. At the end of the period, the Global Traffic Manager no longer uses the expired signature. The default value is 604800 seconds.

ttl Specifies the amount of time, in d:h:m:s, h:m:s, m:s, or seconds, that a DNS server can cache the key. The default value is 86400.

The value of the ttl option must be less than the difference between the values of the rollover-period and expiration-period options.

0 seconds indicates that the key is not cached.

use-fips

Specifies the type of FIPS-compliant hardware security module to use when storing, and signing with, the private key. The default value is none. The choice of external attempts to use a network-attached FIPS device if configured; otherwise internal uses the FIPS device within the BIG-IP.

If this option is set to internal or external and a FIPS device is not present, the system automatically resets the value to none.

Itm dns dnssec zone

NAME

zone - Configures DNSSEC zones on the BIG-IP(r) system.

MODULE

itm dns dnssec

SYNTAX

Configure the zone component within the Itm dns dnssec module using the syntax in the following sections.

CREATE/MODIFY

```
create zone [name]
modify zone [name]
options:
  app-service [[string] | none]
  description [string]
  [enabled | disabled]
  ds-algorithm [ sha1 | sha256 ] DEPRECATED - see ds-algorithms
  ds-algorithms [ add | delete | replace-all-with ] {
    [ sha1 | sha256 ] ...
  }
  external-delegations
    [add | delete | modify | replace-all-with] {
[DNS zone name] {
  options:
    ds-records
      [add | delete | modify | replace-all-with] {
[ DS record ] ...
      }
    secure [ enabled | disabled ]
}
}
  indicate-authenticated [ enabled | disabled ]

DELETE
delete zone [name]

DESCRIPTION
You can use the zone component to configure and view information about a DNSSEC zone.

EXAMPLES
list zone mySecureZone

Displays the properties of the DNSSEC zone named mySecureZone.

OPTIONS
app-service
Specifies the name of the application service to which the zone belongs. The default value is none. Note:
If the strict-updates option is enabled on the application service that owns the object, you cannot
modify or delete the zone. Only the application service can modify or delete the zone.

description
User defined description.

ds-algorithm
This option is deprecated in v14.0.0 and is replaced by ds-algorithms. Specifies the hash algorithm to
use when creating the Delegation Signer (DS) resource record. The default value is sha1.

ds-algorithms
Specifies the hash algorithms to use when creating Delegation Signer (DS) resource records. The default
value is sha1. A DS record is generated in a given SEP for each algorithm that is configured.

[enabled | disabled]
Specifies whether the DNSSEC zone is enabled or disabled.

Note: You must associate both a key signing and a zone signing key with the zone before complete signing
of client requests can occur.

external-delegations
Specifies the names of delegated subzones of this zone, where the BIG-IP is not responsible for the
DNSSEC signing.

ds-records
Specifies the DNSSEC delegation signer (DS) resource records (RRs) that correspond to the Key-
Signing-Keys (KSKs) of the external delegated zone. They indicate that the external delegated zone
is DNSSEC enabled. These records are used to establish the DNSSEC chain of trust from zone to
subzone.

secure
Specifies whether or not the external delegation is secured through the use of DS records. Default
value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression
syntax.

indicate-authenticated
The Authenticated Data (AD) flag is TRUE for DNSSEC zone authoritative answers when this setting is
enabled. The default value is disabled.

keys Specifies the keys that you want to configure for the zone.

name Specifies a unique name for the component. This option is required for the commands create, delete, and
modify.

nsec3-algorithm
Specifies the hash algorithm to use when creating the Next Secure (NSEC3) resource record. The default
value is SHA1. Other algorithms are not currently supported, so selecting SHA256 will revert to SHA1 with
a warning message.

nsec3-iterations
Specifies the number of times to hash the Next Secure (NSEC3) names. The default value is 1.

publish-cds-cdnskey

Specifies whether or not we will respond to CDS and CDNSKEY type queries for the DNSSEC Zone. The default value is disabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secure-delegations

Specifies the DNSSEC zones on the BIG-IP that are delegated subzones of the zone as determined by the name of the zones. This list is read-only and automatically generated based on the DNSSEC Zones configured on the BIG-IP.

seps Displays the Secure Entry Point(s) (DS and DNSKEY resource records used as client trust anchors) of the zone. This list is read-only and automatically generated based on the DNSSEC Key Key-Signing-Keys (KSKs) configured on a DNSSEC Zone.

Each list entry includes the following attributes:

dnskey

String representation of the DNSKEY resource record. Note this will be a Key-Signing-Key (KSK).

ds This option is deprecated in v14.0.0 and is replaced by ds-records. String representation of the DS resource record.

ds-records

String representations of DS resource records. There will be one DS record for each ds-algorithm configured on the DNSSEC Zone.

generation-id

Generation ID of DNSSEC Key used to create the SEP.

key-name

Name of DNSSEC Key which was used to create the SEP.

xfr-primary-soa-serial

The learned zone SOA serial number from the primary server.

xfr-soa-serial

The advertised zone SOA serial number to all clients.

SEE ALSO

ltm dns nameserver

NAME

nameserver - Configures DNS nameservers on the BIG-IP(r) system.

MODULE

ltm dns

SYNTAX

Configure the nameserver component within the ltm dns module using the syntax in the following sections.

CREATE/MODIFY

create nameserver [name]

modify nameserver [name]

options:

address [ip address]

app-service [[string] | none]

description [[string] | none]

port [unsigned integer]

route-domain [route-domain name | none]

tsig-key [tsig-key name | none]

edit nameserver [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

reset-stats nameserver
reset-stats nameserver [[[name] | [glob] | [regex]] ...]

DISPLAY
list nameserver
list nameserver [[[name] | [glob] | [regex]] ...]
options:

show nameserver [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
global
field-fmt

DELETE
delete nameserver [name]

DESCRIPTION

You can use the nameserver component to configure nameservers and to view information about the nameservers.

EXAMPLES

create nameserver myNameserver address 127.0.0.1 port 53

Creates the nameserver, myNameserver, given the address and port.

list nameserver myNameserver

Displays the properties of the nameserver myNameserver.

OPTIONS

address
Specifies the IP address of the nameserver. The default value is 127.0.0.1.

app-service
Specifies the name of the application service to which the nameserver belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the nameserver. Only the application service can modify or delete the nameserver.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

port Specifies the service port of the nameserver. The default value is 53.

route-domain
Specifies the route domain that the nameserver uses for outbound traffic. The default value is the default route domain.

tsig-key
Specifies the TSIG key used to communicate with this nameserver for zone transfers. If the nameserver is a client, then this TSIG key is used to verify the query and sign the response. If the nameserver is a transfer target for DNS Express nameserver, then this TSIG key should match that of the master nameserver.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

DISPLAY

list tsig-key

list tsig-key [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DELETE

delete tsig-key [name]

DESCRIPTION

You can use the tsig-key component to configure TSIG keys and to view information about the keys.

EXAMPLES

create tsig-key myKey algorithm hmacmd5 secret ABCDEFG

Creates the TSIG key, myKey, given the algorithm and secret (both required).

list tsig-key myKey

Displays the properties of the TSIG key myKey.

OPTIONS

algorithm

Specifies the algorithm to use to generate the key.

app-service

Specifies the name of the application service to which the TSIG key belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the TSIG key. Only the application service can modify or delete the TSIG key.

description

User defined description.

glob

Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Specifies the string representation of the key's shared secret.

SEE ALSO

field-fmt

DELETE

delete zone [name]

DESCRIPTION

You can use the zone component to configure and view information about a zone.

EXAMPLES

list zone myZone

Displays the properties of the zone named myZone.

create zone myZone transfer-clients add { nameserver1 nameserver2 }

Creates a zone named myZone, which allows zone data to be transferred to nameserver1 and nameserver2.

OPTIONS

app-service

Specifies the name of the application service to which the zone belongs. The default value is none. Note:
If the strict-updates option is enabled on the application service that owns the object, you cannot
modify or delete the zone. Only the application service can modify or delete the zone.

description

User defined description.

dns-express-allow-notify

Specifies a list of IP addresses, in addition to the DNS Zone's DNS-Express Server address, which are

allowed to notify the BIGIP of DNS Zone changes. A notify message coming from an IP which is neither the address of the zone's DNS Express server nor an address in this list will be dropped by the BIGIP.

`dns-express-enabled` [yes | no]
Specifies whether DNS Express is enabled to process queries for this zone. The default value is yes.

`dns-express-notify-action` [consume | bypass | repeat]
Action to take when a NOTIFY query is received for a configured zone. Options are consume, bypass, and repeat. Default is consume, meaning the NOTIFY query is seen only by DNS Express. bypass means the query will NOT go to DNS Express, but any backend DNS resource (subject to DNS profile unhandled-query-action). repeat means the NOTIFY will go to both DNS Express and any backend DNS resource. If TSIG is configured, the signature is only validated for consume and repeat actions. NOTIFY responses are assumed to be sent by the backend DNS resource, except when the action is consume and DNS Express will generate a response.

`dns-express-notify-tsig-verify`
Verify NOTIFY query TSIG for a DNS Express zone. Default is yes.

`dns-express-server`
Specifies the server from which to retrieve zone information for DNS Express.

`glob` Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

Note: A successful zone transfer must occur before this zone can service DNS requests.

`regex`
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

`response-policy`
Specifies if this is a response policy zone. If this is set to yes, this zone may be assigned as an RPZ to a DNS Cache. Default is no.

`server-tsig-key`
Specifies the server side TSIG key associated with the DNS zone. It should match the TSIG Key associated with the master name servers.

`transfer-clients`
Specifies the nameservers allowed to transfer the zone from BIGIP.

SEE ALSO
create, delete, edit, glob, list, show, modify, regex, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

show eviction-policy

show eviction-policy [[[name] | [glob] | [regex]] ...]

options:

all-properties
default

DELETE

delete eviction-policy [name]

DESCRIPTION

You use the eviction policy to specify which flows to terminate when the connection limits for the box are approached. The eviction policy contains strategies which select the flows to terminate. Additionally, the eviction policy defines parameters used to determine when flows are considered to be slow. Slow flows are terminated according to the policy, even when the Big-IP is not under duress and the connection limits are not approached.

When applied to the global context, the eviction policy low-water and high-water limits are with respect to memory available on the Big-IP. When applied to a virtual server or a route domain, the limits are with respect to the connection limit on the virtual server or route domain, respectively.

It is possible to monitor slow flows, accumulating metrics on the number of flows under the designated slow flow transfer limit. To do so, enable slow-flows, but disable throttling on the slow flow.

Note: Monitoring or killing slow flows will incur a performance penalty.

Note: The strategies applied here work on a cyclic sweep of all connections on the Big-IP. These do not run at the granularity to guarantee eviction of a particular flow or type of flow, but are statistical and opportunistic.

The bias-bytes algorithm attempts to select the flows that have sent and received the fewest bytes on the connection.

The bias-idle algorithm attempts to select the flows that have been idle the longest.

The bias-oldest algorithm attempts to select the oldest flows.

The low-priority-geographies algorithm selects flows that are in low-priority geographies according to the GeoIP database loaded onto the box.

The low-priority-port algorithm selects flows that are in the provided list of low-priority ports and protocols.

The low-priority-route-domain algorithm selects flows that are in the provided list of low-priority route domains.

The low-priority-virtual-server algorithm selects flows that are in the provided list of low-priority virtual servers.

EXAMPLES

```
create eviction-policy my_eviction_policy { low-water 70 high-water 80 slow-flow { enabled true threshold-bps 50 throttling disabled } strategies { bias-idle { enabled true } } }
```

Creates an eviction policy named `my_eviction_policy`, which accumulates statistics on the current number of slow flows but does not terminate any flows that are considered slow. The bias-idle algorithm is used to kill flows when the limits on the context are approached. The aggressive sweeper will activate at 80 percent of capacity, and deactivate when load is reduced to 70 percent of capacity.

```
modify eviction-policy my_eviction_policy { strategies { low-priority-geographies { enabled true countries replace-all-with { AZ BZ } } } }
```

Modifies the eviction policy named `my_eviction_policy`, enabling the low-priority geography strategy and dropping flows from Azerbaijan (AZ) and Belize (BZ).

```
delete eviction-policy my_eviction_policy
```

Deletes the eviction policy named `my_eviction_policy`.

OPTIONS

`description`

Provides a user-defined description for the policy.

`app-service`

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`low-water`

Specifies the aggressive sweeper activation threshold as a percentage of total capacity. The allowable range is 50 - 100, and the low-water value must be lower than or equal to the high-water value. To disable killing flows when limits are met or exceeded, set the low-water and high-water to 100 percent. Default value is 85 percent.

`high-water`

Specifies the target maximum load on the context. The adaptive reaper will be more aggressive as this limit is approached. The allowable range is 50 - 100, and the high-water value must be higher than or equal to the low-water value. To disable killing flows when limits are met or exceeded, set the low-water and high-water to 100 percent. Defaults to 95 percent.

`slow-flow`

Specifies whether to monitor and possibly remove flows considered to be slow.

`enabled`

If true, the slow-flow monitoring and possible removal are activated. If false, the remaining slow-flow attributes are unused. The default value is false.

`eviction-type`

Indicates whether the threshold is based on an absolute count of slow flows, or a percentage of the total flows on the context where the eviction policy is applied. There is no default value.

`grace-period`

Specifies the minimum age of a slow flow before the flow is killed.

`maximum`

Provides the count or percentage at which slow flows will be killed. If eviction-type is count, this value is the absolute number of slow flows allowed; if eviction-type is percent, this is the percentage of flows on the context that are allowed to fall under the threshold-bps before being killed.

`threshold-bps`

Provides the threshold under which flows are considered to be slow, in bytes per second.

`throttling`

Indicates whether to kill flows that are considered slow. If set to enabled, flows that fall under the threshold-bps are subject to being killed according to the defined maximum number of flows.

`strategies`

Defines the strategies to be used to select flows for eviction in the eviction policy.

`bias-bytes`

Defines how to use the bias-bytes eviction strategy.

delay

The delay allowed for new flows to transfer content, to prevent killing infant flows.

enabled

Specifies whether to use the bias-bytes algorithm. If false, the bias-bytes algorithm is not used. The default value is false.

bias-idle

Defines how to use the bias-idle eviction strategy.

enabled

Specifies whether to use the bias-idle algorithm. If false, the bias-idle algorithm is not used. The default value is false.

bias-oldest

Defines how to use the bias-oldest eviction strategy.

enabled

Specifies whether to use the bias-oldest algorithm. If false, the bias-oldest algorithm is not used. The default value is false.

low-priority-geographies

Defines how to use the low-priority geographies eviction strategy.

countries

Provides a list of country codes considered low-priority candidates to evict, based on GeoIP information.

enabled

Specifies whether to use the low-priority-geographies algorithm. If false, the low-priority-geographies algorithm is not used. The default value is false.

low-priority-port

Defines how to use the low-priority-port eviction strategy.

enabled

Specifies whether to use the low-priority-port algorithm. If false, the low-priority-port algorithm is not used. The default value is false.

ports

Provides a list of ports considered low-priority candidates to evict.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

port-number

Specifies the port number considered low-priority. The number provided can be either a number (e.g., 80) or a name (e.g., http).

protocol

Specifies the protocol considered low-priority. The default value is any.

low-priority-route-domain

Defines how to use the low-priority-route-domain eviction strategy.

enabled

Specifies whether to use the low-priority-route-domain algorithm. If false, the low-priority-route-domain algorithm is not used. The default value is false.

names

Specifies a list of route domain names considered to be low-priority candidates to evict.

low-priority-virtual-server

Defines how to use the low-priority-virtual-server eviction strategy.

enabled

Specifies whether to use the low-priority-virtual-server algorithm. If false, the low-priority-virtual-server algorithm is not used. The default value is false.

names

Specifies a list of virtual server names considered to be low-priority candidates to evict.

Itm global-settings

SYNTAX

Configure the connection component within the Itm global-settings module using the syntax shown in the following sections.

MODIFY

modify connection

options:

adaptive-reaper-hiwater [integer]
adaptive-reaper-lowwater [integer]
auto-last-hop [disabled | enabled]
default-vs-syn-challenge-threshold [infinite | integer]
global-flow-eviction-policy [name]
global-syn-challenge-threshold [infinite | integer]
syncookies-threshold [integer]
vlan-keyed-conn [disabled | enabled]
vlan-syn-cookie [disabled | enabled]

DISPLAY

list connection

list connection [option name]

show running-config connection

show running-config connection [option name]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the connection component to modify how the system processes connections.

EXAMPLES

modify connection auto-last-hop disabled

Specifies that the system does not automatically map the last hop for pools.

list connection

Displays the global settings for how the system processes connections.

OPTIONS

adaptive-reaper-hiwater

IMPORTANT This command has been deprecated (as of 11.6.0). Please use Itm eviction-policy instead. Specifies, in a percentage, the memory usage at which the system stops establishing new connections. Once the system meets the reaper high-water mark, the system does not establish new connections until the memory usage drops below the reaper low-water mark. The adaptive reaper settings help mitigate the effects of a denial-of-service attack.

The available range is 85 - 100. The default value is 95. To disable the adaptive reaper, set the high-water mark to 100.

adaptive-reaper-lowwater

IMPORTANT This command has been deprecated (as of 11.6.0). Please use Itm eviction-policy instead. Specifies, in percent, the memory usage at which the system silently purges stale connections, without sending reset packets (RST) to the client. If the memory usage remains above the low-water mark after the purge, then the system starts purging established connections closest to their service timeout.

The available range is 70 - 100. The default value is 85. To disable the adaptive reaper, set the low-water mark to 100.

auto-last-hop

Specifies that the system automatically maps the last hop for pools. The default value is enabled.

default-vs-syn-challenge-threshold

Specifies the default value of per-virtual server SYN Cookie activation threshold per chassis. The default value is infinite. The valid range is 128 - 1024K or infinite (encoded as 0).

global-flow-eviction-policy

Specifies the flow eviction policy to use when approaching memory usage limits. The settings in the policy determine the adaptive reaper high and low water marks, and help determine which client connections to terminate when memory limits have exceeded the "low-water" threshold in the eviction policy. The settings help mitigate the effects of a denial-of-service attack.

global-syn-challenge-threshold

Specifies the default value of the global SYN Cookie activation threshold per TMM. The default value is 64K. The valid range is 2048 - 4096K or infinite (encoded as 0).

syncookies-threshold

This option is deprecated in version 13.0.0 and is replaced by default-vs-syn-challenge-threshold. Specifies the number of new or untrusted TCP connections that can be established before the system activates the SYN Cookies authentication method for subsequent TCP connections. The default value is 16384.

vlan-keyed-conn

Enables or disables VLAN-keyed connections. You use VLAN-keyed connections when traffic for the same connection must pass through the system several times, on multiple pairs of VLANs (or in different VLAN groups). The default value is enabled.

vlan-syn-cookie

Enables or disables the hardware per-VLAN SYN cookie protection on platforms with supported firmware. The default value is enabled.

BIG-IP 2016-09-06 ltm global-settings connection(1)

ltm global-settings general

NAME

general - Configures the general properties for the BIG-IP(r) and VIPRION(r) local traffic management systems.

MODULE

ltm global-settings

SYNTAX

Configure the general component within the ltm global-settings module using the syntax shown in the following sections.

MODIFY

modify general

options:

gratuitous-arp-rate [integer value: 0 ~ 2147483647]
l2-cache-timeout [integer value: 0 ~ 2147483647]
maintenance-mode [disabled | enabled]
mgmt-auto-lasthop [disabled | enabled]
share-single-mac [unique | global | vmw-compat]
snat-packet-forward [disabled | enabled]

DISPLAY

list general

list general [option name]

show running-config general

show running-config general [option name]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the general component to modify how the system processes local traffic.

EXAMPLES

modify general maintenance-mode enabled

Places the Local Traffic Manager system in maintenance mode.

list general

Displays the general properties of the local traffic management system.

OPTIONS

gratuitous-arp-rate

Specifies how fast gratuitous ARPs can be sent. If it is 0, then gratuitous ARPs are sent without pause. Otherwise, it specifies how many gratuitous ARPs can be sent every second. The default value is 0. The range is 0 (zero) to 2147483647."

l2-cache-timeout

Specifies, in seconds, the amount of time that records remain in the Layer 2 forwarding table, when the MAC address of the record is no longer detected on the network.

The default value is 300 seconds. The range is 0 (zero) to 2147483647 seconds.

maintenance-mode

Specifies, when enabled, that the unit is in maintenance mode. In maintenance mode, the system stops accepting new connections and slowly finishes off existing connections.

The default value is disabled.

mgmt-auto-lasthop

Specifies, when enabled, that auto-lasthop should be used for incoming traffic to the management port. That means return traffic will be sent to the MAC address that originated the traffic rather than looked up using the routing and ARP/NDP tables.

The default value is enabled.

share-single-mac

Specifies the Media Access Control address (MAC address) that the system assigns to a VLAN. The default value is unique, which indicates that a VLAN uses a unique MAC address from the pool of mac addresses assigned to each hardware platform. The global value indicates that all of the VLANs on the system use the same MAC address. The vmw-compatible value indicates that the MAC address of a vlan is allocated in a manner compatible with VMware(tm) vSwitch, and restricts vlans to a single interface, with no trunks allowed. Changing the value of this feature requires a manual restart of all TMOS daemons.

snat-packet-forward

Enables or disables SNAT packet forwarding. The default value is enabled.

BIG-IP 2017-06-28 ltm global-settings general(1)

ltm global-settings rule

NAME

rule - Configures the iRule properties for the BIG-IP(r) and VIPRION(r) local traffic management systems.

MODULE

ltm global-settings

SYNTAX

Configure the rule component within the ltm global-settings module using the syntax shown in the following sections.

MODIFY

modify rule

options:

rule-aborted-log-ratio [integer value: 0 ~ 2147483647]

DISPLAY

list rule

list rule [option name]

show running-config rule

show running-config rule [option name]

options:

all-properties

non-default-properties

one-line

DESCRIPTION

You can use the rule component to modify how the system processes iRule conditions.

EXAMPLES

modify rule rule-aborted-log-ratio 5

Instructs the system to generate one log message for every 5 aborted iRule executions.

list rule

Displays the iRule properties of the local traffic management system.

OPTIONS

rule-aborted-log-ratio

Specifies the ratio of log messages generated when iRule executions are aborted. If set to 1, every aborted execution is logged. If set higher, every n aborted executions will result in one log message. If set to 0, no message is generated when executions are aborted.

Note, this setting is per TMM across all iRules; the implication is that if the value is set to a number greater than 1 in order to reduce the rate of log messages, all aborted rule executions are affected.

If there are multiple rules that could cause this condition where one rule is causing an excessive amount of such logs (and this condition is considered non important), and another rule where this condition signifies a problem, and the ratio is set to a large number, the occurrence of this condition for the second rule could be lost.

The default value is 1. The range is 0 (zero) to 2147483647.

BIG-IP 2017-02-10 ltm global-settings rule(1)

ltm global-settings traffic-control

NAME

traffic-control - Configures the global settings that pertain to traffic control for the BIG-IP(r) and VIPRION(r) local traffic management systems.

MODULE

ltm global-settings

SYNTAX

Configure the traffic-control component within the ltm global-settings module using the syntax shown in the following sections.

MODIFY

modify traffic-control

options:

accept-ip-options [disabled | enabled]
accept-ip-source-route [disabled | enabled]
allow-ip-source-route [disabled | enabled]
continue-matching [disabled | enabled]
max-icmp-rate [integer value: 0 ~ 2147483647]
max-reject-rate [integer value: 1 ~ 1000]
max-reject-rate-timeout [integer value: 0 ~ 300]
min-path-mtu [integer value: 68 ~ 1500]
path-mtu-discovery [disabled | enabled]
port-find-linear [integer value: 0 ~ 61439]
port-find-random [integer value: 0 ~ 1024]
port-find-threshold-warning [disabled | enabled]
port-find-threshold-trigger [integer value: 1 ~ 12]
port-find-threshold-timeout [integer value: 0 ~ 300]
reject-unmatched [disabled | enabled]

DISPLAY

list traffic-control

list traffic-control [option name]

show running-config traffic-control

show running-config traffic-control [option name]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the traffic-control component to modify how the system processes local traffic.

EXAMPLES

modify traffic-control accept-ip-options enabled

Specifies that the system accepts IPv4 packets with IP options.

list traffic-control

Displays the local traffic control global settings.

OPTIONS

accept-ip-options

Specifies whether the system accepts IPv4 packets with IP options. The default value is disabled.

accept-ip-source-route

Specifies whether the system accepts IPv4 packets with IP source route options that are destined for Traffic Management Microkernel (TMM). The default value is disabled.

To enable this option, you must also enable the accept-ip-options option.

allow-ip-source-route

Specifies whether the system allows IPv4 packets with IP source route options enabled to be routed through Traffic Management Microkernel (TMM). The default value is disabled.

To enable this option, you must also enable the accept-ip-options option.

continue-matching

Specifies whether the system matches against a less-specific virtual server when the more-specific one is disabled. When continue-matching is disabled, the default value, the system drops connections that request a disabled virtual server. In this case, the system rejects or drops packets depending on the value of the reject-unmatched option.

max-icmp-rate

Specifies the maximum rate per second at which the system issues Internet Control Message Protocol (ICMP) errors. The default value is 100 errors per second. The range is from 0 (zero) to 2147483647 errors per second. This option is useful for preventing ICMP-message storms.

max-reject-rate

Specifies the maximum rate per second at which the system issues reject packets (TCP RST or ICMP port unreachable). The default value is 250 per second. The range is from 1 to 1000 per second.

max-reject-rate-timeout

Specifies the time in seconds which the system ignores icmp port unreachable and tcp rst ratelimits on becoming active after a failover. The default value is 30 seconds. The range is from 0 to 300 seconds.

min-path-mtu

Specifies the minimum packet size that can traverse the path without suffering fragmentation, also known as path Maximum Transmission Unit(MTU). The default value is 296. The range is from 68 to 1500.

path-mtu-discovery

Specifies, when enabled, that the system discovers the maximum transmission unit (MTU) that it can send over a path, without fragmenting TCP packets. The default value is enabled.

port-find-linear

Specifies the maximum of ports to linearly search for outbound connections. The default value is 16. The range is from 0 to 61439.

port-find-random

Specifies the maximum of ports to randomly search for outbound connections. The default value is 16. The range is from 0 to 1024.

port-find-threshold-warning

Specifies if the ephemeral port-exhaustion threshold warning is to be monitored. The default is enabled.

port-find-threshold-trigger

Specifies the threshold warning's trigger which is the value of random port attempts when attempting to find an unused outbound port for a connection. The default is 8. The valid range is 1 - 12.

port-find-threshold-timeout

Specifies the threshold warning's timeout. This is the time in seconds since the last trigger value was hit and will drop the tuple if not hit. The default is 30 (1/2 minute) with range from 0 - 300.

reject-unmatched

Specifies, when enabled, that the system returns a TCP RESET or ICMP_UNREACH packet if no virtual servers on the system match the destination address of the incoming packet. When this option is disabled, the system silently drops the unmatched packet. The default value is enabled.

Itm ifile

NAME

ifile - Configures an iFile.

MODULE

Itm

SYNTAX

Configure the iFile component within the Itm module using the syntax shown in the following sections.

CREATE/MODIFY

create ifile [name]

modify ifile [name]

options:

app-service [[string] | none]

description [string]

file-name [ifile file object name]

edit ifile [[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DISPLAY

list ifile

list ifile [[name] | [glob] | [regex]] ...]

show running-config ifile

show running-config ifile [[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DELETE

delete ifile [name]

DESCRIPTION

You can use the ifile component to configure an iFile. The iFile can then be referenced from an iRule, to allow loading an external file into an iRule.

EXAMPLES

create ifile my_ifile file-name ifile_file_object_name

Creates an iFile named my_ifile, that gets its contents from the file object ifile_file_object_name.

list ifile all-properties

Displays all of the properties of all of the iFiles.

delete ifile my_ifile

Deletes the iFile named my_ifile.

OPTIONS

app-service

Specifies the name of the application service to which the iFile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the iFile. Only the application service can modify or delete the iFile.

description

User defined description.

file-name

The name of the iFile File Object that this iFile uses.

SEE ALSO

```

```
show running-config lsn-log-profile [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
non-default-properties
one-line
```

DELETE

```
delete lsn-log-profile [name | all]
```

DESCRIPTION

A LSN log profile allows fine grain control of the logging for LSN translation events. When attached to an LSN pool, you can control the events to enable logging, and the elements in the log entry.

EXAMPLES

```
create ltm lsn-log-profile my_lsn_log_profile end-inbound-session { action enabled } end-outbound-session {
action enabled }
```

Creates the LSN log profile `my_lsn_log_profile` that generates log entries for both inbound and session when the translation session ends.

```
delete lsn-log-profile my_lsn_log_profile
```

Deletes the LSN log profile named `my_lsn_log_profile`.

OPTIONS

app-service

Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

csv-format

When enabled, use CSV log format for log entries. The default value is disabled.

events

The type of LSN translation events available for logging control.

start-outbound-session

Event for start of outbound translation session, when the outbound flow is created.

end-outbound-session

Event for end of outbound translation session, when the outbound flow is deleted.

start-inbound-session

Event for start of incoming connection to a translated address.

end-inbound-session

Event for end of incoming connection to a translated address.

quota-exceeded

Event for when client exceeded allocated resource limit.

errors

Event for when LSN encountered errors while attempting translation for clients.

subscriber-id

When enabled, the subscriber ID associated with a subscriber IP address will be printed in the logs.

action

Specify the logging action to be taken when a particular event is encountered.

enabled

Logging is enable for the event, whether translation is from the primary pool member or backup pool member.

backup-allocation-only

Logging is enable for the event, when translation is take from backup pool member only.

disabled

Logging is disable for the event.

elements

Optional elements that can be added to the log message.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

DESCRIPTION

A large-scale NAT (LSN) pool is a set of networks and port numbers that the BIG-IP system uses as public-side addresses and ports. When you assign an LSN pool to a virtual server, the virtual server's clients have their private addresses (and/or ports) translated to a public address and/or port from the LSN pool. The public-side addresses and ports in the LSN pool are called translation addresses and ports.

EXAMPLES

```
create lsn-pool my_lsn_pool1 mode napt persistence { mode address-port timeout 600 } members add {
10.10.10.0/24 10.10.20.0/24 } translation-port-range 4000:5000 client-connection-limit 100
```

Creates the LSN pool my_lsn_pool1 that contains the translation addresses in the range of (members) 10.10.10.0/24 and 10.10.20.0/24, translation port range 4000-5000, with a client connection limit of 100 connections per client. The translated address and port are persisted for 600 seconds. This LSN pool operates in NAPT mode (Network Address and Port Translation mode), which is the default mode if not specified.

```
delete lsn-pool my_lsn_pool1
```

Deletes the LSN pool named my_lsn_pool1.

OPTIONS

```
app-service
```

Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot

modify or delete this object. Only the application service can modify or delete this object.

backup-members

Specifies translation IP addresses available in the backup pool which is used by DNAT translation mode if DNAT mode translation fails and falls back to NAT mode. This is a collection of IP prefixes with their prefix lengths.

client-connection-limit

The maximum number of simultaneous translated connections a client or subscriber is allowed to have.

description

User defined description.

egress-interfaces

The set of interfaces on which the source address translation is allowed or disallowed. If egress-interfaces-enabled is specified, the source address translation is allowed only on the specified set of interfaces. If egress-interfaces-disabled is specified, source address translation is disabled on specified interfaces.

egress-interfaces-disabled

Source address translation is not allowed on the interfaces specified in the egress-interfaces set.

egress-interfaces-enabled

Source address translation is allowed on the interfaces specified in the egress-interfaces set.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hairpin-mode

Enable or disable hairpinning for incoming connections.

When a client sends a packet to another client in the same private network, hairpin mode sends the packet directly to the destination client's private address; the BIG-IP system immediately translates the packet's public-side destination address. Rather than going out to the public network and coming back later for translation, the packet takes a hairpin turn at the BIG-IP device.

icmp-echo

Enable or disable ICMP echo on translated addresses.

inbound-connections

Modifies the inbound-connection mode for incoming connections to translation endpoints. A translation endpoint is the public-side address and port (X':x') for a private-side address (X:x). You can allow one of three algorithms for managing inbound connections:

Automatic

creates inbound mappings automatically from outbound traffic and allows inbound connections. Consider an outbound mapping from X:x to X':x'. If a connection comes from X:x through X':x', the BIG-IP system automatically creates a reverse mapping from X':x' back to X:x. A public-side station can respond through the X':x' address. This allows the BIG-IP system to provide Endpoint Independent Filtering (EIF) as defined in section 5 of RFC 4787
().

Explicit

only allows inbound connections for mappings that are explicitly created by another party, such as iRules or a PCP request. For example, if a PCP request creates a mapping of X:x to X':x' and the client at X:x uses it, an external caller can respond to the client through X':x'. However, if a client at M:m automatically makes a NAT'ed connection through M':m', the BIG-IP does not support an inbound connection from M':m' back to M:m.

Disabled

disables inbound connections to translation end-points (X':x'). If there is a mapping of X (a private-side IP address) to X' (a public-side IP), connections can only go out from X through X'. If a public-side recipient tries to answer at the client's public-side X' address, the BIG-IP system does not map X' back to X. The inbound connection never happens.

Port Control Protocol (PCP) is not supported if you use this setting.

log-publisher

Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile

Specify the name of the LSN log profile which controls the logging of translation events. See help ltm lsn-log-profile for more details on the logging profile sub-system. Use the "ltm lsn-log-profile profile" component to set up a LSN log profile.

members

Specifies the set of translation IP addresses available in the pool. This is a collection of IP prefixes with their prefix lengths. All public-side addresses come from the subnets you enter in this property.

mode Specifies which kind of translation address mapping is performed when an address is translated. Available options are NAT, Deterministic, and PBA.

NAPT (Network Address Port Translation) assigns translation addresses and ports in round-robin fashion. The algorithm first cycles through translation addresses and then through translation ports.

Deterministic (DNAT) is a reversible translation method. A given client address and port always translates to a particular public address and port from the LSN pool. This method has the following restrictions:

it is only available for NAT44 translations,
it does not support connections through DS-Lite tunnels,
subscriber connections must be received over a VLAN with the property, cmp-hash, set to "source ip,"
the egress to the Internet must be over a VLAN with the property, cmp-hash, set to "dest ip,"
any virtual server ("ltm virtual") that uses this LSN pool must have a source property set to an IP prefix containing fewer than 231 addresses. For example, the source cannot be 0.0.0.0/0.

PBA (Port Block Allocation) assigns 'blocks' of the translation addresses and ports to individual clients. All client connections are restricted to the allocated port blocks. Only block allocations and deallocations are logged in order to reduce the volume of logs.

subscriber connections must be received over a VLAN with the property, cmp-hash, set to "source ip,"
the egress to the Internet must be over a VLAN with the property, cmp-hash, set to "dest ip,"

You can access your VLAN configurations through the "net vlan" component. You can find the VLANs used by your virtual server by showing or listing the "ltm virtual" component.

name Specifies a unique name for the lsn-pool component. This option is required for the commands create, delete, and modify.

persistence
Configure the persistence settings for LSN translation entries. Persistence is the preservation of a public-side IP address for a client from session to session.

persistence.mode
Configure the persistence mode for LSN translation entries. You can enter address, address-port, or none.

address
causes the BIG IP software to attempt to keep the IP address persistent but not necessarily the port. If a client's private IP address:port combination is X:x, it's public-side address may be X':a in one session, X':b in the next session, X':c in a third session, and so on.

address-port
causes the BIG IP software to attempt to keep the IP address and port persistent. If a client's private IP address:port combination is X:x, and it's public-side address is X':x' in the first session, it remains X':x' in all future sessions.

This is called "Endpoint Independent Mapping" in RFC 4787 ().

This is the only supported setting for PCP, which you configure with the pcp property.

none prevents the BIG IP software from attempting any IP address or port persistence. An address:port combination of X:x is never guaranteed to have the same public-side address or port in two sessions.

persistence.timeout
After the most-recent session where address:port X:x translated to X':x' on the public side, a timer begins. If the timer expires before X:x has another session, X' or x' may be used as the public side of another address:port. Use this parameter to set the timeout (in seconds) for address and port persistence.

pcp A Port Control Protocol (PCP) client can set (or at least learn) its own translation (public-side) IP address and/or port. It can also set the address and/or port of a third-party client. PCP is defined in RFC 6887 (see).

pcp.profile
Specifies the PCP profile to use for this LSN pool. This PCP profile defines the settings to use for communication with PCP clients. Use the create ltm profile pcp command to create a new PCP profile.

PCP requires a profile (defined with this property) and either a pcp.selfip or a pcp.dslite tunnel where clients can send their PCP requests.

If you remove this profile option, you must specifically remove any pcp.selfip or pcp.dslite tunnel, too.

pcp.selfip
Specifies the PCP Server self-IP address for this LSN pool. The virtual server's clients send their PCP packets to this address. Use the create net self command to create a self-IP address, then use that address for this parameter. Choose a self-IP address in a VLAN that is reachable by the virtual server's clients.

pcp.dslite
Specifies a DS-LITE tunnel for PCP packets. Whenever a client sends a PCP packet through this tunnel, the BIG-IP device uses the PCP profile you choose with the pcp.profile property.

A DS-LITE tunnel places each IPv4 packet into the payload of an IPv6 packet. The IPv6 packet carries the IPv4 packet between customer equipment and the BIG-IP system, which then removes the IPv4 packet, uses NAT to translate its IPv4 addresses, and sends it to its destination.

You cannot use this property if the mode property is set to Deterministic.

port-block-allocation
Configures the port block settings for PBA mode.

port-block-allocation.block-idle-timeout
Configures the time after the last connection using the block is freed that the block assignment expires.

The default value is 3600 seconds.

port-block-allocation.block-lifetime

Configures the timeout after which the block is no longer used for new port allocations. The block becomes a zombie block. The default is 0 which corresponds to an infinite timeout.

port-block-allocation.block-size

Configures the number of ports in a block. The default value is 64.

port-block-allocation.client-block-limit

Configures the number of blocks that can be assigned to a single subscriber IP address. The default value is 1.

port-block-allocation.zombie-timeout

Configures the timeout after which connections using the zombie block are killed. After connections are killed zombie block is freed after port-block-allocation.block-idle-timeout. This parameter is unused unless the port-block-allocation.block-lifetime is set. The default value is 0 which corresponds to infinite timeout.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

route-advertisement

Specifies whether route advertisement is enabled or disabled for translated IP addresses.

translation-port-range

Specifies the range of port numbers available for use with translation IP addresses.

failure-cause

Displays the failure-cause table for this lsn-pool. There are many different possible failure causes and only the failures that occur will be displayed. This information can be useful for determining why a translation is failing.

ltm message-routing diameter peer

NAME

peer - Configures a peer for routing Diameter protocol messages.

MODULE

ltm message-routing diameter

SYNTAX

Configure the peer component within the ltm message-routing diameter module using the syntax shown in the following sections.

CREATE/MODIFY

create peer [name]

modify peer [name]

options:

app-service [[string] | none]

auto-initialization [enabled | disabled]

auto-initialization-interval [integer]

connection-mode [per-peer | per-blade | per-tmm | per-client | per-client-per-blade |

per-client-per-tmm | per-peer-alternate-tmm | per-client-alternate-tmm]

description [string]

number-connections [integer]

pool [name]

ratio [integer]

transport-config [transport-config]

edit peer [[[name] | [glob] | [regex]] ...]

options:

all-properties

DISPLAY
list peer
list peer [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 one-line

DELETE
delete peer [name]

DESCRIPTION

You can use the peer component to manage a named Diameter peer. A peer specifies the pool for the Diameter router to use as the destination for Diameter routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

EXAMPLES

```
create peer my_peer { pool my_pool transport { type virtual name my_vip }
```

Creates a Diameter peer named my_peer which uses the settings of my_vip to establish a connection with a pool member from pool my_pool.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auto-initialization

If enabled, the BIGIP will automatically create outbound connections to the active pool members in the specified pool using the configuration of the specified transport-config. For auto-initialization to attempt to create a connection, the peer must be included in a route that is attached to a router instance. For each router instance that the peer is contained in, a connection will be initiated. The auto-initialization logic will verify at a configurable interval if the a connection exists between the BIG-IP and the pool members of the pool. If a connection does not exist, it will attempt to reestablish one. The default is disabled.

auto-initialization-interval

Specifies the interval (in milliseconds) that attempts to initiate a connection occur. Valid ranges are from 500ms to 65535ms. The default is 5000ms.

connection-mode

Specifies how the number of connections per host is limited. Note a host (specified in the referred pool) may exist more than one peer object, and those peer objects may have different settings for connection-mode and number_connections. Thus, these settings specify how messages routed through this peer are distributed between a set of connections, not the maximum number of connections to a specified host. The default value is per-peer.

per-blade

Specifies the number of connections to a remote host per blade in the cluster.

per-client

Specifies the number of connections to a remote host per client connection.

per-client-per-blede

Specifies the number of connections to a remote host per client connection for each blade.

per-client-per-tmm

Specifies the number of connections to a remote host per client connection for each tmm.

per-peer

Specifies the number of connections to a remote host.

per-peer-alternate-tmm

Specifies the number of connections to a remote host. Any new connections will be opened on an alternate TMM to spread CPU usage.

per-client-alternate-tmm

Specifies the number of connections to a remote host per client connection. Any new connections will be opened on an alternate TMM to spread CPU usage.

per-tmm

Specifies the number of connections to a remote host per TMM in the system.

description

User defined description.

number-connections

Specifies the distribution of connections between the BIG-IP system and a remote host. The default value is 1.

pool Specifies the name of the pool to which the Diameter parser routes messages.

ratio

Specifies the ratio the Diameter router uses to select a peer from a list of peers for the ltm message-routing diameter route. The default value is 1.

transport-config

Specifies the name of the transport configuration (ltm message-routing diameter transport-config) the message router uses to create an outgoing connection.

DELETE

delete router [name]

DESCRIPTION

You can use the router component to manage a Diameter router profile.

EXAMPLES

```
create router my_router_profile defaults-from router
```

Creates a Diameter router profile named my_router_profile using the system defaults.

```
create router my_router_profile routes add { route1 route2 }
```

Creates a Diameter profile named my_router_profile with two static routes.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

associate-clientside-to-poolmember

If enabled, the configured routes will be scanned for a pool member that matches a new clientside connection. If found, the clientside connection will be associated with the pool member allowing the activity on the clientside connection to be included with the activity of the pool member. The default value is disabled.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is router.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ha-message-sweeper-interval

Specifies the maximum time in milliseconds that a message will be held on the standby device as it waits for the active device to route the message. Messages on the standby device held for longer then the configurable sweeper interval, will be dropped. The default value is 1000 milliseconds.

ignore-peer-port

If selected (enabled), any connection from a configured peer will be suitable for routing a message to, regardless of its remote port number. The default value is enabled.

irule-scope-message

If set to yes, iRule events are scoped to the message executing (each message has its own execution context). This allows multiple messages to process iRules concurrently without waiting for commands from other messages. If set to no, all Diameter iRule events are scoped to the connection flow (that is all share a single execution context per flow) and therefore are forced to execute one at a time even though they are processing independent messages (this is the legacy mode). The default value is no. Some existing iRules might need to be adjusted to use the per-message scope.

max-pending-bytes

Limits the number of bytes contained within messages held pending while waiting for a connection to a peer. If irule-scope-message is set to yes, also limits the number of bytes contained within messages that may concurrently process iRule events. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator. The default value is 65536.

max-pending-messages

Limits the number of messages held pending while waiting for a connection to a peer. If irule-scope-message is set to yes, also limits the number of messages that may concurrently process iRule events. Once the limit is reached, any additional messages to the peer will be flagged as undeliverable and returned to the originator. The default value is 64.

max-retries

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

mirrored

If enabled, connection created on the active device of the traffic-group specified, will be mirrored on the standby device. Messages processed on the active device will also be mirrored and perform equivalent processing on the standby device.

partition

Displays the administrative partition within which the component resides.

per-peer-stats

If enabled, the profile specific statistics will be captured for each pool member. The default value is disabled.

pending-request-sweeper-interval

Specifies the interval in milliseconds between passes of the pending request sweeper. The pending request sweeper will delete pending request entries that are older than twice the transaction-timeout. If set to 0 the sweeper will be disabled. The default value is 60000ms.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

routes

Specifies a list of static routes. The ordering of the route entries is insignificant.

supported-applications

Defines the list of application ID values that will be supported. If a message is received with an Auth-Application-ID or Acct-Application-ID AVP that does not match any of the values in this list, it will be dropped and the connection will be reset. A value of 0 will match all application IDs. The default value is none.

traffic-group

Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

transaction-timeout

Specifies the maximum time (in seconds) between a request and its response. A provisional response restarts the timer. The default value is 10 seconds. Note: This may not affect all transactions. The scenarios where the system waits for response (eg. a final response for REGISTER request), are impacted by dropping any persistent data maintained for the request.

use-local-connection

Enables or disables a preference for local connections established by the ingress TMM over connections established by other TMM's when selecting the egress connection to destination peer. By default this attribute is enabled.

DELETE

delete session [name]

DESCRIPTION

You can use the session component to manage a Diameter session profile.

EXAMPLES

create session my_session_profile defaults-from session

Creates a Diameter session profile named my_session_profile using the system defaults.

create session my_session_profile { reset-on-timeout disabled }

Creates a Diameter profile named my_session_profile that will not reset the connection when watchdog failure exceed maximum-watchdog-failures.

OPTIONS

acct-application-id

Specifies as an integer the Accounting identifier for specific application, as specified in RFC 6733.

This value will be appended at the end of array-acct-application-id in capabilities exchange messages if it doesn't already exist in it.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

array-acct-application-id

Specifies as a whitespace separated list of integers the Accounting identifier(s) for specific

application(s), as specified in RFC 6733.

array-auth-application-id

Specifies as a whitespace separated list of integers the Authentication and Authorization identifier(s) for specific application(s), as specified in RFC 6733.

array-retransmission-result-codes

Specifies as a whitespace separated list of integers that define result codes that if received in an answer message will trigger retransmission.

auth-application-id

Specifies as an integer the Authentication and Authorization identifier for specific application, as specified in RFC 6733. This value will be appended at the end of array-auth-application-id in capabilities exchange messages if it doesn't already exist in it.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is `diametersession`.

description

User defined description.

dest-host-rewrite

Specifies the destination host AVP to which the specified value on the egress will be rewritten.

dest-realm-rewrite

Specifies the destination realm AVP to which the specified value on the egress will be rewritten.

discard-unroutable

When selected (enabled), messages that do not match any known route will be silently discarded. When disabled, unroutable messages are routed back to the connection where they came from. The default value is enabled.

disconnect-peer-action

Specifies the state of peer based on Disconnect Peer Request received from peer. The default value is none. The options are:

none Terminates connection on receiving DPR. Connection can be re-established between peer and BIGIP.

disable

A node continues to process persistent and active connections. It can accept new connections only if the connections belong to an existing persistent session.

force-offline

A node allows existing connections to time out, but no new connections are allowed.

egress-critical-message-rate-limit

If the number of messages egressed to a peer (pool member) in a second exceeds the provided limit, a SNMP trap, The number of messages sent to a peer is above the critical rate limit threshold, will be sent. If the number of messages egressed to a peer (pool member) in a second drops below the provided limit, a SNMP trap, The number of messages sent to a peer is back under the critical rate limit threshold, will be sent. A value of 0 will disable the SNMP trap. The default value is 0.

egress-major-message-rate-limit

If the number of messages egressed to a peer (pool member) in a second exceeds the provided limit, a SNMP trap, The number of messages sent to a peer is above the major rate limit threshold, will be sent. If the number of messages egressed to a peer (pool member) in a second drops below the provided limit, a SNMP trap, The number of messages sent to a peer is back under the major rate limit threshold, will be sent. A value of 0 will disable the SNMP trap. The default value is 0.

dynamic-route-insertion

Specifies whether dynamic route insertion is enabled for this Diameter session profile. If enabled, routes will be added to route incoming messages toward the connected peer, by its origin-host. The default value is disabled.

dynamic-route-lookup

Specifies whether dynamic route lookup is enabled for this Diameter session profile. If enabled, the destination-host of messages received via this profile will be used to find a route added from connections with dynamic-route-insertion enabled. The default value is disabled.

dynamic-route-timeout

Specifies how long after a connection is closed will the dynamic route be deleted from the route table. The default value is 300

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

handshake-timeout

Specifies the number of seconds before the peer handshake times out. The default is 10 seconds.

host-ip-address

Specifies the value that will be used in the Host-IP-Address AVP sent in Capabilities-Exchange-Request and Capabilities-Exchange-Answer messages. When unset (default), the Diameter router will use the virtual server's IP address.

ingress-critical-message-rate-limit

If the number of messages received from a peer (pool member) in a second exceeds the provided limit, a

SNMP trap, The number of messages from a peer is above the critical rate limit threshold, will be sent. If the number of messages received from a peer (pool member) in a second drops below the provided limit, a SNMP trap, The number of messages from a peer is back under the critical rate limit threshold, will be sent. A value of 0 will disable the SNMP trap. The default value is 0.

ingress-major-message-rate-limit

If the number of messages received from a peer (pool member) in a second exceeds the provided limit, a SNMP trap, The number of messages from a peer is above the major rate limit threshold, will be sent. If the number of messages received from a peer (pool member) in a second drops below the provided limit, a SNMP trap, The number of messages from a peer is back under the major rate limit threshold, will be sent. A value of 0 will disable the SNMP trap. The default value is 0.

loop-detection

Specifies whether loop detection will be performed on requests received by this session profile. The default value is enabled. When set, the Diameter session profile will reject messages that it has already seen. See RFC 6733 section 6.1.3.

max-message-size

Specifies the maximum number of bytes acceptable in a Diameter message. The default value is 0 which indicates that there is no message size restriction for this session. Note: Message size is also restricted by the database variable "diameter.message.maxlen"; the smallest value is used as a maximum. Messages exceeding this size are silently discarded.

max-retransmissions

Specifies the maximum number of retransmissions of a Diameter message. The default value is 0.

max-watchdog-failures

Specifies the maximum number of device watchdog failures that the traffic management system can receive before it tears down the connection. After the system receives this number of device watchdog failures, it closes the connection. The default value is 1.

origin-host

Specifies the identifier of the originating server in the form siteserver.f5.com. Must specify the origin-host.

origin-host-rewrite

Specifies the value to rewrite to the Origin-Host AVP on egress.

origin-realm

Specifies the Origin-Realm AVP data. Must specify the origin-realm.

origin-realm-rewrite

Specifies the value to rewrite to the Origin-Realm AVP on egress.

peer-delay-critical-limit

If the average peer delay exceeds the provided limit, a SNMP trap, PeerHealth exceeds critical, will be generated. If the average peer delay drops below the provided limit, a SNMP trap, PeerHealth back under critical, will be generated. A value of 0 will disable the SNMP trap. The default value is 0.

persist-avp

Specifies the Diameter AVP that is used for persistence. The format is avp[index] for a single AVP or a[x]:b[y]:c[z]:d[w] for a grouped AVP. There may be at most 4 AVPs in a group. The AVP name is used as the session-key; it may be an ASCII string or numeric ID in the range 1 to 4294967295 (AVP code can be specified instead of AVP name). Note: The default value is "SESSION-ID[0]". A grouped-avp can be specified with the following syntax: grouped-avp-name[index]:nested-avp1[index1]:nested-avp2[index2], where "nested-avp1" and "nested-avp2" are the AVPs in the grouped AVP.

persist-timeout

Specifies the timeout value (in seconds) for persistence entries. The default value is 180. Note: Its recommended to have the persist-timeout to be greater than transaction timeout, specified in the Diameter router configuration, as the lesser of the two is used when creating the persist record on receiving of the first Diameter request message. Upon receiving of the response for the first Diameter request message the persistence record is updated with the persist-timeout value. For any subsequent responses received the persist timeout is updated for the persist record.

persist-type Specifies the type of the persistence. The options are:

avp Persist based on avp in the message.

custom

Persist based on a custom key set using iRule.

none Persistence is disabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout

When enabled, the system resets the connection when the number of watchdog failures exceeds the value of max-watchdog-failures. The default value is enabled.

respond-unroutable

When selected (enabled), messages that do not match any known route will be transformed into an error answer message and sent to the originator of the request. When disabled, unroutable request messages are routed back to the connection where they came from. The default value is disabled.

retransmission-action

Specifies the action performed when retransmission has been triggered for a request message. The options are:

disabled

Retransmission is disabled. This is the default action.

busy An answer message is generated with a TOO_BUSY result code and returned to the originator of the request.

unable

An answer message is generated with a UNABLE_TO_DELIVER result code and returned to the originator of the request.

retransmit

The request message will be retransmitted.

retransmit-alternate

The request message can be retransmitted to a different pool member.

retransmission-queue-limit-high

Specifies the high watermark for the retransmission queue (in percentage). If the retransmission queue exceeds this limit the transport window will begin closing. A value of 0 will disable closing the transport window. Valid range from 0 to 100. The default value is 90.

retransmission-queue-limit-low

Specifies the low watermark for the retransmission queue (in percentage). If the retransmission queue drops below this limit the transport window will reopen. Valid range from 0 to 100. The default value is 60.

retransmission-queue-max-bytes

Specifies the maximum number of bytes that can be stored in a connections retransmission queue. A value of 0 will disable this limit. The default value is 131072 bytes.

retransmission-queue-max-messages

Specifies the maximum number of messages that can be stored in a connections retransmission queue. A value of 0 will disable this limit. The default value is 1024 messages.

retransmission-timeout

Specifies the timeout for retransmission of a Diameter request (in seconds). A value of 0 will disable the retransmission timer. The default value is 10 seconds.

route-unconfigured-peers

When enabled, all connections will be allowed. When disabled, connections from peers whose IP addresses cannot be found in a statically configured route will be rejected. The default value is enabled.

vendor-id

Specifies the vendor identification number assigned to your diameter server by the Internet Assigned Numbers Authority (IANA). The default value is 3375.

vendor-specific-vendor-id

Specifies the vendor ID number that will be sent in Vendor-Specific-Application-ID AVPs. A value of 0 disables the feature. If this value is set, exactly one of either vendor-specific-acct-app-id or vendor-specific-auth-app-id must also be specified. The default value is 0.

vendor-specific-acct-app-id

Specifies the accounting application ID number that will be sent in Vendor-Specific-Application-ID AVPs. A value of 0 disables the feature. If this value is set, vendor-specific-vendor-id must be set and vendor-specific-auth-app-id must be unset. The default value is 0.

vendor-specific-auth-app-id

Specifies the authentication/authorization application ID number that will be sent in Vendor-Specific-Application-ID AVPs. A value of 0 disables the feature. If this value is set, vendor-specific-vendor-id must be set and vendor-specific-acct-app-id must be unset. The default value is 0.

watchdog-timeout

Specifies the watchdog timeout in seconds. This setting specifies the number of seconds that a connection is idle before the device watchdog request is sent. A value of 0 means BIG-IP will not send a device watchdog request to either client or server side. The default value is 10 seconds.

Itm message-routing diameter route

NAME

route - Configures a static route for use in Diameter protocol message routing.

MODULE

Itm message-routing diameter

SYNTAX

Configure the route component within the Itm message-routing diameter module using the syntax shown in the following sections.

CREATE/MODIFY

create route [name]

modify route [name]

options:

app-service [[string] | none]

application-id [integer]

description [string]

destination-realm [[string] | none]

origin-realm [[string] | none]

peer-selection-mode [ratio | sequential]

peers { [none] | [peer_name ...] }

virtual-server [virtual-server_name]

edit route [[[name] | [glob] | [regex]] ...]

options:

all-properties

DISPLAY

list route

list route [[[name] | [glob] | [regex]] ...]

show running-config route

show running-config route [[[name] | [glob] | [regex]] ...]

options:

all-properties

one-line

DELETE

delete route [name]

DESCRIPTION

You can use the route component to define origin and destination realms, virtual server, peers, and peer selection mode of a message routing Diameter static route.

EXAMPLES

create route my_route

Creates a route instance named my_route using the system defaults.

create route my_route peers { peer1 peer2 }

Creates a route instance named my_route that will use two peers for forwarding messages.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

application-id

Specifies the application-id to match in the Diameter message. Default value 0 matches every application-id.

description

User defined description.

destination-realm

When specified, match the Destination-Realm AVP value in the message. Default value of "" specifies all destination-realms may be routed.

origin-realm

When specified, match the Origin-Realm AVP value in the message. Default value of "" specifies all origin-realms may be routed.

peer-selection-mode

Specifies the mode of selecting a peer from a list of peers. The options are:

ratio

Peers are selected based on their weights in comparison with other peers.

sequential

Peers are selected in the order listed. All traffic will route the first peer unless all pool

members in the peer are marked down.

peers

Specifies an ordered list of peers to use for forwarding messages.

virtual-server

Restricts routing for this route to connections originating on the specified virtual server. The default value is none which means the route is not restricted and messages originating on any connection may be routed to the route.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, show, tmsh, ltm message-routing diameter route

COPYRIGHT

BIG-IP 2016-03-14 ltm message-routing diameter route(1)

ltm message-routing diameter transport-config

NAME

transport-config - Configures a Diameter transport-config instance for routing Diameter message protocol messages.

MODULE

ltm message-routing diameter

SYNTAX

Configure the transport-config component within the ltm message-routing diameter module using the syntax shown in the following sections.

CREATE/MODIFY

```
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  profiles [add | delete | replace-all-with] {
    [profile_name ...] {
context [all | clientside | serverside]    read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] ] }
  source-address-translation {
    options:
pool [ [pool_name] | none]
type [ automap | snat | none ]
  }
  source-port [integer]
  source-port-mode [change | preserve | preserve-strict]
```

```
edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete transport-config [name]
```

DESCRIPTION

You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

EXAMPLES

```
create transport-config my_transport-config
```

Creates a transport-config instance named `my_transport-config` using the system defaults.

```
create transport-config my_transport-config { profiles add { my_diameter my_tcp } }
```

Creates a transport-config instance named `my_transport-config` that will use two profiles, `my_diameter` and `my_tcp`, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

OPTIONS

`app-service`

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`description`

User defined description.

`profiles`

Specifies a list of profiles that the outgoing connection uses to use to direct and manage traffic. The default value is none.

`rules`

Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

`source-address-translation`

Specifies the type of source address translation enabled for the transport configuration, as well as the pool that the source address translation uses.

`pool` Specifies the name of a SNAT pool used by the specified transport configuration.

`type` Specifies the type of source address translation associated with the specified transport configuration.

The options are:

`automap`

Specifies the use of self IP addresses for transport configuration server source address translation.

`none` Specifies no source address translation is used by the transport configuration.

`snat` Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

`source-port`

Specifies the source port to be used for the connection being created. If `source-port-mode` is change, this setting has no effect. The default value is 0.

`source-port-mode`

Specifies how the system should select a source port for the outgoing connection. The default value is change.

The options are:

`change`

Selects an ephemeral source port for the outgoing connection.

`preserve`

Attempts to use the value of `source-port` for the outgoing connection, if specified. Otherwise attempts to preserve the source port of the incoming connection.

`preserve-strict`

Forces the outgoing connection to use the value of `source-port`, if specified. Otherwise forces the new connection to preserve the source port of the incoming connection. The system will fail to create a new outgoing connection if the specified source port is already in use.

SEE ALSO

DISPLAY

list peer

list peer [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete peer [name]

DESCRIPTION

You can use the peer component to manage a named generic message peer. A peer specifies the pool for the generic message parser to use as the destination for generic message routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

EXAMPLES

```
create peer my_peer { pool my_pool transport { type virtual name my_vip } }
```

Creates a generic message peer named my_peer which uses the settings of my_vip to establish a connection with a pool member from pool my_pool.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auto-initialization

If enabled, the BIGIP will automatically create outbound connections to the active pool members in the specified pool using the configuration of the specified transport-config. For auto-initialization to attempt to create a connection, the peer must be included in a route that is attached to a router instance. For each router instance that the peer is contained in, a connection will be initiated. The auto-initialization logic will verify at a configurable interval if the a connection exists between the BIG-IP and the pool members of the pool. If a connection does not exist, it will attempt to reestablish one. The default is disabled.

auto-initialization-interval

Specifies the interval (in milliseconds) that attempts to initiate a connection occur. Valid ranges are from 500ms to 65535ms. The default is 5000ms.

connection-mode

Specifies how the number of connections per host is limited. Note a host (specified in the referred pool) may exist more than one peer object, and those peer objects may have different settings for connection-mode and number_connections. Thus, these settings specify how messages are routed through this peer are distributed between a set of connections, not the maximum number of connections to a specified host. The default value is per-peer.

per-peer

Specifies the number of connections to a remote host.

per-blade

Specifies the number of connections to a remote host per blade in the cluster.

per-tmm

Specifies the number of connections to a remote host per TMM in the system.

per-client
Specifies the number of connections to a remote host per client connection.

per-client-per-blede
Specifies the number of connections to a remote host per client connection for each blade.

per-client-per-tmm
Specifies the number of connections to a remote host per client connection for each tmm.

per-peer-alternate-tmm
Specifies the number of connections to a remote host. Any new connections will be opened on an alternate TMM to spread CPU usage.

per-client-alternate-tmm
Specifies the number of connections to a remote host per client connection. Any new connections will be opened on an alternate TMM to spread CPU usage.

description
User defined description.

number-connections
Specifies the distribution of connections between the BIG-IP system and a remote host. The default value is 1.

pool Specifies the name of the pool to which the generic parser routes messages.

ratio
Specifies the ratio the generic message parser uses to select a peer from a list of peers for the ltm message-routing generic route. The default value is 1.

transport-config
Specifies the name of the transport configuration (ltm message-routing generic transport-config) the message router uses to create an outgoing connection.

show protocol [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

DELETE

delete protocol [name]

DESCRIPTION

You can use the protocol component to implement a named generic message parser for use with the message routing framework. You can create a protocol component, and then add it to a virtual server. You do this when you want to separate a stream of bytes, from a connection to a peer, into messages for routing. This also enables a set of iRule commands to create, populate, and route messages.

EXAMPLES

create protocol my_protocol defaults-from genericmsg

Creates a message protocol component named my_protocol using the system defaults.

create protocol my_protocol { welcome-message hello }

Creates a protocol instance named my_protocol that sends a welcome message of "hello" to any new connection.

OPTIONS

defaults-from

Specifies the protocol that you want to use as the parent protocol. The new protocol inherits all of the settings and values from the specified parent protocol. The default value is genericmsg.

description

User defined description.

disable-parser

When set to yes, the generic message parser is disabled. The parser ignores all incoming packets and does not directly send message data. This mode supports iRule script protocol implementations that generate messages from the incoming transport stream and send messages on the outgoing transport stream.

max-egress-buffer

Specifies the maximum size of the send buffer in bytes. If the number of bytes in the send buffer for a connection exceeds this value, the generic message parser stops receiving outgoing messages from the router until the size of the buffer drops below this setting. The default value is 32768.

max-message-size

Specifies the maximum size of a received message. If a message exceeds this size, the connection is reset. The default value is 32768.

message-terminator

Specifies the string of characters used to terminate a message. If the message-terminator parameter is empty, the generic message parser does not separate the input stream into messages. The default value is \n.

no-response

When set to yes, matching of responses to requests is disabled. The default value is no.

SEE ALSO

BIG-IP 2014-10-17 ltm message-routing generic protocol(1)

ltm message-routing generic route

NAME

route - Configures a static route the generic message parser uses to route generic message protocol messages.

MODULE

ltm message-routing generic

SYNTAX

Configure the route component within the ltm message-routing generic module using the syntax shown in the following sections.

CREATE/MODIFY

```
create route [name]
modify route [name]
options:
  app-service [[string] | none]
  description [string]
  destination-address [string]
  peer-selection-mode [ sequential | ratio ]
  peers { [peer-name] }
  source-address [string]

edit route [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

reset-stats route
reset-stats route [ [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list route
list route [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete route [name]
```

DESCRIPTION

You can use the route component to manage a generic message static route.

EXAMPLES

```
create route my_route
```

Creates a static route named my_route that uses a wildcard value for the source-address and destination-address parameters. This acts as a default route.

```
create route my_route { destination-address helpdesk peers add { peer1 peer2 } }
```

Creates a static route named my_route that contains two peers, peer1 and peer2. Messages routed with a destination-address of helpdesk are routed to a pool member contained in peer1 or peer2, based on the specified peer-selection-mode.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

destination-address

Specifies the destination address of the route. If this parameter is not present, the generic message parser considers the destination-address as a wildcard that matches all message destination addresses. The default value is none.

description

User defined description.

peer-selection-mode

Specifies the method the generic message parser uses to select a peer from the specified list of peers. The default value is sequential.

sequential

Specifies that the generic message parser selects the first peer in the list of peers. If the protocol retransmits the message, the generic message parser uses another pool member in the first peer. If all pool members in a peer are unavailable, the generic message parser uses the next peer in the list.

ratio

Specifies that the generic message parser selects a peer from a list of peers based on the relative ratio values of each peer. For example if three peers have ratios of 1, 1, and 2, the first 2 peers have a 25% (1/4) probability of being selected and the third peer has a 50% (2/4) probability of being selected.

peers

Specifies a list of peers.

source-address

Specifies the source address of the route. If this parameter is not present, the generic message parser considers the source-address as a wildcard that matches all message sources addresses. The default value is none.

SEE ALSO

DELETE

delete router [name]

DESCRIPTION

You can use the router component to manage a generic message router instance. All virtual servers containing

the same router instance share the same route table and can route messages between peers.

EXAMPLES

```
create router my_router defaults-from messagerouter
```

Creates a message router instance named my_router using the system defaults.

```
create router my_router { routes add { route1 route2 } }
```

Creates a router instance named my_router that contains two static routes, route1 and route2.

OPTIONS

app-service

Specifies the name of the application service to which the router belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the router. Only the application service can modify or delete the router.

defaults-from

Specifies the profile that you want to use as the parent profile. The new profile inherits all of the settings and values from the specified parent profile. The default value is messagerouter.

description

User defined description.

ignore-client-port

If set to yes, the system ignores the remote port on clientside connections (connections where the peer connected to the BIG IP system) when searching for an existing connection. The default value is no.

irule-scope-message

If set to yes, iRule events are scoped to the message executing (each message has its own execution context). This allows multiple messages to process iRules concurrently without waiting for commands from other messages. If set to no, all genericmsg iRule events are scoped to the connection flow (that is all share a single execution context per flow) and therefore are forced to execute one at a time even though they are processing independent messages (this is the legacy mode). The default value is no. Some existing iRules might need to be adjusted to use the per-message scope.

ha-message-sweeper-interval

Specifies the maximum time in milliseconds that a message will be held on the standby device as it waits for the active device to route the message. Messages on the standby device held for longer then the configurable sweeper interval, will be dropped. The default value is 1000 milliseconds.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

max-pending-bytes

Limits the number of bytes contained within messages held pending while waiting for a connection to a peer. If irule-scope-message is set to yes, also limits the number of bytes contained within messages that may concurrently process iRule events. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator. The default value is 32768.

max-pending-messages

Limits the number of messages held pending while waiting for a connection to a peer. If irule-scope-message is set to yes, also limits the number of messages that may concurrently process iRule events. Once the limit is reached, any additional messages to the peer will be flagged as undeliverable and returned to the originator. The default value is 64.

max-retries

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

mirrored

If enabled, connection created on the active device of the traffic-group specified, will be mirrored on the standby device. Messages processed on the active device will also be mirrored and perform equivalent processing on the standby device.

per-peer-stats

If enabled, the profile specific statistics will be captured for each pool member. The default value is disabled.

traffic-group

Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

use-local-connection

If true, the router will route a message to an existing connection on the same TMM as the message was received on. If an existing connection is not found, it will route the message through an existing connection based on a deterministic algorithm that may be on another TMM. If a matching existing connection is not found, it will create a connection on the current TMM. Setting this flag may limit the number of connections that are created to a peer.

routes

Specifies a list of static routes for the router instance to use.

ltm message-routing generic transport-config

NAME

transport-config - Configures a message transport-config instance for routing generic message protocol messages.

MODULE

ltm message-routing generic

SYNTAX

Configure the transport-config component within the ltm message-routing generic module using the syntax shown in the following sections.

CREATE/MODIFY

```
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  profiles [add | delete | replace-all-with] {
    [profile_name ...] {
context [all | clientside | serverside]    read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] ] }
  source-address-translation {
    options:
pool [ [pool_name] | none]
type [ automap | snat | none ]
  }
  source-port [integer]
  source-port-mode [change | preserve | preserve-strict]
```

```
edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete transport-config [name]
```

DESCRIPTION

You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

EXAMPLES

```
create transport-config my_transport-config
```

Creates a transport-config instance named my_transport-config using the system defaults.

```
create transport-config my_transport-config { profiles add { my_genericmsg my_tcp } }
```

Creates a transport-config instance named my_transport-config that will use two profiles, my_genericmsg and my_tcp, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

profiles
Specifies a list of profiles that the outgoing connection uses to direct and manage traffic. The default value is none.

rules
Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

source-address-translation
Specifies the type of source address translation enabled for the transport configuration, as well as the pool that the source address translation uses.

pool Specifies the name of a SNAT pool used by the specified transport configuration.

type Specifies the type of source address translation associated with the specified transport configuration.

The options are:

automap
Specifies the use of self IP addresses for transport configuration server source address translation.

none Specifies no source address translation is used by the transport configuration.

snat Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

source-port
Specifies the source port to be used for the connection being created. If source-port-mode is change, this setting has no effect. The default value is 0.

source-port-mode
Specifies how the system should select a source port for the outgoing connection. The default value is change.

The options are:

change
Selects an ephemeral source port for the outgoing connection.

preserve
Attempts to use the value of source-port for the outgoing connection, if specified. Otherwise attempts to preserve the source port of the incoming connection.

preserve-strict
Forces the outgoing connection to use the value of source-port, if specified. Otherwise forces the new connection to preserve the source port of the incoming connection. The system will fail to create a new outgoing connection if the specified source port is already in use.

ltm message-routing mqtt peer

NAME
peer - Configures a peer for routing MQTT message protocol messages.

MODULE
ltm message-routing mqtt

SYNTAX

Configure the peer component within the ltm message-routing mqtt module using the syntax shown in the following sections.

```
CREATE/MODIFY
create peer [name]
modify peer [name]
options:
  app-service [[string] | none]
  description [string]
  pool [name]
  transport-config [ transport-config ]

edit peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list peer
list peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete peer [name]
```

DESCRIPTION

You can use the peer component to manage a named MQTT peer. A peer specifies the pool for the MQTT router to use as the destination for MQTT routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

EXAMPLES

```
create peer my_peer { pool my_pool transport { type virtual name my_vip } }
```

Creates a MQTT peer named my_peer which uses the settings of my_vip to establish a connection with a pool member from pool my_pool.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

pool Specifies the name of the pool to which the MQTT parser routes messages.

transport-config

Specifies the name of the transport configuration (ltm message-routing mqtt transport-config) the message router uses to create an outgoing connection.

DELETE
delete router [name]

DESCRIPTION
You can use the router component to manage a MQTT router profile.

EXAMPLES
create router my_router_profile defaults-from router

Creates a MQTT router profile named my_router_profile using the system defaults.

create router my_router_profile route route1

Creates a MQTT router profile named my_router_profile with a static route.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is router.

description
User defined description.

glob
Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

max-pending-bytes
Specifies the maximum number of bytes contained within pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator. The default value is 32768.

max-payload-pending-bytes
Specifies the maximum number of payload bytes contained within pending messages that will be held before exerting flow control and eventually closing the TCP window. The default value is 32768.

max-pending-messages
Specifies the maximum number of pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator. The default value is 64.

max-retries

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

per-peer-stats

If enabled, the profile specific statistics will be captured for each pool member. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

route

Specifies a static route.

traffic-group

Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

use-local-connection

Enables or disables a preference for local connections established by the ingress TMM over connections established by other TMM's when selecting the egress connection to destination peer.

SEE ALSO

partition

show session

show session [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

DELETE

delete session [name]

DESCRIPTION

You can use the session component to manage a MQTT session profile.

EXAMPLES

create session my_session_profile defaults-from session

Creates a MQTT session profile named my_session_profile using the system defaults.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is session.

description

User defined description.

clientid-prefix

Specifies the client-id prefix that will be used when sending the CONNECT message to the broker.

keepalive-int

Specifies the keepalive interval that will be used when sending the CONNECT message to the broker.

peered-session-mode

Set this option to peer a client session with server session. When either side terminates the peered session will terminate immediately.

proxy-topic-prefix

Specifies a prefix that will be added to topic of messages that belong to the proxy.

client-will-handling-mode

Specifies the will handling mode to control will action for ungraceful shutdown of the client session.

server-will-handling-mode

Specifies the will handling mode to control will action for ungraceful shutdown of proxy's session with the broker.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

partition

Displays the administrative partition within which the component resides.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, tmsh

field-fmt

DELETE

delete route [name]

DESCRIPTION

You can use the route component to define the URI's, virtual server, peers and peer selection mode of a message routing MQTT static route.

EXAMPLES

create route my_route

Creates a route instance named my_route using the system defaults.

create route my_route peer peer1

Creates a route instance named my_route that will use peer1 for forwarding messages.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

peer Specifies a peer to use for forwarding messages.

virtual-server

Specifies the virtual server on which connections will be routed to this route. If the virtual server is unset, messages originating on any connection may be routed to the route.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, show, tmsh, ltm message-routing mqtt route

BIG-IP 2018-10-20 ltm message-routing mqtt route(1)

ltm message-routing mqtt transport-config

NAME

transport-config - Configures a mqtt transport-config instance for routing mqtt message protocol messages.

MODULE

ltm message-routing mqtt

SYNTAX

Configure the transport-config component within the ltm message-routing mqtt module using the syntax shown in the following sections.

CREATE/MODIFY

```
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  profiles [add | delete | replace-all-with] {
    [profile_name ...] {
context [all | clientside | serverside]    read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] ] }
  source-address-translation {
    options:
pool [ [pool_name] | none]
type [ automap | snat | none ]
  }
  source-port [integer]
  source-port-mode [change | preserve | preserve-strict]
```

```
edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete transport-config [name]
```

DESCRIPTION

You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

EXAMPLES

```
create transport-config my_transport-config
```

Creates a transport-config instance named my_transport-config using the system defaults.

```
create transport-config my_transport-config { profiles add { my_mqttmsg my_tcp } }
```

Creates a transport-config instance named my_transport-config that will use two profiles, my_mqttmsg and my_tcp, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

profiles

Specifies a list of profiles that the outgoing connection uses to use to direct and manage traffic. The default value is none.

rules

Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

source-address-translation

Specifies the type of source address translation enabled for the transport configuration, as well as the

pool that the source address translation uses.

pool Specifies the name of a SNAT pool used by the specified transport configuration.

type Specifies the type of source address translation associated with the specified transport configuration.

The options are:

automap

Specifies the use of self IP addresses for transport configuration server source address translation.

none Specifies no source address translation is used by the transport configuration.

snat Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

source-port

Specifies the source port to be used for the connection being created. If source-port-mode is change, this setting has no effect. The default value is 0.

source-port-mode

Specifies how the system should select a source port for the outgoing connection. The default value is change.

The options are:

change

Selects an ephemeral source port for the outgoing connection.

preserve

Attempts to use the value of source-port for the outgoing connection, if specified. Otherwise attempts to preserve the source port of the incoming connection.

preserve-strict

Forces the outgoing connection to use the value of source-port, if specified. Otherwise forces the new connection to preserve the source port of the incoming connection. The system will fail to create a new outgoing connection if the specified source port is already in use.

ltm message-routing sip peer

NAME

peer - Configures a peer for routing SIP message protocol messages.

MODULE

ltm message-routing sip

SYNTAX

Configure the peer component within the ltm message-routing sip module using the syntax shown in the following sections.

CREATE/MODIFY

create peer [name]

modify peer [name]

options:

app-service [[string] | none]

auto-initialization [enabled | disabled]

auto-initialization-interval [integer]

connection-mode [per-peer | per-blade | per-tmm | per-client | per-client-per-blade |

per-client-per-tmm | per-peer-alternate-tmm | per-client-alternate-tmm]

description [string]

number-connections [integer]

pool [name]

ratio [integer]

transport-config [transport-config]

edit peer [[[name] | [glob] | [regex]] ...]

options:

- all-properties
- non-default-properties

DISPLAY

list peer

list peer [[[name] | [glob] | [regex]] ...]

options:

- all-properties
- non-default-properties
- one-line
- partition

DELETE

delete peer [name]

DESCRIPTION

You can use the peer component to manage a named SIP peer. A peer specifies the pool for the SIP router to use as the destination for SIP routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

EXAMPLES

```
create peer my_peer { pool my_pool transport { type virtual name my_vip } }
```

Creates a SIP peer named my_peer which uses the settings of my_vip to establish a connection with a pool member from pool my_pool.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auto-initialization

If enabled, the BIGIP will automatically create outbound connections to the active pool members in the specified pool using the configuration of the specified transport-config. For auto-initialization to attempt to create a connection, the peer must be included in a route that is attached to a router instance. For each router instance that the peer is contained in, a connection will be initiated. The auto-initialization logic will verify at a configurable interval if the a connection exists between the BIG-IP and the pool members of the pool. If a connection does not exist, it will attempt to reestablish one. The default is disabled.

auto-initialization-interval

Specifies the interval (in milliseconds) that attempts to initiate a connection occur. Valid ranges are from 500ms to 65535ms. The default is 5000ms.

connection-mode

Specifies how the number of connections per host is limited. Note a host (specified in the referred pool) may exist more than one peer object, and those peer objects may have different settings for connection-mode and number_connections. Thus, these settings specify how messages routed through this peer are distributed between a set of connections, not the maximum number of connections to a specified host. The default value is per-peer.

per-peer

Specifies the number of connections to a remote host.

per-blade

Specifies the number of connections to a remote host per blade in the cluster.

per-tmm

Specifies the number of connections to a remote host per TMM in the system.

per-client

Specifies the number of connections to a remote host per client connection.

per-client-per-blade

Specifies the number of connections to a remote host per client connection for each blade.

per-client-per-tmm

Specifies the number of connections to a remote host per client connection for each tmm.

per-peer-alternate-tmm

Specifies the number of connections to a remote host. Any new connections will be opened on an alternate TMM to spread CPU usage.

per-client-alternate-tmm

Specifies the number of connections to a remote host per client connection. Any new connections will be opened on an alternate TMM to spread CPU usage.

description

User defined description.

number-connections

Specifies the distribution of connections between the BIG-IP system and a remote host. The default value is 1.

pool Specifies the name of the pool to which the SIP parser routes messages.

ratio

Specifies the ratio the SIP router uses to select a peer from a list of peers for the ltm message-routing sip route. The default value is 1.

transport-config

Specifies the name of the transport configuration (ltm message-routing sip transport-config) the message router uses to create an outgoing connection.

```

```

DELETE
delete router [name]

```

DESCRIPTION

You can use the router component to manage a SIP router profile.

EXAMPLES

```
create router my_router_profile defaults-from router
```

Creates a SIP router profile named my_router_profile using the system defaults.

```
create router my_router_profile routes add { route1 route2 }
```

Creates a SIP profile named my_router_profile with two static routes.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is router.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

log-publisher

Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile

Specify the name of the ALG log profile which controls the logging of ALG . See help Itm alg-log-profile for more details on the logging profile sub-system. Use the "Itm alg-log-profile profile" component to set up a ALG log profile.

max-pending-bytes

Specifies the maximum number of bytes contained within pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator. The default value is 32768.

max-pending-messages

Specifies the maximum number of pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator. The default value is 64.

max-retries

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

mirrored

If enabled, connection created on the active device of the traffic-group specified, will be mirrored on the standby device. Messages processed on the active device will also be mirrored and perform equivalent processing on the standby device.

Important: Changing traffic groups, with Connection Mirroring enabled, drops all mirrored connections and loses all persistence data. If you change traffic groups, mirroring must restart.

per-peer-stats

If enabled, the profile specific statistics will be captured for each pool member. The default value is disabled.

operation-mode

Specifies the behavior of the routing instance. The options are:

load-balancing
Messages will be load balanced.

application-level-gateway
The virtual will act as a forwarding virtual, forwarding messages to the server of peer identified as the destination address of the incoming connection. The messages will be inspected so that associated media flows can be created.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

routes
Specifies a list of static routes. The ordering of the route entries is insignificant.

session.transaction-timeout
Specifies the maximum time (in seconds) between a request and its response. A provisional response restarts the timer. This may not affect all transactions. The scenarios where the system waits for response (eg. a final response for REGISTER request), are impacted by dropping any persistent data maintained for the request.

session.max-session-timeout
This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum duration (in seconds) the media for a call remains active. After this period call media is terminated.

traffic-group
Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group
Read-only property that indicates if the traffic-group is inherited from the parent folder.

media-proxy.max-media-sessions
This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum number of media sessions that are allowed per call.

media-proxy.media-inactivity-timeout
This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum duration (in seconds) that a media flow is active with no RTP packets. After this period the media flow is removed. This attribute is applicable only to RTP packets. Inactivity time applicable to RTCP packets is max-session-timeout.

max-global-registrations
This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum number of registrations allowed. If the limit is reached the registrations are dropped. A default value of 0 indicates the limit is ignored."

nonregistered-subscriber-callout
This attribute is valid when the operation-mode is application-level-gateway with translation. Enables non-registered subscriber to initiate calls. The default value is enabled.

nonregistered-subscriber-listener
This attribute is valid when the operation-mode is application-level-gateway with translation. Enables creation of an ephemeral listener when a non-registered subscriber initiates a calls. If enabled, Non-registered subscribers will be able to receive incoming calls. The default value is enabled.

concurrent-sessions-per-subscriber
This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum number of concurrent calls allowed per subscriber. It denotes the concurrent From-URI in the call matching the registration key. If the limit exceeds then the call is dropped. Default value of 0 indicates that the limit is ignored."

registration-timeout
This attribute is valid when the operation-mode is application-level-gateway with LSN source-address-translation. Specifies the maximum duration (in seconds) that a registration entry remains active while a response has not been received from the registrar. After this period the registration entry is removed from the registration table, unless the registrar has responded. A default value of 0 means this timeout is ignored and the Expires header value is used.

dialog_establishment_timeout
This attribute is valid when the operation-mode is application-level-gateway. Specifies the timeout (in seconds) that represents the Timer B as per RFC 3261, the INVITE transaction timeout. The dialog-establishment-timeout is used by the Call Table. The default value is 32 seconds.

use-local-connection
Enables or disables a preference for local connections established by the ingress TMM over connections established by other TMM's when selecting the egress connection to destination peer.

ltm message-routing sip profile session

NAME

session - Configures a Session Initiation Protocol (SIP) Session profile.

MODULE

ltm message-routing sip profile

SYNTAX

Configure the session component within the ltm message-routing sip profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create session [name]
modify session [name]
options:
  honor-route-mode [loose | strict]
  record-route-mode [single | double]
  service-port [integer]
  allow-unknown-methods [disabled | enabled]
  app-service [[string] | none]
  custom-via [[via-header] | none]
  defaults-from [[name] | none]
  description [string]
  do-not-connect-back [disabled | enabled]
  generate-response-on-failure [disabled | enabled]
  honor-via [disabled | enabled]
  insert-record-route-header [disabled | enabled]
  honor-route-header [disabled | enabled]
  insert-via-header [disabled | enabled]
  maintenance-mode [disabled | enabled]
  loop-detection [disabled | enabled]
  loop-detection-mode [Loose | Strict]
  max-forwards-check [disabled | enabled]
  max-msg-header-count [integer]
  max-msg-header-size [integer]
  max-msg-size [integer]
  passthru-mode [disabled | enabled ]
  persistence {
    persist-key [Call-ID | Custom | Src-Addr]
    persist-timeout [integer]
    persist-type [session | none]
  }
  enable-sip-firewall [no | yes]
```

```
edit session [ [ [name] | [glob] | [regex] ] ... ]
options:

options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

DELETE

delete session [name]

DESCRIPTION

You can use the session component to manage a SIP session profile.

EXAMPLES

create session my_session_profile defaults-from session

Creates a SIP session profile named my_session_profile using the system defaults.

create session my_session_profile { insert-record-route-header enabled }

Creates a SIP profile named my_session_profile with insertion of record-route header in requests which establish a dialog.

OPTIONS

allow-unknown-methods

If enabled, SIP messages with unknown methods will be parsed and routed. The default value is disabled.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

custom-via Specifies the value the system uses for the Sent-by field of the Via header when the Insert Via Header setting is enabled. Note: The value that you enter must include a format of SIP/SIP-version/protocol, followed by a Sent-By value. For example, SIP/2.0/TCP www.siterequest.com:4343 or SIP/2.0/SCTP 10.10.4.32.
defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is session.

description

User defined description.

do-not-connect-back

Enables or disables whether a connection to a request originator is re-established (if it no longer exists) in order to deliver a response. When disabled, responses that cannot be forwarded using an existing connection are dropped.

generate-response-on-failure

Enables or disables sending failure response messages such as 4xx, 5xx and 6xx, when a SIP request is being dropped. Note: Where it is specified "silently" discarded/dropped, no error response is generated. In any case, a dropped message (request/response) is tracked by the Messages Dropped Statistic.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

honor-via

Enables or disables honoring any via which is not inserted by the system for routing the response. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to \"application level gateway\".

insert-record-route-header

Enables or disables the insertion of a record-route header in requests that establish dialog. When enabled, along with the URI, the custom parameters may be added to facilitate the routing of subsequent requests within this call to avoid route lookup. The record route URI is the local-IP and port of flows that are used for forwarding the message. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to \"application level gateway\".

record-route-mode

"Single" mode will insert one Record-Route header into requests and rewrite the header on response as recommended in RFC 3261. "Double" mode will insert two Record-Route headers as recommended in RFC 5658.

honor-route-header

Enables or disables honoring of a route header in requests of an established dialog. When enabled, topmost route from the route list will be inspected and removed if it belongs to BIGIP. Also message will be routed to location mention in the following route in the route list. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to \"application level gateway\".

honor-route-mode

Determines how to insert and handle Record-Route/Route headers in requests. "Loose" mode derives Record-Route and Route processing from RFC 3261, while "Strict" uses RFC 2543.

insert-via-header

Enables or disables insertion of top via. When enabled, custom parameters to help route the response back are inserted, along with sent-by field of via. The source address:port of the flow forwarding the request is filled as value for sent-by field of the via unless a custom via value is specified. The custom parameters inserted to help routing, helps improve performance as it facilitates routing without any lookup. The via is inserted at egress side of the flow, after the SIP_REQUEST_SEND event. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to \"application level gateway\".

maintenance-mode

Enables or disables maintenance mode. When enabled, SIP response \"503 Service Unavailable\" will be sent for incoming SIP request. SIP response will be dropped.

passthru-mode

Enables or disables passthru mode. When enabled, if the first message received in a flow is not a SIP message, the profile will enter passthru mode. The flow will stay in passthru mode for its lifetime. In passthru mode, all data is passed on without modification or validation.

loop-detection

Enables or disables loop-detection checking. When a loop is detected, the request is discarded. An error response is sent, if configured. A request is detected as seen before (forwarded/spiraled/looped) only if self inserted via is found in the message and the value of its branch param plays a key role in detecting loop versus spiral. Hence enabling via insertion becomes a requirement to do loop detection check. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to \"application level gateway\".

loop-detection-mode

Loop detection logic generates a unique hash per transaction based on several attributes including Cseq, To, From, Call-ID, Route, Request-URI and Chassis serial number. Loop-detection-mode value of Loose will skip "To" attribute in the hash calculation.

max-forwards-check

Enables or disables checking on max-forwards. The max-forwards header field serves to limit the number of hops a request can transit on the way to its destination. If 0, the request is discarded. An error response is sent, if configured. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to \"application level gateway\".

max-msg-header-count

Indicates the maximum count of expected SIP message header fields. A message that exceeds this limit is silently discarded.

max-msg-header-size

Indicates the maximum SIP message header size (in bytes). A message which exceeds this size is silently discarded.

max-msg-size

Indicates the maximum number acceptable SIP message size (in bytes). A message which exceeds this size is silently discarded.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

persistence

Configure the persistence settings.

persistence.persist-key

Specifies the method which should be used to extract the key value that is used to persist on. The options are:

Call-ID

Persist based on the "Call-ID" header field value in the message.

Custom

Persist based on the custom key specified using an iRule.

Src-Addr

Persist based on originating IP address in the message.

The default option is Call-ID.

persistence.persist-timeout

Specifies the timeout value of persistence entries in seconds. Upon receiving of the response for the initial SIP Request message, the persistence record is updated with the persist-timeout value.

persistence.persist-type

Specifies the type of the persistence to be used for the specified "persist-key" attribute value. The options are:

session

Persistence is enabled guaranteeing that messages containing a given persistence key will be delivered to the same peer.

none Persistence is disabled.

The default option is session.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

enable-sip-firewall

Indicates whether to enable the Application Firewall Security policy. When enabled, the configured AFM security features will apply to the virtual server(s) using this SIP session profile.

ltm message-routing sip route

NAME

route - Configures a static route for use in Session Initiation Protocol (SIP) message routing.

MODULE

ltm message-routing sip

SYNTAX

Configure the route component within the ltm message-routing sip module using the syntax shown in the following sections.

CREATE/MODIFY

create route [name]

modify route [name]

options:

app-service [[string] | none]

description [string]

from-uri [string]

peer-selection-mode [ratio | sequential]

peers { [none] | [peer_name ...] }

request-uri [string]

to-uri [string]

virtual-server [virtual-server_name]

edit route [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list route

list route [[[name] | [glob] | [regex]] ...]

show running-config route

show running-config route [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

partition

show route

show route [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

DELETE

delete route [name]

DESCRIPTION

You can use the route component to define the URI's, virtual server, peers and peer selection mode of a message routing SIP static route.

EXAMPLES

create route my_route

Creates a route instance named my_route using the system defaults.

create route my_route peers { peer1 peer2 }

Creates a route instance named my_route that will use two peers for forwarding messages.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

from-uri

Specifies the patterns to be matched against the From field of a SIP message. This URI will be matched as a case insensitive method. It should be in the form of user@domain. The "sip:" prefix should not be present. Any additional modifiers (for example port or transport) should also not be present. It may begin with a wildcard, "*". If empty, it will be treated as if the entire URI was a wildcard (matching all From-URIs).

peer-selection-mode

Specifies the mode of selecting a peer from a list of peers. The options are:

ratio

Peers are selected based on their weights in comparison with other peers.

sequential

Peers are selected in the order listed. All traffic will route the first peer unless all pool members in the peer are marked down.

peers

Specifies an ordered list of peers to use for forwarding messages.

request-uri

Specifies the patterns to be matched against the request-uri field of a SIP message. This URI will be matched as a case insensitive method. It should be in the form of user@domain. The "sip:" prefix should not be present. Any additional modifiers (for example port or transport) should also not be present. It may begin with a wildcard, "*". If empty, it will be treated as if the entire URI was a * wildcard (matching all Request-URIs).

to-uri

Specifies the patterns to be matched against the To field of a SIP message. This URI will be matched as a case insensitive method. It should be in the form of user@domain. The "sip:" prefix should not be present. Any additional modifiers (for example port or transport) should also not be present. It may begin with a wildcard, "*". If empty, it will be treated as if the entire URI was a wildcard (matching all To-URIs).

virtual-server

Specifies the virtual server on which connections will be routed to this route. If the virtual server is unset, messages originating on any connection may be routed to the route.

BIG-IP 2016-03-14 ltm message-routing sip route(1)

ltm message-routing sip transport-config

NAME

transport-config - Configures a sip transport-config instance for routing sip message protocol messages.

MODULE

ltm message-routing sip

SYNTAX

Configure the transport-config component within the ltm message-routing sip module using the syntax shown in the following sections.

CREATE/MODIFY

```
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  profiles [add | delete | replace-all-with] {
    [profile_name ...] {
context [all | clientside | serverside]    read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] ] }
  source-address-translation {
    options:
pool [ [pool_name] | none]
```

```
type [ automap | snat | none ]
}
source-port [integer]
source-port-mode [change | preserve | preserve-strict]
```

```
edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete transport-config [name]
```

DESCRIPTION

You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

EXAMPLES

```
create transport-config my_transport-config
```

Creates a transport-config instance named my_transport-config using the system defaults.

```
create transport-config my_transport-config { profiles add { my_sipmsg my_tcp } }
```

Creates a transport-config instance named my_transport-config that will use two profiles, my_sipmsg and my_tcp, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

profiles

Specifies a list of profiles that the outgoing connection uses to use to direct and manage traffic. The default value is none.

rules

Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

source-address-translation

Specifies the type of source address translation enabled for the transport configuration, as well as the pool that the source address translation uses.

pool Specifies the name of a SNAT pool used by the specified transport configuration.

type Specifies the type of source address translation associated with the specified transport configuration.

The options are:

automap

Specifies the use of self IP addresses for transport configuration server source address translation.

none Specifies no source address translation is used by the transport configuration.

snat Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

source-port

Specifies the source port to be used for the connection being created. If source-port-mode is change, this setting has no effect. The default value is 0.

source-port-mode

Specifies how the system should select a source port for the outgoing connection. The default value is change.

The options are:

change

Selects an ephemeral source port for the outgoing connection.

preserve

Attempts to use the value of source-port for the outgoing connection, if specified. Otherwise attempts to preserve the source port of the incoming connection.

preserve-strict

Forces the outgoing connection to use the value of source-port, if specified. Otherwise forces the new connection to preserve the source port of the incoming connection. The system will fail to create a new outgoing connection if the specified source port is already in use.

BIG-IP 2019-10-07 ltm message-routing sip transport-config(1)

ltm monitor diameter

NAME

diameter - Configures a monitor for Diameter protocol resources.

MODULE

ltm monitor

SYNTAX

Configure the diameter component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create diameter [name]

modify diameter [name]

options:

acct-application-id [[integer] | none]

app-service [[string] | none]

auth-application-id [[integer] | none]

defaults-from [name]

description [string]

host-ip-address [[ip address] | none]

interval [integer]

manual-resume [enabled | disabled]

mode [tcp | mr-tcp | mr-sctp]

origin-host [[ip address] | none]

origin-realm [[hostname] | none]

product-name [name]

time-until-up [integer]

timeout [integer]

up-interval [integer]

vendor-id [integer]

vendor-specific-acct-application-id [[integer] | none]

vendor-specific-auth-application-id [[integer] | none]

vendor-specific-vendor-id [[integer] | none]

edit diameter [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list diameter

list diameter [[[name] | [glob] | [regex]] ...]

show diameter [[[name] | [glob] | [regex]] ...]

show running-config diameter

show running-config diameter [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete diameter [name]

Note: You cannot delete default monitors.

DESCRIPTION

You can use the diameter component to configure a custom monitor, or you can use the default Diameter monitor that the Local Traffic Manager provides. This type of monitor checks the health of Diameter protocol resources.

EXAMPLES

```
create diameter my_diameter defaults-from diameter
```

Creates a monitor named `my_diameter` that inherits properties from the default Diameter monitor.

```
list diameter
```

Displays the properties of all of the Diameter monitors.

OPTIONS

`acct-application-id`

Specifies the ID of the accounting portion of a Diameter application. If you specify this option, you must also specify a value for the `auth-application-id` option. The default value is none.

Note that the `acct-application-id` and `auth-application-id` attribute-value-pair (AVP), and the `vendor-specific-auth-application-id` and `vendor-specific-acct-application-id` AVP are mutually exclusive. You can only specify one of these AVPs.

`app-service`

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

`auth-application-id`

Specifies the ID of the authentication and authorization portion of a Diameter application. If you specify this option, you must also specify a value for the `acct-application-id` option. The default value is none.

Note that the `acct-application-id` and `auth-application-id` attribute-value-pair (AVP), and the `vendor-specific-auth-application-id` and `vendor-specific-acct-application-id` AVP are mutually exclusive. You can only specify one set of these AVPs.

`defaults-from`

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `firepass`.

`description`

User defined description.

`glob` Displays the items that match the `glob` expression. See help `glob` for a description of `glob` expression syntax.

`host-ip-address`

Specifies the IP address of the sender of the Diameter message for the Diameter protocol peer discovery feature. The default value is none.

`interval`

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the `up-interval` option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

`manual-resume`

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value is disabled.

Note that if you set the `manual-resume` option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

`mode` Specifies the transport protocol that the monitor uses to communicate with the target. The default mode is `tcp`. The options are:

`tcp` Specifies that the monitor uses TCP to communicate with the target.

`mr-tcp`

Specifies that the monitor uses TCP with the message-routing framework to communicate with the target.

`mr-sctp`

Specifies that the monitor uses SCTP with the message-routing framework to communicate with the target.

The modes beginning with "mr-" use an in-TMM monitor based on the message-routing framework (MRF). The other modes use the legacy external monitor.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`origin-host`

Specifies the IP address from which the Diameter message originates. The default value is the fully-

qualified domain name of the BIG-IP system.

origin-realm

Specifies the realm in which the host from which the Diameter message originates resides. The default value is f5.com.

partition

Displays the administrative partition within which the component resides.

product-name

Specifies the vendor-assigned name of the Diameter application. The value of this option must remain constant across firmware revisions for the same product. The default value is F5 BIGIP Diameter Health Monitoring.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

vendor-id

Specifies the IANA SMI Network Management Private Enterprise Code assigned to the vendor of the Diameter application. The default value is 3375.

vendor-specific-acct-application-id

Specifies the ID of the vendor-specific accounting portion of a Diameter application. If you specify this option, you must also specify a value for the vendor-specific-auth-application-id option. The default value is none.

Note that the acct-application-id and auth-application-id attribute-value-pair (AVP), and the vendor-specific-auth-application-id and vendor-specific-acct-application-id AVP are mutually exclusive. You can only specify one of these AVPs.

vendor-specific-auth-application-id

Specifies the ID of the vendor-specific authentication and authorization portion of a Diameter application. If you specify this option, you must also specify a value for the vendor-specific-acct-application-id option. The default value is none.

Note that the acct-application-id and auth-application-id attribute-value-pair (AVP), and the vendor-specific-auth-application-id and vendor-specific-acct-application-id AVP are mutually exclusive. You can only specify one of these AVPs.

vendor-specific-vendor-id

Specifies the ID of a vendor-specific Diameter application. The system uses this ID to advertise support for the application. The default value is none.

BIG-IP 2019-10-30 ltm monitor diameter(1)

NAME

dns - Configures a Domain Name System (DNS) monitor.

MODULE

ltm monitor

SYNTAX

Configure the dns component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create dns [name]
modify dns [name]
options:
  accept-rcode [no-error | anything]
  adaptive [enabled | disabled]
  adaptive-divergence-type [relative | absolute]
  adaptive-divergence-value [integer]
  adaptive-limit [integer]
  adaptive-sampling-timespan [integer]
  answer-contains [query-type | any-type | anything]
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
  interval [integer]
  manual-resume [enabled | disabled]
  qname [string]
  qtype [a | aaaa]
  recv [none | [string] ]
  reverse [enabled | disabled]
  time-until-up [integer]
  timeout [integer]
  transparent [disabled | enabled]
  up-interval [integer]
```

```
edit dns [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list dns
list dns [ [ [name] | [glob] | [regex] ] ... ]
show dns [ [ [name] | [glob] | [regex] ] ... ]
show running-config dns
show running-config dns [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete dns [name]
```

Note: You cannot delete default monitors.

RUN

```
run dns [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]
```

STOP

```
stop dns [name]
```

DESCRIPTION

You can use the dns component to configure a custom monitor. This type of monitor verifies the DNS service by attempting to send DNS requests generated using the parameters provided to a pool, pool member, or virtual server and validating the DNS response.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create dns my_dns defaults-from dns qname www.test.com
```

Creates a monitor named my_dns that inherits properties other than qname from the default DNS monitor.

```
list dns
```

Displays the properties of all of the DNS monitors.

```
run dns my_dns destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_dns against a target node at 10.10.10.10:80.

stop dns my_dns

Cancels a one-shot test of the custom monitor my_dns in progress.

show dns my_dns test-result

Displays the result of the most recent one-shot test of the custom monitor my_dns.

OPTIONS

accept_rcode

Specifies the RCODE required in the response for an 'up' status. The default value is no-error.

The options are:

no-error

Specifies that the status of the node will be marked up if the received dns message has RCODE = NOERROR.

anything

Specifies that the status of the node will be marked up irrespective of the RCODE in the dns message received.

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

answer_contains

Specifies the record types required in the answer section of the response in order to mark the status of a node up. The default value is query-type.

The options are:

query-type

Specifies that the response should contain at least one answer of which the resource record type matches the qtype.

any-type

Specifies that the dns message should contain at least one answer.

anything

Specifies that an empty answer section is enough to mark the status of the node up.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is dns.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member

and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)
Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

qname
Specifies the query name that the monitor send a DNS query for. The default value is Enter a query name.

qtype
Specifies the query type of that the monitor sends a query. The default value is a.

The options are:

a Specifies that the monitor will send a DNS query of type A.

aaaa Specifies that the monitor will send a DNS query of type AAAA.

recv Specifies the ip address that the monitor looks for in the dns response's resource record sections. The ip address should be specified in the dotted-decimal notation or ipv6 notation. The default value is none. If no recv value is specified, then the dns message will be checked against accept_rcode and answer_contains monitor parameters respectively.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse
Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful receive string match marks the monitored object down instead of up. You can use the this mode only if you configure recv option.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-08-16 Itm monitor dns(1)

Itm monitor external

NAME

external - Configures an external monitor.

MODULE

Itm monitor

SYNTAX

Configure the external component within the Itm monitor module using the syntax in the following sections.

CREATE/MODIFY

create external [name]

modify external [name]

options:

args [[arguments] | none]

app-service [[string] | none]

defaults-from [name]

description [string]

destination [[ipv4 address[:port]] | [ipv6 address[:port]]]

interval [integer]

manual-resume [enabled | disabled]

run [none | [external monitor]]

time-until-up [integer]

timeout [integer]

user-defined [[name] [value] | [name] none]

up-interval [integer]

edit external [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list external

list external [[[name] | [glob] | [regex]] ...]

show external [[[name] | [glob] | [regex]] ...]

show running-config external

show running-config external [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

test-result

DELETE

delete external [name]

Note: You cannot delete default monitors.

RUN

run external [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP

stop external [name]

DESCRIPTION

You can use the external component to configure a custom monitor, or you can use the default external monitor that the Local Traffic Manager provides. Using this type of monitor, you can use your own programs to monitor services.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create external my_external defaults-from external

Creates a monitor named my_external that inherits properties from the default external monitor.

list external

Displays the properties of all of the external monitors.

run external my_external destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_external against a target node at 10.10.10.10:80.

stop external my_external

Cancels a one-shot test of the custom monitor my_external in progress.

show external my_external test-result

Displays the result of the most recent one-shot test of the custom monitor my_external.

OPTIONS

args Specifies any command-line arguments that the external program requires. The default value is none.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is external.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:*.

Possible values are:

: Specifies to perform a health check on the address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

run Specifies the external monitor file to be executed by the external monitor. The default value is none.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 zero, which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

user-defined

Specifies any user-defined command-line arguments and variables that the external program requires. Use the following syntax to specify a user defined parameter.

modify external my_external user-defined my_param_name my_param_value

Use the following syntax to remove a user defined parameter.

modify external my_external user-defined my_param_name none

SEE ALSO

create, delete, edit, glob, list, modify, regex, run, show, stop, tmsh

COPYRIGHT

BIG-IP 2017-08-16 ltm monitor external(1)

ltm monitor firepass

NAME

firepass - Configures a FirePass(r) monitor.

MODULE

ltm monitor

SYNTAX

Configure the firepass component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create firepass [name]

modify firepass [name]

options:

app-service [[string] | none]

cipherlist [list]

concurrency-limit [integer]

defaults-from [name]

description [string]

```
destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
interval [integer]
max-load-average [integer]
password [password]
time-until-up [integer]
timeout [integer]
up-interval [integer]
username [ [name] | none]
```

```
edit firepass [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list firepass
list firepass [ [ [name] | [glob] | [regex] ] ... ]
show firepass [ [ [name] | [glob] | [regex] ] ... ]
show running-config firepass
show running-config firepass [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

```
DELETE
delete firepass [name]
```

Note: You cannot delete default monitors.

```
RUN
run firepass [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

```
STOP
stop firepass [name]
```

DESCRIPTION

You can use the firepass component to configure a custom monitor, or you can use the default Firepass monitor that the Local Traffic Manager provides. This type of monitor checks the health of FirePass systems.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create firepass my_firepass defaults-from firepass
```

Creates a monitor named my_firepass that inherits properties from the default Firepass monitor.

```
list firepass
```

Displays the properties of all of the Firepass monitors.

```
run firepass my_firepass destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_firepass against a target node at 10.10.10.10:80.

```
stop firepass my_firepass
```

Cancels a one-shot test of the custom monitor my_firepass in progress.

```
show firepass my_firepass test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_firepass.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

cipherlist

Specifies the list of ciphers for this monitor. The default value is HIGH:!ADH.

concurrency-limit

Specifies the maximum percentage of licensed connections currently in use under which the monitor marks the FirePass system up. The default value is 95.

For example, a value of 95 percent means that the monitor marks the FirePass system up until 95 percent of licensed connections are in use. When the number of in-use licensed connections exceeds 95 percent, the monitor marks the FirePass system down.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is firepass.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

max-load-average

Specifies the number that the monitor uses to mark the FirePass system up or down. The system compares the value of this option to a one-minute average of the FirePass system load. When the FirePass system-load average falls within the specified value, the monitor marks the FirePass system up. When the average exceeds the value, the monitor marks the system down.

The default value is 12.0.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password, if the monitored target requires authentication. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is gtmuser.

SEE ALSO

BIG-IP 2017-08-16 ltm monitor firepass(1)

ltm monitor ftp

NAME

ftp - Configures a File Transfer Protocol (FTP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the ftp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create ftp [name]

modify ftp [name]

options:

app-service [[string] | none]

debug [no | yes]

defaults-from [name]

description [string]

destination [[ipv4 address[:port]] | [ipv6 address[:port]]]

filename [[filename] | none]

interval [integer]

manual-resume [enabled | disabled]

mode [passive | port]

password [none | [password]]

time-until-up [integer]

timeout [integer]

up-interval [integer]

username [name]

edit ftp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list ftp

list ftp [[[name] | [glob] | [regex]] ...]

show ftp [[[name] | [glob] | [regex]] ...]

show running-config ftp

show running-config ftp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

test-result

DELETE

delete ftp [name]

Note: You cannot delete default monitors.

RUN

run ftp [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP

stop ftp [name]

DESCRIPTION

You can use the ftp component to configure a custom monitor, or you can use the default FTP monitor that the Local Traffic Manager provides. This type of monitor verifies the FTP service by attempting to download a specific file to the /var/tmp directory on the system. Once downloaded successfully, the file is not saved.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create ftp my_ftp defaults-from ftp

Creates a monitor named my_ftp that inherits properties from the default FTP monitor.

list ftp

Displays the properties of all of the FTP monitors.

run ftp my_ftp destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_ftp against a target node at 10.10.10.10:80.

stop ftp my_ftp

Cancels a one-shot test of the custom monitor my_ftp in progress.

show ftp my_ftp test-result

Displays the result of the most recent one-shot test of the custom monitor my_ftp.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is ftp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

filename

Specifies the full path and file name of the file that the system attempts to download. The health check is successful if the system can download the file. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor

checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

mode Specifies the data transfer process (DTP) mode. The default value is passive.

The options are:

passive

Specifies that the monitor sends a data transfer request to the FTP server. When the FTP server receives the request, the FTP server then starts and establishes the data connection.

port Specifies that the monitor starts and establishes the data connection with the FTP server.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

password

Specifies the password, if the monitored target requires authentication. The default value is none.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 zero, which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor ftp(1)

ltm monitor gateway-icmp

NAME

gateway-icmp - Configures a Gateway Internet Control Message Protocol (ICMP) monitor.

MODULE
 ltm monitor

SYNTAX
 Configure the gateway-icmp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create gateway-icmp [name]
modify gateway-icmp [name]
options:
  adaptive [enabled | disabled]
  adaptive-divergence-type [relative | absolute]
  adaptive-divergence-value [integer]
  adaptive-limit [integer]
  adaptive-sampling-timespan [integer]
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  interval [integer]
  manual-resume [enabled | disabled]
  time-until-up [integer]
  timeout [integer]
  transparent [enabled | disabled]
  up-interval [integer]
```

```
edit gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list gateway-icmp
list gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
show gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
show running-config gateway-icmp
show running-config gateway-icmp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete gateway-icmp [name]
```

Note: You cannot delete default monitors.

RUN

```
run gateway-icmp [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

STOP

```
stop gateway-icmp [name]
```

DESCRIPTION

You can use the gateway-icmp component to configure a custom monitor, or you can use the default Gateway ICMP monitor that the Local Traffic Manager provides. This type of monitor monitors a pool that implements gateway fail-safe for high availability.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create gateway-icmp my_icmp defaults-from gateway_icmp
```

Creates a monitor named my_icmp that inherits properties from the default Gateway ICMP monitor.

```
list gateway-icmp
```

Displays the properties of all of the Gateway ICMP monitors.

```
run gateway-icmp my_gateway-icmp destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_gateway-icmp against a target node at 10.10.10.10:80.

```
stop gateway-icmp my_gateway-icmp
```

Cancels a one-shot test of the custom monitor my_gateway-icmp in progress.

```
show gateway-icmp my_gateway-icmp test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_gateway-icmp.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is gateway_icmp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

  partition
  test-result

DELETE
delete http [name]

```

Note: You cannot delete default monitors.

```

RUN
run http [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]

STOP
stop http [name]

```

DESCRIPTION

You can use the http component to configure a custom monitor, or you can use the default HTTP monitor that the Local Traffic Manager provides. This type of monitor verifies the HTTP service by attempting to receive specific content from a Web page.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```

create http my_http defaults-from http

Creates a monitor named my_http that inherits properties from the default HTTP monitor.

list http

Displays the properties of all of the HTTP monitors.

run http my_http destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_http against a target node at 10.10.10.10:80.

stop http my_http

Cancels a one-shot test of the custom monitor my_http in progress.

show http my_http test-result

Displays the result of the most recent one-shot test of the custom monitor my_http.

```

OPTIONS

adaptive
Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type
Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value
Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool

member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is http.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

ip-dscp

Specifies the differentiated services code point (DSCP). DSCP is a 6-bit value in the Differentiated Services (DS) field of the IP header. It can be used to specify the quality of service desired for the packet. The valid range for this value is 0 to 63 (hex 0x0 to 0x3f). The default value is zero.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-disable

Specifies a text string that the monitor looks for in the returned resource. If the text string is matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

You specify a recv-disable string in the same way that you specify a recv string.

If you specify a recv-disable string, you must also specify a recv string. You cannot specify a recv-disable string, if the reverse option is enabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object.

The default setting is GET /, which retrieves a default HTML file for a web site. To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html.

Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

```

Note: You cannot delete default monitors.

RUN

```
run http2 [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

STOP

```
stop http2 [name]
```

DESCRIPTION

You can use the http2 component to configure a custom monitor, or you can use the default HTTP/2 monitor that the Local Traffic Manager provides. This type of monitor verifies the HTTP/2 service by attempting to receive specific content from a Web page over HTTP/2.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create http2 my_http2 defaults-from http2
```

Creates a monitor named my_http2 that inherits properties from the default HTTP/2 monitor.

```
list http2
```

Displays the properties of all of the HTTP/2 monitors.

run http2 my_http2 destination 10.10.10.10:443

Runs a one-shot test of the custom monitor my_http2 against a target node at 10.10.10.10:443.

stop http2 my_http2

Cancels a one-shot test of the custom monitor my_http2 in progress.

show http2 my_http2 test-result

Displays the result of the most recent one-shot test of the custom monitor my_http2.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is http2.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

ip-dscp

Specifies the differentiated services code point (DSCP). DSCP is a 6-bit value in the Differentiated Services (DS) field of the IP header. It can be used to specify the quality of service desired for the packet. The valid range for this value is 0 to 63 (hex 0x0 to 0x3f). The default value is zero.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-disable

Specifies a text string that the monitor looks for in the returned resource. If the text string is matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

You specify a recv-disable string in the same way that you specify a recv string.

If you specify a recv-disable string, you must also specify a recv string. You cannot specify a recv-disable string, if the reverse option is enabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object.

The default setting is GET /, which retrieves a default HTML file for a web site. To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html.

Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

ssl-profile

Specifies the server side SSL profile that this monitor will use to ping the monitored node or target.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

test-result

DELETE
delete https [name]

Note: You cannot delete default monitors.

RUN
run https [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP
stop https [name]

DESCRIPTION

You can use the https component to configure a custom monitor, or you can use the default HTTPS monitor that the Local Traffic Manager provides. This type of monitor verifies the HTTPS service by attempting to receive specific content from a Web page protected by Secure Socket Layer (SSL) security.

Note that one of the pre-configured HTTPS monitors is named https_443, which performs a health check on a server using the IP address supplied by the pool member and port 443.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create https my_https defaults-from https

Creates a monitor named my_https that inherits properties from the default HTTPS monitor.

list https

Displays the properties of all of the HTTPS monitors.

run https my_https destination 10.10.10.10:443

Runs a one-shot test of the custom monitor my_https against a target node at 10.10.10.10:443.

stop https my_https

Cancels a one-shot test of the custom monitor my_https in progress.

show https my_https test-result

Displays the result of the most recent one-shot test of the custom monitor my_https.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%). If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

cert Deprecated since v13.1.0. Use ssl-profile instead. Specifies a file object for a client certificate that the monitor sends to the target SSL server. The default value is none.

cipherlist

Deprecated since v13.1.0. Use ssl-profile instead.

compatibility

Deprecated since v13.1.0. Use ssl-profile instead. Specifies, when enabled, that the SSL options setting (in OpenSSL) is set to ALL. The default value is enabled.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is https.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

ip-dscp

Specifies the differentiated services code point (DSCP). DSCP is a 6-bit value in the Differentiated Services (DS) field of the IP header. It can be used to specify the quality of service desired for the packet. The valid range for this value is 0 to 63 (hex 0x0 to 0x3f). The default value is zero.

key Deprecated since v13.1.0. Use ssl-profile instead. Specifies the RSA private key if the monitored target requires authentication. The key must be surrounded by quotation marks, for example, key \"client.key\". Note that if you specify a key, you must also specify a value for the cert option. The default value is none.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-disable

Specifies a text string that the monitor looks for in the returned resource. If the text string is matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

You specify a recv-disable string in the same way that you specify a recv string.

If you specify a recv-disable string, you must also specify a recv string. You cannot specify a recv-disable string, if the reverse option is enabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object.

The default setting is GET /, which retrieves a default HTML file for a web site. To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html.

Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

ssl-profile

Specifies the server side SSL profile that this monitor will use to ping the monitored node or target.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

DELETE

delete icmp [name]

Note: You cannot delete default monitors.

RUN

run icmp [name] [destination [ip address]]

STOP

stop icmp [name]

DESCRIPTION

You can use the icmp component to configure a custom monitor, or you can use the default ICMP monitor that the Local Traffic Manager provides.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create icmp my_icmp defaults-from icmp

Creates a monitor named my_icmp that inherits properties from the default ICMP monitor.

list icmp

Displays the properties of all of the ICMP monitors.

run icmp my_icmp destination 10.10.10.10

Runs a one-shot test of the custom monitor my_icmp against a target node at IP address 10.10.10.10.

stop icmp my_icmp

Cancels a one-shot test of the custom monitor my_icmp in progress.

show icmp my_icmp test-result

Displays the result of the most recent one-shot test of the custom monitor my_icmp.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is icmp.

description

User defined description.

destination

Specifies the IP address of the resource that is the destination of this monitor. The default value is *.

Possible values are:

* Specifies to perform a health check on the IP address of the node.

IP address

Specifies to perform a health check on the IP address that you specify, and mark the associated node up or down accordingly.

IP address (with the transparent option enabled)

Specifies to perform a health check on the IP address that you specify, route the check through the IP address of the associated node, and mark the IP address of the associated node up or down accordingly.

This option is required for the command run, unless an IP address is specified in the destination option for the custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

test-result

DELETE
delete imap [name]

Note: You cannot delete default monitors.

RUN
run imap [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP
stop imap [name]

DESCRIPTION

You can use the imap component to configure a custom monitor, or you can use the default IMAP monitor that the Local Traffic Manager provides. This type of monitor verifies IMAP by attempting to open a specified mail folder on a server. This monitor is similar to the POP3 monitor.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create imap my_imap defaults-from imap

Creates a monitor named my_imap that inherits properties from the default IMAP monitor.

list imap

Displays the properties of all of the IMAP monitors.

run imap my_imap destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_imap against a target node at 10.10.10.10:80.

stop imap my_imap

Cancels a one-shot test of the custom monitor my_imap in progress.

show imap my_imap test-result

Displays the result of the most recent one-shot test of the custom monitor my_imap.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is imap.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:.*.

Possible values are:

. Specifies to perform a health check on the IP address and port supplied by a pool member.

***:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

folder

Specifies the name of the folder on the IMAP server that the monitor tries to open. The default value is INBOX.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name

Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

show running-config inband

show running-config inband [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete inband [name]

Note: You cannot delete default monitors.

DESCRIPTION

You can use the inband component to configure a custom monitor, or you can use the default Inband monitor that the Local Traffic Manager provides. With this type of monitor the BIG-IP(r) system can perform passive monitoring as part of client requests.

EXAMPLES

create inband my_inband defaults-from inband

Creates a monitor named my_inband that inherits properties from the default Inband monitor.

list inband

Displays the properties of all of the Inband monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is inband.

description

User defined description.

failure-interval

Specifies an interval, in seconds. If the number of failures specified in the failures option occurs within this interval, the system marks the pool member as being unavailable. The default value is 30.

failures

Specifies the number of failures that the system allows to occur, within the time period specified in the failure-interval option, before marking a pool member unavailable. The default value is 3, which means that the system marks the pool member unavailable at the fourth failure. The multiple tmm processes use a per-process number to calculate failures, depending on the specified load. For example, for the Round Robin load balancing method, if there are N tmm processes and M pool members, and the Failures setting is set to L, then up to $N * M * L + 1$ failures can occur before the system marks the node as down.

Specifying a value of 0 (zero) disables this option.

A failure can be either a failure to connect or a failure of the pool member to respond within the time specified in the response-time option.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

response-time

Specifies an amount of time, in seconds. If the pool member does not respond with data after the specified amount of time has passed, the number of failures in this interval increments by 1. Specifying a value of 0 (zero) disables this option.

retry-time

Specifies the amount of time in seconds after the pool member has been marked unavailable before the system retries to connect to the pool member. Specifying a value of 0 (zero) disables this option.

SEE ALSO

BIG-IP 2017-04-05 ltm monitor inband(1)

ltm monitor ldap

NAME

ldap - Configures a Lightweight Directory Access Protocol (LDAP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the ldap component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create ldap [name]

modify ldap [name]

options:

app-service [[string] | none]

base [none | [string]]

chase-referrals [no | yes]

debug [no | yes]

defaults-from [name]

description [string]

destination [[ipv4 address[:port]] | [ipv6 address[:port]]]

filter [[LDAP key] | none]

interval [integer]

mandatory-attributes [no | yes]

manual-resume [enabled | disabled]

password [none | [password]]

security [none | ssl | tls]

```

time-until-up [integer]
timeout [integer]
up-interval [integer]
username [ [name] | none]

edit ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list ldap
list ldap [ [ [name] | [glob] | [regex] ] ... ]
show ldap [ [ [name] | [glob] | [regex] ] ... ]
show running-config ldap
show running-config ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result

DELETE
delete ldap [name]

```

Note: You cannot delete default monitors.

```

RUN
run ldap [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]

STOP
stop ldap [name]

```

DESCRIPTION

You can use the ldap component to configure a custom monitor, or you can use the default LDAP monitor that the Local Traffic Manager provides. This type of monitor verifies the LDAP service by attempting to authenticate the specified user.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```

create ldap my_ldap defaults-from ldap

Creates a monitor named my_ldap that inherits properties from the default LDAP monitor.

list ldap

Displays the properties of all of the LDAP monitors.

run ldap my_ldap destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_ldap against a target node at 10.10.10.10:80.

stop ldap my_ldap

Cancels a one-shot test of the custom monitor my_ldap in progress.

show ldap my_ldap test-result

Displays the result of the most recent one-shot test of the custom monitor my_ldap.

```

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.
 Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

base Specifies the location in the LDAP tree from which the monitor starts the health check. A sample value is dc=bigip-test,dc=net. The default value is none.

chase-referrals

Specifies whether the monitor upon receipt of an LDAP referral entry chases that referral. The default value is yes.

The options are:

no Specifies that the system will treat a referral entry as a normal entry and refrain from querying the remote LDAP server(s) pointed to by the referral entry.

yes Specifies that the system upon receiving any referral entry from the monitored LDAP server query, the system will then query the corresponding LDAP server(s) pointed to by the LDAP query. If the

query for the referral is unsuccessful the system will mark the monitored LDAP server down.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is ldap.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:*.

Possible values are:

: Specifies to perform a health check on the address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

filter

Specifies an LDAP key for which the monitor searches. A sample value is objectclass=*. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

mandatory-attributes

Specifies whether the target must include attributes in its response to be considered up. The default value is no.

The options are:

no Specifies that the system performs only a one-level search (based on the value of the filter option), and does not require that the target returns any attributes.

yes Specifies that the system performs a sub-tree search, and if the target returns no attributes, the target is considered down.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for

a description of regular expression syntax.

security

Specifies the secure communications protocol that the monitor uses to communicate with the target. The default value is none. The options are:

none Specifies that the system does not use a security protocol for communications with the target.

ssl Specifies that the system uses the SSL protocol for communications with the target.

tls Specifies that the system uses the TLS protocol for communications with the target.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor ldap(1)

ltm monitor module-score

NAME

module-score - Configures a Module Score monitor that monitors the performance of a pool or node, rather than the health of the pool or node.

MODULE

ltm monitor

SYNTAX

Configure the module-score component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create module-score [name]

modify module-score [name]

options:

app-service [[string] | none]

debug [no | yes]

defaults-from [name]

description [string]

interval [integer]

pool [name]

snmp-community [none | [string]]

snmp-ip-address [[ip address] | none]

snmp-port [port]

snmp-version [string]

```

time-until-up [integer]
timeout [integer]
up-interval [integer]

edit module-score [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list module-score
list module-score [ [ [name] | [glob] | [regex] ] ... ]
show module-score [ [ [name] | [glob] | [regex] ] ... ]
show running-config module-score
show running-config module-score [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete module-score [name]

```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the module-score component to configure a custom monitor, or you can use the default Module Score monitor that the Local Traffic Manager provides. This type of monitor enables global and local traffic management systems to load balance in a proportional manner to local traffic management virtual servers associated with the Web Accelerator(tm) and Application Security Manager modules. When you configure a Module Score type of monitor, the local traffic management system uses SNMP to pull the gtm_score values from the downstream virtual servers and set the dynamic ratios on the associated upstream local traffic management pool members or nodes.

More specifically, the Module Score monitor retrieves the gtm_score values from the virtual server and the gtm_vs_score values associated with the virtual server. Then, if a pool name is not specified, this monitor sets the dynamic ratio on the node that is associated with the virtual server.

The BIG-IP(r) system uses the lowest non-zero value of the gtm_vs_score values to set the dynamic ratio. If all gtm_vs_score values are zero, then the gtm_score value is used to set the dynamic ratios. If you specify a pool name in the monitor definition, then the dynamic ratio is set on the pool member.

Note: If you want to distribute traffic to a cluster of WebAccelerator or Application Security Manager virtual servers, you must create a separate custom Module Score monitor for each back-end Local Traffic Manager system.

EXAMPLES

```
create module-score my_module-score defaults-from module_score
```

Creates a monitor named my_module-score that inherits properties from the default Module Score monitor.

```
list module-score
```

Displays the properties of all of the Module Score monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is module_score.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the

resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

pool Specifies a Local Traffic Manager pool name. Use this option if you want the system to set dynamic ratios on a pool member instead of on the associated node for the pool member. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

snmp-community
Specifies the identifier for the SNMP community. The default value is public.

snmp-ip-address
Specifies the IP address of the SNMP server. The default value is none.

snmp-port
Specifies the port associated with the SNMP server. The default value is 161.

snmp-version
Specifies the SNMP version in use by the system. The default value is v2c.

time-until-up
Specifies the amount of time in seconds after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-04-05 Itm monitor module-score(1)

Itm monitor mqtt

NAME
mqtt - Configures a Message Queuing Telemetry Transport (MQTT) monitor.

MODULE
Itm monitor

SYNTAX
Configure the mqtt component within the Itm monitor module using the syntax in the following sections.

CREATE/MODIFY
create mqtt [name]

```
modify mqtt [name]
options:
  app-service [[string] | none]
  clientid [ [name] | none]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  interval [integer]
  manual-resume [enabled | disabled]
  mqtt-version [[string] | none]
  password [none | [password] ]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [ [name] | none]
```

```
edit mqtt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list mqtt
list mqtt [ [ [name] | [glob] | [regex] ] ... ]
show mqtt [ [ [name] | [glob] | [regex] ] ... ]
show running-config mqtt
show running-config mqtt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete mqtt [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the mqtt component to configure a custom monitor, or you can use the default mqtt monitor that the Local Traffic Manager provides. This type of monitor verifies the mqtt service by attempting to establish mqtt connection with mqtt server.

EXAMPLES

```
create mqtt my_mqtt defaults-from mqtt
```

Creates a monitor named my_mqtt that inherits properties from the default mqtt monitor.

```
list mqtt
```

Displays the properties of all of the mqtt monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

clientid

Specifies the client identifier to send to MQTT server. The default value is empty.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mqtt.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool

member (the gateway) is marked up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

mqtt-version
Specifies a version to communicate with MQTT server. Default value is 3.1.1.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

SEE ALSO
create, delete, edit, glob, list, modify, regex, show, tmsh

BIG-IP 2017-09-05 ltm monitor mqtt(1)

ltm monitor mssql

NAME
mssql - Configures a Microsoft(r) Windows(r) Structured Query Language (MSSQL) monitor.

MODULE
 ltm monitor

SYNTAX
 Configure the mssql component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create mssql [name]
modify mssql [name]
options:
  app-service [[string] | none]
  count [integer]
  database [ [name] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  interval [integer]
  manual-resume [enabled | disabled]
  password [none | [password] ]
  recv [none | [string] ]
  recv-column [none | [string] ]
  recv-row [none | [string] ]
  send [none | [string] ]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [[name] | none]
```

```
edit mssql [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list mssql
list mssql [ [ [name] | [glob] | [regex] ] ... ]
show mssql [ [ [name] | [glob] | [regex] ] ... ]
show running-config mssql
show running-config mssql [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete mssql [name]
```

Note: You cannot delete default monitors.

RUN

```
run mssql [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

STOP

```
stop mssql [name]
```

DESCRIPTION

You can use the mssql component to configure a custom monitor, or you can use the default Microsoft Windows SQL monitor that the Local Traffic Manager provides. This type of monitor verifies Microsoft Windows SQL-based services.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create mssql my_mssql defaults-from mssql
```

Creates a monitor named my_mssql that inherits properties from the default MSSQL monitor.

```
list mssql
```

Displays the properties of all of the MSSQL monitors.

```
run mssql my_mssql destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_mssql against a target node at 10.10.10.10:80.

```
stop mssql my_mssql
```

Cancels a one-shot test of the custom monitor my_mssql in progress.

show mssql my_mssql test-result

Displays the result of the most recent one-shot test of the custom monitor my_mssql.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

count

Specifies the number of monitor probes after which the connection to the database will be terminated. Count value of zero indicates that the connection will never be terminated. The default value is zero.

database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mssql.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database.

If you do not specify a value for both the send and rcv options, the monitor performs a simple service check and connect only.

rcv-column

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and rcv options. The default value is none.

rcv-row

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and rcv options. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the rcv option and ignores the option even if not null.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 Itm monitor mssql(1)

Itm monitor mysql

NAME

mysql - Configures a MySQL(r) monitor.

MODULE

Itm monitor

SYNTAX

Configure the mysql component within the Itm monitor module using the syntax in the following sections.

CREATE/MODIFY

create mysql [name]

modify mysql [name]

options:

app-service [[string] | none]

```
count [integer]
database [ [name] | none]
debug [no | yes]
defaults-from [name]
description [string]
destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
interval [integer]
manual-resume [enabled | disabled]
password [none | [password] ]
recv [none | [string] ]
recv-column [none | [string] ]
recv-row [none | [string] ]
send [none | [string] ]
time-until-up [integer]
timeout [integer]
up-interval [integer]
username [[name] | none]
```

```
edit mysql [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list mysql
list mysql [ [ [name] | [glob] | [regex] ] ... ]
show mysql [ [ [name] | [glob] | [regex] ] ... ]
show running-config mysql
show running-config mysql [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

```
DELETE
delete mysql [name]
```

Note: You cannot delete default monitors.

```
RUN
run mysql [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

```
STOP
stop mysql [name]
```

DESCRIPTION

You can use the mysql component to configure a custom monitor, or you can use the default MySQL monitor that the Local Traffic Manager provides. This type of monitor verifies MySQL-based services.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create mysql my_mysql defaults-from mysql
```

Creates a monitor named my_mysql that inherits properties from the default MySQL monitor.

```
list mysql
```

Displays the properties of all of the MySQL monitors.

```
run mysql my_mysql destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_mysql against a target node at 10.10.10.10:80.

```
stop mysql my_mysql
```

Cancels a one-shot test of the custom monitor my_mysql in progress.

```
show mysql my_mysql test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_mysql.

OPTIONS

```
app-service
```

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

```
count
```

Specifies the number of monitor probes after which the connection to the database will be terminated.

Count value of zero indicates that the connection will never be terminated. The default value is zero.

database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mysql.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-column

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

recv-row

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor mysql(1)

ltm monitor nntp

NAME

nntp - Configures a Network News Transfer Protocol (NNTP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the nntp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
create nntp [name]
modify nntp [name]
options:
 app-service [[string] | none]
 debug [no | yes]
 defaults-from [name]
 description [string]
 destination [[ipv4 address[:port]] | [ipv6 address[:port]]]
 interval [integer]
 manual-resume [enabled | disabled]
 newsgroup [[name] | none]
 password [none | [password]]
 time-until-up [integer]
 timeout [integer]
 up-interval [integer]
 username [[name] | none]

edit nntp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list nntp

list nntp [[[name] | [glob] | [regex]] ...]

show nntp [[[name] | [glob] | [regex]] ...]

show running-config nntp

show running-config nntp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

test-result

DELETE

delete nntp [name]

Note: You cannot delete default monitors.

RUN

run nntp [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP

stop nntp [name]

DESCRIPTION

You can use the nntp component to configure a custom monitor, or you can use the default NNTP monitor that the Local Traffic Manager provides. This type of monitor verifies the Usenet News protocol service by attempting to retrieve a newsgroup identification string from the server.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create nntp my_nntp defaults-from nntp

Creates a monitor named my_nntp that inherits properties from the default NNTP monitor.

list nntp

Displays the properties of all of the NNTP monitors.

run nntp my_nntp destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_nntp against a target node at 10.10.10.10:80.

stop nntp my_nntp

Cancels a one-shot test of the custom monitor my_nntp in progress.

show nntp my_nntp test-result

Displays the result of the most recent one-shot test of the custom monitor my_nntp.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is nntp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

newsgroup

Specifies the name of the newsgroup that you are monitoring, for example alt.car.mercedes. The default value is none.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

ltm monitor none

NAME

none - Disables monitoring for a node or pool member.

MODULE

ltm monitor

SYNTAX

Apply the none monitor using the syntax in the following sections. The "none" attribute is indicated when viewing the listed node.

MODIFY

modify ltm node [[name] | [glob] | [regex]] ...] monitor none

DISPLAY

list ltm node monitor

DESCRIPTION

To disable monitoring on the node or pool member, set the monitor to none.

EXAMPLES

modify ltm pool [name] monitor none

Apply a none monitor on a pool.

modify ltm pool members modify { [name] { monitor none } }

Apply a none monitor on a pool member.

modify ltm node [name] monitor none

Apply a none monitor on a node.

list ltm node monitor

Displays the monitor applied to all nodes.

list ltm node [name] monitor

Displays the monitor applied to a specific node.

list ltm pool p1 members { all { monitor } }

Displays the monitor applied to all pools' members.

list ltm pool [name] members { monitor }

Displays the monitor applied to a pool's members.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

test-result

DELETE

delete oracle [name]

Note: You cannot delete default monitors.

RUN

run oracle [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP

stop oracle [name]

DESCRIPTION

You can use the oracle component to configure a custom monitor, or you can use the default Oracle monitor that the Local Traffic Manager provides. This type of monitor verifies Oracle database services.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create oracle my_oracle defaults-from oracle

Creates a monitor named my_oracle that inherits properties from the default Oracle monitor.

list oracle

Displays the properties of all of the Oracle monitors.

run oracle my_oracle destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_oracle against a target node at 10.10.10.10:80.

stop oracle my_oracle

Cancels a one-shot test of the custom monitor my_oracle in progress.

show oracle my_oracle test-result

Displays the result of the most recent one-shot test of the custom monitor my_oracle.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

count

Specifies the number of monitor probes after which the connection to the database will be terminated. Count value of zero indicates that the connection will never be terminated. The default value is zero.

database

Specifies the name of the database with which the monitor attempts to communicate. The proper format for database name is ::. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is oracle.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-column

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

recv-row

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

Itm monitor pop3

NAME

pop3 - Configures a Post Office Protocol (POP3) monitor.

MODULE

Itm monitor

SYNTAX

Configure the pop3 component within the Itm monitor module using the syntax in the following sections.

CREATE/MODIFY
create pop3 [name]
modify pop3 [name]
options:
 app-service [[string] | none]
 debug [no | yes]
 defaults-from [name]
 description [string]
 destination [[ipv4 address[:port]] | [ipv6 address[:port]]]
 interval [integer]
 manual-resume [enabled | disabled]
 password [none | [password]]
 time-until-up [integer]
 timeout [integer]
 up-interval [integer]
 username [[name] | none]

edit pop3 [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list pop3
list pop3 [[[name] | [glob] | [regex]] ...]
show pop3 [[[name] | [glob] | [regex]] ...]
show running-config pop3
show running-config pop3 [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line
 partition
 test-result

DELETE
delete pop3 [name]

Note: You cannot delete default monitors.

RUN
run pop3 [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP
stop pop3 [name]

DESCRIPTION

You can use the pop3 component to configure a custom monitor, or you can use the default POP3 monitor that the Local Traffic Manager provides. This type of monitor verifies the POP3 service by attempting to connect to a pool, pool member, or virtual server, log on as the specified user, and log off.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create pop3 my_pop3 defaults-from pop3

Creates a monitor named my_pop3 that inherits properties from the default POP3 monitor.

list pop3

Displays the properties of all of the POP3 monitors.

run pop3 my_pop3 destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_pop3 against a target node at 10.10.10.10:80.

stop pop3 my_pop3

Cancels a one-shot test of the custom monitor my_pop3 in progress.

show pop3 my_pop3 test-result

Displays the result of the most recent one-shot test of the custom monitor my_pop3.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and

labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is pop3.

description
User defined description.

destination
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor pop3(1)

ltm monitor postgresql

NAME
postgresql - Configures a PostgreSQL(r) monitor.

MODULE
ltm monitor

SYNTAX
Configure the postgresql component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
create postgresql [name]
modify postgresql [name]
options:
 app-service [[string] | none]
 count [integer]
 database [[name] | none]
 debug [no | yes]
 defaults-from [name]
 description [string]
 destination [[ipv4 address[:port]] | [ipv6 address[:port]]]
 interval [integer]
 manual-resume [enabled | disabled]
 password [none | [password]]
 recv [none | [string]]
 recv-column [none | [string]]
 recv-row [none | [string]]
 send [none | [string]]
 time-until-up [integer]
 timeout [integer]
 up-interval [integer]
 username [[name] | none]

edit postgresql [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list postgresql
list postgresql [[[name] | [glob] | [regex]] ...]
show postgresql [[[name] | [glob] | [regex]] ...]
show running-config postgresql
show running-config postgresql [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line
 partition
 test-result

DELETE
delete postgresql [name]

Note: You cannot delete default monitors.

RUN

run postgresql [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP

stop postgresql [name]

DESCRIPTION

You can use the postgresql component to configure a custom monitor, or you can use the default PostgreSQL monitor that the Local Traffic Manager provides. This type of monitor verifies PostgreSQL-based services.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create postgresql my_postgresql defaults-from postgresql

Creates a monitor named my_postgresql that inherits properties from the default PostgreSQL monitor.

list postgresql

Displays the properties of all of the PostgreSQL monitors.

run postgresql my_postgresql destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_postgresql against a target node at 10.10.10.10:80.

stop postgresql my_postgresql

Cancels a one-shot test of the custom monitor my_postgresql in progress.

show postgresql my_postgresql test-result

Displays the result of the most recent one-shot test of the custom monitor my_postgresql.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

count

Specifies the number of monitor probes after which the connection to the database will be terminated. Count value of zero indicates that the connection will never be terminated. The default value is zero.

database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is postgresql.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and

port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-column
Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

recv-row
Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor postgresql(1)

ltm monitor radius-accounting

NAME

radius-accounting - Configures a RADIUS accounting monitor for the BIG-IP(r) Local Traffic Manager.

MODULE

ltm monitor

SYNTAX

Configure the radius-accounting component within the ltm monitor module using the syntax shown in the following sections.

CREATE/MODIFY

create radius-accounting [name]

modify radius-accounting [name]

options:

app-service [[string] | none]

debug [no | yes]

defaults-from [[name] | none]

description [string]

destination [ip address]

interval [integer]

manual-resume [disabled | enabled]

nas-ip-address [ip address]

secret [string]

time-until-up [integer]

timeout [integer]

up-interval [integer]

username [none | [string]]

edit radius-accounting [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list radius-accounting

list radius-accounting [[[name] | [glob] | [regex]] ...]

show radius-accounting [[[name] | [glob] | [regex]] ...]

show running-config radius-accounting

show running-config radius-accounting [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete radius-accounting [name]

Note: You cannot delete default monitors.

DESCRIPTION

You can use the radius-accounting component to configure a custom monitor, or you can use the default RADIUS accounting monitor that the Local Traffic Manager provides. This type of monitor provides information about the usage of the RADIUS service for accounting purposes.

EXAMPLES

create radius-accounting my_radius_acct defaults-from radius_accounting

Creates a monitor named my_radius_acct that inherits properties from the default RADIUS accounting monitor.

list radius-accounting

Displays the properties of all of the RADIUS accounting monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is radius.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

nas-ip-address

Specifies the network access server IP address that the system uses to identify itself to the RADIUS server. Using this option, multiple BIG-IP(r) systems can appear as a single network access device to the RADIUS server. The default value is none.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Specifies the secret the monitor needs to communicate with the resource. The default value is none.

time-until-up

Specifies the amount of time in seconds after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

SEE ALSO

DISPLAY

list radius

list radius [[[name] | [glob] | [regex]] ...]

show radius [[[name] | [glob] | [regex]] ...]

show running-config radius

show running-config radius [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

test-result

DELETE

delete radius [name]

Note: You cannot delete default monitors.

RUN

run radius [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP

stop radius [name]

DESCRIPTION

You can use the radius component to configure a custom monitor, or you can use the default RADIUS monitor that the Local Traffic Manager provides. This type of monitor verifies the RADIUS service by attempting to authenticate the specified user.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create radius my_radius defaults-from radius

Creates a monitor named my_radius that inherits properties from the default RADIUS monitor.

list radius

Displays the properties of all of the RADIUS monitors.

run radius my_radius destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_radius against a target node at 10.10.10.10:80.

stop radius my_radius

Cancels a one-shot test of the custom monitor my_radius in progress.

show radius my_radius test-result

Displays the result of the most recent one-shot test of the custom monitor my_radius.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is radius.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression

syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

nas-ip-address

Specifies the network access server IP address that the system uses to identify itself to the RADIUS server. With this option, multiple BIG-IP systems can appear as a single network access device to the RADIUS server. The default value is none.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Specifies the secret the monitor must use when contacting the resource. The default value is none.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

ltm monitor real-server

NAME

real-server - Configures a RealServer(r) monitor.

MODULE

ltm monitor

SYNTAX

Configure the real-server component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create real-server [name]

modify real-server [name]

options:

app-service [[string] | none]

defaults-from [name]

description [string]

interval [integer]

metrics [[metrics] | none]

time-until-up [integer]

timeout [integer]

edit real-server [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list real-server

list real-server [[[name] | [glob] | [regex]] ...]

show real-server [[[name] | [glob] | [regex]] ...]

show running-config real-server

show running-config real-server [[[name] | [glob] | [regex]] ...]

options:

agent

all-properties

command

method

non-default-properties

one-line

partition

DELETE

delete real-server [name]

Note: You cannot delete default monitors.

DESCRIPTION

You can use the real-server component to configure a custom monitor, or you can use the default RealServer monitor that the Local Traffic Manager provides. This type of monitor checks the performance of a pool, pool member, or virtual server that is running the RealServer data collection agent, and then dynamically load balances traffic accordingly.

EXAMPLES

```
create real-server my_real-server defaults-from real_server
```

Creates a monitor named my_real-server that inherits properties from the default RealServer monitor.

```
list real-server
```

Displays the properties of all of the RealServer monitors.

OPTIONS

agent

Displays the agent for the monitor. The default agent is Mozilla/4.0 (compatible: MSIE 5.0; Windows NT). You cannot modify the agent.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

command

Displays the command that the system uses to obtain the metrics from the resource. See the documentation for this resource for information on available commands. You cannot modify the command.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is real-server.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 5 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

method

Displays the GET method. You cannot modify the method.

metrics

Specifies the performance metrics that the commands collect from the target. The default value is ServerBandwidth:1.5, CPUPercentUsage, MemoryUsage, TotalClientCount.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

```
list rpc
list rpc [ [ [name] | [glob] | [regex] ] ... ]
show rpc [ [ [name] | [glob] | [regex] ] ... ]
show running-config rpc
show running-config rpc [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete rpc [name]
```

Note: You cannot delete default monitors.

RUN

```
run rpc [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

STOP

```
stop rpc [name]
```

DESCRIPTION

You can use the rpc component to configure a custom monitor, or you can use the default RPC monitor that the Local Traffic Manager provides. This type of monitor queries the RPC server, and verifies the availability of a given program.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create rpc my_rpc defaults-from rpc
```

Creates a monitor named my_rpc that inherits properties from the default RPC monitor.

```
list rpc
```

Displays the properties of all of the RPC monitors.

```
run rpc my_rpc destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_rpc against a target node at 10.10.10.10:80.

```
stop rpc my_rpc
```

Cancels a one-shot test of the custom monitor my_rpc in progress.

```
show rpc my_rpc test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_rpc.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is rpc.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The

default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

mode Specifies the protocol that the monitor uses to communicate with the target. The default value is tcp.

The options are:

tcp Specifies that the monitor uses the TCP protocol to communicate with the target object.

udp Specifies that the monitor uses the UDP protocol to communicate with the target object.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

program-number

Specifies the number of the program for which you want the monitor to verify availability. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

version-number

Specifies the number of the version for which you want the monitor to verify availability. The default value is none.

ltm monitor sasp

NAME

sasp - Configures a Server Application State Protocol (SASP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the sasp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create sasp [name]

modify sasp [name]

options:

app-service [[string] | none]

defaults-from [name]

description [string]

interval [integer]

mode [pull | push]

primary-address [ip address]

protocol [tcp | udp]

secondary-address [[ip address] | none]

service [none | [port]]

time-until-up [integer]

timeout [integer]

edit sasp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list sasp

list sasp [[[name] | [glob] | [regex]] ...]

show sasp [[[name] | [glob] | [regex]] ...]

show running-config sasp

show running-config sasp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete sasp [name]

Note: You cannot delete default monitors.

DESCRIPTION

You can use the sasp component to configure a custom monitor, or you can use the default FTP monitor that the Local Traffic Manager provides. This type of monitor verifies the availability of IBM Group Workload Managers network resources.

EXAMPLES

create sasp my_sasp defaults-from sasp

Creates a monitor named my_sasp that inherits properties from the default SASP monitor.

list sasp

Displays the properties of all of the SASP monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `sasp`.

description
User defined description.

glob Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

interval
Specifies the frequency at which the system issues the monitor check. The default value is `auto`.

mode Specifies whether the load balancer should send Get Weight Request messages (pull) or receive Send Weights messages (push) from the GWM. The default mode is `push`.

name Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

partition
Displays the administrative partition within which the component resides.

primary-address
Specifies the IP address of the primary Group Workload Manager.

protocol
Specifies the protocol that the monitor uses to communicate with the target. The default value is `tcp`.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

secondary-address
Specifies the IP address of the secondary Group Workload Manager.

service
Specifies the port through which the SASP monitor communicates with the Group Workload Manager. The default port is `3860`.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 100 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

SEE ALSO
`create`, `delete`, `edit`, `glob`, `list`, `modify`, `regex`, `show`, `tmsh`

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2017-11-17 `ltm monitor sasp(1)`

ltm monitor scripted

NAME
`scripted` - Configures a Scripted monitor.

MODULE
`ltm monitor`

SYNTAX
Configure the scripted component within the `ltm monitor` module using the syntax in the following sections.

CREATE/MODIFY
create scripted [name]
modify scripted [name]
options:
 app-service [[string] | none]
 debug [no | yes]
 defaults-from [name]
 description [string]
 destination [[ipv4 address[:port]] | [ipv6 address[:port]]]
 filename [[filename] | none]
 interval [integer]
 manual-resume [enabled | disabled]
 time-until-up [integer]
 timeout [integer]
 up-interval [integer]

edit scripted [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list scripted
list scripted [[[name] | [glob] | [regex]] ...]
show scripted [[[name] | [glob] | [regex]] ...]
show running-config scripted
show running-config scripted [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line
 partition
 test-result

DELETE
delete scripted [name]

Note: You cannot delete default monitors.

RUN
run scripted [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP
stop scripted [name]

DESCRIPTION

You can use the scripted component to configure a custom monitor, or you can use the default scripted monitor that the Local Traffic Manager provides.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create scripted my_scripted defaults-from scripted

Creates a monitor named my_scripted that inherits properties from the default scripted monitor.

list scripted

Displays the properties of all of the scripted monitors.

run scripted my_scripted destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_scripted against a target node at 10.10.10.10:80.

stop scripted my_scripted

Cancels a one-shot test of the custom monitor my_scripted in progress.

show scripted my_scripted test-result

Displays the result of the most recent one-shot test of the custom monitor my_scripted.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is scripted.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

`*:port`

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

filename

Specifies the name of a file in the `/config/eav/` directory on the system. The user-created file contains the send and expect data that the monitor uses for the monitor check. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is

up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-08-16 ltm monitor scripted(1)

ltm monitor sip

NAME

sip - Configures a Session Initiation Protocol (SIP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the sip component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create sip [name]
modify sip [name]
options:
  app-service [[string] | none]
  cert [ [cert list] | none]
  cipherlist [string]
  compatibility [enabled | disabled]
  debug [ no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
  filter [any | none | status]
  filter-neg [any | none | status]
  headers [ [new line separated headers] | none]
  interval [integer]
  key [ [key] | none]
  manual-resume [enabled | disabled]
  mode [sips | tcp | tls | udp | mr-tls | mr-sips | mr-tcp | mr-udp | mr-sctp]
  request [none | [string] ]
  time-until-up [integer]
  up-interval [integer]
  username [ [name] | none]
```

```
edit sip [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
  all-properties
  non-default-properties
```

DISPLAY

```
list sip
list sip [ [ [name] | [glob] | [regex] ] ... ]
show sip [ [ [name] | [glob] | [regex] ] ... ]
show running-config sip
show running-config sip [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete sip [name]
```

Note: You cannot delete default monitors.

RUN

```
run sip [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]
```

STOP
stop sip [name]

DESCRIPTION

You can use the sip component to configure a custom monitor, or you can use the default SIP monitor that the Local Traffic Manager provides. This type of monitor checks the status of SIP Call-ID services on a device. The SIP protocol enables real-time messaging, voice, data, and video.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create sip my_sip defaults-from sip

Creates a monitor named my_sip that inherits properties from the default SIP monitor.

list sip

Displays the properties of all of the SIP monitors.

run sip my_sip destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_sip against a target node at 10.10.10.10:80.

stop sip my_sip

Cancels a one-shot test of the custom monitor my_sip in progress.

show sip my_sip test-result

Displays the result of the most recent one-shot test of the custom monitor my_sip.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

cert Specifies a fully-qualified path for a client certificate that the monitor sends to the target SSL server. The default value is none. Currently ignored for "mr-" modes.

cipherlist

Specifies the list of ciphers for this monitor. The default value is DEFAULT:+SHA:+3DES:+kEDH. Currently ignored for "mr-" modes.

compatibility

Specifies, when enabled, that the SSL options setting (in OpenSSL) is set to ALL. The default value is enabled. Currently ignored for "mr-" modes.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is sip.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

filter

Specifies the SIP status codes that the target can return to be considered up. By default the system always accepts status codes whose value is in the 100, 200 or 300s.

The options are:

any Specifies that the monitor accepts any SIP status codes.

none Specifies that the monitor does not accept any other SIP status codes. This is the default value.

status

Specifies one or more status codes that you want to add to the monitor.

filter-neg

Specifies the SIP status codes that the target can return to be considered down. By default the system always accepts status codes according to sip-monitor.filter. After checking that, the status code is checked against this key. If a code is also in sip-monitor.filter, the node is marked up.

The options are:

any Specifies that the monitor rejects all SIP status codes that are not in sip-monitor.filter.

none Specifies that the monitor does not specifically reject any other SIP status codes. This is the default value.

status

Specifies one or more status codes that you want to add to the monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

headers

Specifies the set of SIP headers in the SIP message that is sent to the target. Separate each header with a new line. The default value is none.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

key Specifies the key if the monitored target requires authentication. The default value is none. Currently ignored for "mr-" modes.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

mode Specifies the transport protocol that the monitor uses to communicate with the target. The default mode is udp. The options are:

sips Specifies that the monitor uses SIPS to communicate with the target.

tcp Specifies that the monitor uses TCP to communicate with the target.

tls Specifies that the monitor uses TLS to communicate with the target, and the SIP URI is SIPS.

udp Specifies that the monitor uses UDP to communicate with the target.

mr-tls

Specifies that the monitor uses TLS with the message-routing framework to communicate with the target. This is serverside SSL over TCP. Note: Customizing the SSL-related options (cert, cipherlist, compatibility, key) is currently ignored for this mode, and the monitor will operate with the default values.

mr-sips

Specifies that the monitor uses SIPS with the message-routing framework to communicate with the target. This is TLS mode with "sips" replacing "sip" in the SIP message headers. Note: Customizing the SSL-related options (cert, cipherlist, compatibility, key) is currently ignored for this mode, and the monitor will operate with the default values.

mr-tcp

Specifies that the monitor uses TCP with the message-routing framework to communicate with the target.

mr-udp

Specifies that the monitor uses UDP with the message-routing framework to communicate with the target.

`mr-sctp`

Specifies that the monitor uses SCTP with the message-routing framework to communicate with the target.

The modes beginning with "mr-" use an in-TMM monitor based on the message-routing framework (MRF). The other modes use the legacy monitor based on message-based load balancing (MBLB).

`name` Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

`request`

Specifies the SIP request line in the SIP message that is sent to the target. The default value is none.

`test-result`

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

`time-until-up`

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is

`timeout`

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

`up-interval`

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2019-10-28 ltm monitor sip(1)

ltm monitor smb

NAME

smb - Configures a Server Message Bloc (SMB)/Common Internet File System (CIFS) monitor.

MODULE

ltm monitor

SYNTAX

Configure the smb component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create smb [name]

modify smb [name]

options:

app-service [[string] | none]

debug [no | yes]

defaults-from [name]

```
description [string]
destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
get [none | [filename] ]
interval [integer]
manual-resume [enabled | disabled]
password [none | [password] ]
server [ [NETBIOS name] | none]
service [ [[name] | [integer]] | none]
time-until-up [integer]
timeout [integer]
up-interval [integer]
username [ [name] | none]
```

```
edit smb [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list smb
list smb [ [ [name] | [glob] | [regex] ] ... ]
show smb [ [ [name] | [glob] | [regex] ] ... ]
show running-config smb
show running-config smb [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

```
DELETE
delete smb [name]
```

Note: You cannot delete default monitors.

```
RUN
run smb [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]
```

```
STOP
stop smb [name]
```

DESCRIPTION

You can use the smb component to configure a custom monitor, or you can use the default SMB monitor that the Local Traffic Manager provides. This type of monitor verifies the availability of an SMB/CIFS server. You can use this type of monitor to either check the availability of the server as a whole, the availability of a specific service on the server, or the availability of a specific file used by a service.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create smb my_smb defaults-from smb
```

Creates a monitor named my_smb that inherits properties from the default SMB monitor.

```
list smb
```

Displays the properties of all of the SMB monitors.

```
run smb my_smb destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_smb against a target node at 10.10.10.10:80.

```
stop smb my_smb
```

Cancels a one-shot test of the custom monitor my_smb in progress.

```
show smb my_smb test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_smb.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `smb`.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

`*:port`

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command `run`, unless an IP address and service port are specified in the `destination` option for the specified custom monitor.

get Specifies a file associated with a service. The default value is `none`.

The monitor uses the relative path to the service itself when attempting to locate the file. You are not required to specify a value for this option; however, if you elect to use this option you must also specify a value for the `service` option.

glob Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the `up-interval` option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the `manual-resume` option is disabled.

Note that if you set the `manual-resume` option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands `create`, `delete`, `modify`, `run` and `stop`.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is `none`.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

server

Specifies the NetBIOS name of the SMB/CIFS server for which this monitor checks for availability. You must specify a server for this monitor to function. The default value is `none`.

service

Specifies a specific service on the SMB/CIFS for which you want to verify availability. The default value is `none`.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the

node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the user name if the monitored target requires authentication. The default value is none.

partition

test-result

DELETE
delete smtp [name]

Note: You cannot delete default monitors.

RUN
run smtp [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP
stop smtp [name]

DESCRIPTION

You can use the smtp component to configure a custom monitor, or you can use the default SMTP monitor that the Local Traffic Manager provides. This type of monitor checks the status of a pool, pool member, or virtual server by issuing standard SMTP commands.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create smtp my_smtp defaults-from smtp

Creates a monitor named my_smtp that inherits properties from the default SMTP monitor.

list smtp

Displays the properties of all of the SMTP monitors.

run smtp my_smtp destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_smtp against a target node at 10.10.10.10:80.

stop smtp my_smtp

Cancels a one-shot test of the custom monitor my_smtp in progress.

show smtp my_smtp test-result

Displays the result of the most recent one-shot test of the custom monitor my_smtp.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is smtp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the

destination option for the specified custom monitor.

domain

Specifies the domain name to check, for example, bigipinternal.com. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

Itm monitor snmp-dca-base

NAME

snmp-dca-base - Configures a base Simple Network Management Protocol (SNMP) Data Center Audit monitor.

MODULE

Itm monitor

SYNTAX

Configure the snmp-dca-base component within the Itm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create snmp-dca-base [name]
modify snmp-dca-base [name]
options:
  app-service [[string] | none]
  community [ [name] | none]
  cpu-coefficient [ [integer] | none]
  defaults-from [name]
  description [string]
  interval [integer]
  time-until-up [integer]
  timeout [integer]
  user-defined [ [name] [value] | [name] none ]
  version [ [integer] | none]

edit snmp-dca-base [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list snmp-dca-base
list snmp-dca-base [ [ [name] | [glob] | [regex] ] ... ]
show snmp-dca-base [ [ [name] | [glob] | [regex] ] ... ]
show running-config snmp-dca-base
show running-config snmp-dca-base [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete snmp-dca-base [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the snmp-dca-base component to configure a custom monitor, or you can use the default base SNMP DCA monitor that the Local Traffic Manager provides. This type of monitor checks the performance of a server running an SNMP agent such as UC Davis. Use this monitor only when you want the load balancing destination to be based solely on user data, and not CPU, memory or disk use.

EXAMPLES

```
create snmp-dca-base my_snmp-dca-base defaults-from snmp_dca_base
```

Creates a monitor named my_snmp-dca-base that inherits properties from the default base SNMP DCA monitor.

```
list snmp-dca-base
```

Displays the properties of all of the base SNMP DCA monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

community

Specifies the community name that the BIG-IP system must use to authenticate with the host server through SNMP. The default value is public.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is snmp_dca_base.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

user-defined

Specifies any user-defined command-line arguments and variables that the external program requires. Use the following syntax to specify a user defined parameter.

modify external my_external user-defined my_param_name my_param_value

Use the following syntax to remove a user defined parameter.

modify external my_external user-defined my_param_name none

version

Specifies the version of SNMP that the host server uses. The default value is none.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

partition

DELETE
delete snmp-dca [name]

Note: You cannot delete default monitors.

DESCRIPTION

You can use the snmp-dca component to configure a custom monitor, or you can use the default SNMP DCA monitor that the Local Traffic Manager provides. This type of monitor checks the performance of a server running an SNMP agent such as UC Davis, for the purpose of load balancing traffic to that server.

EXAMPLES

create snmp-dca my_snmp-dca defaults-from snmp_dca

Creates a monitor named my_snmp-dca that inherits properties from the default SNMP DCA monitor.

list snmp-dca

Displays the properties of all of the SNMP DCA monitors.

OPTIONS

agent-type
Specifies the type of agent. The default value is ucd.

app-service
Specifies the name of the application service to which the monitor belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

community
Specifies the community name that the BIG-IP system must use to authenticate with the host server through SNMP. The default value is public.

cpu-coefficient
Specifies the coefficient that the system uses to calculate the weight of the CPU threshold in the dynamic ratio load balancing algorithm. The default value is 1.5.

cpu-threshold
Specifies the maximum acceptable CPU usage on the target server. The default value is 80 percent.

defaults-from
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is snmp_dca.

description
User defined description.

disk-coefficient
Specifies the coefficient that the system uses to calculate the weight of the disk threshold in the dynamic ratio load balancing algorithm. The default value is 2.0.

disk-threshold
Specifies the maximum acceptable disk usage on the target server. The default value is 90 percent.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

memory-coefficient
Specifies the coefficient that the system uses to calculate the weight of the memory threshold in the dynamic ratio load balancing algorithm. The default value is 1.0.

memory-threshold
Specifies the maximum acceptable memory usage on the target server. The default value is 70 percent.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for

a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

user-defined

Specifies attributes for a monitor that you define. The default value is none.

version

Specifies the version of SNMP that the host server uses. The default value is none.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

parameter-type [bool | int | long | string]

parameter-value [none | [integer] | [string]]

password [none | [password]]

protocol [http | https]

return-type [bool | char | double | int | long | short | string]

return-value [none | [integer] | [string]]

soap-action [string]

time-until-up [integer]

timeout [integer]

up-interval [integer]

url-path [none | [string]]

username [[name] | none]

edit soap [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list soap

```
list soap [ [ [name] | [glob] | [regex] ] ... ]
show soap [ [ [name] | [glob] | [regex] ] ... ]
show running-config soap
show running-config soap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

```
DELETE
delete soap [name]
```

Note: You cannot delete default monitors.

```
RUN
run soap [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

```
STOP
stop soap [name]
```

DESCRIPTION

You can use the soap component to configure a custom monitor, or you can use the default SOAP monitor that the Local Traffic Manager provides. This type of monitor tests a Web service based on SOAP.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create soap my_soap defaults-from soap
```

Creates a soap monitor that inherits values from the system default SOAP monitor.

```
list soap
```

Displays the properties of all of the SOAP monitors.

```
run soap my_soap destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_soap against a target node at 10.10.10.10:80.

```
stop soap my_soap
```

Cancels a one-shot test of the custom monitor my_soap in progress.

```
show soap my_soap test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_soap.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the type of monitor you want to use to create the new monitor. The default value is soap.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member

and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

expect-fault

Specifies whether the value of the method option causes the monitor to expect a SOAP fault message. The default value is no.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

method

Specifies the method by which the monitor contacts the resource.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

namespace

Specifies the name space for the Web service you are monitoring, for example, http://example.com/. The default value is none.

parameter-name

If the method has a parameter, specifies the name of that parameter. The default value is none.

parameter-type

Specifies the parameter type. The default value is bool.

parameter-value

Specifies the value for the parameter. The default value is none.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

protocol

Specifies the protocol that the monitor uses to communicate with the target, http or https. The default value is http.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

return-type

Specifies the type for the returned parameter. The default value is bool.

return-value

Specifies the value for the returned parameter. The default value is none.

soap-action

Specifies the value for the SOAPAction header. The default value is the empty string.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds

with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

url-path

Specifies the URL for the Web service that you are monitoring, for example, /services/myservice.aspx. The default value is none.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the user name if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor soap(1)

ltm monitor tcp-echo

NAME

tcp-echo - Configures a Transmission Control Protocol (TCP) Echo monitor.

MODULE

ltm monitor

SYNTAX

Configure the tcp-echo component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create tcp-echo [name]

modify tcp-echo [name]

options:

adaptive [enabled | disabled]

adaptive-divergence-type [relative | absolute]

adaptive-divergence-value [integer]

adaptive-limit [integer]

adaptive-sampling-timespan [integer]

app-service [[string] | none]

defaults-from [name]

description [string]

destination [[ipv4 address[:port]] | [ipv6 address[:port]]]

interval [integer]

manual-resume [enabled | disabled]

time-until-up [integer]

timeout [integer]

transparent [disabled | enabled]

up-interval [integer]

edit tcp-echo [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list tcp-echo

list tcp-echo [[[name] | [glob] | [regex]] ...]

show tcp-echo [[[name] | [glob] | [regex]] ...]

show running-config tcp-echo

show running-config tcp-echo [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

test-result

DELETE
delete tcp-echo [name]

Note: You cannot delete default monitors.

RUN
run tcp-echo [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP
stop tcp-echo [name]

DESCRIPTION

You can use the tcp-echo component to configure a custom monitor, or you can use the default TCP Echo monitor that the Local Traffic Manager provides. This type of monitor checks the status of a resource, using TCP Echo.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create tcp-echo my_tcp-echo defaults-from tcp_echo

Creates a monitor named my_tcp-echo that inherits properties from the default TCP Echo monitor.

list tcp-echo

Displays the properties of all of the TCP Echo monitors.

run tcp-echo my_tcp-echo destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_tcp-echo against a target node at 10.10.10.10:80.

stop tcp-echo my_tcp-echo

Cancels a one-shot test of the custom monitor my_tcp-echo in progress.

show tcp-echo my_tcp-echo test-result

Displays the result of the most recent one-shot test of the custom monitor my_tcp-echo.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%). If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is tcp_echo.

description

User defined description.

destination

Specifies the IP address of the resource that is the destination of this monitor. The default value is *.

Possible values are:

- * Specifies to perform a health check on the IP address of the node.

IP address

Specifies to perform a health check on the IP address that you specify, and mark the associated node up or down accordingly.

IP address (with the transparent option enabled)

Specifies to perform a health check on the IP address that you specify, route the check through the IP address of the associated node, and mark the IP address of the associated node up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

Itm monitor tcp-half-open

NAME

tcp-half-open - Configures a Transmission Control Protocol (TCP) Half Open monitor.

MODULE

Itm monitor

SYNTAX

Configure the tcp-half-open component within the Itm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create tcp-half-open [name]
modify tcp-half-open [name]
options:
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  interval [integer]
  manual-resume [enabled | disabled]
  time-until-up [integer]
  timeout [integer]
  transparent [disabled | enabled]
  up-interval [integer]
```

```
edit tcp-half-open [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list tcp-half-open
list tcp-half-open [ [ [name] | [glob] | [regex] ] ... ]
show tcp-half-open [ [ [name] | [glob] | [regex] ] ... ]
show running-config tcp-half-open
show running-config tcp-half-open [ [ [name] | [glob] |
  [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete tcp-half-open [name]
```

Note: You cannot delete default monitors.

RUN

```
run tcp-half-open [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

STOP

```
stop tcp-half-open [name]
```

DESCRIPTION

You can use the tcp-half-open component to configure a custom monitor, or you can use the default TCP Half Open monitor that the Local Traffic Manager provides.

For more information about configuring monitors, refer to the Configuration Guide for BIG-IP(r) Local Traffic Manager(r).

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create tcp-half-open my_tcp-half-open defaults-from tcp_half_open
```

Creates a monitor named my_tcp-half-open that inherits properties from the default TCP Half Open monitor.

```
list tcp-half-open
```

Displays the properties of all of the TCP Half Open monitors.

run tcp-half-open my_tcp-half-open destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_tcp-half-open against a target node at 10.10.10.10:80.

stop tcp-half-open my_tcp-half-open

Cancels a one-shot test of the custom monitor my_tcp-half-open in progress.

show tcp-half-open my_tcp-half-open test-result

Displays the result of the most recent one-shot test of the custom monitor my_tcp-half-open.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is tcp_half_open.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *:.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

stop tcp [name]
```

DESCRIPTION

You can use the tcp component to configure a custom monitor, or you can use the default TCP monitor that the Local Traffic Manager provides.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create tcp my_tcp defaults-from tcp
```

Creates a monitor named my_tcp that inherits properties from the default TCP monitor.

```
list tcp
```

Displays the properties of all of the TCP monitors.

```
run tcp my_tcp destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_tcp against a target node at 10.10.10.10:80.

```
stop tcp my_tcp
```

Cancels a one-shot test of the custom monitor my_tcp in progress.

```
show tcp my_tcp test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_tcp.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The

default value is tcp.

description
User defined description.

destination
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)
Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

ip-dscp
Specifies the differentiated services code point (DSCP). DSCP is a 6-bit value in the Differentiated Services (DS) field of the IP header. It can be used to specify the quality of service desired for the packet. The valid range for this value is 0 to 63 (hex 0x0 to 0x3f). The default value is zero.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-disable
Specifies a text string that the monitor looks for in the returned resource. If the text string is matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

You specify a recv-disable string in the same way that you specify a recv string.

If you specify a recv-disable string, you must also specify a recv string. You cannot specify a recv-disable string, if the reverse option is enabled.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse
Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object. The default setting is GET /, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-08-16 ltm monitor tcp(1)

ltm monitor udp

NAME

udp - Configures a User Datagram Protocol (UDP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the udp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create udp [name]

modify udp [name]

options:

adaptive [enabled | disabled]

adaptive-divergence-type [relative | absolute]

adaptive-divergence-value [integer]

adaptive-limit [integer]

adaptive-sampling-timespan [integer]

app-service [[string] | none]

debug [no | yes]

defaults-from [name]

description [string]

destination [[ipv4 address[:port]] | [ipv6 address[:port]]]

interval [integer]

manual-resume [enabled | disabled]

```
recv [none | [string] ]
recv-disable [none | [string] ]
reverse [enabled | disabled]
send [none | [string] ]
time-until-up [integer]
timeout [integer]
transparent [disabled | enabled]
up-interval [integer]
```

```
edit udp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list udp
list udp [ [ [name] | [glob] | [regex] ] ... ]
show udp [ [ [name] | [glob] | [regex] ] ... ]
show running-config udp
show running-config udp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

```
DELETE
delete udp [name]
```

Note: You cannot delete default monitors.

```
RUN
run udp [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

```
STOP
stop udp [name]
```

DESCRIPTION

You can use the udp component to configure a custom monitor, or you can use the default UDP monitor that the Local Traffic Manager provides. This type of monitor verifies the UDP service by attempting to send UDP packets to a pool, pool member, or virtual server and receiving a reply.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create udp my_udp defaults-from udp
```

Creates a monitor named my_udp that inherits properties from the default UDP monitor.

```
list udp
```

Displays the properties of all of the UDP monitors.

```
run udp my_udp destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_udp against a target node at 10.10.10.10:80.

```
stop udp my_udp
```

Cancels a one-shot test of the custom monitor my_udp in progress.

```
show udp my_udp test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_udp.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool

member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is udp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

. Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

recv-disable

Specifies a text string that the monitor looks for in the returned resource. If the text string is

matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

The recv-disable string may be specified the same way a recv string may be specified.

If the recv-disable string is configured, the recv string must be non-empty. The recv-disable string may not be configured if reverse mode is enabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object. The default value is GET /, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if it is not null. The default value is none.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-08-16 ltm monitor udp(1)

ltm monitor virtual-location

NAME

virtual-location - Configures a Virtual Location monitor.

MODULE

ltm monitor

SYNTAX

Configure the virtual-location component within the ltm monitor module using the syntax shown in the following sections.

CREATE/MODIFY

```
create virtual-location [name]
modify virtual-location [name]
options:
  app-service [[string] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  interval [integer]
  pool [name]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
```

```
edit virtual-location [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list virtual-location
list virtual-location [ [ [name] | [glob] | [regex] ] ... ]
show virtual-location [ [ [name] | [glob] | [regex] ] ... ]
show running-config virtual-location
show running-config virtual-location
    [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete virtual-location [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

The Virtual Location monitor will determine if a pool member which has a virtual IP is currently a local pool member with its arp entry existing on a local VLAN, or, a remote pool member with its ARP entry existing on a tunnel VLAN. If the pool member is local it will set the pool member's priority to 2. If the pool member is remote it will set the priority to 1 (a lower priority). The Virtual Location will always return up as the availability for the pool member. It is necessary to use an additional monitor to check the availability status of the pool member.

You can use the virtual-location component to configure a custom monitor, or you can use the default Virtual Location monitor that the Local Traffic Manager provides.

EXAMPLES

```
create virtual-location my_virtual-location defaults-from virtual_location pool aPool
```

Creates a monitor named my_virtual-location that inherits properties from the default Virtual Location monitor.

```
list virtual-location
```

Displays the properties of all of the Virtual Location monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. The default setting is no. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The options are no (specifies that the system does not redirect error messages and additional information related to this monitor.) and yes (specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.)

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is virtual_location.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

pool Specifies the pool for the target pool member. This is a required argument.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2016-03-14 ltm monitor virtual-location(1)

ltm monitor wap

NAME

wap - Configures a Wireless Application Protocol (WAP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the wap component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create wap [name]

modify wap [name]

options:

accounting-node [none | [RADIUS server name]]

accounting-port [[integer] | none]

app-service [[string] | none]

call-id [none | [RADIUS server 11 digit phone number]]

debug [no | yes]

defaults-from [name]

description [string]

destination [[ipv4 address[:port]] | [ipv6 address[:port]]]

framed-address [none | [RADIUS framed IP address]]
interval [integer]
manual-resume [enabled | disabled]
recv [none | [string]]
secret [none | [password]]
send [none | [string]]
server-id [none | [RADIUS NAS-ID]]
session-id [none | [RADIUS session ID]]
time-until-up [integer]
timeout [integer]
up-interval [integer]

edit wap [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list wap
list wap [[[name] | [glob] | [regex]] ...]
show wap [[[name] | [glob] | [regex]] ...]
show running-config wap
show running-config wap [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition
test-result

DELETE
delete wap [name]

Note: You cannot delete default monitors.

RUN
run wap [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP
stop wap [name]

DESCRIPTION

You can use the wap component to configure a custom monitor, or you can use the default WAP monitor that the Local Traffic Manager provides. This type of monitor requests the URL specified in the send option, and finds the string specified in the recv option somewhere in the data returned by the URL response.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an Itm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create wap my_wap defaults-from wap

Creates a monitor named my_wap that inherits properties from the default WAP monitor.

list wap

Displays the properties of all of the WAP monitors.

run wap my_wap destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_wap against a target node at 10.10.10.10:80.

stop wap my_wap

Cancels a one-shot test of the custom monitor my_wap in progress.

show wap my_wap test-result

Displays the result of the most recent one-shot test of the custom monitor my_wap.

OPTIONS

accounting-node

Specifies the RADIUS server that provides authentication for the WAP target. Note that if you configure the accounting-port option, but you do not configure the this option, the system assumes that the RADIUS server and the WAP server are the same system.

accounting-port

Specifies the port that the monitor uses for RADIUS accounting. The default value is none. A value of 0 (zero) disables RADIUS accounting.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot

modify or delete the monitor. Only the application service can modify or delete the monitor.

call-id

Specifies the 11-digit phone number for the RADIUS server. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is wap.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

***:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

framed-address

Specifies the RADIUS framed IP address. The default value is none.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

recv Specifies the text string that the monitor looks for in the returned resource. The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names. If you do not specify both a value for both the send and recv options, the monitor performs a simple service check and connect only. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@{regular expression}`) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Specifies the password the monitor needs to access the resource. The default value is none.

send Specifies the text string that the monitor sends to the target object. The default setting is GET /, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if it is not null. The default value is none.

server-id

Specifies the RADIUS NAS-ID for this system when configuring a RADIUS server. The default value is none.

session-id

Specifies the RADIUS session identification number when configuring a RADIUS server. The default value is none.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-08-16 ltm monitor wap(1)

ltm monitor wmi

NAME

wmi - Configures a Windows Management Infrastructure (WMI) monitor.

MODULE

ltm monitor

SYNTAX

Configure the wmi component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create wmi [name]

modify wmi [name]

options:

agent [string]

app-service [[string] | none]

command [[command] | none]

defaults-from [name]

description [string]

interval [integer]

metrics [[value] | none]

password [none | [password]]

time-until-up [integer]

timeout [integer]

url [none | [URL]]

```

username [ [name] | none]

edit wmi [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list wmi
list wmi [ [ [name] | [glob] | [regex] ] ... ]
show wmi [ [ [name] | [glob] | [regex] ] ... ]
show running-config wmi
show running-config wmi [ [ [name] | [glob] | [regex] ] ... ]
options:
  agent
  all-properties
  method
  non-default-properties
  one-line
  partition
  post

DELETE
delete wmi [name]

```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the wmi component to configure a custom monitor, or you can use the default WMI monitor that the Local Traffic Manager provides. This type of monitor checks the performance of a pool, pool member, or virtual server that is running the WMI data collection agent, and then dynamically load balances traffic accordingly.

EXAMPLES

```
create wmi my_wmi defaults-from wmi
```

Creates a monitor named my_wmi that inherits properties from the default WMI monitor.

```
list wmi
```

Displays the properties of all of the WMI monitors.

OPTIONS

agent

Displays the agent for the monitor. The default agent is Mozilla/4.0 (compatible: MSIE 5.0; Windows NT).

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

command

Specifies the command that the system uses to obtain the metrics from the resource. See the documentation for this resource for information on available commands.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is wmi.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 5 seconds.

method

Displays the GET method. You cannot modify the method.

metrics

Specifies the performance metrics that the commands collect from the target. The default value is LoadPercentage, DiskUsage, PhysicalMemoryUsage:1.5, VirtualMemoryUsage:2.0.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

post

Specifies the mechanism that the monitor uses for posting. The default value is RespFormat=HTML.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at

sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

url Specifies the URL that the monitor uses. The default value is /scripts/f5Isapi.dll.

username

Specifies the user name if the monitored target requires authentication. The default value is none.

SEE ALSO

BIG-IP 2017-04-05 ltm monitor wmi(1)

ltm nat-stats

NAME nat-stats - Shows Network address translation roll up statistics.

MODULE

cgnat afm

SYNTAX

Display NAT stats per roll-up-level using the following syntax.

DISPLAY

show nat-stats roll-up-level [...]

name [...] stat [...]

options:

all (where applicable)

recursive

DESCRIPTION

This command displays NAT stats per roll up level specified. Supported stat types for each roll up level may vary.

roll-up-levels

lsn-pool - Provide the stats for lsn-pool.

fw-nat-source-translation-object - Provide the stats for FWNAT source translation object.

translation-address - Provide the stats for a translation address. Applicable only at nat-stats level high.

global - Provide the cumulative stats at global level.

stat types

all - Display all applicable stats for this level.

total-addrs - Provide the current total of translation addresses at each reporting level.

total-endpoints - Provide the current total of translation endpoints at each reporting level.

total-port-blks - Provide the current number of total port blocks at each reporting level.

active-addrs - Provide the current number of translation addresses that are actively being used.

active-endpoints - Provide the current number of active translation endpoints.

in-use-port-blks - Provide the current number of port blocks in use at each reporting level, if that level includes an address used in a NAT PBA pool.

active-subscribers - Provide the current number of unique subscriber addresses that have an active translation. Applicable only at nat-stats level medium.

active-connections - Provide the current number of active connections at each reporting level.

cumulative-subscribers - Provide the total number of unique subscribers that have connected for each reporting level. Applicable only at nat-stats level medium.

cumulative-translations - Provide the cumulative number of translation mappings that have occurred.

peak-subscribers - Provide count of max number of unique, concurrent subscribers. Applicable only at nat-stats level medium.

peak-translations - Provide count of max number of concurrent translations.

port-reservations - Provide counts of number of port reservations by Application-Layer Gateways (ALGs).

hairpin-connections - Provide the cumulative number of hairpin connections at each reporting level.

persistence-entries - Provide the number of persistence entries. Applicable only at nat-stats level high.
inbound-entries - Provide counts of inbound entries, flows, and failures.
inbound-connections - Provide the number of active inbound connections.
inbound-failures - Provide the number of inbound failures.
failure-count - Provide the number of translation errors.

EXAMPLES

show ltm nat-stats roll-up-level fw-nat-source-translation-object name /Common/snat1 stat all Displays all available stats for roll up type source translation object /Common/snat1.

field-fmt

DELETE

delete nat [name]

DESCRIPTION

A network address translation (NAT) defines a mapping between an originating IP address and an IP address that you specify.

A primary reason for defining a NAT is to allow one of the servers in the server array behind the traffic management system to start communication with a computer in front of, or external to, the system.

EXAMPLES

```
create nat new_nat translation-address 10.0.140.100 originating-address 11.0.0.100
```

The node behind the system with the IP address 10.0.140.100 has a presence in front of the BIG-IP(r) System as IP address 11.0.0.100.

```
delete nat new_nat
```

Permanently deletes the NAT from the system configuration.

Additional Restrictions

The nat component has the following additional restrictions:

- A virtual server cannot use the IP address specified in the NAT.
- A NAT should not use an IP address of a BIG-IP system.
- A NAT cannot use an originating or translated IP address defined for and used by a SNAT or another NAT.
- You must delete a NAT before you can redefine it.

OPTIONS

app-service

Specifies the name of the application service to which the NAT belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the NAT. Only the application service can modify or delete the NAT.

arp Enables or disables Address Resolution Protocol (ARP).

description

User defined description.

[enabled | disabled]

Enables or disables the NAT. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

inherited-traffic-group

Indicates if the traffic-group is inherited from the parent folder. This property is read only.

originating-address

Specifies the IP address from which traffic is being initiated.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

traffic-group

Specifies the traffic group of the failover device group on which the NAT is active. The default traffic group is inherited from the containing folder.

translation-address

Specifies the IP address that is translated or mapped, and the IP address to which it is translated or mapped. This option is required when creating a NAT. This option may not be changed after the nat has been created.

unit Specifies the unit in a redundant system. Derived from traffic-group. This property is read only.

vlan

Specifies a list of existing VLANs on which access to the NAT is enabled or disabled. A NAT is accessible on all VLANs by default.

vlan-disabled

Indicates the NAT is disabled on the list of VLANs.

vlan-enabled

Indicates the NAT is enabled on the list of VLANs.

DELETE

delete node [name]

DESCRIPTION

Displays information about nodes, and sets attributes of nodes and node IP addresses.

EXAMPLES

`list node all-properties`

Displays all of the properties of all of the nodes.

`modify node all monitor none`

Removes all monitor associations from nodes.

`create node myNode address 10.10.10.15`

Creates a node named myNode with an IP address of 10.10.10.15.

`modify node myNode monitor none`

Removes all monitor associations from the node, myNode.

`show node`

Displays statistics and status for all nodes in the system configuration.

`show node all-properties`

Displays statistics and status for all nodes in the system configuration. If the system includes Packet Velocity(r) ASIC (PVA) and PVA Assist capabilities, this command displays status and statistics for that feature.

`mv /ltm node /Common/10.10.10.15 to-folder /Common/all_nodes`

Moves the node 10.10.10.15 to a folder named all_nodes, where all_nodes has already been created under /Common.

Note: If you wish to change the name of the node, you must use the nodes same IP Address or a name that does not represent an IP Address that does not match the address configured on the node.

Please refer to the mv manual page for additional examples on how to use the mv command.

OPTIONS

`address`

Specifies the IP address of the node.

`app-service`

Specifies the name of the application service to which the node belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the node. Only the application service can modify or delete the node.

`connection-limit`

Specifies the maximum number of connections that a node or node address can handle. The default value is 0 (zero).

`description`

Specifies a user-defined description.

`[down | up]`

Marks the node up or down. The default value is down.

`dynamic ratio`

Sets the dynamic ratio number for the node. The ratio weights are based on continuous monitoring of the servers and are therefore continually changing. The default value is 1.

Dynamic Ratio load balancing can currently be implemented on RealNetworks RealServer platforms, on Windows platforms equipped with Windows Management Instrumentation (WMI), or on a server equipped with either the UC Davis SNMP agent or Windows 2000 Server SNMP agent.

`glob` Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

`metadata`

Associates user defined data, each of which has a name and value pair and persistence. The default value is persistent, which saves the data to the config file.

`fqdn` Specifies the attributes for defining a fully qualified domain name for the node.

`name` Specifies the fully-qualified domain name of the node.

`address-family`

Specifies whether the fqdn should consider IPv4, IPv6, or IP-agnostic address family.

`autopopulate`

Specifies whether a node defined by a fully-qualified domain name should automatically scale to the set of IP addresses returned by the DNS query. If disabled, only one ephemeral node is generated from the first IP address returned by DNS. The default is disabled.

`interval`

Specifies the interval, in seconds, to instantiate DNS queries on a fully-qualified domain name. The default is 3600. A value of 'ttl' uses the TTL value obtained from the DNS server.

down-interval

Specifies the interval for the domain name resolution operation when a DNS query fails. The default is 5.

logging

Specifies whether the monitor applied should log its actions. Logs are stored in `/var/log/monitors/` and are regularly rotated and compressed. The default value is disabled. This option isn't a part of configuration and will reset to disabled on load. This option doesn't sync.

monitor

Specifies the name of the monitor that you want to associate with the node. The default value is none.

partition

Displays the administrative partition in which the node object resides.

rate-limit

Specifies the maximum number of connections per second allowed for a node or node address. The default value is 'disabled'.

ratio

Specifies the fixed ratio value used for a node during Ratio load balancing. The default value is 1.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

session

Establishing a session with a node is establishing the ability of the client to persist to the node when making new connections. When a node is session disabled, clients that have already established sessions with the node may create new connections, but a client that has not already established a session may not create a new one (or make a connection which would create a new session). This feature is used to gently drain connections from a node, typically as part of a maintenance operation. The default value is user-enabled.

state

Specifies the current state of the node. Use user-down to indicate that the node may not handle any new connections. Use user-up, after using user-down, to indicate that the node may accept new connections.

to-folder

This is used with the mv command to specify a folder in which to move the node to.

Note: nodes can be moved to any folder under `/Common`, but dependencies upon it may restrict moving it out of `/Common`.

  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete cookie [name]
options:
  all

```

DESCRIPTION

You can use the cookie component to configure cookie persistence for the BIG-IP(r) system. Cookie persistence uses an HTTP cookie stored on a client's computer to allow the client to connect to the same server previously visited at a web site.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile avoids having to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

```
list cookie
```

Displays all cookie persistence profiles.

```
create cookie cookie_persistence defaults-from cookie
```

Creates a custom cookie persistence profile named `cookie_persistence` that inherits its settings from the default cookie persistence profile.

```
mv cookie /Common/my_cookie_profile to-folder /Common/my_folder
```

Moves a custom cookie persistence profile named `my_cookie_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`always-send`

Send the cookie persistence entry on every reply, even if the entry has previously been supplied to the client. The default value is disabled.

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`cookie-name`

Specifies a unique name for the cookie. This option is required.

`defaults-from`

Specifies the existing profile from which the system imports settings for the new profile. The default value is `cookie`, the system default cookie persistence profile.

`description`

User defined description.

cookie-encryption

Specifies the way in which cookie format will be used: disabled: generate old format, unencrypted, preferred: generate encrypted cookie but accept both encrypted and old format, and required: cookie format must be encrypted. Default is required.

cookie-encryption-passphrase

Specifies a passphrase to be used for cookie encryption.

expiration

Specifies the cookie expiration date in the format d:h:m:s, h:m:s, m:s or seconds. (hours 0-23, minutes 0-59, seconds 0-59). The time period must be less than 24856 days.

You can use "session-cookie" (0 seconds) to indicate that the cookie expires when the browser closes.

encrypt-cookie-poolname

Specifies whether the pool-name in the inserted BigIPServer default cookie should be encrypted. The default value is disabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

httponly

Specifies whether the httponly attribute should be enabled or disabled for the inserted cookies. The default value is enabled.

secure

Specifies whether the secure attribute should be enabled or disabled for the inserted cookies. The default value is enabled.

hash-length

Specifies the cookie hash length. The length is the number of bytes to use when calculating the hash value. The default value is 0 (zero) bytes.

hash-offset

Specifies the cookie hash offset. The offset is the number of bytes in the cookie to skip before calculating the hash value. The default value is 0(zero) bytes.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

method

Specifies the type of cookie processing that the system uses. The default value is insert.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. This option is applicable only when the value of the method option is hash. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the duration of the persistence entries. The default value is 180 seconds.

to-folder

cookie persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

show running-config dest-addr [[[name] | [glob] | [regex]] ...]

options:

- all
- all-properties
- non-default-properties
- one-line
- partition

DELETE

delete dest-addr [name]

options:

- all

DESCRIPTION

You can use the dest-addr component to configure a destination address affinity persistence profile for the BIG-IP(r) system. Also known as sticky persistence, destination address affinity persistence supports TCP and UDP protocols, and directs session requests to the same server based solely on the destination IP address of a packet.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

list dest-addr

Displays all destination address affinity persistence profiles.

create dest-addr da_persistence defaults-from dest-addr

Creates a custom destination address affinity persistence profile named da_persistence that inherits its settings from the default destination address affinity persistence profile.

mv dest-addr /Common/my_dest-addr_profile to-folder /Common/my_folder

Moves a custom destination address persistence profile named `my_dest-addr_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the existing profile from which the system imports settings for the new profile. The default value is `dest_addr`, the system default destination address affinity persistence profile.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`hash-algorithm`

Specifies the system uses hash persistence load balancing. The default value is `default` (no hash persistence).

The options are:

`carp` Specifies to use the Cache Array Routing Protocol (CARP) to select the pool member for LB. The input to CARP is the hash value of destination address.

`default`

no hash persistence.

`mask` Specifies an IP mask. This is the mask used by simple persistence for connections. The default value is `::`.

`match-across-pools`

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

`match-across-services`

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

`match-across-virtuals`

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

`mirror`

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`override-connection-limit`

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`timeout`

Specifies the duration of the persistence entries. The default value is 180 seconds.

`to-folder`

`dest-addr` persistence profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

SEE ALSO

Itm persistence global-settings

NAME

global-settings - Configures persistence for the BIG-IP(r) system.

MODULE

Itm persistence

SYNTAX

Configure the global-settings component within the Itm persistence module using the syntax in the following sections.

MODIFY

modify global-settings [option name]

options:

description [string]

dest-addr-limit-mode [timeout | maxcount]

dest-addr-max [integer]

proxy-group [string]

edit global-settings [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list global-settings

list global-settings [[[name] | [glob] | [regex]] ...]

show running-config global-settings

show running-config global-settings

[[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DESCRIPTION

You can use the global-settings component within the Itm persistence module to configure persistence for the system.

For information about configuring session persistence for a virtual server, see the man pages for the following components: Itm persistence hash, Itm persistence msrdp, Itm persistence sip, Itm persistence source-addr, Itm persistence ssl, and Itm persistence universal.

EXAMPLES

list global-settings

Displays the global persistence configuration.

modify global-settings dest-addr-limit-mode maxcount

Sets the value of the option dest-addr-limit-mode to maxcount, which indicates that a persistence session is limited by the maximum number of requests to the destination address.

OPTIONS

description

User defined description.

dest-addr-limit-mode

Specifies that a persistence session is limited by either the number of seconds before the persistence entry times out, or by a maximum number of requests to the destination address. The default value is timeout.

dest-addr-max

Specifies the maximum number of entries that the persistence table can contain at any one time, when the value of the option dest-addr-limit-mode is maxcount. The default value is 2048 entries.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

proxy-group

Specifies a group of servers that are configured to process all of the requests from a single source address during a persistence session. The default value is aol.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

list, Itm virtual, modify, regex, show, tmsh

DESCRIPTION

You can use the hash component to configure a hash persistence profile for the BIG-IP(r) system. Hash persistence can also be activated from an existing iRule.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server.

Using a persistence profile means that you do not have to write an iRule to implement a type of persistence.

You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

list hash

Displays all hash persistence profiles.

create hash hash_persistence defaults-from hash

Creates a custom hash persistence profile named hash_persistence that inherits its settings from the default hash persistence profile.

mv hash /Common/my_hash_profile to-folder /Common/my_folder

Moves a custom hash persistence profile named my_hash_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is hash, the system default cookie persistence profile.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hash-algorithm

Specifies the algorithm the system uses for hash persistence load balancing. The default value is default.

The options are:

carp Specifies to use the Cache Array Routing Protocol (CARP) to select the pool member for LB.

default

Specifies to use indexing of pool members to select the pool member for LB.

hash-buffer-limit

Specifies the maximum buffer length the system collects to locate the hashing pattern for hash persistence load balancing. The default value is 0 (zero).

hash-end-pattern

Specifies the string that describes the ending location of the hash pattern that the system uses to perform hash persistence load balancing. The default value is none.

hash-length

Specifies the length of data within the packet in bytes that the system uses to calculate the hash value when performing hash persistence load balancing. The default value is 0 (zero) bytes.

hash-offset

Specifies the start offset within the packet from which the system begins the hash when performing hash persistence load balancing. The default value is 0 (zero).

hash-start-pattern

Specifies the string that describes the start location of the hash pattern that the system uses to perform hash persistence load balancing. The default value is none.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at

sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rule Specifies a rule name, if you are using a rule for universal persistence.

timeout

Specifies the duration of the persistence entries. The default value is 180 seconds.

to-folder

hash persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

DESCRIPTION

You can use the host component to configure a host persistence profile for the BIG-IP(r) system. Host persistence uses the HTTP Host header passed in a HTTP request to determine which pool member to pick. Host

persistence can also be activated from an existing iRule.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

list host

Displays all host persistence profiles.

create host host_persistence defaults-from host

Creates a custom host persistence profile named host_persistence that inherits its settings from the default host persistence profile.

mv host /Common/my_host_profile to-folder /Common/my_folder

Moves a custom host persistence profile named my_host_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is host, the system default host persistence profile.

description

User defined description.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the duration of the persistence entries. The default value is 180 seconds.

to-folder

host persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

DESCRIPTION

You can use the msrdp component to configure an MSRDP persistence profile for the BIG-IP(r) system. MSRDP persistence provides an efficient way of load balancing traffic and maintaining persistent sessions between Windows clients and servers that are running the Microsoft Terminal Services service. The recommended scenario for enabling the MSRDP persistence feature is to create a load balancing pool that consists of members running Windows .NET Server 2003, Enterprise Edition, or later, where all members belong to a Windows cluster and participate in a Windows session directory.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

list msrdp

Displays all MSRDP persistence profiles.

create msrdp msrdp_persistence defaults-from msrdp

Creates a custom MSRDP persistence profile named msrdp_persistence that inherits its settings from the default MSRDP persistence profile

mv msrdp /Common/my_msrdp_profile to-folder /Common/my_folder

Moves a custom MSRDP persistence profile named my_msrdp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is msrdp, the system default cookie persistence profile.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

has-session-dir

Specifies whether the Microsoft terminal services are configured with a session directory, so the system does not load balance the initial connection. The default value is yes.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the duration of the persistence entries. The default value is 300 seconds.

to-folder

msrdp persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

ltm persistence persist-records

NAME

persist-records - Displays or deletes persistence records.

MODULE

ltm persistence

SYNTAX

Configure the persist-records component within the ltm persistence module using the syntax in the following sections.

DISPLAY

show persist-records

options:

client-addr [ip address]
key [string]
mode [cookie | destination-address | hash | msrdp | sip |
source-address | ssl-session-id | universal]
node-addr [ip address]
node-port [integer]
pool [string]
save-to-file [filename]
virtual [string]

DELETE

delete persist-records

options:

client-addr [ip address]
key [string]
mode [cookie | destination-address | hash | msrdp | sip |
source-address | ssl-session-id | universal]
node-addr [ip address]
node-port [integer]
pool [string]
virtual [string]

DESCRIPTION

You can use the persist-records component to either display or delete records of persistent connections.

EXAMPLES

show persist-records

Displays all persistent connections on the BIG-IP(r) system.

delete persist-records client-addr 172.19.255.1

Deletes all persistent connections that originate from the client IP address, 172.19.255.1.

OPTIONS

client-addr

Specifies the IP address of the client from which the persistent connections you want to view or delete persist.

key Specifies a string that the system is using to persist the connections you want to view or delete.

mode Specifies the type of persistence of the connections you want to view or delete. The options are:

cookie

Cookie persistence uses an HTTP cookie stored on a client's computer to allow the client to connect to the same server previously visited at a web site.

destination-address

Also known as sticky persistence, destination address affinity persistence supports TCP and UDP protocols, and directs session requests to the same server based solely on the destination IP address of a packet.

hash Hash persistence is based on an existing iRule.

msrdp

MSRDP persistence provides an efficient way of load balancing traffic and maintaining persistent sessions between Windows(r) clients and servers that are running the Microsoft(r) Terminal Services service. The recommended scenario for enabling the MSRDP persistence feature is to create a load balancing pool that consists of members running Windows .NET Server 2003, Enterprise Edition, or later, where all members belong to a Windows cluster and participate in a Windows session directory.

sip Session Initiation Protocol (SIP) persistence is a type of persistence available for server pools.

You can configure SIP persistence for proxy servers that receive SIP messages sent through UDP. The BIG-IP system currently supports persistence for SIP messages sent through UDP, TCP, or SCTP.

source-address

Also known as simple persistence, source address affinity persistence supports TCP and UDP protocols, and directs session requests to the same server based solely on the source IP address of a packet. When you specify a source address as the mode of persistence, you must specify an IP address using the client-addr option.

ssl-session-id

SSL persistence is a type of persistence that tracks non-terminated SSL sessions, using the SSL session ID. Even when the client's IP address changes, the system still recognizes the connection as being persistent based on the session ID. Note that the term, non-terminated SSL sessions, refers to sessions in which the system does not perform the tasks of SSL certificate authentication and encryption/re-encryption.

universal

Universal persistence allows you to write an expression that defines what to persist on in a packet. The expression, written using the same expression syntax that you use in iRules(r), defines some sequence of bytes to use as a session identifier.

node-addr

Specifies the IP address of the node with which the client sessions that you want to view or delete remain persistent.

node-port
Specifies the port number of the node with which the client sessions that you want to view or delete remain persistent.

pool
Specifies the pool member with which the client sessions that you want to view or delete remain persistent.

save-to-file
Specifies the file which persist-records information can be save to. With this option, it can write a file larger than 2GB.

virtual
Specifies the virtual server with which the client sessions that you want to view or delete remain persistent.

SEE ALSO

delete, show, tmsh

DESCRIPTION

You can use the sip component to configure a SIP persistence profile for the BIG-IP(r) system. SIP persistence is a type of persistence available for server pools. You can configure SIP persistence for proxy servers that receive SIP messages sent through UDP. The BIG-IP system currently supports persistence for SIP messages sent through UDP, TCP, or SCTP.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

list sip

Displays all SIP persistence profiles.

create sip sip_persistence defaults-from sip_info

Creates a custom SIP persistence profile named sip_persistence that inherits its settings from the default SIP persistence profile.

mv sip /Common/my_sip_profile to-folder /Common/my_folder

Moves a custom SIP persistence profile named my_sip_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is sip_info, the system default cookie persistence profile.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

sip-info

Specifies the SIP header field on which you want SIP sessions to persist. The default value is none.

timeout

Specifies the duration of the persistence entries. The default value is 180 seconds.

to-folder

sip persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

show running-config source-addr[[[name] | [glob] | [regex]] ...]

options:

all
all-properties
non-default-properties
one-line
partition

DELETE

delete source-addr [name]

options:

all

DESCRIPTION

You can use the source-addr component to configure a source address affinity persistence profile for the BIG-IP(r) system. Also known as simple persistence, source address affinity persistence supports TCP and UDP protocols, and directs session requests to the same server based solely on the source IP address of a packet.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

list source-addr

Displays all source address affinity persistence profiles.

create source-addr simple_persistence defaults-from source_addr

Creates a custom source address affinity persistence profile named simple_persistence that inherits its settings from the default source address affinity persistence profile.

mv source-addr /Common/my_source-addr_profile to-folder /Common/my_folder

Moves a custom source address persistence profile named my_source-addr_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is source_addr, the system default cookie persistence profile.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hash-algorithm

Specifies the system uses hash persistence load balancing. The default value is default (no hash persistence).

The options are:

carp Specifies to use the Cache Array Routing Protocol (CARP) to select the pool member for LB. The input to CARP is the hash value of source address.

default

no hash persistence.

map-proxies

Enables or disables the map proxies attribute. The default value is disabled.

This attribute controls whether a source address will first be checked against an IP data-group/class to determine whether it is a well-known proxy address. If it matches the IP class, then the source address will be mapped to a single IP address for the purposes of persistence. The default well known proxy class is based on a pre-defined data-group "aol" which represents the AOL(r) company's previously-published list of proxies. Using this feature enables you to use client/source IP address persistence with a simple persist mask, but forces all clients matching the IP class to persist to the same server. The IP data-group/class may also be changed using either the map-proxy-class profile attribute or globally by changing the DB variable Persist.WellKnownProxyClass. Also, the IP address used for mapping a single source IP address for persistence may also be specifically set using the map-proxy-address profile attribute.

map-proxy-address

Specifies the single IP address to use when the source address matches the proxy data-group/class. The default value is any which results in the default behavior of using one of the IP addresses from the proxy data-group/class. Note: This mapped IP address does not have to be contained in the IP data-group/class. It may actually be any IP address since it is only used for keying the persistence record.

map-proxy-class

Specifies the data-group/class to use for determining whether a source address is from a proxy. The default value is none which will result in map_proxies using the class defined by the DB variable Persist.WellKnownProxyClass.

mask Specifies an IP mask. This is the mask used by simple persistence for connections. The default value is ::.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit
Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout
Specifies the duration of the persistence entries. The default value is 180 seconds.

to-folder
source-addr persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

DESCRIPTION

You can use the ssl component to configure a destination address affinity persistence profile for the BIG-IP(r) system. SSL persistence is a type of persistence that tracks non-terminated SSL sessions, using the SSL session ID. Even when the client's IP address changes, the system still recognizes the connection as being persistent based on the session ID. Note that the term, non-terminated SSL sessions, refers to sessions in which the system does not perform the tasks of SSL certificate authentication and encryption/re-encryption.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

list ssl

Displays all SSL persistence profiles.

create ssl ssl_persistence defaults-from ssl

Creates a custom SSL persistence profile named ssl_persistence that inherits its settings from the default SSL persistence profile.

mv ssl /Common/my_ssl_profile to-folder /Common/my_folder

Moves a custom SSL persistence profile named my_ssl_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is ssl, the system default cookie persistence profile.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the duration of the persistence entries. The default value is 300 seconds.

to-folder

ssl persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

DESCRIPTION

You can use the universal component to configure a universal persistence profile for the BIG-IP(r) system.

With universal persistence you can write an expression that defines what to persist on in a packet. The expression, written using the same expression syntax that you use in iRules(r), defines some sequence of bytes to use as a session identifier.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server.

Using a persistence profile means that you do not have to write an iRule to implement a type of persistence.

You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

list universal

Displays all universal persistence profiles.

create universal uni_persistence defaults-from universal

Creates a custom universal persistence profile named `uni_persistence` that inherits its settings from the default universal persistence profile.

`mv universal /Common/my_universal_profile` to-folder `/Common/my_folder`

Moves a custom universal persistence profile named `my_universal_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the existing profile from which the system imports settings for the new profile. The default value is `universal`, the system default cookie persistence profile.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`match-across-pools`

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

`match-across-services`

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

`match-across-virtuals`

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

`mirror`

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`override-connection-limit`

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`rule` Specifies an iRule name when you are using a rule for universal persistence.

`timeout`

Specifies the duration of the persistence entries. The default value is 180 seconds.

`to-folder`

universal persistence profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

NAME

policy-strategy - Configures policy-strategy for Centralized Policy Manager.

MODULE

ltm

DESCRIPTION

The policy-strategy component stores the different matching strategies employed by LTM Policy engine. Strategy comes into play when a policy has multiple rules, and the behavior of the policy can be customized as the situation requires.

There are 3 pre-defined matching strategies: "first-match", "all-match", and "best-match". A "first-match" strategy terminates the matching engine on the first condition that matches and executes that rule's actions. An "all-match" strategy will execute the actions for all conditions that match.

The "best-match" strategy is intended for situations when multiple conditions match simultaneously, and allows for the more specific match to win. For example, one rule may match the http-uri hostname while another may match the http-uri extension. The system has a built-in table defining combinations of event, operand, and selector, and an associated precedence value for each combination. When multiple rules match in a "best-match" situation, then the condition with the lowest ordinal value of event-operand-selector precedence is declared to be the most specific, and its actions are executed.

Generally policy-strategy should not require additions or changes. However, it could make sense to create user-defined policy-strategy when a "best-match" strategy is desired, but the built-in precedence table does not reflect the organization's idea of which operand-selector combinations are most specific.

For additional details, refer to Local Traffic Policy documentation on the AskF5 knowledge base at <http://support.f5.com>.

CREATE/MODIFY

create policy-strategy [name]

modify policy-strategy [name]

options:

[strategy | [all-match | best-match | first-match]]

operands [add | delete | modify | replace-all-with] {

ORDINAL {

[OPERAND] [EVENT] [SELECTOR]

}

}

[app-service [VALUE | none]]

[partition VALUE]

where

strategy

Specifies the match method: all-match, best-match, or first-match.

operands

Define a combination of event, operand, selector, and associate it with an ordinal precedence value.

ORDINAL

Integer precedence value, lower value indicates a higher precedence.

OPERAND

Entity to compare, see some examples in Precedence Table below, or ltm_policy documentation for list with descriptions.

EVENT

Framework event like request or response, default is "request" if not specified.

SELECTOR

More specific part of operand, default is "all" if not specified. See some examples in the Precedence Table below, or ltm_policy documentation for list and descriptions.

app-service

Specifies the name of the application service to which the policy strategy belongs. The default value is "none" if not specified. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the policy strategy. Only the application service can modify or delete the policy strategy.

DISPLAY

list policy-strategy

list policy-strategy [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete policy-strategy [name]

EXAMPLES

create policy-strategy my_strategy strategy first-match

Creates the policy strategy my_strategy which matches the first rule selected.

Precedence Table

Ordinal Event Operand Selector

Ltm policy

NAME

policy - Configures a policy for Centralized Policy Manager.

MODULE

ltm

SYNTAX

Create or modify LTM Policies within the ltm module, using the syntax shown in the following sections.

Policies exist in 2 forms, draft and published. Only draft policies can be modified, and only published policies can be applied to a virtual server. A draft policy can be turned into a published policy using the publish command. A draft copy can be obtained from a published policy using modify [name] create-draft. Draft policies are placed in a Drafts folder.

For additional details, refer to Local Traffic Policy documentation on the AskF5 knowledge base at <http://support.f5.com>.

CREATE/MODIFY

```
create policy Drafts/[name]
```

```
modify policy Drafts/[name]
```

options:

```
strategy [STRING | none]
```

```
copy-from [name | Drafts/name]
```

```
create-draft
```

```
rules [add | delete | modify | replace-all-with] {
```

```

field-fmt
```

DELETE

```
delete policy [name]
```

Note: Before a policy can be deleted, it must be removed from all virtual servers holding a reference to it.

DESCRIPTION

An LTM Policy is a set of rules which can be attached to a virtual server to efficiently process traffic.

Similar in concept to iRules, Policies can inspect requests and responses, and perform programmed actions.

The controls and requires aspects for a policy are automatically set by the system based on an inspection of the conditions and actions specified in LTM Policy rules. User should not specify either of these.

EXAMPLES

```
create policy Drafts/my_policy
```

```
strategy my_strategy
```

Creates a Local Traffic Manager policy in the Drafts folder named my_policy. The strategy determining policy actions is my_strategy. Draft policies may be modified, but cannot be applied to a virtual server until they

are published.

create Itm policy Drafts/new_policy copy-from published_policy
create Itm policy Drafts/new_policy copy-from Drafts/old_policy

Creates a Local Traffic Manager policy based on an existing published policy, and from an existing draft policy, respectively.

modify Itm policy new_policy create-draft

Creates a draft policy of an existing published policy.

publish Itm policy Drafts/my_policy

Takes a policy that was created or modified in the Drafts folder, and publishes it. Published policies can then be applied to a virtual server.

delete policy my_policy

Deletes the policy named my_policy.

show policy

Displays statistics and status for all Local Traffic Manager policies in the system configuration.

show policy all-properties

Displays statistics and status for all Local Traffic Manager policies in the system configuration.

Note that if the system includes Packet Velocity(r) ASIC (PVA) and PVA Assist capabilities, this command displays status and statistics for that feature.

list policy my_policy

Displays properties of the policy named my_policy.

app-service - Specifies the name of the application service to which the policy belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the policy. Only the application service can modify or delete the policy.

CONTROLS_ASPECT is one or more of the following:

none - Associated with unrestricted actions that are always available, like logging.

forwarding - Enables many options for Forwarding connections to the back end.

caching - Caching enable or disable on a per-request basis.

compression - Actions which enable / disable compression and decompression. Virtual server will need to have an appropriate compression profile applied.

acceleration - Enable or disable Web Acceleration

asm - Enable or disable Application Security Management

avr - Enable or disable Application Visibility Reporting

l7dos - Enable or disable Layer 7 Denial-of-Service protection

bot-defense - Enable or disable Unified Bot Defense protection

classification - Used by the Traffic classification engine

request-adaptation - Enable or disable Request Adaptation

response-adaptation - Enable or disable Response Adaptation

client-ssl - Enable or disable SSL connection on the client side

server-ssl - Enable or disable SSL connection on the server side

websocket - Actions related to WebSockets

REQUIRES_ASPECT is one or more of the following:

none - Associated with conditions that are always available, like cpu-usage, with no specific profiles required to be attached to a virtual server

http - Makes available HTTP-protocol conditions. A profile that communicates using the HTTP protocol needs to be attached to a virtual server with this policy.

http-explicit - Makes available HTTP Explicit Proxy specific conditions. An HTTP Explicit Proxy profile needs to be attached to a virtual server with this policy.

http-connect - Makes available HTTP Connect specific conditions. An HTTP Connect profile needs to be attached to a virtual server with this policy.

tcp - A TCP profile needs to be attached to a virtual with this policy. Makes available TCP-specific conditions.

client-ssl - A Client-SSL profile needs to be attached to a virtual with this policy.

server-ssl - A Server-SSL profile needs to be attached to a virtual with this policy.

classification - A classification profile needs to be attached to a virtual with this policy.

Data Types

BOOLEAN - [true* | false]

NUMBER - signed 32-bit integer

STRING - Bare_string -or- "quoted string"

TCLSTRING - A STRING optionally containing Tcl command substitutions to be evaluated at runtime. If string begins with the 4-character prefix "tcl:", then the prefix is removed and the rest of the string is passed to the Tcl interpreter. If no prefix, then whole string is treated as a plain string with no Tcl interpreter overhead. Examples:

log request message "tcl:This is Tcl-enabled and the URI is [HTTP::uri]"

log request message "This is just a plain old string"

IP_ADDRESS - IPv4 or IPv6 address

Comparison operators

Core to defining conditions is the need to compare quantities at run time against pre-defined values. LTM Policy allows you to specify single or multiple values in a comparison.

NUMBER_COMPARISON

[not] [equals* | less | greater | less-or-equal | greater-or-equal]
values { VAL1 [[VAL2] ...]}

Sample numeric comparisons:

not greater values { 1024 } # no more than 1024

values { 80 443 8080 } # compare against 80, 443, or 8080, equals implied

STRING_COMPARISON

[not] [equals* | starts-with | ends-with | contains]
values { VAL1 [[VAL2] ...]} [case-insensitive* | case-sensitive]

Sample string comparisons:

equals values { Abel bAkEr chArLle } # case-insensitive match of 3 candidates

values { Abel bAkEr chArLle } # same as above, equals implied

ends-with values { html txt } # match if string ends with either candidate

contains values { "jj83Q@@#@#AFRT@==" } case-sensitive # match value, case must match

*default if not specified

CONDITION_SPEC

A CONDITION_SPEC, or condition specification, is where you can tell the system the specific attributes you would like to inspect and use as a trigger for action.

Conditions are associated with an event, so conditions can be evaluated at different times during a request-response cycle.

Below is a list of all supported conditions, the events during which they can be evaluated, additional qualifiers, and parameters.

http-uri

Inspect the URI on a request and match on various parts or the entire URI (since 11.4.0)

Specifying http-uri in a condition automatically adds "requires {http}" to the policy.

```
http-uri [proxy-request* | request | proxy-connect]
[all STRING_COMPARISON
 [normalized BOOL]
]
[scheme STRING_COMPARISON
 [normalized BOOL]
]
[host STRING_COMPARISON
 [normalized BOOL]
]
[port NUMBER_COMPARISON
 [normalized BOOL]
]
[path STRING_COMPARISON
 [normalized BOOL]
]
```

```

[extension STRING_COMPARISON
 [normalized BOOL]
]
[query-string STRING_COMPARISON
 [normalized BOOL]
]
[query-param STRING_COMPARISON
 name STRING
 [normalized BOOL]
]
[unnamed-query-param STRING_COMPARISON
 index NUMBER
 [normalized BOOL]
]
[path-segment STRING_COMPARISON
 index NUMBER
 [normalized BOOL]
]
[urllcat
 [normalized BOOL]
]

```

where

all - match on the full URI
normalized - Convert URI to standard form for consistent comparison.
scheme - match on the scheme, e.g. http, https, ftp,
file
normalized - Convert URI to standard form for consistent comparison.
host - match on the hostname in the URI
normalized - Convert URI to standard form for consistent comparison.
port - match on the port number in the URI
normalized - Convert URI to standard form for consistent comparison.
path - match on the URI path
normalized - Convert URI to standard form for consistent comparison.
extension - match on the file extension in the URI, e.g. jpg, html, cgi
normalized - Convert URI to standard form for consistent comparison.
query-string - match against text in the query string
normalized - Convert URI to standard form for consistent comparison.
query-param - match value of the named query parameter from the query string
name - Specify the name of the particular query parameter whose value is to be used
normalized - Convert URI to standard form for consistent comparison.
unnamed-query-param - match the value of a query parameter by a numeric index instead of by name
index - The numeric order of the query parameter whose value is to be used, starting at 1. Negative values indicate counting right to left.
normalized - Convert URI to standard form for consistent comparison.
path-segment - Match a part of the URI path by a numeric index
index - The numeric order of a segment in the path, starting at 1. Negative values indicate counting right to left.
normalized - Convert URI to standard form for consistent comparison.
urllcat - Run URI through a categorization engine. List of categories - 'tmsh list sys url-db url-category'
normalized - Convert URI to standard form for consistent comparison.

tcp

Inspect and match on various TCP properties of a connection (since 11.5.0)

Specifying tcp in a condition automatically adds "requires {tcp}" to the policy.

```

tcp [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
request | response | proxy-request | proxy-connect |
proxy-response | ws_request | ws_response |
classification-detected]
[address IP_COMPARISON
 [internal BOOL]
 [local BOOL]
]

```

```

]
[port NUMBER_COMPARISON
[internal BOOL]
[local BOOL]
]
[mss NUMBER_COMPARISON
[internal BOOL]
]
[rtt NUMBER_COMPARISON
[internal BOOL]
]
[vlan STRING_COMPARISON
[internal BOOL]
]
[vlan-id NUMBER_COMPARISON
[internal BOOL]
]
[route-domain NUMBER_COMPARISON
[internal BOOL]
]

```

where

address - Match on IP address. By default the IP address is the one associated with the external interface, remote end of the connection.

internal - Internal specifies the IP address of the endpoint on the "internal" side of the connection.

local - Local specifies the IP address of the local side of the connection, i.e. not the remote side.

port - Match on port number. By default the port is the one associated with the external interface, remote end of the connection.

internal - Internal specifies the port of the endpoint on the "internal" side of the connection.

local - Local specifies the port of the local side of the connection, i.e. not the remote side.

mss - Compare the TCP maximum segment size on the external network interface.

internal - Refers to the maximum segment size on the internal interface.

rtt - Inspect the round trip time on the external network interface.

internal - Refers to the round trip time on the internal interface.

vlan - Compare traffic with specified vlan on the external network interface.

internal - Refers to the vlan on the internal interface.

vlan-id - Compare traffic with specified vlan-id number on the external network interface.

internal - Refers to the vlan-id on the internal interface.

route-domain - Compare traffic with specified route domain number on the external network interface.

internal - Specifies the route domain on the internal interface.

Examples

tcp address matches values { 141.202.53.16 }

tcp address internal matches values { 192.168.63.1 192.168.63.121 }

tcp port matches values { 8080 3128 }

client-ssl

Inspect properties of the SSL connection on the client side of the device. (since 11.4.0)

Specifying client-ssl in a condition automatically adds "requires {client-ssl}" to the policy.

```

client-ssl [proxy-request* | request | proxy-connect |
proxy-response | response]
[protocol STRING_COMPARISON]
[cipher STRING_COMPARISON]
[cipher-bits NUMBER_COMPARISON]

```

where

protocol - Compare SSL protocol name

cipher - Cipher name

cipher-bits - cipher strength in number of bits

http-method

Inspect the request's HTTP method, e.g. GET, POST, HEAD (since 11.4.0)

Specifying http-method in a condition automatically adds "requires {http}" to the policy.

```
http-method [request* | proxy-request]
all STRING_COMPARISON
```

Example

```
http-method all values { POST }
```

http-version

Inspect the version of an HTTP request or response (since 11.4.0)

Specifying http-version in a condition automatically adds "requires {http}" to the policy.

```
http-version [proxy-request* | request | proxy-connect |
proxy-response | response]
[all STRING_COMPARISON]
[protocol STRING_COMPARISON]
[major NUMBER_COMPARISON]
[minor NUMBER_COMPARISON]
```

where

all - Compare against full version string
protocol - HTTP protocol
major - Numeric major part of HTTP version
minor - Numeric minor part of HTTP version

Examples

```
http-version all contains values { HTTP/1.1 }
http-version protocol values { HTTP }
http-version major values { 1 }
http-version minor greater-or-equal values { 0 }
```

http-status

Inspect the HTTP response's status (since 11.4.0)

Specifying http-status in a condition automatically adds "requires {http}" to the policy.

```
http-status [proxy-response* | response]
[all STRING_COMPARISON]
[code NUMBER_COMPARISON]
[text STRING_COMPARISON]
```

where

all - Compare against full HTTP status response
including both code and text
code - Numeric HTTP response status code
text - HTTP response status string, e.g.
"Authentication Required"

Examples

```
http-status response values { "HTTP/1.1 200 OK" }
http-status response code values { 401 }
http-status response text contains values { "Authentication Required" }
```

http-host

Match against an HTTP request's Host: header (since 11.4.0)

Specifying http-host in a condition automatically adds "requires {http}" to the policy.

```
http-host [proxy-request* | request | proxy-connect]
[all STRING_COMPARISON]
[host STRING_COMPARISON]
[port NUMBER_COMPARISON]
```

where

all - Compare against full Host header string
host - compare against hostname
port - compare against port number

Examples

```
http-host values { example.com }
http-host host values { ns1.example.com ns2.example.com }
http-host port values { 80 443 3128 8080 }
```

http-header

Match against any HTTP header (since 11.4.0)

Specifying http-header in a condition automatically adds "requires {http}" to the policy.

```
http-header [proxy-request* | request | proxy-connect |
proxy-response | response]
all STRING_COMPARISON
name STRING
```

Example

```
http-header response name Content-type starts-with values { text/ }
```

http-referer

Inspect HTTP Referer: header or specific parts of the URI value. (since 11.4.0)

Specifying http-referer in a condition automatically adds "requires {http}" to the policy.

```
http-referer [proxy-request* | request | proxy-connect]
[all STRING_COMPARISON
[normalized BOOL]
]
[scheme STRING_COMPARISON
[normalized BOOL]
]
[host STRING_COMPARISON
[normalized BOOL]
]
[port NUMBER_COMPARISON
[normalized BOOL]
]
[path STRING_COMPARISON
[normalized BOOL]
]
[extension STRING_COMPARISON
[normalized BOOL]
]
[query-string STRING_COMPARISON
[normalized BOOL]
]
[path-segment STRING_COMPARISON
index NUMBER
[normalized BOOL]
]
[query-param STRING_COMPARISON
name STRING
[normalized BOOL]
]
[unnamed-query-param STRING_COMPARISON
index NUMBER
[normalized BOOL]
]
[urlicat
[normalized BOOL]
]
```

where

all - entire URI, e.g.

http://example.com/path/to/page.cgi?a=b&c=d

normalized - Convert URI to standard form for consistent comparison.

scheme - e.g. http, https, ftp

normalized - Convert URI to standard form for consistent comparison.

host - DNS hostname or IP address

normalized - Convert URI to standard form for consistent comparison.

port - numeric port number, e.g. 80

normalized - Convert URI to standard form for consistent comparison.

path - URI path, e.g. /path/to

normalized - Convert URI to standard form for consistent comparison.

extension - document extension, e.g. cgi

normalized - Convert URI to standard form for consistent comparison.

query-string - full query string, e.g. a=b&c=d

normalized - Convert URI to standard form for consistent comparison.

path-segment - path segment by numerical index

index - Identify a segment of a path by its numerical order starting at 1. Negative values indicate counting right to left.

normalized - Convert URI to standard form for consistent comparison.

query-param - value of query param by name
 name - Identify a query string parameter by its name
 normalized - Convert URI to standard form for consistent comparison.
 unnamed-query-param - value of query parameter by numerical index
 index - Identify a query string parameter by its numerical order starting at 1. Negative values indicate counting right to left.
 normalized - Convert URI to standard form for consistent comparison.
 urlcat - Run URI through a categorization engine. List of categories - 'tmsh list sys url-db url-category'
 normalized - Convert URI to standard form for consistent comparison.

Examples

http-referer request all contains values { cgi }
 http-referer request all scheme values { http https }
 http-referer request all host values { example.com 127.0.0.1 }
 http-referer request all port values { 80 8080 }
 http-referer request all path contains values { /cgi-bin/ }
 http-referer request all extension contains values { xml xhtml xsd }
 http-referer request all query-string contains values { __utmz }
 http-referer path-segment index 2 values { to }
 http-referer query-parameter name foo contains values { bar }
 http-referer request unnamed-query-param index 1 values { a }

http-cookie

Inspect an HTTP request's Cookie: header (since 11.4.0)

Specifying http-cookie in a condition automatically adds "requires {http}" to the policy.

```

http-cookie [proxy-request* | request | proxy-connect]
all STRING_COMPARISON
name STRING
  
```

Example

http-cookie name User values { xyz123 }

http-set-cookie

Inspect an HTTP response's Set-Cookie: header (since 11.4.0)

Specifying http-set-cookie in a condition automatically adds "requires {http}" to the policy.

```

http-set-cookie [proxy-response* | response]
[value STRING_COMPARISON
name STRING
]
[version STRING_COMPARISON
name STRING
]
[path STRING_COMPARISON
name STRING
]
[domain STRING_COMPARISON
name STRING
]
[expiry STRING_COMPARISON
name STRING
]
  
```

where

value - value of the named cookie named by the parameter
 version - version of the named cookie
 path - path of the named cookie
 domain - value of the domain specified by the named cookie
 cookie
 expiry - Time when validity of named cookie expires, in RFC 6265 format (Wdy, DD Mon YYYY HH:MM:SS GMT)

Examples

http-set-cookie response value name Cust-Id values { org177 org187 org197 }
 http-set-cookie response version name mycook values { 1.1 }
 http-set-cookie response path name mycook values { /private/cgi-bin/ }
 http-set-cookie response domain name mycook values { example.com }
 http-set-cookie response expiry name MyCookie contains values { "Wed, 09 Jun 2021" }

http-basic-auth

Inspect an HTTP request's username/password specified for Basic authentication. (since 11.4.0)

Specifying http-basic-auth in a condition automatically adds "requires {http}" to the policy.

```
http-basic-auth [proxy-request* | request | proxy-connect]
[username STRING_COMPARISON]
[password STRING_COMPARISON]
```

where

username - basic authentication username
password - basic authentication password

Example

```
http-basic-auth password not values { password }
```

http-proxy

Inspect properties of the HTTP Explicit Proxy feature (since 13.1.0)

Specifying http-proxy in a condition automatically adds "requires {http-explicit}" to the policy.

```
http-proxy [request*]
[address IP_COMPARISON]
[port NUMBER_COMPARISON]
[route-domain NUMBER_COMPARISON]
```

where

address - The resolved IP address

Examples

```
http-proxy address equals values { 10.0.0.1 }
http-proxy port matches values { 80 }
http-proxy route-domain matches values { 2 }
```

http-connect

Inspect properties of the HTTP Proxy Connect feature (since 13.1.0)

Specifying http-connect in a condition automatically adds "requires {http-connect}" to the policy.

```
http-connect [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
proxy-request | request | proxy-connect |
proxy-response | response]
[host STRING_COMPARISON]
[port NUMBER_COMPARISON]
```

where

host - The host sent to the remote proxy

Examples

```
http-proxy-connect host matches values { http://example.com }
http-proxy-connect port matches values { 80 }
```

ssl-extension

Inspect SSL extensions being negotiated during HELLO phase. (since 11.4.0)

This condition is available to all policies.

```
ssl-extension [ssl-client-hello* | ssl-server-hello]
[server-name STRING_COMPARISON]
[alpn STRING_COMPARISON]
[alpn STRING_COMPARISON]
[index NUMBER]
]
```

where

server-name - server name indication
alpn - application layer protocol negotiation

Example

```
ssl-extension ssl-client-hello server-name values { secure43.example.org }
```

ssl-cert

Inspect properties of an SSL certificate. (since 11.4.0)

Specifying ssl-cert in a condition automatically adds "requires {server-ssl}" to the policy.

```
ssl-cert [ssl-server-handshake*]  
common-name STRING_COMPARISON  
[index NUMBER]
```

where

common-name - hostname covered by the SSL certificate

geoip

Specify a condition based upon properties of the geographical location of the IP address, such as continent code, country code, city, region, or organization. The default is to inspect the external interface, remote endpoint. (since 11.5.0)

This condition is available to all policies.

```
geoip [client-accepted* | ssl-client-hello |  
ssl-client-serverhello-send | ssl-server-hello |  
ssl-server-handshake | server-connected |  
proxy-request | request | proxy-connect |  
proxy-response | response]  
[continent STRING_COMPARISON  
[internal BOOL]  
[local BOOL]  
]  
[country-code STRING_COMPARISON  
[internal BOOL]  
[local BOOL]  
]  
[country-name STRING_COMPARISON  
[internal BOOL]  
[local BOOL]  
]  
[region-code STRING_COMPARISON  
[internal BOOL]  
[local BOOL]  
]  
[region-name STRING_COMPARISON  
[internal BOOL]  
[local BOOL]  
]  
[org STRING_COMPARISON  
[internal BOOL]  
[local BOOL]  
]  
[isp STRING_COMPARISON  
[internal BOOL]  
[local BOOL]  
]
```

where

continent - Two-character continent code: AF, AN, AS, OC, EU, NA, SA
country-code - Two-character country code as defined in ISO-3166-2
country-name - Full name of country
region-code - Abbreviation of State, Province, or country-specific region
region-name - Full name of State, Province, or country-specific region
org - Organization associated with address
isp - Internet Service Provider associated with address

Examples

```
geoip continent values { NA }  
geoip country-code values { us }  
geoip country-name values { "United States" }  
geoip region-code values { NY CA TX }  
geoip region-name values { Washington Oregon Idaho }  
geoip organization values { "Acme Widgets" }  
geoip isp values { "Fastcast Networks" "Responsive Cable Inc." }
```

cpu-usage

Specify a condition based upon CPU usage percentage for the past 15 seconds, 1 minute or 5 minutes intervals. (since 11.5.0)

This condition is available to all policies.

```
cpu-usage [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
proxy-request | request | proxy-connect |
proxy-response | response]
[last-15secs NUMBER_COMPARISON]
[last-1min NUMBER_COMPARISON]
[last-5mins NUMBER_COMPARISON]
```

where

last-15secs - CPU usage ratio % over the past 15 seconds, 0-100
last-1min - CPU usage ratio % over the past minute, 0-100
last-5mins - CPU usage ratio % over the past 5 minutes, 0-100

Examples

```
cpu-usage request last-15secs 8
cpu-usage response last-1min 10
cpu-usage last-5mins 12
```

http-user-agent

Specify a condition based upon User Agent sub-string, i.e. version, browser type, or mobile device make and model. (since 11.4.0)

Specifying http-user-agent in a condition automatically adds "requires {http}" to the policy.

```
http-user-agent [proxy-request* | request]
[device-make STRING_COMPARISON]
[device-model STRING_COMPARISON]
[browser-type STRING_COMPARISON]
[browser-version STRING_COMPARISON]
[ua-token STRING_COMPARISON]
name STRING
]
```

where

device-make - Make of device
device-model - Model of device
browser-type - Browser name/type
browser-version - Browser version string
ua-token - Sub version string associated with specified parameter

Examples

```
http-user-agent device-make values { Samsung ASUS }
http-user-agent device-model values { DroidX }
http-user-agent request browser-type values { Mozilla }
http-user-agent request browser-version values { "37.0.2049.0" }
http-user-agent user-agent-token name Mozilla values { 9.0 }
```

websocket

Specify a condition based upon properties of a websockets connection. (since 12.1.0)

Specifying websocket in a condition automatically adds "requires {websocket}" to the policy.

```
websocket [ws_request* | ws_response]
[protocol STRING_COMPARISON]
[extension STRING_COMPARISON]
[version STRING_COMPARISON]
[ws_key STRING_COMPARISON]
```

where

protocol - value of the Sec-WebSocket-Protocol header
extension - value of the Sec-WebSocket-Extensions header
version - value of the Sec-WebSocket-Version header
ws_key - value of the masking-key

classification

Specify a condition based on flow's classification results. (since 13.0.0)

Specifying classification in a condition automatically adds "requires {classification}" to the policy.

```
classification [classification-detected*]
[application STRING_COMPARISON]
[application-id ]
```

[application-risk]
[category STRING_COMPARISON]
[category-id]
[url-category STRING_COMPARISON]
[url-category-id]

where

application - Classification Application Name
application-id - Classification Application ID
application-risk - Classification Application Risk
category - Application's category name
category-id - Application's category ID
url-category - URL's category name
url-category-id - URL's category ID

Examples

application values { cnn youtube }
application-id values { 1245 }
application-risk greater-or-equal values { 3 }
category values { News_And_Media }
category-id values { 16666 }
url-category starts-with values { News }
url-category-id values { 25555 }

iprep

Perform a reputation lookup on IP address (since 13.1.0)

This condition is available to all policies.

iprep [client-accepted* | proxy-request | request |
server-connected]
all
[internal BOOL]
[local BOOL]

Example

iprep all values { "Spam Sources" "Denial of Service" }

ACTION_SPEC

An ACTION_SPEC, or action specification, is where you can tell the system the specific programmed actions you would like to take.

Actions are associated with an event, and depending on the action, can be set to run at different times during the request-response cycle.

Below is a list of all supported actions, the events during which they can be executed, their specific sub-actions, and parameters (if any).

Itm-policy

Provides the ability to disable LTM Policy processing on a request by request basis. (since 11.4.0)

This action is available to all policies.

itm-policy [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
proxy-request | request | proxy-connect |
proxy-response | response]
disable*

http

Provides the ability to enable or disable Big Ip's HTTP filter processing (since 11.4.0)

This action is available to all policies.

http [client-accepted* | proxy-request | request |
response | server-connected]
[enable*]
[disable]

http-uri

Modify the request's URI or path or query string. Setting URI value overrides path and query-string setting. (since 11.4.0)

This action is available to all policies.

http-uri [proxy-request* | request | proxy-connect]
replace*
[value TCLSTRING]
[path TCLSTRING]

[query-string TCLSTRING]

http-host

Modify the request's Host: header (since 11.4.0)

This action is available to all policies.

```
http-host [proxy-request* | request | proxy-connect]
replace*
value TCLSTRING
```

http-header

Modify HTTP header in request or response (since 11.4.0)

This action is available to all policies.

```
http-header [proxy-request* | request | proxy-connect |
proxy-response | response]
[replace*
 name STRING
 value TCLSTRING
]
[insert
 name STRING
 value TCLSTRING
]
[remove
 name STRING
]
```

http-referer

Modify the request's Referer: header (since 11.4.0)

This action is available to all policies.

```
http-referer [proxy-request* | request | proxy-connect]
[replace*
 [value TCLSTRING]
]
[insert
 value TCLSTRING
]
[remove]
```

where

replace - Replace request's Referer: header.
value - New value for request's Referer: header.
Values beginning with "tcl:" are treated as Tcl
command substitutions and expanded before use.

insert - Insert an HTTP Referer: header into the
request
value - New value for request's Referer: header.
Values beginning with "tcl:" are treated as Tcl
command substitutions and expanded before use.
remove - Remove the HTTP Referer: header from the
request

http-cookie

Modify the request's Cookie: header (since 11.4.0)

This action is available to all policies.

```
http-cookie [proxy-request* | request | proxy-connect]
[insert*
 name STRING
 [value TCLSTRING]
]
[remove
 name STRING
]
```

where

insert - Insert an HTTP Cookie: header into the
request
name - Name of the cookie being inserted into
request's Cookie: header.
value - New value for the cookie in the request's
Cookie: header. Values beginning with "tcl:" are
treated as Tcl command substitutions and expanded
before use.
remove - Remove the HTTP Cookie: header from the

request

name - Name of the cookie being inserted into request's Cookie: header.

Examples

```
http-cookie request insert name "Source-IP" value "tcl:[IP::remote_addr]"
http-cookie remove name "X-Tracker"
```

http-set-cookie

Modify the response's Set-Cookie: header (since 11.4.0)

This action is available to all policies.

```
http-set-cookie [response*]
[insert*
  name STRING
  value TCLSTRING
  [domain TCLSTRING]
  [path TCLSTRING]
]
[remove
  name STRING
]
```

where

insert - Insert an HTTP Set-Cookie: header into the response

name - Name of the cookie being inserted into response's Set-Cookie: header.
value - New value for the cookie in the response's Set-Cookie: header. Values beginning with "tcl:" are treated as Tcl command substitutions and expanded before use.

domain - Value for the domain attribute of a cookie in Set-Cookie header. Tcl command substitutions are allowed for this field.

path - Value for the path attribute of a cookie in Set-Cookie header. Tcl command substitutions are allowed for this field.

remove - Remove the HTTP Cookie: header from the request

name - Name of the cookie to be removed from response's Set-Cookie: header.

http-reply

Redirect an HTTP request to a different URL (since 11.4.0)

Specifying http-reply in an action automatically adds "controls {forwarding}" to the policy.

```
http-reply [proxy-request* | request | response]
redirect*
  location TCLSTRING
  [code NUMBER]
```

where

redirect - Redirect an HTTP request to a different URL

location - The new URL for which a redirect response will be sent. A Tcl command substitution can be used for this field.

code - Optional HTTP response code for redirect. Default value is 302 if not specified. Valid values are in the range of 300-399.

log

Write messages to local or remote system log (since 11.4.0)

This action is available to all policies.

```
log [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
proxy-request | request | proxy-connect |
proxy-response | response | ws_request |
ws_response | classification-detected]
write*
  [message TCLSTRING]
  [facility STRING]
  [priority STRING]
  [ip_address STRING]
  [port NUMBER]
```

where

write - Write a message to the system log files, local or remote

message - The message to write to the system log.

A Tcl command substitution is allowed here.

facility - Standard syslog facility associated

with message, such as auth, kern, daemon, user.

priority - Standard syslog priority associated

with message, such as emerg, alert, err, warning, notice, info, debug.

ip_address - For remote logging, the IP address of the remote syslog server.

port - For remote logging, the port number of the remote syslog server.

Examples

log request message "tcl:This is Tcl-enabled and the URI is [HTTP::uri]"

log request message "This is just a plain old string"

log request message "Something serious is happening!" priority alert

pem

Classify traffic (since 11.4.0)

Specifying pem in an action automatically adds "controls {classification}" to the policy.

```
pem [ssl-client-hello* | ssl-client-serverhello-send |
ssl-server-hello | ssl-server-handshake |
proxy-request | request | response]
  classify*
    [application STRING]
    [category STRING]
    [protocol STRING]
    [defer BOOL]
    [ssl-session-id BOOL]
```

where

classify - Classify traffic

ce

Classify traffic (since 12.1.0)

Specifying ce in an action automatically adds "controls {ce}" to the policy.

```
ce [ssl-client-hello* | ssl-server-hello |
ssl-server-handshake | request | response]
  classify*
    [application STRING]
    [category STRING]
```

where

classify - Classify traffic

cache

Control caching (since 11.4.0)

Specifying cache in an action automatically adds "controls {caching}" to the policy.

```
cache [client-accepted* | proxy-request | request |
response | server-connected]
  [enable*
    [pin BOOL]
  ]
  [disable]
```

where

enable - Enable caching for a connection

disable - Disable caching for a connection

compress

Control compression (since 11.4.0)

Specifying compress in an action automatically adds "controls {compression}" to the policy.

```
compress [client-accepted* | proxy-request | request |
response | server-connected]
  [enable*]
  [disable]
```

where

enable - Enable compression for a connection
disable - Disable compression for a connection

decompress

Control decompression (since 11.4.0)

Specifying decompress in an action automatically adds "controls {compression}" to the policy.

```
decompress [client-accepted* | proxy-request | request |  
response | server-connected]  
[enable*]  
[disable]
```

where

enable - Enable decompression for a connection
disable - Disable decompression for a connection

forward

Many options for controlling where a connection is forwarded (since 11.4.0)

Specifying forward in an action automatically adds "controls {forwarding}" to the policy.

```
forward [client-accepted* | ssl-client-hello |  
ssl-client-serverhello-send | proxy-request |  
request]  
[select*  
[pool STRING]  
[fallback-pool STRING]  
[clone-pool STRING]  
[node STRING]  
[snat STRING]  
[snatpool STRING]  
[nexthop STRING]  
[vlan STRING]  
[vlan-id NUMBER]  
[virtual STRING]  
[rateclass STRING]  
]  
[reset]
```

where

select - Select appropriate location for forwarding the connection based on specified parameters. While all of the parameters are marked as optional, at least one must be specified.

pool - Forward connection to the specified pool.

fallback-pool - Forward connection to the specified pool when the default pool does not have active members.

clone-pool - Clone traffic to the specified clone pool.

node - Forward connection to the specified node.

snat - Control snat automap.

snatpool - Forward connection to the specified snat pool.

nexthop - Set the next destination for the connection to the specified endpoint. A vlan or vlan-id must also be specified.

vlan - Forward connection to the specified vlan.

vlan-id - Forward connection to the vlan specified by the vlan-id.

virtual - Forward connection to the specified virtual server.

rateclass - Control rate class properties on the connection.

reset - Deprecated. See target "shutdown connection".

shutdown

Reset connection (since 13.1.0)

This action is available to all policies.

```
shutdown [client-accepted* | ssl-client-hello |  
ssl-client-serverhello-send | ssl-server-hello |  
ssl-server-handshake | server-connected |  
proxy-request | request | proxy-connect |  
proxy-response | response | ws_request |  
ws_response]  
connection*
```

where

connection - Terminate the connection through the Big IP.

persist

Many options for controlling how a connection is persisted (since 12.0.0)

Specifying persist in an action automatically adds "controls {persistence}" to the policy.

```
persist [client-accepted* | proxy-request | request]
[disable]
[src-addr*
 [netmask STRING]
 [timeout NUMBER]
]
[dest-addr
 [netmask STRING]
 [timeout NUMBER]
]
[cookie-insert
 [name STRING]
 [expiry STRING]
]
[cookie-rewrite
 [name STRING]
 [expiry STRING]
]
[cookie-passive
 [name STRING]
]
[cookie-hash
 name STRING
 [offset NUMBER]
 [length NUMBER]
 [timeout NUMBER]
]
[universal
 key TCLSTRING
 [timeout NUMBER]
]
[hash
 key TCLSTRING
 [timeout NUMBER]
]
[carp
 key TCLSTRING
 [timeout NUMBER]
]
```

where

disable - Disable persistence

src-addr - Persist the connection based on the source IP address.

netmask - Network mask, e.g. 192.168.13.23/16 or 10.0.2.15/255.0.0.0.

timeout - Timeout value in seconds.

dest-addr - Persist the connection based on the destination IP address.

netmask - Network mask, e.g. 192.168.13.23/16 or 10.0.2.15/255.0.0.0.

timeout - Timeout value in seconds.

cookie-insert - Persist the connection using cookie insertion method

name - cookie name

expiry - Expiration duration expressed as [Dd]

[[HH:]MM:]SS

cookie-rewrite - Persist the connection using cookie rewrite method

name - cookie name

expiry - Expiration duration expressed as [Dd]

[[HH:]MM:]SS

cookie-passive - Persist the connection using cookie passive method

name - cookie name

cookie-hash - Persist the connection using cookie hash method

name - cookie name

offset - offset into hash

length - substring length

timeout - Timeout value in seconds.

universal - persistence based on user-defined key

key - The key to use. Tcl command substitution is allowed.

timeout - Timeout value in seconds.

hash - persistence based on hash of the key
key - The key to use. Tcl command substitution is allowed.
timeout - Timeout value in seconds.
carp - hash persistence using Cache Array Routing Protocol (CARP) algorithm
key - The key to use. Tcl command substitution is allowed.
timeout - Timeout value in seconds.

wam

Control web acceleration (since 11.4.0)

Specifying wam in an action automatically adds "controls {wam}" to the policy.

```
wam [client-accepted* | proxy-request | request]
[enable*]
[disable]
```

where

enable - Enable web acceleration for a connection
disable - Disable web acceleration for a connection

asm

Control web security (since 11.4.0)

Specifying asm in an action automatically adds "controls {asm}" to the policy.

```
asm [client-accepted* | proxy-request | request]
[enable*]
policy STRING
]
[disable]
```

where

enable - Enable web security for a connection
policy - name of security policy to enable
disable - disable web security for the connection

l7dos

Enable or disable Layer 7 Denial-of-Service processing (since 11.4.0)

Specifying l7dos in an action automatically adds "controls {l7dos}" to the policy.

```
l7dos [client-accepted* | proxy-request | request]
[enable*]
[from-profile STRING]
]
[disable]
```

where

enable - turn on Layer 7 DOS protection
from-profile - name of DOS profile to enable
disable - turn off Layer 7 DOS protection

bot-defense

Enable or disable Unified Bot Defense processing (since 14.1.0)

Specifying bot-defense in an action automatically adds "controls {bot-defense}" to the policy.

```
bot-defense [client-accepted* | proxy-request | request]
[enable*]
[from-profile STRING]
]
[disable]
```

where

enable - turn on Bot Defense protection
from-profile - name of bot-defense profile to enable
enable
disable - turn off Bot Defense protection

avr

Enable or disable Application Visibility and Reporting (since 11.4.0)

Specifying avr in an action automatically adds "controls {avr}" to the policy.

```
avr [client-accepted* | proxy-request | request]
```

```
[enable*]  
[disable]
```

where

enable - turn on reporting
disable - turn off reporting

tcl

Set a Tcl variable in runtime environment (since 11.4.0)

This action is available to all policies.

```
tcl [client-accepted* | ssl-client-hello |  
ssl-client-serverhello-send | ssl-server-hello |  
ssl-server-handshake | server-connected |  
proxy-request | request | proxy-connect |  
proxy-response | response]  
  set-variable*  
    name STRING  
    expression STRING
```

where

set-variable - set a Tcl variable in the runtime
environment
name - name of variable
expression - Tcl expression to evaluate

Example

```
tcl set-variable expression tcl:[HTTP::uri] name my_uri
```

request-adapt

Enable or disable request adaptation, optionally sending traffic to specified internal virtual server (since 11.4.0)

Specifying request-adapt in an action automatically adds "controls {request-adaptation}" to the policy.

```
request-adapt [client-accepted* | server-connected |  
proxy-request | request | response]  
  [enable*  
    [internal-virtual STRING]  
  ]  
  [disable]
```

where

enable - turn on request adaptation
internal-virtual - which internal virtual server
disable - turn off request adaptation

response-adapt

Enable or disable response adaptation, optionally sending traffic to specified internal virtual server (since 11.4.0)

Specifying response-adapt in an action automatically adds "controls {response-adaptation}" to the policy.

```
response-adapt [client-accepted* | server-connected |  
proxy-request | request | response]  
  [enable*  
    [internal-virtual STRING]  
  ]  
  [disable]
```

where

enable - turn on response adaptation
internal-virtual - which internal virtual server
disable - turn off response adaptation

tcp-nagle

Enable or disable Nagle's algorithm on a connection, or allow BIG-IP to determine the best setting. (since 11.4.0)

This action is available to all policies.

```
tcp-nagle [client-accepted* | request]  
  [enable*  
    [auto-mode BOOL]  
  ]  
  [disable]
```

where

enable - turn on Nagle
auto-mode - turn on Auto Nagle
disable - turn off Nagle

server-ssl

Enable or disable encrypted connections to backend servers (since 11.4.0)

Specifying server-ssl in an action automatically adds "controls {server-ssl}" to the policy.

server-ssl [client-accepted* | proxy-request | request |
proxy-connect | proxy-response | server-connected]
[enable*]
[disable]

where

enable - encrypted connection to backend
disable - plaintext connection to backend

client-ssl

Enable or disable encrypted connections to client (since 13.1.0)

Specifying client-ssl in an action automatically adds "controls {client-ssl}" to the policy.

client-ssl [client-accepted*]
[enable*]
[disable]

where

enable - encrypted connection to client
disable - plaintext connection to client

ssl-intercept

Switch the SSL Intercept feature between bypass and intercept modes (since 13.1.0)

Specifying ssl-intercept in an action automatically adds "controls {ssl-intercept}" to the policy.

ssl-intercept [ssl-client-serverhello-send*]
[enable*]
[disable]

where

enable - SSL Intercept feature is in intercept mode
disable - SSL Intercept feature is in bypass mode

websocket

Enable or disable websocket processing (since 12.1.0)

Specifying websocket in an action automatically adds "controls {websocket}" to the policy.

websocket [client-accepted* | ws_request | ws_response |
proxy-request | request | proxy-connect |
proxy-response | response | server-connected]
[enable*]
[disable]

where

enable - turn on websocket filter
disable - turn off websocket filter

classification

Perform classification/enforcement of the connection (since 13.0.0)

Specifying classification in an action automatically adds "controls {classification}" to the policy.

classification [ssl-client-hello* | ssl-client-serverhello-send |
ssl-server-hello | ssl-server-handshake |
proxy-request | request | response | classification-detected]
[drop]
[reject]

where

drop - Silently drop connection
reject - Gracefully close connection

server-ssl-profile

Dynamic selection of SSL server profile (since 13.1.0)

Specifying server-ssl-profile in an action automatically adds "controls {server-ssl}" to the policy.

```
server-ssl-profile [server-connected*]  
select*  
name STRING
```

http-proxy

Enable or Disable the HTTP Explicit Proxy (since 13.1.0)

This action is available to all policies.

```
http-proxy [proxy-request*]  
[enable*]  
[disable]
```

where

enable - turn on the HTTP Explicit Proxy feature
disable - turn off the HTTP Explicit Proxy feature

http-uri-rewrite

Enable or Disable the rewriting of HTTP URI's into proxy form (since 13.1.0)

This action is available to all policies.

```
http-uri-rewrite [client-accepted* | ssl-client-hello |  
ssl-server-hello | ssl-server-handshake |  
proxy-request | request | server-connected]  
[enable*]  
[disable]
```

where

enable - turn on rewriting the URI into proxy form
disable - turn off rewriting the URI into proxy form

http-connect

Control the HTTP Proxy Connect feature (since 13.1.0)

This action is available to all policies.

```
http-connect [client-accepted* | ssl-client-hello |  
proxy-request | request | server-connected |  
proxy-connect | proxy-response]  
[enable*]  
[disable]  
[replace  
[port NUMBER]  
[host STRING]  
]  
[retry]
```

where

enable - turn on the HTTP Proxy Connect feature
disable - turn off the HTTP Proxy Connect feature
retry - retry the HTTP CONNECT

DELETE
delete pool [name]

```

Note: You must remove all references to a pool before you can delete the pool.

DESCRIPTION

You can use this pool component to configure the pool definitions on the Local Traffic Manager. A load balancing pool is a logical set of devices, such as Web servers, that you group together to receive and process traffic.

EXAMPLES

```
create pool my_pool members add { 10.2.3.11:http 10.2.3.12:http }
```

Creates a Local Traffic Manager pool named my_pool with two members, 10.2.3.11 and 10.2.3.12, using the default values for the pool and pool members.

```
delete pool my_pool
```

Deletes the pool named my_pool.

```
show pool
```

Displays statistics and status for all Local Traffic Manager pools in the system configuration.

```
show pool all-properties
```

Displays statistics and status for all Local Traffic Manager pools in the system configuration.

Note that if the system includes Packet Velocity(r) ASIC (PVA) and PVA Assist capabilities, this command displays status and statistics for that feature.

```
list pool my_pool
```

Displays properties of the pool named my_pool.

```
mv /ltm pool /Common/my_pool to-folder /Common/some_folder
```

Moves an LTM pool named my_pool and all of its Pool Members to the folder named some_folder, where some_folder has already been created under /Common.

Please refer to the mv manual page for additional examples on how to use the mv command.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

allow-nat

Specifies whether the pool can load balance network address translation (NAT) connections. The default value is yes.

allow-snat

Specifies whether the pool can load balance secure network address translation (SNAT) connections. The default value is yes.

app-service

Specifies the name of the application service to which the pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the pool. Only the application service can modify or delete the pool.

autoscale-group-id

Deprecated since v13.1.0. Specifies the autoscale-group id as reported by Amazon Web Services(AWS).

description

User defined description.

gateway-failsafe-device

Specifies that the pool is a gateway failsafe pool in a redundant configuration. The gateway-failsafe-device identifies the device that depends on the gateway. If the monitor associated with the pool reports that the gateway is down, the device goes to the standby state. The default value for this string is empty, the feature is not configured.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

traffic-acceleration-status

Displays the current Traffic-Acceleration status. Indicates whether the pool is in-use by or dedicated to a virtual server that uses a traffic-acceleration profile.

ignore-persisted-weight

Discounts the weight of connections made to pool members selected through persistence, rather than as a result of the algorithm configured on the pool. If the connection's weight is ignored, then it is not treated as a 'pick' for that pool member, and does not influence subsequent pool member load balancing decisions.

This option only impacts pools configured with one of the following load balancing modes: observed-member, observed-node, predictive-member, predictive-node, ratio-least-connections-member, ratio-least-connections-node, ratio-member, or ratio-node.

The default value is no, which results in persisted pool member connections being accounted for during load balancing calculations.

ip-tos-to-client

Specifies the Type of Service (ToS) level to use when sending packets to a client. The default value is 65535 (pass-through).

ip-tos-to-server

Specifies the ToS level to use when sending packets to a server. The default value is 65535 (pass-through).

link-qos-to-client

Specifies the Link Quality of Service (QoS) level to use when sending packets to a client. The default value is 65535 (pass-through).

link-qos-to-server

Specifies the Link QoS level to use when sending packets to a server. The default value is 65535 (pass-through).

load-balancing-mode

Specifies the modes that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

dynamic-ratio-member

Specifies that the system distributes connections based on various aspects of real-time server performance analysis, such as the number of current connections per node or the fastest node response time.

This mode is similar to the dynamic-ratio-node mode, except that weights are based on continuous monitoring of the servers and are therefore continually changing.

dynamic-ratio-node

Specifies that the system distributes connections based on various aspects of real-time server performance analysis, such as the number of current connections per node or the fastest node response time.

This mode is similar to the dynamic-ratio-member mode, except that weights are based on continuous monitoring of the servers and are therefore continually changing.

fastest-app-response

Specifies that the system passes a new connection based on the fastest response of all currently active nodes in a pool. This mode might be particularly useful in environments where nodes are distributed across different logical networks.

fastest-node

Specifies that the system passes a new connection based on the fastest response of all pools of which a server is a member. This mode might be particularly useful in environments where nodes are distributed across different logical networks.

least-connections-member

Specifies that the system passes a new connection to the node that has the least number of current connections in the pool. This mode works best in environments where the servers or other equipment you are load balancing have similar capabilities.

This dynamic load balancing mode distributes connections based on various aspects of real-time server performance analysis, such as the current number of connections per node or the fastest node response time.

least-connections-node

Specifies that the system passes a new connection to the node that has the least number of current connections out of all pools of which a node is a member. This mode works best in environments where

the servers or other equipment you are load balancing have similar capabilities.

This dynamic load balancing mode distributes connections based on various aspects of real-time server performance analysis, such as the number of current connections per node, or the fastest node response time.

least-sessions

Specifies that the system passes a new connection to the node that has the least number of current sessions. This mode works best in environments where the servers or other equipment you are load balancing have similar capabilities.

This dynamic load balancing mode distributes connections based on various aspects of real-time server performance analysis, such as the number of current sessions.

observed-member

Specifies that the system ranks nodes based on the number of connections. Nodes that have a better balance of fewest connections receive a greater proportion of the connections.

This mode differs from the least-connections-member mode, which measures connections only at the moment of load balancing, while the observed-member mode tracks the number of Layer 4 connections to each node over time and creates a ratio for load balancing.

This dynamic load balancing mode works well in any environment, but may be particularly useful in environments where node performance varies significantly.

observed-node

Specifies that the system ranks nodes based on the number of connections. Nodes that have a better balance of fewest connections receive a greater proportion of the connections.

This mode differs from least-connections-node mode, which measures connections only at the moment of load balancing, while the observed-node mode tracks the number of Layer 4 connections to each node over time and creates a ratio for load balancing.

This dynamic load balancing method works well in any environment, but may be particularly useful in environments where node performance varies significantly.

predictive-member

Uses the ranking method used by the observed-member mode, except that the system analyzes the trend of the ranking over time, determining whether a node's performance is improving or declining. The nodes in the pool with better performance rankings that are currently improving, rather than declining, receive a higher proportion of the connections. This dynamic load balancing mode works well in any environment.

predictive-node

Uses the ranking method used by the observed-node mode, except that the system analyzes the trend of the ranking over time, determining whether a node's performance is improving or declining. The nodes in the pool with better performance rankings that are currently improving, rather than declining, receive a higher proportion of the connections. This dynamic load balancing mode works well in any environment.

queue-depth-limit

Specifies the maximum number of connections that may simultaneously be queued to go to any member of this pool. The default is zero which indicates there is no limit.

queue-on-connection-limit

Enable or disable queuing connections when pool member or node connection limits are reached. When queuing is not enabled, new connections are reset when connection limits are met. The default value is disabled.

queue-time-limit

Specifies the maximum time, in milliseconds, a connection will remain enqueued. The default is zero which indicates there is no limit.

ratio-least-connections-member

Specifies that the system weights connections to each pool member based on the value of the ratio weight defined for each pool member. If a ratio weight is unspecified, it will be treated as a default value of '1'.

ratio-least-connections-node

Specifies that the system weights connections to each pool member based on the value of the ratio weight defined for the pool member's node. If a ratio weight is unspecified, it will be treated as a default value of '1'.

ratio-member

Specifies that the number of connections that each machine receives over time is proportionate to a ratio weight you define for each machine within the pool.

ratio-node

Specifies that the number of connections that each machine receives over time is proportionate to a ratio weight you define for each machine across all pools of which the server is a member.

ratio-session

Specifies that the number of sessions that each machine receives over time is proportionate to a ratio weight that you define for each machine within the pool.

round-robin

Specifies that the system passes each new connection request to the next server in line, eventually

distributing connections evenly across the array of machines being load balanced. This mode works well in most configurations, especially if the equipment that you are load balancing is roughly equal in processing speed and memory.

weighted-least-connections-member

Specifies that the system passes a new connection to the pool member that is handling the lowest percentage of the specified maximum number of concurrent connections allowed. This mode works best in environments where the servers or other equipment you are load balancing have different but quantified capability limits.

This mode requires that you specify a value for the connection-limit option for all members of the pool, but does not require all servers or other equipment you are load balancing to have similar capabilities.

weighted-least-connections-node

Specifies that the system passes a new connection to the node that is handling the lowest percentage of the specified connection limit. This mode works best in environments where the servers or other equipment you are load balancing have different but quantified capability limits.

This mode requires that you specify a value for the connection-limit option for all nodes, but does not require all servers or other equipment you are load balancing to have similar capabilities.

members

Adds, deletes, or replaces a set of pool members, by specifying a node name and service port in the format [node name/port]. If a node by the specified name does not exist, it will be created. You can configure the following options for a pool member:

address

Specifies the IP address of a pool member if a node by the name specified does not already exist.

app-service

Specifies the name of the application service to which the pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the pool member. Only the application service can modify or delete the pool member.

connection-limit

Specifies the maximum number of concurrent connections allowed for a pool member. The default value is 0 (zero).

description

User defined description.

dynamic-ratio

Specifies a range of numbers that you want the system to use in conjunction with the ratio load balancing method. The default value is 1.

fqdn Specifies the attributes for defining a fully qualified domain name for the node.

name Specifies the fully-qualified domain name of the node.

address-family

Specifies whether the fqdn should consider IPv4, IPv6, or IP-agnostic address family.

autopopulate

Specifies whether a node defined by a fully-qualified domain name should automatically scale to the set of IP addresses returned by the DNS query. If disabled, only one ephemeral node is generated from the first IP address returned by DNS. The default is disabled.

interval

Specifies the interval, in seconds, to instantiate DNS queries on a fully-qualified domain name. The default is 3600. A value of 'ttl' uses the TTL value obtained from the DNS server.

down-interval

Specifies the interval for the domain name resolution operation when a DNS query fails. The default is 5.

inherit-profile

Specifies whether the pool member inherits the encapsulation profile from the parent pool. The default value is enabled. If you disable inheritance, no encapsulation takes place, unless you specify another encapsulation profile for the pool member using the profiles attribute.

logging

Specifies whether the monitor applied should log its actions. Logs are stored in /var/log/monitors/ and are regularly rotated and compressed. The default value is disabled. This option isn't a part of configuration and will reset to disabled on load. This option doesn't sync.

monitor

Specifies the health monitors that are configured to monitor the pool member. The default value is default, the system monitors the pool member using the monitors specified for the pool.

You can specify:

Â• A single monitor, for example, modify pool mypool members modify { pool_member_1:80 { monitor http } }.

Â• Multiple monitors, for example, modify pool mypool members modify { pool_member_1:80 { monitor

http and https } }.

Â· A minimum number of monitors, for example, modify pool mypool members modify { pool_member_1:80 { monitor min 1 of { http https } } }.

Â· No monitor rule or remove a monitor rule, for example, modify pool mypool members modify { pool_member_1:80 { monitor none } }.

profiles

Specifies the encapsulation profile to use for the pool member, when the inherit-profile attribute is disabled. The default value is none.

priority-group

Specifies the priority group within the pool for this pool member. Valid values are 0 through 65535. The system sends traffic to groups in order of priority. The default value is 0.

rate-limit

Specifies the maximum number of connections per second allowed for a pool member. The default value is 'disabled'.

ratio

Specifies the weight of the pool member for load balancing purposes. The default value is 1.

session

Establishing a session with a pool member is establishing the ability of the client to persist to the pool member when making new connections. When a pool member is session disabled, clients that have already established sessions with the pool member may create new connections, but a client that has not already established a session may not create a new one (or make a connection which would create a new session). This feature is used to gently drain connections from a node, typically as part of a maintenance operation. The default value is user-enabled.

The value of this property can be set by system or by user. If the value is set by system, the property will not be displayed in "Edit" command. But, users can add this field in if they need to modify this property. The values which user can set for this property are user-enabled and user-disabled.

state

user-down forces the pool member offline, overriding monitors. user-up reverts the user-down. When user-up, this displays the monitor state.

metadata

Associates user-defined data, each of which has name and value pair and persistence. The default value is persistent, which saves the data to the config file.

min-active-members

Specifies the minimum number of members that must be up for traffic to be confined to a priority group when using priority-based activation. The default value is 0 (zero). An active member is a member that is up (not marked down) and is handling fewer connections than its connection limit.

min-up-members

Specifies the minimum number of pool members that must be up; otherwise, the system takes the action specified in the min-up-members-action option.

Use this option for gateway pools in a redundant system where a unit number is applied to the pool. This indicates that the pool is configured only on the specified unit.

min-up-members-action

Specifies the action to take if min-up-members-checking is enabled, and the number of active pool members falls below the number specified in the min-up-members option. The default value is failover. The options are:

reboot

Specifies that when the min-up-members-checking option is enabled, and the number of active pool members is less than the number specified in the min-up-members option, the system restarts.

restart-all

Specifies that when the min-up-members-checking option is enabled, and the number of active pool members is less than the number specified in the min-up-members option, the system restarts.

failover

Specifies, for a redundant system, that when the min-up-members-checking option is enabled, and the number of active pool members is less than the number specified in the min-up-members option, the system fails over.

min-up-members-checking

Enables or disables the min-up-members feature. If you enable this feature, you must also specify a value for both the min-up-members and min-up-members-action options.

monitor

Specifies the health monitors that the system uses to determine whether it can use this pool for load balancing. The monitor marks the pool up or down based on whether the monitor is successful. The default value is none.

You can specify:

Â· A single monitor, for example, modify pool mypool monitor http.

Â· Multiple monitors, for example, modify pool mypool monitor http and https.

Â· A minimum number of monitors, for example, modify pool mypool monitor min 1 of {http and https}.

Â· No monitor rule or remove a monitor rule, for example, modify pool mypool monitor none.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the pool resides.

profiles
Specifies the profile to use for encapsulation. The default value is none, which indicates no encapsulation.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reselect-tries
When set to the default value of 0 (zero) the system does not attempt to load balance to another pool member after a passive failure. A passive failure is a pool member connection failure.

When set to any other value, the system attempts to load balance to another pool member after a passive failure, and if that attempt also results in a passive failure, the system repeats the process until the specified number of reselection tries is reached.

reset-stats
Resets the statistics for the specified component to 0 (zero).

service-down-action
Specifies the action to take if the service specified in the pool is marked down. The options are:

drop Specifies that the system drops connections when a the service is marked down.

none Specifies that the system takes no action when a the service is marked down. This is the default value.

reselect
Specifies that the system reselects a node for the next packet that comes in on a Layer 4 connection, if the service of the existing connection is marked down.

reset
Specifies that the system resets when a the service is marked down.

slow-ramp-time
Specifies, in seconds, the ramp time for the pool. This provides the ability to cause a pool member that has just been enabled, or marked up, to receive proportionally less traffic than other members in the pool. The proportion of traffic the member accepts is determined by how long the member has been up in comparison to the value of the slow-ramp-time option for the pool.

For example, if the load-balancing-mode of a pool is round-robin and it has a slow-ramp-time of 60 seconds, when a pool member has been up for only 30 seconds, the pool member receives approximately half the amount of new traffic as other pool members that have been up for more than 60 seconds. After the pool member has been up for 45 seconds, it receives approximately three quarters of the new traffic.

The slow-ramp-time option is particularly useful when used with the least-connections-member load balancing mode. The default value is 10.

to-folder
This is used with the mv command to specify a folder in which to move the pool and its members to.

Note: pools can be moved to any folder under /Common, but dependencies upon it may restrict moving it out of /Common.

```

DESCRIPTION
 Use the analytics component to create, modify, display, or delete an analytics profile for use with analytics functionality.

EXAMPLES
 create analytics my_analytics_profile defaults-from analytics

Creates a custom analytics profile named my_analytics_profile that inherits its settings from the system default analytics profile.

list analytics

Displays the properties of all analytics profiles.

OPTIONS
 app-service
 Specifies the name of the application service to which the profile belongs. The default value is none.
 Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

alerts
 Adds, deletes, or replaces a set of analytics alerts. You can configure the following options for an analytics alert:

app-service
 Specifies the name of the application service to which the alert belongs. The default value is none.
 Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the alert. Only the application service can modify or delete the alert.

granularity
 Specifies a granularity level on which the alert is defined.

The options are:

application
 Specifies that an alert is triggered for applications for which a threshold is breached.

pool-member
 Specifies that an alert is triggered for pool members for which a threshold is breached.

virtual-server
 Specifies that an alert is triggered for virtual servers for which a threshold is breached.

metric
 Specifies a metric on which the alert is defined.

The options are:

average-page-load-time
 Specifies that an alert is triggered when the average time it takes for the client to respond to a request breaches the defined threshold.

average-request-throughput

Specifies that an alert is triggered when the average number of bits per second the system processed, based on requests only, breaches the defined threshold.

average-response-throughput

Specifies that an alert is triggered when the average number of bits per second the system processed, based on responses only, breaches the defined threshold.

average-server-latency

Specifies that an alert is triggered when the average time it takes for the web server to respond to a request breaches the defined threshold.

average-tps

Specifies that an alert is triggered when the average number of transactions per second breaches the defined threshold.

max-page-load-time

Specifies that an alert is triggered when the longest time it takes for the client to respond to a request breaches the defined threshold.

max-request-throughput

Specifies that an alert is triggered when the maximum number of bits per second the system processed, based on requests only, breaches the defined threshold.

max-response-throughput

Specifies that an alert is triggered when the maximum number of bits per second the system processed, based on requests only, breaches the defined threshold.

max-server-latency

Specifies that an alert is triggered when the longest time it takes for the web server to respond to a request breaches the defined threshold.

max-tps

Specifies that an alert is triggered when the largest number of transactions per second breaches the defined threshold.

name Specifies a unique name for an alert. This option is required for the commands create, delete, and modify.

sample-period

Specifies that the alert metric is triggered when the conditions that trigger the alert last a defined amount of time, measured in seconds. The default value is 300.

threshold

Specifies the threshold that must be breached in order for the system to generate alert.

threshold-relation

Specifies whether the metric value must be below or above the metric.

The options are:

above

Specifies that an alert is issued if metric current value is above the threshold.

below

Specifies that an alert is issued if metric current value is below the threshold.

captured-traffic-external-logging

Enables or disables the external logging of captured traffic.

captured-traffic-internal-logging

Enables or disables the internal logging of captured traffic.

collect-page-load-time

Enables or disables the collection of the page load time statistics. The page load time is the round-trip latency between client end-users and the servers, that is, the round-trip time between an end-user's request for a page until the time the response finishes loading.

collect-geo

Enables or disables the collection of the names of the countries from where the traffic was sent.

collect-http-throughput

Enables or disables the collection of throughput statistics. This property has been deprecated. As of v11.3.0, HTTP throughput is always collected.

collect-http-timing-metrics

Enables or disables the collection of HTTP timing metrics.

collect-ip

Enables or disables the collection of client IPs statistics.

collect-max-tps-and-throughput

Enables or disables the collection of maximum TPS and throughput for all collected entities.

collect-methods

Enables or disables the collection of HTTP methods statistics.

`collect-response-codes`

Enables or disables the collection of response codes returned by the servers.

`collect-server-latency`

Enables or disables the collection of server latency statistics. This property has been deprecated. As of v11.3.0, server latency is always collected.

`collect-subnets`

Enables or disables the collection of client side subnets.

`collect-url`

Enables or disables the collection of requested URL statistics.

`collect-user-agent`

Enables or disables the collection of user agents.

`collect-user-sessions`

Enables or disables the collection of the unique user sessions.

`collected-stats-external-logging`

Enables or disables the external logging of the collected statistics.

`collected-stats-internal-logging`

Enables or disables the internal logging of the collected statistics.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is analytics.

`description`

User defined description.

`external-logging-publisher`

Specifies the external logging publisher used to send statistical data to one or more destinations.

`glob` Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

`notification-by-email`

Enables or disables sending the analytics alerts by email.

`notification-by-snmp`

Enables or disables sending the analytics alerts by SNMP traps. notification-by-syslog must be enabled.

`notification-by-syslog`

Enables or disables logging of the analytics alerts into the Syslog.

`notification-email-addresses`

Specifies which email addresses receive alerts by email when notification-by-email is enabled.

`partition`

Displays the administrative partition within which the component resides.

`publish-irule-statistics`

Enables or disables publishing analytics statistics for iRules.

`sampling`

Enables or disables transaction sampling. This attribute can be set in the default profile only. The default value is disabled.

`session-cookie-security`

Specifies the condition for adding a secure attribute to the session cookie. The options are:

`always`

The secure attribute is always added to the session cookie.

`never`

The secure attribute is never added to the session cookie.

`ssl-only`

The secure attribute is only added to the session cookie when the virtual server has a client-SSL profile. This is the default value.

`session-timeout-minutes`

Specifies the number of minutes of user non-activity before the system considers the session to be over.

`smtp-config`

Specifies the SMTP configuration to be used with analytics.

`subnet-masks`

Adds, deletes, or replaces predefined subnet addresses. This options defines the display names given to certain subnet addresses seen in the client IP subnets report.

subnet

Subnet address. IPv4 addresses will be masked by 255.255.255.0. IPv6 addresses will be masked by ffff:ffff:ffff:ffff::.

countries-for-stat-collection

Manage a list of 10 predefined countries that are used for collecting AVR statistics

ips-for-stat-collection

Manage a list of 10 predefined IP addresses that are used for collecting AVR statistics.

subnets-for-stat-collection

Manage a list of 10 predefined URLs that are used for collecting AVR statistics.

urls-for-stat-collection

Manage a list of 10 predefined subnet addresses that are used for collecting AVR statistics. IPv4 addresses will be masked by 255.255.255.0. IPv6 addresses will be masked by ffff:ffff:ffff:ffff::.

traffic-capture

Adds, deletes, or replaces an analytics traffic capture definition. You can configure the following options for an analytics traffic capture:

app-service

Specifies the name of the application service to which the analytics traffic capture belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the analytics traffic capture. Only the application service can modify or delete the analytics traffic capture.

captured-protocols

Specifies whether the system captures traffic data sent using all protocols, or only one type of protocol.

The options are:

all Specifies that the system captures traffic data sent using all protocols.

http Specifies that the system captures traffic data sent using http protocol.

https

Specifies that the system captures traffic data sent using https protocol.

client-ips

Adds, deletes, or replaces a set of client IP addresses from/to which captured traffic is sent.

dos-activity

Specifies whether the system captures traffic data mitigated by DoS Layer 7 Enforcer or regardless of DoS activity.

The options are:

any Specifies that system does not filter traffic data by DoS activity.

mitigated-by-dosl7

Specifies that the system captures only traffic data mitigated by DoS Layer 7 Enforcer.

methods

Adds, deletes, or replaces a set of HTTP methods used to send requests from which traffic is captured.

name Specifies a unique name for an analytics traffic capture. This option is required for the commands create, delete, and modify.

node-addresses

Adds, deletes, or replaces a set of node addresses from/to which captured traffic is sent.

request-captured-parts

Specifies what parts of the request data the system captures.

The options are:

all Specifies that the system captures all the parts of the request data.

body Specifies that the system captures the body of the request data.

headers

Specifies that the system captures the HTTP headers of the request data.

none Specifies that the system does not capture the request data.

request-content-filter-search-part

Specifies which part of the request is filtered by a specific string.

The options are:

all Specifies that the system filters all the parts of the request data.

body Specifies that the system filters the body of the request data.

headers

Specifies that the system filters the HTTP headers of the request data.

none Specifies that system does not filter the request data.

uri Specifies that the system filters the URI path component, including the query string, of the request data.

request-content-filter-search-string

Specifies the string by which a request data is filtered, or none.

response-captured-parts

Specifies what parts of the response data the system captures.

The options are:

all Specifies that the system captures all the parts of the response data.

body Specifies that the system captures the body of the response data.

headers

Specifies that the system captures the HTTP headers of the response data.

none Specifies that the system does not capture the response data.

response-codes

Adds, deletes, or replaces a set of HTTP response codes from which traffic is captured.

response-content-filter-search-part

Specifies which part of the response is filtered by a specific string.

The options are:

all Specifies that the system filters all the parts of the response data.

body Specifies that the system filters the body of the response data.

headers

Specifies that the system filters the HTTP headers of the response data.

none Specifies that system does not filter the response data.

response-content-filter-search-string

Specifies the string by which the response data is filtered, or none.

url-path-prefixes

Adds, deletes, or replaces a set of URL path prefixes on which traffic can be captured (both to and from).

user-agent-substrings

Adds, deletes, or replaces a set of user agent substrings on which traffic can be captured (both to and from).

virtual-servers

Adds, deletes, or replaces a set of virtual servers from/to which captured traffic is sent.

Itm profile certificate-authority

NAME

certificate-authority - Defines the settings necessary to authenticate the client certificate.

MODULE

ltm profile

SYNTAX

Configure the certificate-authority within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create certificate-authority [name]
modify certificate-authority [name]
options:
 authenticate-depth
 ca-file
 crl-file
 default-name
 description
 update-crl

edit certificate-authority [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list certificate-authority
list certificate-authority [[[name] | [glob] | [regex]] ...]
 app-service
 partition

show certificate-authority
show certificate-authority [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 field-fmt
non-default-properties
 one-line

DESCRIPTION

Use the certificate-authority component to modify or display a certificate-authority profile.

EXAMPLES

```
create ltm profile certificate-authority mycaprofile { ca-file ca.crt }
```

Creates a certificate authority profile named mycaprofile using the system defaults.

```
modify ltm profile certificate-authority mycaprofile { authenticate-depth 3 }
```

Modifies the authenticate-depth setting to 3 for the certificate authority profile named mycaprofile.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

authenticate-depth

Specifies the authenticate depth. This is the client certificate chain maximum traversal depth.

ca-file

Specifies the certificate authority file name or, you can use default for the default certificate authority file name. Configures certificate verification by specifying a list of client or server certificate authorities that the traffic management system trusts.

crl-file

Specifies the certificate revocation list file name. You can use default for the default certificate revocation file name.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified.

description

User defined description.

name Specifies the profile instance name. This option is required for the modify command.

partition

Specifies the administrative partition within which the profile resides.

regex

Specifies the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

update-crl

Automatically updates the CRL file.

SEE ALSO

edit, glob, list, modify, regex, show, tmsh,

list classification [[[name] | [glob] | [regex]] ...]

show running-config classification

show running-config classification [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete classification [name]

DESCRIPTION

Use the classification component to create, modify, delete or display a classification profile.

EXAMPLES

create classification my_cl { irule-event off preset /Common/ce }

Creates classification profile named my_cl with Classification Engine configuration /Common/ce and iRule event disabled.

edit classification my_cl

Edits the classification profile named my_cl.

list classification my_cl

Displays the properties of the my_cl classification profile.

delete classification my_cl

Deletes the my_cl classification profile.

OPTIONS

description

User defined description.

app-detection

Enables / Disables Application Detection feature.

urlcat

Enables / Disables URL categorization feature.

irule-event

Enables / disables CLASSIFICATION_DETECTED iRule event generation.

log-publisher

Specifies the log publisher name

preset

Specifies Classification Engine configuration. Refer to Itm classification ce for more details

SEE ALSO

Itm profile client-ldap

NAME

client-ldap - Configures an Client LDAP profile.

MODULE

Itm profile

SYNTAX

Configure the client-ldap component within the Itm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create client-ldap [name]

modify client-ldap [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

activation-mode [none | allow | require]

edit client-ldap [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list client-ldap

list client-ldap [[[name] | [glob] | [regex]] ...]

show running-config client-ldap

show running-config client-ldap [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DELETE

delete client-ldap [name]

DESCRIPTION

You can use the client-ldap component to create, modify, display, or delete an Client LDAP profile with which you can manage Client LDAP traffic.

EXAMPLES

create client-ldap my_clientldap_profile defaults-from clientldap

Creates a custom Client LDAP profile named my_clientldap_profile that inherits its settings from the system default Client LDAP profile.

list client-ldap

Displays the properties of all Client LDAP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot

modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is smtp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

activation-mode

Sets the activation-mode STARTTLS. The options are NONE, ALLOW, or REQUIRE. The default value is REQUIRE.

SEE ALSO

create, delete, edit, glob, list, Itm virtual, modify, regex, reset-stats, show, sys provision, tmsb

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

DELETE
delete client-ssl [all | [name]]
options:
recursive

DESCRIPTION

You can use the client-ssl component to create, modify, or delete a custom Client SSL profile, or display a custom or default Client SSL profile.

Client-side profiles allow the traffic management system to handle authentication and encryption tasks for any SSL connection coming into a traffic management system from a client system.

EXAMPLES

create client-ssl my_clientssl_profile

Creates a clientssl profile named my_clientssl_profile using the system defaults.

create clientssl my_clientssl_profile authenticate-depth number

Creates a Client SSL profile named my_clientssl_profile using the system defaults, except that a user is authenticated with depth number.

mv client-ssl /Common/my_client-ssl_profile to-folder /Common/my_folder

Moves a custom client-ssl profile named my_client-ssl_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

alert-timeout

Specifies the maximum time period in seconds to keep the SSL session active after alert message is sent, or indefinite. The default value is indefinite.

allow-non-ssl

Enables or disables non-SSL connections. Specify enabled when you want non-SSL connections to pass through the traffic management system as clear text. The default value is disabled.

allow-dynamic-record-sizing

Enables or disables dynamic application record sizing. Specify enabled when you want to allow dynamic record sizing. The default value is disabled.

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

authenticate

Specifies how often the system authenticates a user. The default value is once. Note that if this is set to always session cache and session ticket will be disabled.

authenticate-depth

Specifies the authenticate depth. This is the client certificate chain maximum traversal depth. The default value is 9.

bypass-on-client-cert-fail

Enables or disables SSL forward proxy bypass on failing to get client certificate that server asks for. When enabled and the SSL handshake cannot be completed because of failure to get the client certificate, SSL traffic bypasses the BIG-IP system untouched, without decryption/encryption. The default value is disabled. Conversely, you can specify enabled to use this feature.

bypass-on-handshake-alert

Enables or disables SSL forward proxy bypass on receiving handshake_failure, protocol_version or unsupported_extension alert message during the serverside SSL handshake. When enabled and there is an SSL handshake_failure, protocol_version or unsupported_extension alert during the serverside SSL handshake, SSL traffic bypasses the BIG-IP system untouched, without decryption/encryption. The default value is disabled. Conversely, you can specify enabled to use this feature.

c3d-client-fallback-cert

Specifies the client certificate to use in SSL client certificate constrained delegation. This certificate will be used if client does not provide a cert during the SSL handshake. The default value is none.

c3d-drop-unknown-ocsp-status

Specifies the BIG-IP action when the OCSP responder returns unknown status. The default value is drop, which causes the connection to be dropped. Conversely, you can specify ignore, which causes the

connection to ignore the unknown status and continue.

c3d-ocsp

Specifies the SSL client certificate constrained delegation OCSP object that the BIG-IP SSL should use to connect to the OCSP responder and check the client certificate status.

ca-file

Specifies the certificate authority (CA) file name. Configures certificate verification by specifying a list of client or server CAs that the traffic management system trusts. The default value is none.

cache-size

Specifies the SSL session cache size. For client-side profiles only, you can configure timeout and size values for the SSL session cache. Because each profile maintains a separate SSL session cache, you can configure the values on a per-profile basis. The default value is 262144.

cache-timeout

Specifies the SSL session cache timeout value. This specifies the number of usable lifetime seconds of negotiated SSL session IDs. The default value is 3600 seconds. Acceptable values are integers greater than or equal to 0 and less than or equal to 86400.

cert This option is deprecated and is maintained here for backward compatibility reasons. Please check **cert-key-chain** option to add certificate, key, passphrase and chain to the profile.

cert-extension-includes

Specifies the extensions of the web server certificates to be included in the generated certificates using SSL Forward Proxy. For example, { basic-constraints }. The default value is none. The extensions are:

basic-constraints

Basic Constraints are used to indicate whether the certificate belongs to a CA.

extended-key-usage

Extended Key Usage is used, typically on a leaf certificate, to indicate the purpose of the public key contained in the certificate.

key-usage

Key Usage provides a bitmap specifying the cryptographic operations which may be performed using the public key contained in the certificate; for example, it could indicate that the key should be used for signature but not for encipherment.

subject-alternative-name

Subject Alternative Name allows identities to be bound to the subject of the certificate. These identities may be included in addition to or in place of the identity in the subject field of the certificate.

subject-directory-attributes

Subject Directory Attributes are used to convey identification attributes (for example, nationality) of the subject.

destination-ip-blacklist

Specifies the data group name of destination ip blacklist when SSL forward proxy bypass feature is enabled.

destination-ip-whitelist

Specifies the data group name of destination ip whitelist when SSL forward proxy bypass feature is enabled.

forward-proxy-bypass-default-action

Specifies the SSL forward proxy bypass default action. The default option is intercept.

hostname-blacklist

Specifies the data group name of hostname blacklist when SSL forward proxy bypass feature is enabled.

hostname-whitelist

Specifies the data group name of hostname whitelist when SSL forward proxy bypass feature is enabled.

inherit-certkeychain

This is read only value used internally.

cert-key-chain

Adds, deletes, or replaces a set of certificate, key, passphrase, chain (usage specifies whether this item is used for Server or CA, where Server is the default and CA is for SSL forward proxy). client-ssl profile requires at least one cert/key pair to work. Multiple cert/key types can be associated to a client-ssl profile using following options:

cert Specifies the name of the certificate installed on the traffic management system for the purpose of terminating or initiating an SSL connection. You can specify the default certificate name, which is default.crt.

chain

Specifies or builds a certificate chain file that a client can use to authenticate the profile. The default value is none.

key Specifies the name of a key file that you generated and installed on the system. When selecting this option, type a key file name or use the default value default.key.

passphrase

Specifies the key passphrase, if required. The default value is none.

cert-lifespan

Specifies the lifespan of the certificate generated using the SSL forward proxy feature. The default value is 30.

cert-lookup-by-ipaddr-port

Specifies whether to perform certificate look up by IP address and port number.

chain

This option is deprecated and is maintained here for backward compatibility reasons. Please check cert-key-chain option to add certificate, key, passphrase and chain to the profile.

cipher-group

Specifies a cipher group. If the cipher group is not blank or none, the ciphers string will be used.

ciphers

Specifies a cipher name. The default value is DEFAULT, which uses the default ciphers.

client-cert-ca

Specifies the client cert certificate authority name. The default value is none.

crl-file

Specifies the certificate revocation list file name. The default value is none.

allow-expired-crl

Use the specified CRL file even if it has expired. The default value is disabled.

defaults-from

This setting specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is clientssl.

description

User defined description.

generic-alert

Enables or disables generic-alert. The default option is enabled, which causes the SSL profile to use generic alert number. Conversely, you can specify disabled to cause SSL profile to use alert number defined in RFC5246/RFC6066 strictly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

handshake-timeout

Specifies the handshake timeout in seconds. The default value is 10 seconds.

key This option is deprecated and is maintained here for backward compatibility reasons. Please check cert-key-chain option to add certificate, key, passphrase and chain to the profile.

maximum-record-size

Specifies the profile's maximum record size. The range is 128 - 16384. The default value is 16384.

mod-ssl-methods

Enables or disables ModSSL method emulation. Enable this option when OpenSSL methods are inadequate, for example, when you want to use SSL compression over TLSv1. The default value is disabled.

mode Specifies the profile mode, which enables or disables SSL processing. The default value is enabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

options

Enables options, including some industry-related workarounds. Enter options inside braces, for example, {dont-insert-empty-fragments}.

The default value is dont-insert-empty-fragments no-tlsv1.3. The options are:

dont-insert-empty-fragments

Disables a countermeasure against an SSL 3.0/TLS 1.0 protocol vulnerability affecting CBC ciphers. These ciphers cannot be handled by certain broken SSL implementations. This option has no effect for connections using other ciphers.

no-session-resumption-on-renegotiation

When performing renegotiation as an SSL server, this option always starts a new session (that is, session resumption requests are only accepted in the initial handshake). The system ignores this option for server-side SSL.

gmssl1.1

Enable GMSSLv1.1 protocol.

no-ssl

Do not use any version of the SSL protocol.

no-ssl3

Do not use the SSLv3 protocol.

no-tls

Do not use any version of the TLS protocol.

no-tls1

Do not use the TLSv1.0 protocol.

no-tls1.1

Do not use the TLSv1.1 protocol.

no-tls1.2

Do not use the TLSv1.2 protocol.

no-tls1.3

Do not use the TLSv1.3 protocol.

no-dtls

Do not use any version of the DTLS protocol.

no-dtls1.0

Do not use the DTLSv1.0 protocol.

no-dtls1.2

Do not use the DTLSv1.2 protocol.

passive-close

Specifies how to handle passive closes.

none Disables all workarounds. Note that F5 Networks does not recommend this option.

notify-cert-status-to-virtual-server

Specifies whether to propagate the status of the certificates of this clientssl profile to the virtual servers that are using this clientssl profile.

ocsp-stapling

Specifies whether to enable OCSP stapling.

single-dh-use

Creates a new key when using temporary/ephemeral DH parameters. This option must be used to prevent small subgroup attacks, when the DH parameters were not generated using strong primes (for example, when using DSA-parameters). If strong primes were used, it is not strictly necessary to generate a new DH key during each handshake, but F5 Networks recommends it. Enable the Single DH Use option whenever temporary or ephemeral DH parameters are used.

tls-rollback-bug

Disables version rollback attack detection. During the client key exchange, the client must send the same information about acceptable SSL/TLS protocol levels as it sends during the first hello. Some clients violate this rule by adapting to the server's answer. For example, the client sends an SSLv2 hello and accepts up to SSLv3.1 (TLSv1), but the server only processes up to SSLv3. In this case, the client must still use the same SSLv3.1 (TLSv1) announcement. Some clients step down to SSLv3 with respect to the server's answer and violate the version rollback protection. The system ignores this option for server-side SSL.

partition

Displays the administrative partition within which the profile resides.

passphrase

This option is deprecated and is maintained here for backward compatibility reasons. Please check cert-key-chain option to add certificate, key, passphrase and chain to the profile.

peer-cert-mode

Specifies the peer certificate mode. The default value is ignore.

peer-no-renegotiate-timeout Specifies the timeout in seconds when the server sends Hello Request and waits for ClientHello before it sends Alert with fatal alert. You can also specify indefinite. The default is 10 seconds.

proxy-ca-cert

Specifies the name of the certificate file that is used as the certification authority certificate when SSL forward proxy feature is enabled. The certificate should be generated and installed by you on the system. When selecting this option, type a certificate file name. (This option is deprecated since v14.0.0, suggest to use cert-key-chain with usage CA to add SSL forward proxy CA key/cert.)

proxy-ca-key

Specifies the name of the key file that is used as the certification authority key when SSL forward proxy feature is enabled. The key should be generated and installed by you on the system. When selecting this option, type a key file name. (This option is deprecated since v14.0.0, suggest to use cert-key-chain with usage CA to add SSL forward proxy CA key/cert.)

proxy-ca-passphrase

Specifies the passphrase of the key file that is used as the certification authority key when SSL forward proxy feature is enabled. When selecting this option, type the passphrase corresponding to the selected proxy-ca-key. (This option is deprecated since v14.0.0, suggest to use cert-key-chain with usage CA to add SSL forward proxy CA key/cert.)

proxy-ssl

Enabling this option requires a corresponding server ssl profile with proxy-ssl enabled to perform transparent SSL decryption. This allows further modification of application traffic within an SSL tunnel while still allowing the server to perform necessary authorization, authentication, auditing steps.

proxy-ssl-passthrough

Enabling this option requires a corresponding server ssl profile with proxy-ssl-passthrough enabled. This allows Proxy SSL to passthrough the traffic when ciphersuite negotiated between the client and server is not supported. The default option is disabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

renegotiate-max-record-delay

Specifies the maximum number of SSL records that the traffic management system can receive before it renegotiates an SSL session. After the system receives this number of SSL records, it closes the connection. This setting applies to client profiles only. The default value is indefinite.

renegotiate-period

Specifies the number of seconds required to renegotiate an SSL session. The default value is indefinite.

renegotiate-size

Specifies the size of the application data, in megabytes, that is transmitted over the secure channel. If the size of the data is higher than this value, the traffic management system must renegotiate the SSL session. The default value is indefinite.

renegotiation

Specifies whether renegotiations are enabled. The default value is enabled. When renegotiations are disabled, and the system is acting as an SSL server, and a COMPAT or NATIVE cipher is negotiated, the system will abort the connection. Additionally, when renegotiations are disabled, and the system is acting as an SSL client, the system will ignore the server's HelloRequest messages.

retain-certificate

APM module requires storing certificate in SSL session. When set to false, certificate will not be stored in SSL session. The default value is true.

secure-renegotiation

Specifies the secure renegotiation mode. The default value is require. When secure renegotiation is required, any client attempting to renegotiate that does not support secure renegotiation will have its connection aborted. When secure renegotiation is set to require-strict, any client attempting to connect that does not support secure renegotiation will have its initial handshake denied. When secure renegotiation is set to request, unpatched clients will be permitted to renegotiate. This setting is NOT recommended however, as it is subject to active man-in-the-middle attacks.

max-renegotiations-per-minute

Specifies the maximum number of renegotiation attempts allowed in a minute. The default value is 5.

max-active-handshakes

Specifies the maximum number allowed SSL active handshakes. The default value is 0.

max-aggregate-renegotiation-per-minute

Specifies the maximum number of aggregate renegotiation attempts allowed in a minute. The default value is indefinite.

server-name

Specifies the server names to be matched with SNI (server name indication) extension information in ClientHello from a client connection. Wildcard is supported by using wildcard character "*" to match multiple names.

sni-default

When true, this profile is the default SSL profile when the server name in a client connection does not match any configured server names, or a client connection does not specify any server name at all.

sni-require

When this option is enabled, a client connection that does not specify a known server name or does not support SNI extension will be rejected.

ssl-sign-hash

Specifies SSL sign hash algorithm which is used to sign and verify SSL Server Key Exchange and Certificate Verify messages for the specified SSL profiles. The default value is sha1.

strict-resume

Enables or disables strict-resume. The default option is disabled, which causes the SSL profile to resume an uncleanly shut down SSL session. Conversely, you can specify enabled to prevent an SSL session from being resumed after an unclean shutdown.

unclean-shutdown

By default, the SSL profile performs unclean shutdowns of all SSL connections, which means that underlying TCP connections are closed without exchanging the required SSL shutdown alerts. If you want to force the SSL profile to perform a clean shutdown of all SSL connections, set this option to disabled.

session-mirroring

Enables or disables the mirroring of sessions to high availability peer. By default, this setting is disabled, which causes the system to not mirror ssl sessions.

session-ticket

Enables or disables session-ticket. The default option is disabled, which causes the SSL profile not to use session ticket per RFC 5077. Conversely, you can specify enabled to cause SSL profile to use session ticket per RFC 5077.

session-ticket-timeout

Specifies the session ticket timeout. The default value is 0 which means cache timeout is used.

source-ip-blacklist

Specifies the data group name of source ip blacklist when SSL forward proxy bypass feature is enabled.

source-ip-whitelist

Specifies the data group name of source ip whitelist when SSL forward proxy bypass feature is enabled.

data-0rtt

Specifies if TLSv1.3 should accept 0-RTT with early data, with or without anti-replay. To protect against packet replay, F5 recommends that you enable anti-replay. The default value is disabled, which means TLSv1.3 will discard any early data.

ssl-c3d

Enables or disables SSL client certificate constrained delegation. The default option is disabled. Conversely, you can specify enabled to use the SSL client certificate constrained delegation.

ssl-forward-proxy

Enables or disables SSL forward proxy feature. The default option is disabled. Conversely, you can specify enabled to use the SSL Forward Proxy Feature.

ssl-forward-proxy-bypass

Enables or disables SSL forward proxy bypass feature. The default option is disabled. Conversely, you can specify enabled to use the SSL Forward Proxy Bypass Feature.

ssl-forward-proxy-verified-handshake

Specifies, when enabled, that in SSL forward proxy mode, the system should always do a TLS handshake with the server first before doing the client handshake. When disabled, the system will do the server handshake first only if it has not previously forged and cached the server certificate; once the server certificate is ready, the system will always handshake first with the client. The default value is disabled.

to-folder

client-ssl profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

```

```

DELETE
delete dhcpv4 [name]

```

DESCRIPTION
 You can use the dhcpv4 profile to manage DHCPv4 network traffic.

EXAMPLES

```

create dhcpv4 my_dhcpv4_profile defaults-from dhcpv4

Creates a custom DHCPv4 profile named my_dhcpv4_profile that inherits its settings from the system default DHCPv4 profile.

list dhcpv4 all-properties

Displays all properties for all DHCPv4 profiles.

create dhcpv4 new_dhcpv4_profile {
mode relay
idle-timeout 120
transaction-timeout 45
default-lease-time 3600
ttl-value 0
ttl-dec-value by-2

```

```

max-hops 4
subscriber-discovery {
    enabled true
    subscriber-id {
        format mac-and-relay-option
        suboption-id1 1
        separator1 -
    }
}
authentication {
    enabled true
    virtual new_authen_vs
    user-name {
        format mac-and-relay-option
        suboption-id1 1
        separator1 -
    }
}
relay-agent-id {
    add false
    remove true
} }

```

Creates a DHCPv4 profile named `new_dhcpv4_profile` with idle-timeout value of <120 seconds>, transaction-timeout of <45 seconds>, default-lease-time of 3600 seconds, ttl-dec-value of 2 and max-hops of 4. The BIG-IP virtual will work in relay mode, with subscriber discovery enabled and configured with the subscriber-id format set to mac-and-relay-option and configured to use only suboption 1 (the first suboption ID) of the relay-agent info option (option 82) and to use the - to concatenate the MAC address to the first suboption ID. The authentication is enabled and its user-name equals the subscriber-id and the authentication virtual name is new_authen_vs. It also does not add relay agent option 82 but removed it (if exists) from the server-to-client messages.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

default-lease-time

Provides the default value in seconds of DHCPv4 lease time in case it was missing in the client-server exchange. The default is 86400.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is dhcpv4.

description

User defined description.

lease-query-max-retry

Specifies the maximum number of retries for a DHCPv4 lease query request.

lease-query-only

Specifies if a DHCPv4 virtual that uses this profile can be used for DHCP lease query only or for DHCP discovery as well.

mode Specifies the operation mode of the DHCP virtual. If the virtual to run in relay mode, then it means that it is acting as a standard DHCPv4 relay agent. This means that the relay will change some of the DHCPv4 packet fields before sending it to either the client or server. The forwarding mode is similar to relay except that the virtual will not modify the standard fields, instead it will forward the message from client to server and vice-versa. The default is relay.

idle-timeout

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 60 seconds.

transaction-timeout

Specifies DHCPv4 transaction timeout, in seconds. The transactions should complete within the timeout specified. If a transaction does not complete for any reason, it is removed. The default value is 45 seconds.

authentication

Manages the subscriber authentication attributes.

enabled

To enable or disable subscriber authentication. If enabled, then user has to fill the following fields. Default is false.

virtual

Specifies the authentication virtual server name.

user-name

Manages the authentication user name's attributes. The user-name is what will be used to authenticate the DHCP client.

format

Specifies the user-name format. The options are: MAC address, MAC + relay-agent option, relay-

agent option or tcl-snippet. The concatenation symbol is defined as separator1.

suboption-id1

The relay-agent option (option 82) first suboption ID. The default is 1.

suboption-id2

The relay-agent option (option 82) second suboption ID. The default is 2.

separator1

A string that is used to concatenate the MAC address and the relay-agent info option (option 82) to create the authentication user-name. The default is @.

separator2

A string that is used to concatenate the relay-agent info option (option 82) suboptions 1 and 2 to create the authentication user-name. The default is @.

tcl-snippet

A tcl snippet to format the user name. This value will be taken into account only if the format value was chosen to be tcl-snippet.

subscriber-discovery

Manages the subscriber discovery attributes.

enabled

To enable or disable subscriber discovery. If enabled, then user has to fill the following fields. Default is false.

subscriber-id

Manages the subscriber-id attributes. The subscriber-id is used by SPM to create, delete and update subscriber sessions.

format

Specifies the subscriber-id format. The options are: MAC address, MAC + relay-agent option, relay-agent option or tcl-snippet. The concatenation symbol is defined as separator1.

suboption-id1

The relay-agent info option (option 82) first suboption ID. The default is 1.

suboption-id2

The relay-agent info option (option 82) second suboption ID. The default is 2.

separator1

A string that is used to concatenate the MAC address and the relay-agent info option (option 82) to create the subscriber-id. The default is @.

separator2

A string that is used to concatenate the relay-agent info option (option 82) suboptions 1 and 2 to create the subscriber-id. The default is @.

tcl-snippet

A tcl snippet to format the subscriber-id. This value will be taken into account only if the format value was chosen to be tcl-snippet.

relay-agent-id

Manages the relay agent information option (option 82) attributes. As a relay, the DHCP virtual can insert this option.

add Specifies if the user wants the DHCP relay agent to insert option 82 or not. Default is false.

remove

Specifies if the user wants the DHCP relay agent to remove option 82 from the server-to-client traffic or not. Default is false.

suboptions

Manages the inserted relay agent information option (option 82) suboptions. We allow only two suboptions to be inserted.

id1 An integer to represent the first suboption ID. Default is 1.

value1

A string to represent the first suboption value.

id2 An integer to represent the second suboption ID. Default is 2.

value2

A string to represent the second suboption value.

ttl-value

Specifies the ttl absolute value that the user may want to set for each outgoing DHCP packet. Default is 0; and in this case, we use the ttl-dec-value field.

ttl-dec-value

Specifies the amount that the DHCP virtual will use to decrement the ttl for each outgoing DHCP packet. Default is by-1.

max-hops

Specifies the maximum number of relay agents that the DHCPv4 messages pass through before they are

discarded. The default is 4.

```

```
format mac-and-option37
```

```
separator1 @
```

```
}
```

```
}
```

```
authentication {
```

```
enabled true
```

```
virtual new_authen_vs
```

```
user-name {
```

```
format mac-and-option37
```

```
separator1 @
```

```
}
```

```
}
```

```
remote-id-option {
```

```
add false
```

```
remove true
```

```
}
```

```
subscriber-id-option {
```

```
add false
```

```
remove true
```

```
}
```

```
}
```

Creates a DHCPv6 profile named new_dhcpv6_profile with idle-timeout value of <120 seconds>, transaction-timeout of <45 seconds> and default-lease-time of 3600 seconds. The BIG-IP virtual will work in relay mode, with subscriber discovery enabled and configured with the subscriber-id format set to mac-and-option37 (remote-id relay agent option) and to use the @ to concatenate both MAC address and option 37. The authentication is enabled and its user-name equals the subscriber-id and the authentication virtual name is new_authen_vs. It also does not add either option 37 or options 38 (remote-id option and subscriber-id option) but remove them (if exists) from the server-to-client messages.

OPTIONS

```
app-service
```

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

```
default-lease-time
```

Provides the default value in seconds of DHCPv6 lease time in case it was missing in the client-server exchange. The default is 86400.

```
defaults-from
```

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is dhcpv6.

description

User defined description.

lease-query-max-retry

Specifies the maximum number of retries for a DHCPv6 lease query request.

lease-query-only

Specifies if a DHCPv6 virtual that uses this profile can be used for DHCP lease query only or for DHCP discovery as well.

mode Specifies the operation mode of the DHCP virtual. If the virtual to run in relay mode, then it means that it is acting as a standard DHCPv6 relay agent. This means that the relay will encapsulate the original messages into one of the relay messages before it send it to the server or the client. In the forwarding mode, the virtual will just forward the message to either the server or the client. The default is relay.

idle-timeout

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 60 seconds.

transaction-timeout

Specifies DHCPv6 transaction timeout, in seconds. The transactions should complete within the timeout specified. If a transaction does not complete for any reason, it is removed. The default value is 45 seconds.

authentication

Manages the subscriber authentication attributes.

enabled

To enable or disable subscriber authentication. If enabled, then user has to fill the following fields. Default is false.

virtual

Specifies the authentication virtual server name.

user-name

Manages the authentication user name's attributes. The user-name is what will be used to authenticate the DHCP client.

format

Specifies the user-name format. The options are: MAC address, option37, MAC + option37, option38, MAC + option38, option37 + option38, mac + option37 + option38 tcl-snippet. The concatenation symbols are defined as separator1 and separator2.

separator1

A string that is used to concatenate the MAC address and the first two strings of the authentication user-name. The default is @.

separator2

A string that is used to concatenate the MAC address and the second two strings of the authentication user-name. The default is @.

tcl-snippet

A tcl snippet to format the user name. This value will be taken into account only if the format value was chosen to be tcl-snippet.

subscriber-discovery

Manages the subscriber discovery attributes.

enabled

To enable or disable subscriber discovery. If enabled, then user has to fill the following fields. Default is false.

subscriber-id

Manages the subscriber-id attributes. The subscriber-id is used by SPM to create, delete and update subscriber sessions.

format

Specifies the user-name format. The options are: MAC address, option37, MAC + option37, option38, MAC + option38, option37 + option38, mac + option37 + option38 tcl-snippet. The concatenation symbols are defined as separator1 and separator2.

separator1

A string that is used to concatenate the first two strings of the subscriber-id. The default is @.

separator2

A string that is used to concatenate the second two strings of the subscriber-id. The default is @.

tcl-snippet

A tcl snippet to format the subscriber-id. This value will be taken into account only if the format value was chosen to be tcl-snippet.

remote-id-option

Manages the DHCPv6 relay agent remote-id option (option 37) attributes. As a relay, the DHCP virtual can insert or remove this option.

add Specifies if the user wants the DHCP relay agent to insert option 37 or not. Default is false.

remove

Specifies if the user wants the DHCP relay agent to remove option 37 from the server-to-client traffic or not. Default is false.

enterprise-number

Specifies the enterprise number of the inserted remote-id option (option 37).

value

A string to represent the remote-id option value.

subscriber-id-option

Manages the DHCPv6 relay agent subscriber-id option (option 38) attributes. As a relay, the DHCP virtual can insert or remove this option.

add Specifies if the user wants the DHCP relay agent to insert option 38 or not. Default is false.

remove

Specifies if the user wants the DHCP relay agent to remove option 38 from the server-to-client traffic or not. Default is false.

value

A string to represent the subscriber-id option value.

DELETE

delete diameter [name]

DESCRIPTION

You can use the diameter component to configure a profile to manage Diameter network traffic.

EXAMPLES

create diameter my_diameter_profile defaults-from diameter

Creates a Diameter profile named my_diameter_profile that inherits its settings from the system default Diameter profile.

list diameter

Displays the properties of all Diameter profiles.

mv diameter /Common/my_diameter_profile to-folder /Common/my_folder

Moves a custom diameter profile named my_diameter_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

connection-prime

When enabled, and the system receives a capabilities exchange request from the client, the system will establish connections and perform handshaking with all the servers prior to sending the capabilities exchange answer to the client. The default value is disabled.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is diameter.

description

User defined description.

destination-realm

This attribute has been deprecated as of BIG-IP v11.3.0. Specifies the realm to which messages are routed. A value of none indicates that the destination-realm option is disabled. The default value is none.

You can specify a fully qualified domain name as an ASCII string. For more information about this option, see RFC 3588 section 6.6.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

handshake-timeout

Specifies the handshake timeout in seconds. This setting specifies the maximum number of seconds that a connection can be idle after the capabilities exchange request was sent to the server. The default value is 10. The system will reset the connection after it has timed out.

You can specify a numeric value in the range 0 to 4294967295. The recommended value is in the range of 5 to 30

host-ip-rewrite

When enabled and the message is a capabilities exchange request or capabilities exchange answer, rewrite the host-ip-address attribute with the system's egress IP address. The default value is enabled.

max-retransmit-attempts

Specifies the maximum number of retransmit attempts. This setting specifies the maximum number of

attempts that BIG-IP will take to retransmit the request messages if it does not receive the corresponding answer messages. If retransmit is unsuccessful, after maximum attempts, BIG_IP will send an error response. The default value is 1.

You can specify a numeric value in the range 0 to 4294967295. The recommended value is in the range of 1 to 10

max-watchdog-failure

Specifies the maximum number of device watchdog failures that the traffic management system can take before it tears down the connection. After the system receives this number of device watchdog failures, it closes the connection. The default value is 10.

You can specify a numeric value in the range 0 to 4294967295.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

origin-host

This attribute has been deprecated as of BIG-IP v11.3.0. Please use, origin-host-to-client or origin-host-to-server. Specifies the origin host of BIG-IP. The origin-host is used to overwrite the server's actual origin host attribute when it responds to the client. A value of none indicates that origin-host is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.3.

origin-host-to-client

Specifies the origin host to client of BIG-IP. The origin-host-to-client is used to overwrite the server's actual origin host attribute when it responds to the client. A value of none indicates that origin-host-to-client is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.3.

origin-host-to-server

Specifies the origin host to server of BIG-IP. The origin-host-to-server is used to overwrite the client's actual origin host attribute when it responds to the server. A value of none indicates that origin-host-to-server is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.3.

origin-realm

This attribute has been deprecated as of BIG-IP v11.3.0. Please use, origin-realm-to-client or origin-realm-to-server. Specifies the origin realm of BIG-IP. The origin-realm is used to overwrite the server's actual origin realm attribute when it responds to the client. A value of none indicates that origin-realm is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.4.

origin-realm-to-client

Specifies the origin realm of BIG-IP. The origin-realm-to-client is used to overwrite the server's actual origin realm attribute when it responds to the client. A value of none indicates that origin-realm-to-client is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.4.

origin-realm-to-server

Specifies the origin realm to server of BIG-IP. The origin-realm-to-server is used to overwrite the client's actual origin realm attribute when it responds to the server. A value of none indicates that origin-realm-to-server is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.4.

overwrite-destination-host

This attribute has been deprecated as of BIG-IP v11.3.0. When you enable this option, the system replaces the value of the destination host field in the Diameter header with the BIG-IP(r) pool member address. When you disable this option, the system does not modify the destination host field. The default value is enabled.

parent-avp

Specifies the name of the Diameter attribute that the system uses to indicate if the persist-avp option is embedded in a grouped avp. A value of none indicates that the value of the persist-avp option is not embedded in a grouped avp. The default value is none.

You can specify an ASCII string or a numeric ID in the range 1 to 4294967295. Acceptable strings can be found in RFC 3588 section 4.5.

partition

Displays the administrative partition within which the profile resides.

persist-avp

Specifies the name of the Diameter attribute that the system persists on. A value of none indicates that persistence is disabled. The default value is session-id.

You can specify an ASCII string or a numeric ID in the range 1 to 4294967295. Acceptable strings can be found in RFC 3588 section 4.5.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at

sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout

When it is enabled and the watchdog failures exceed the max watchdog failure, the system resets the connection. The default value is enabled.

retransmit-timeout

Specifies the retransmit timeout in seconds. This setting specifies the number of seconds to retransmit the request messages if BIG-IP does not receive the corresponding answer messages . The default value is 10.

You can specify a numeric value in the range 0 to 4294967295. The recommended value is in the range of 5 to 30

to-folder

diameter profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

watchdog-timeout

Specifies the watchdog timeout in seconds. This setting specifies the number of seconds that a connection is idle before the device watchdog request is sent. The default value is 0, which means BIG-IP will not send a device watchdog request to either client or server side.

You can specify a numeric value in the range 0 to 4294967295. The recommended value is in the range of 6 to 30

ltm profile dns-logging

NAME

dns-logging - Configures a domain name service logging (DNS Logging) profile.

MODULE

ltm profile

SYNTAX

Configure the dns-logging component within the ltm profile module using the syntax in the following sections.

CREATE/MODIFY

create dns-logging [name]

modify dns-logging [name]

options:

description [string]

enable-query-logging [no | yes]

enable-response-logging [no | yes]

include-complete-answer [no | yes]

include-query-id [no | yes]

include-source [no | yes]

include-timestamp [no | yes]

include-view [no | yes]

log-publisher [name]

edit dns-logging [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

mv dns-logging [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

DISPLAY

list dns-logging

list dns-logging [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line
partition

DELETE
delete dns-logging [name]

DESCRIPTION

You can use this component to create, modify, display, or delete a DNS logging profile, to enable query or response logging, and to define the format of messages themselves.

EXAMPLES

list dns-logging

Displays the properties of all DNS logging profiles.

create dns-logging my_dns_log_profile enable-query-logging yes log-publisher my_pub include-query-id yes

Creates a DNS logging profile with query logging enabled. Messages will be sent to publisher my_pub. Messages will contain the query ID.

mv dns-logging /Common/my_dns_logging_profile to-folder /Common/my_folder

Moves a custom dns-logging profile named my_dns_logging_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

description

User defined description.

enable-query-logging

Log the contents of DNS queries. The default value for this option is yes.

enable-response-logging

Log the contents of DNS responses. The default value is no.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

include-complete-answer

Selects whether all the resource records are included in response log messages. The default value is yes (complete-answer).

include-query-id

Selects whether the query id sent by the client is included in the query and response log messages. The default value is no.

include-source

Selects whether the message originator is included in the query and response log messages. The default value is yes.

include-timestamp

Selects whether the time stamp of the message is included in the query and response log messages. The default value is yes. You may or may not need this depending on whether the destination log servers prepend a time stamp to messages.

include-view

Selects whether the view is included in the query log messages. The default value is yes.

log-publisher

Specifies the log publisher used to deliver messages to one or more destinations. This option must be specified.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

to-folder

dns-logging profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

SEE ALSO

one-line

partition

DELETE

delete dns [name]

DESCRIPTION

You can use this component to create, modify, display, or delete a DNS profile to define how the BIG-IP system handles DNS traffic. You can also display and reset DNS profile statistics.

EXAMPLES

create dns my_dns_profile defaults-from dns

Creates a DNS profile named my_dns_profile that inherits its settings from the system default DNS profile.

list dns

Displays the properties of all DNS profiles.

mv dns /Common/my_dns_profile to-folder /Common/my_folder

Moves a custom dns profile named my_dns_profile to a folder named my_folder, where my_folder has already been

created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

avr-dnsstat-sample-rate

Sets AVR DNS statistics rate. The default value is 0, which means AVR DNS statistics is disabled. If the sampling rate is set to 1, each query will be sent to the analytics database. If the sampling rate is set to an integer N, every Nth query will be sent and the analytics database will count it N times. When sampling rate is greater than one, the statistics will be inaccurate if the traffic volume is low. However, when the traffic volume is high, the system performance will benefit from sampling and the inaccuracy will be negligible. Also be aware that analytics database has its own internal sampling mechanism. The sampling rate does not apply to DNS firewall statistics. AVR DNS statistics contain query name, query type, virtual server IP and client IP.

cache

Specifies the user-created cache that the system uses to cache DNS responses. When you select a cache for the system to use, you must also enable the DNS cache setting.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is dns.

description

User defined description.

dns64

Sets DNS64 mapping mode. The default value is disabled.

dns64-additional-section-rewrite

Sets DNS64 additional section rewriting. For AAAA and A records in additional section, this field specifies how they are being rewritten. The default value is disabled.

dns64-prefix

Specifies DNS64 mapping IPv6 prefix.

dns-security

Indicates the DNS security profile the system uses.

edns0-client-subnet-insert

Indicates, when enabled, that the system should set the edns0 client subnet option to the source address for queries that do not already contain a client subnet option. Also specifies that the system should remove the client subnet option from responses to clients that did not send a client subnet option in their most recent query.

enable-cache

Indicates whether the system caches DNS responses. The default value is no.

enable-dnssec

Indicates whether to perform DNS Security Extension (DNSSEC) operations on the DNS packet, for example, respond to DNSKEY queries; add RRSIGs to response.

enable-dns-express

Indicates whether the dns-express service is enabled. The service handles zone transfers from the primary DNS server.

enable-dns-firewall

Indicates whether DNS firewall capability is enabled. The default value is no.

enable-gtm

Indicates whether the Global Traffic Manager handles DNS resolution for DNS queries and responses that contain Wide IP names. The default value is yes.

enable-hardware-query-validation

On supported platforms, indicates whether the hardware will accelerate query validation. The default value is no.

enable-hardware-response-cache

On supported platforms, indicates whether the hardware will cache responses. The default value is no.

enable-logging

Indicates whether to enable high speed logging for DNS queries and responses or not. Default value is no. When it is set to yes, a DNS profile must be configured with a log-profile.

enable-rapid-response

On supported platforms, indicates whether to allow queries to be answered by Rapid Response. The default value is no. When enabled, if the query name matches a GTM Wide IP name and GTM is enabled on this profile, the DNS query will bypass Rapid Response.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

log-profile

Specifies the DNS logging profile used to configure what events get logged and their message format.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the profile resides.

process-rd
Indicates whether to process client-side DNS packets with Recursion Desired set in the header. The default value is yes. If set to no, processing of the packet will be subject to the unhandled-query-action option.

process-xfr
Indicates whether the system answers zone transfer requests for a DNS zone created on the system. The default value is no. The enable-dns-express and process-xfr settings affect how the system responds to zone transfer requests.

rapid-response-last-action
Specifies what action to take when Rapid Response is enabled and the incoming query has not matched a DNS-Express Zone. Default is drop. Option allow sends non-matching queries up the regular packet processing path. All other options result in a response returned immediately to the client: truncate (truncate), nxdomain (non-existent name), noerror (no data), refuse (REFUSED return code).

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

to-folder
dns profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

unhandled-query-action
Specifies the action to take when a query does not match a Wide IP or a DNS Express Zone. The default value is allow.

use-local-bind
Indicates whether non-GTM and non-dns-express requests should be forwarded to the local BIND.

DELETE
delete fasthttp [name]

DESCRIPTION

You can use this component to create, modify, display, or delete a Fast HTTP profile. This profile provides the ability to accelerate certain HTTP connections such as banner ads.

EXAMPLES

create fasthttp my_fast_http_profile defaults-from fasthttp

Creates a Fast HTTP profile named my_fast_http_profile that inherits its settings from the system default Fast HTTP profile.

mv fasthttp /Common/my_fasthttp_profile to-folder /Common/my_folder

Moves a custom fasthttp profile named my_fasthttp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

show fasthttp

Displays fasthttp profile statistics in the system default units.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

client-close-timeout

Specifies the number of seconds after which the system closes a client connection, when the system either receives a client FIN packet or sends a FIN packet. This option overrides the idle-timeout option. The default value is 5.

server-sack

Specifies whether to support server sack option in cookie response by default. The default value is disabled.

server-timestamp

Specifies whether to support server timestamp option in cookie response by default. The default value is disabled.

receive-window-size

Specifies the window size to use, minimum and default to 65535 bytes, the maximum is 2³¹ for window

scale enabling.

`connpool-idle-timeout-override`

Specifies the number of seconds after which a server-side connection in a OneConnect(tm) pool is eligible for deletion, when the connection has no traffic. This option overrides the `idle-timeout` option. The default value is 0 (zero) seconds, which disables the override setting.

`connpool-max-reuse`

Specifies the maximum number of times that the system can re-use a current connection. The default value is 0 (zero).

`connpool-max-size`

Specifies the maximum number of connections to a load balancing pool. A value of 0 (zero) specifies that a pool can accept an unlimited number of connections. The default value is 2048.

`connpool-min-size`

Specifies the minimum number of connections to a load balancing pool. The default value of 0 (zero) specifies that there is no minimum.

`connpool-replenish`

When enabled, the system replenishes the number of connections to a load balancing pool to the number of connections that existed when the server closed the connection to the pool. The default value is enabled.

When disabled, the system replenishes the connection that was closed by the server, only when there are fewer connections to the pool than the number of connections set in the `connpool-min-size` option.

`connpool-step`

Specifies the increment at which the system makes additional connections available, when all available connections are in use. The default value is 4.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `fasthttp`.

`description`

User defined description.

`force-http10-response`

Specifies whether to rewrite the HTTP version in the status line of the server to HTTP 1.0 to discourage the client from pipelining or chunking data. The default value is disabled.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

`hardware-syn-cookie`

This option is deprecated in version 13.0.0 because it is not a fully functioning feature. Specifies whether or not to use hardware SYN Cookie when cross system limit. The default value is enabled

`header-insert`

Specifies a string that the system inserts as a header in an HTTP request. If the header exists already, the system does not replace it. The default value is none.

`http11-close-workarounds`

Enables or disables HTTP 1.1 close workarounds. The default value is disabled.

`idle-timeout`

Specifies the number of seconds after which a connection is eligible for deletion, when the connection has no traffic. The default value is 300 seconds.

`insert-xforwarded-for`

Specifies whether the system inserts the XForwarded For header in an HTTP request with the client IP address, to use with connection pooling.

The options are:

`disabled`

Specifies that the system does not insert the XForwarded For header.

`enabled`

Specifies that the system inserts the XForwarded For header with the client IP address.

`layer7`

When enabled, the system parses HTTP data in the stream. Disable this option if you want to use the performance HTTP profile to shield against denial-of-service attacks against non-HTTP protocols. The default value is enabled.

`max-header-size`

Specifies the maximum amount of HTTP header data that the system buffers before making a load balancing decision. The default value is 32768.

`max-requests`

Specifies the maximum number of requests that the system can receive on a client connection, before the system closes the connection. The default value of 0 specifies that requests are not limited.

`mss-override`

Specifies a maximum segment size (MSS) override for server connections. The default value is 0 (zero), which corresponds to an MSS of 1460. You can specify any integer between 536 and 1460.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout
When enabled, the system sends a TCP RESET packet when a connection times out, and deletes the connection. The default value is enabled.

server-close-timeout
Specifies the number of seconds after which the system closes a client connection, when the system either receives a client FIN packet or sends a FIN packet. This option overrides the value of the idle-timeout option. The default value is 5.

to-folder
fasthttp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

unclean-shutdown
Specifies how the system handles closing a connection. The options are:

disabled
Prevents an unclean shutdown of a client connection. This is the default value.

enabled
Specifies to permit an unclean shutdown of a client connection.

fast Specifies that the system sends a RESET packet to close the connection only if the client attempts to send further data after the response has completed.

DELETE
 delete fastL4 [name]

DESCRIPTION

You can use this component to create, modify, display, or delete a Fast Layer 4 profile. The Fast L4 profile is the default profile that the system uses when you create a basic configuration for non-UDP (User Datagram Protocol) traffic.

Any changes you make to an active Fast L4 profile (one that is in use by a virtual server) take effect after the value of the idle-timeout option has passed. That means new connections are affected by the profile change immediately. However, for the new values to take effect, old connections need to be either aged out or closed.

=head1 EXAMPLES

create fastl4 my_fastl4_profile defaults-from fastl4

Creates a custom Fast Layer 4 profile named `my_fastl4_profile` that inherits its settings from the system default Fast L4 profile.

`mv fastl4 /Common/my_fastl4_profile to-folder /Common/my_folder`

Moves a custom fastl4 profile named `my_fastl4_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

Please refer to the `mv` manual page for examples on how to use the `mv` command.

`show fastl4`

Displays statistics for all Fast Layer 4 profiles.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `fastl4`.

`description`

User defined description.

`glob` Displays the items that match the `glob` expression. See help `glob` for a description of `glob` expression syntax.

`hardware-syn-cookie`

This option is deprecated in version 13.0.0 and is replaced by `syn-cookie-enable`. Enables or disables hardware SYN cookie support when PVA10 is present on the system. The default value is disabled.

Note that when you set the `hardware-syn-cookie` option to enabled, you may also want to set the following `bigdb` database variables using the `db` component, based on your requirements:

`pva.SynCookies.Full.ConnectionThreshold` (default: 500000)

`pva.SynCookies.Assist.ConnectionThreshold` (default: 500000)

`pva.SynCookies.ClientWindow` (default: 0)

`idle-timeout`

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 300 seconds. You can also specify immediate or indefinite.

When you specify an `idle-timeout` for the Fast L4 profile, for the profile to work properly, the value needs to be greater than the `bigdb` database variable `Pva.Scrub_time_in_msec`.

`ip-tos-to-client`

Specifies an IP Type of Service (ToS) number for the client-side. This option specifies the ToS level that the traffic management system assigns to IP packets when sending them to clients. The default value is 65535, which indicates, do not modify.

`ip-tos-to-server`

Specifies an IP ToS number for the server side. This option specifies the ToS level that the traffic management system assigns to IP packets when sending them to servers. The default value is 65535, which indicates, do not modify.

`keep-alive-interval`

Specifies the keep-alive probe interval, in seconds. The default value is disabled (0 seconds).

`ip-df-mode`

Describe the Don't Fragment (DF) bit setting in the IP Header of the outgoing TCP packet. The available settings are: `Pmtu`: Set the outgoing IP Header DF bit based on IP `pmtu` setting (`tm.pathmtudiscovery`). `Preserve`: Set the outgoing Packet's IP Header DF bit to be same as incoming IP Header DF bit. `Set`: Set the outgoing packet's IP Header DF bit. `Clear`: Clear the outgoing packet's IP Header DF bit. The default setting is `Preserve`.

`ip-ttl-mode`

Describe the outgoing TCP packet's IP Header TTL mode. The available Modes are: `Proxy`: Set the outgoing IP Header TTL value to 255/64 for ipv4/ipv6 respectively. `Preserve`: Set the outgoing IP Header TTL value to be same as the incoming IP Header TTL value. `Decrement`: Set the outgoing IP Header TTL value to be one less than the incoming TTL value. `Set`: Set the outgoing IP Header TTL value to a specific value (as specified by `ip-ttl-v[4|6]`). The default mode is `Decrement`.

`ip-ttl-v4`

Specify the outgoing packet's IP Header TTL value for IPv4 traffic. Maximum TTL value that can be specified is 255. The default is 255.

`ip-ttl-v6`

Specify the outgoing packet's IP Header TTL value for IPv6 traffic. Maximum TTL value that can be specified is 255. The default is 64.

`link-qos-to-client`

Specifies a Link Quality of Service (QoS) (VLAN priority) number for the client side. This option specifies the QoS level that the system assigns to packets when sending them to clients. The default value is 65535, which indicates, do not modify.

link-qos-to-server

Specifies a Link QoS (VLAN priority) number for the server side. This option specifies the QoS level that the system assigns to packets when sending them to servers. The default value is 65535, which indicates, do not modify.

priority-to-client

Specifies internal packet priority for the client side. This option specifies the internal packet priority that the system assigns to packets when sending them to clients. The default value is 65535, which indicates, do not modify.

priority-to-server

Specifies internal packet priority for the server side. This option specifies the internal packet priority that the system assigns to packets when sending them to servers. The default value is 65535, which indicates, do not modify.

loose-close

Specifies that the system closes a loosely-initiated connection when the system receives the first FIN packet from either the client or the server. The default value is disabled.

loose-initialization

Specifies that the system initializes a connection when it receives any Transmission Control Protocol (TCP) packet, rather than requiring a SYN packet for connection initiation. The default value is disabled.

mss-override

Specifies a maximum segment size (MSS) override for server connections. Note that this is also the MSS advertised to a client when a client first connects.

The default value is 0 (zero), which disables this option. You can specify an integer from 256 to 9162.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

pva-acceleration

Specifies the Packet Velocity(r) ASIC acceleration policy. The default value is full. In 12.1, dedicated mode is the new low latency policy which replaces guaranteed. The full and partial mode has same effect for ePVA platforms.

pva-dynamic-client-packets

Specifies the number of client packets before dynamic ePVA hardware re-offloading occurs. The valid value is 0~10. The default value is 2.

pva-dynamic-server-packets

Specifies the number of server packets before dynamic ePVA hardware re-offloading occurs. The valid value is 0~10. The default value is 2.

pva-offload-dynamic

Specifies whether PVA flow dynamic offloading is enabled or not. The default is enabled.

For a flow or flow(s) in a connection to be offloaded to ePVA hardware, both the client (pva-dynamic-client-packets) and server (pva-dynamic-server-packets) flow packets setting need to be satisfied. If only one direction packets need to be taken into consideration, the other direction packets should set to zero.

pva-offload-initial-priority

Specifies the initial epva offload priority of a flow. Priority can be low, medium or high. The default value is medium

pva-offload-dynamic-priority

Specifies if dynamic adjustment of epva offload flow priority is turned on or not. Default value is disabled.

pva-offload-state

This option is deprecated in version 14.1.0 and is replaced by tcp-pva-when-to-offload and other-pva-when-to-offload. Specifies at what stage the ePVA performs hardware offload. The default value is embryonic and implies at TCP CSYN or the first client UDP packet. establish implies TCP 3WAY handshaking or UDP CS round trip are confirmed.

pva-flow-aging

Specifies if automatic aging from ePVA flow cache upon inactive and idle for a period, default to enabled.

pva-flow-evict

Specifies if this flow can be evicted upon hash collision with a new flow learn snoop request, defaults to enabled.

tcp-pva-when-to-offload

Specifies at what stage the ePVA performs hardware offload for TCP traffic. The default value is embryonic and implies at TCP SYN packet. establish implies TCP 3WAY handshaking.

tcp-pva-offload-direction

For tcp protocol traffic only, specifies which side of the traffic can ePVA perform hardware offload for. The default value is bidirectional which implies both side is permitted to offload if threshold exceeds.

client-to-server-only implies only the traffic from client to server is allowed to be offloaded. Even if the traffic from server to client exceeds the threshold, it will not be offloaded. Vice versa, server-to-client-only implies only the traffic from server to client is allowed to be offloaded.

other-pva-whento-offload

Specifies when the ePVA performs hardware offload for stateless protocol traffic. The default value is after-packets-per-direction and implies the client and server traffic is offloaded independently after exceeding their own thresholds. after-packets-both-direction implies both client and server traffic thresholds need to be exceeded, then can both sides get offloaded.

other-pva-offload-direction

For stateless protocol traffic only, specifies which side of the traffic can ePVA perform hardware offload for. The default value is bidirectional which implies both side is permitted to offload if threshold exceeds. client-to-server-only implies only the traffic from client to server is allowed to be offloaded. Even if the traffic from server to client exceeds the threshold, it will not be offloaded. Vice versa, server-to-client-only implies only the traffic from server to client is allowed to be offloaded.

other-pva-clientpkts-threshold

Specifies the number of client packets before ePVA hardware offloading occurs for stateless protocol traffic. The valid value is 0~255. The default value is 2.

other-pva-serverpkts-threshold

Specifies the number of server packets before ePVA hardware offloading occurs for stateless protocol traffic. The valid value is 0~255. The default value is 1.

reassemble-fragments

Specifies whether to reassemble fragments. The default value is disabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout

Specifies whether you want to reset connections on timeout. The default value is enabled.

rtt-from-client

Enables or disables the TCP timestamp options to measure the round trip time to the client. The default value is disabled.

rtt-from-server

Enables or disables the TCP timestamp options to measure the round trip time to the server. The default value is disabled.

server-sack

Specifies whether to support server sack option in cookie response by default. The default value is disabled.

server-timestamp

Specifies whether to support server timestamp option in cookie response by default. The default value is disabled.

receive-window-size

Specifies the window size to use, minimum and default to 65535 bytes, the maximum is 2^{31} for window scale enabling.

software-syn-cookie

This option is deprecated in version 13.0.0 and is replaced by syn-cookie-enable. Enables or disables software SYN cookie support when PVA10 is not present on the system. The default value is disabled.

syn-cookie-dsr-flow-reset-by

Specifies how TCP SYN Flood is handled when syn-cookie-whitelist is enabled and the attack is detected in Direct Server Return(DSR) mode. The default value is none, which is backward-compatible with syn-cookie-whitelist feature in non-DSR mode.

syn-cookie-enable

Enables syn-cookies capability on this virtual server. For the details on the threshold at which syn-cookies are triggered please see default-vs-syn-challenge-threshold and global-syn-challenge-threshold or the tcp-half-open vector in the DoS profile. The default is enabled.

syn-cookie-mss

Specifies a maximum segment size (MSS) for server connections when SYN Cookie is enabled. Note that this is also the MSS advertised to a client when a client first connects.

The default value is 0 (zero), which disables this option. You can specify an integer from 256 to 9162.

syn-cookie-whitelist

Specifies whether or not to use a SYN Cookie WhiteList when doing software SYN Cookies. This means not doing a SYN Cookie for the same src IP address if it has been done already in the previous tm.flowstate.timeout (30) seconds. The default value is disabled.

tcp-close-timeout

Specifies a TCP close timeout in seconds. You can also specify immediate or indefinite. The default value is 5 seconds.

tcp-generate-isn

Specifies whether you want to generate TCP sequence numbers on all SYNs that conform with RFC1948, and allow timestamp recycling. The default value is disabled.

`tcp-handshake-timeout`
Specifies a TCP handshake timeout in seconds. You can also specify immediate or indefinite. The default value is 5 seconds.

`tcp-time-wait-timeout`
Specifies a TCP `time_wait` timeout in milliseconds. The default value is 0 milliseconds.

`tcp-strip-sack`
Specifies whether you want to block the TCP SackOK option from passing to the server on an initiating SYN. The default value is disabled.

`tcp-timestamp-mode`
Specifies how you want to handle the TCP timestamp. The default value is preserve.

`tcp-wscale-mode`
Specifies how you want to handle the TCP window scale. The default value is preserve.

`late-binding`
Specifies whether to enable or disable intelligent selection of a back-end server pool. The default value is disabled. With this option enabled, an iRule can read a Layer 7 (FIX) packet to select a server pool, and then can send the FIX stream down to the ePVA. The ePVA then manages the FIX stream at a low latency, for as long as the stream persists. To keep the latency low, the BIG-IP software does not examine any more Layer-7 data in that FIX stream.

If you enable this option, you also need a FIX profile in the Performance FastL4 Virtual Server configuration.

`explicit-flow-migration`
Specifies whether to have the iRule code determine exactly when the FIX stream drops down to the ePVA hardware. The default value is disabled.

The explicit flow migration state indicates whether connections are automatically migrated into the ePVA hardware (disabled), or the iRule must explicitly migrate them with the `BIGTCP::release_flow` command (enabled).

`client-timeout`
Specifies late binding client timeout in seconds. This is the number of seconds allowed for a client to transmit enough data to select a server pool. If this timeout expires, the `timeout-recovery` option dictates whether to drop the connection or fallback to the normal FastL4 load-balancing method to pick a server pool. The default timeout is 30 seconds.

`timeout-recovery`
Specifies late binding timeout recovery mode. This is the action to take when late binding timeout occurs on a connection. This could be disconnect if only the L7 iRule actions are acceptable to pick a server or fallback if the normal FastL4 load-balancing methods are acceptable to pick a server. The default action is to disconnect.

`to-folder`
fastl4 profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

DESCRIPTION

You can use the fix component to manage an Financial Information eXchange Protocol profile.

EXAMPLES

```
create fix my_fix defaults-from fix
```

Creates an financial information exchange protocol profile named my_fix using the system defaults.

```
create fix my_fix { }
```

Creates an financial information exchange protocol profile named my_fix.

app-service

Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is none.

description

User defined description.

error-action

Specifies the error handling method.

full-logon-parsing

Enable or disable logon message is always fully parsed.

message-log-publisher

Specifies the publisher for message logging.

quick-parsing

Enable or disable quick parsing which parses the basic standard fields and validates message length and checksum.

statistics-sample-interval

Specifies the sample interval in seconds of the message rate.

response-parsing

Enable or disable response parsing which parses the messages from FIX server.

report-log-publisher

Specifies the publisher for error message and status report.

partition

Specifies the administrative partition within which the profile resides.

sender-tag-class

Specifies the tag substitution map between sender id and tag substitution data group.

SEE ALSO

DELETE

delete ftp [name]

DESCRIPTION

Use this command to create, modify, display, or delete an FTP profile with which you can manage FTP traffic.

EXAMPLES

create ftp my_ftp_profile defaults-from ftp

Creates a custom FTP profile named my_ftp_profile that inherits its settings from the system default FTP

profile.

list ftp

Displays the properties of all FTP profiles.

mv ftp /Common/my_ftp_profile to-folder /Common/my_folder

Moves a custom ftp profile named my_ftp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is ftp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

port Specifies a service for the data channel port used for this FTP profile. The default port is ftp-data.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

allow-fts

Deprecated since v14.0.0. Use ftps-mode instead. Allow explicit FTPS negotiation. The default value is disabled.

ftps-mode

Specifies the policy for explicit FTPS negotiation on FTP command channel, including disallow, allow and require. The default is disallow.

Mode disabled

Detects explicit FTPS negotiation, and AUTH TLS command will be dropped.

Mode

Bypasses explicit FTPS negotiation through the BIGIP.

Mode allow

Allows FTPS negotiation, and will intercept TLS if SSL forward proxy is configured on the virtual server.

Mode require

Requires FTPS negotiation to protect the FTP data transfers.

enforce-tls-session-reuse

Enforce data connection to reuse TLS session. The default value is disabled.

allow-active-mode

Allow FTP active transfer mode. The default value is enabled.

security

Enables or disables secure FTP traffic for the BIG-IP(r) Application Security Manager. You can set the security option only if the system is licensed for the BIG-IP Application Security Manager. The default value is disabled.

to-folder

ftp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

translate-extended

This option is enabled by default, and thus, automatically translates RFC2428 extended requests EPSV and EPRT to PASV and PORT when communicating with IPv4 servers.

inherit-parent-profile

Enables the FTP data channel to inherit the TCP profile used by the control channel. If disabled, the data channel uses FastL4 (BigProto) only.

log-publisher

Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log

publisher.

log-profile

Specify the name of the ALG log profile which controls the logging of ALG . See help Itm alg-log-profile for more details on the logging profile sub-system. Use the "Itm alg-log-profile profile" component to set up a ALG log profile.

field-fmt

DELETE

delete georedundancy [name]

DESCRIPTION

You can use the georedundancy component to manage a Geo-Redundancy profile.

EXAMPLES

```
create georedundancy my_georedundancy_profile defaults-from georedundancy
```

Creates a Geo-Redundancy profile named my_georedundancy_profile using the system defaults.

```
create georedundancy my_georedundancy_profile { local-site-id local_site }
```

Creates a Geo-Redundancy profile named my_georedundancy_profile with a name of the local site identification set to local_site.

```
mv georedundancy /Common/my_georedundancy_profile to-folder /Common/my_folder
```

Moves a custom georedundancy profile named my_georedundancy_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

local-site-id

Defines the name to identify local site . The default value is local_site.

remote-site-ids

Defines the list of comma separated names corresponding to remote sites. The default value is remote_site.

read-broker-list

Specifies the list of local site broker's IP addresses and ports for the local TMMs to read the data from. Example: 127.20.1.254:9092, 127.20.2.254:9092.

write-broker-list

Specifies the list of local site broker's IP addresses and ports for the local TMMs to write the data to. Example: 127.20.1.254:9092, 127.20.2.254:9092.

transport-name

Defines the transport profile that Geo-Redundancy half proxy uses to establish connection to brokers. The default value is tcp.

metadata-refresh-interval-ms

Indicates the Topic metadata refresh interval in milliseconds. The metadata is automatically refreshed on error and connect. Use -1 to disable the intervalled refresh. The default value is 300K.

group-id

Defines the client group identifier string. All clients sharing the same group-id belong to the same group.

message-send-max-retries

Specifies the maximum number of attempts that will be made to reload the Diameter session DB from the remote site during startup.

message-timeout-ms

Specifies how often the system will attempt to reload the Diameter session DB from the remote site during startup.

prefix

Indicates a list of session-db key prefixes and for each prefix a session-db global callback gets registered. A prefix when applied to any logical table within the iRule session-db storage would enable replication of the same. These prefix values will only be applied to iRule session bins. The default value is "".

show gtp [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

DELETE

delete gtp [name]

DESCRIPTION

You can use the gtp component to manage a GTP profile.

EXAMPLES

```
create gtp my_gtp_profile defaults-from gtp
```

Creates a GTP profile named my_gtp_profile using the system defaults.

```
create gtp my_gtp_profile { ingress-max 1000 }
```

Creates a GTP profile named my_gtp_profile that specifies the maximum number of messages that can be held in the ingress queue is 1000.

```
mv gtp /Common/my_gtp_profile to-folder /Common/my_folder
```

Moves a custom gtp profile named my_gtp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot

modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is gtp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ingress-max

Specifies the maximum number of messages that can be held in ingress queue. If it is 0, then it is unlimited. The default value is 0.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

field-fmt

global

DELETE

delete html [name]

DESCRIPTION

Use this command to create, modify, display, or delete an HTML profile with which you can manage HTML traffic.

EXAMPLES

create html my_html_profile defaults-from html

Creates a custom HTML profile named my_html_profile that inherits its settings from the system default HTML profile.

list html

Displays the properties of all HTML profiles.

mv html /Common/my_html_profile to-folder /Common/my_folder

Moves a custom HTML profile named my_html_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

Please refer to the mv manual page for examples on how to use the mv command.

OPTIONS

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is html.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

content-detection

Scans initial HTTP payload to look for HTML signatures and enables HTML profile if HTML-like patterns are detected.

content-selection

Matches content-type from response header against a list of content-types and enables HTML profile if a match is found.

rules

Specifies a list of HTML (content rewrite) rules, separated by spaces, that are used for parsing and patching HTML.

to-folder

html profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

SEE ALSO

create, delete, glob, list, ltm virtual, modify, mv, reset-stats, show, tmsh

  field-fmt
  global

DELETE
delete http-compression [name]

```

DESCRIPTION

You can use the http-compression component to create, modify, display, or delete an HTTP Compression profile.

The BIG-IP(r) system installation includes the following default HTTP Compression-type profiles:

- http-compression

- wan-optimized-compression

The default HTTP Compression profile contains values for properties related to managing compression settings.

You can create a new HTTP Compression-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

```
create http-compression my_hc_profile defaults-from http-compression
```

Creates a custom HTTP Compression profile named my_hc_profile that inherits its settings from the system default HTTP Compression profile.

mv http-compression /Common/my_httpcompression_profile to-folder /Common/my_folder

Moves a custom http-compression profile named my_httpcompression_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

allow-http10

Enables or disables compression of HTTP/1.0 server responses. The default value is disabled.

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

browser-workarounds

Deprecated since v13.1.0. Enables or disables browser workarounds. The default value is disabled.

Â· If the client browser is Netscape Navigator(r) version 4.0x, compression is turned off. Netscape advertises that the browser can handle compression gracefully. In this case, F5 Networks disables compression entirely for that class of browser.

Â· If the client browser is Netscape Navigator version 4.x (4.10 and later) and the server response Content-Type is not either text/html or text/plain compression is turned off. This class of Netscape browsers can handle plain text and HTML just fine, but there are known issues with other types of content.

Â· If the client browser is Microsoft(r) Internet Explorer (any version), the server response Content-Type is either text/css or application/x-javascript, and the client connection is over SSL, compression is turned off. The Microsoft article ID for this problem is 825057.

Â· If the client browser is Microsoft Internet Explorer (any version), the server response Content-Type is either text/css or application/x-javascript, and the server sets the header Cache-Control to no-cache, compression is turned off. The Microsoft article ID for this problem is 327286.

buffer-size

Specifies the maximum number of uncompressed bytes that the system buffers before determining whether to compress the response. Useful when the headers of a server response do not specify the length of the response content. The default value is 4096.

content-type-exclude

Specifies a string list of HTTP Content-Type responses that you do not want the system to compress. The default value is none.

content-type-include

Specifies a string list of HTTP Content-Type responses that you want the system to compress. The default value is { text/ application/ (xml|x-javascript) }.

cpu-saver

Enables or disables the CPU saver feature. When the CPU saver is enabled, the system monitors the percent of CPU usage and adjusts compression rates automatically when the CPU usage reaches the percentage defined in the compress-cpu-saver-low and compress-cpu-saver-high options. The default value is enabled.

cpu-saver-high

Specifies the percent of CPU usage at which the system starts automatically decreasing the amount of content being compressed, as well as the amount of compression that the system is applying. The default value is 90.

cpu-saver-low

Specifies the percent of CPU usage at which the system resumes content compression at the user-defined rates. The default value is 75.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is httpcompression.

description

User defined description.

gzip-level

Specifies a value that determines the amount of memory that the system uses when compressing a server response. The default value is 1.

gzip-memory-level

Specifies the amount of memory (in kilobytes) that the system uses when compressing a server response. The system rounds the value up to the nearest power of two. The default value is 8. The maximum value is 256.

gzip-window-size

Specifies the number of kilobytes in the window size that the system uses when compressing a server response. The system rounds the value up to the nearest power of two. The default value is 16k. The maximum value is 128k.

keep-accept-encoding

Specifies where data compression is performed. When enabled, the target server, rather than the BIG-IP local traffic management system, performs data compression. The default value is disabled.

method-prefer
Specifies the type of compression that the system prefers. The default value is gzip.

min-size
Specifies the minimum length in bytes of a server response that is acceptable for compression. The length in bytes applies to content length only, not headers. The default value is 1024.

partition
Displays the administrative partition within which the profile resides.

selective
Enables or disables selective compression mode. Note that the data compression feature compresses HTTP server responses, and not client requests. The default value is disabled.

to-folder
http-compression profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

uri-exclude
Disables compression on a specified list of HTTP Request-URI responses. Use a regular expression to specify a list of URIs you do not want to compress. The default value is none.

uri-include
Enables compression on a specified list of HTTP Request-URI responses. Use a regular expression to specify a list of URIs you want to compress. The default value is { .* }.

vary-header
Enables or disables the insertion of a Vary header into cacheable server responses. The default value is enabled.

DELETE
delete http [name]

DESCRIPTION

You can use the http component to create, modify, display, or delete an HTTP profile.

The BIG-IP(r) system installation includes the following default HTTP-type profiles:

http

The default HTTP profile contains values for properties related to managing HTTP traffic.

You can create a new HTTP-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

create http my_http_profile defaults-from http

Creates a custom HTTP profile named my_http_profile that inherits its settings from the system default HTTP profile.

mv http /Common/my_http_profile to-folder /Common/my_folder

Moves a custom HTTP profile named my_http_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

Please refer to the mv manual page for examples on how to use the mv command.

OPTIONS

accept-xff

Enables or disables trusting the client IP address, and statistics from the client IP address, based on the request's XFF (X-forwarded-for) headers, if they exist.

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

basic-auth-realm

Specifies a quoted string for the basic authentication realm. The system sends this string to a client whenever authorization fails. The default value is none.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is http.

description

User defined description.

encrypt-cookie-secret

Specifies a passphrase for the cookie encryption. The default value is none.

encrypt-cookies

Specifies to encrypt specific cookies that the BIG-IP system sends to a client system. The default value is none.

enforcement

Specifies protocol enforcement options for the HTTP profile:

rfc-compliance

Specifies the behavior when non-rfc compliant traffic is seen. The default is disabled which ignores rfc non-compliance.

excess-client-headers

Specifies the pass-through behavior when max-header-count is exceeded by the client. The default is disabled which rejects the connection.

excess-server-headers

Specifies the pass-through behavior when max-header-count is exceeded by the server. The default is disabled which rejects the connection.

unknown-method

Specifies the behavior when an unknown method is seen. The default is allow which allows all methods, (known or unknown).

known-methods

Specifies the HTTP methods known by the HTTP filter. Combine with the unknown-method field to control behavior when unusual methods are parsed.

max-header-size

Specifies the maximum header size. The default value is 32768.

max-header-count

Specifies the maximum number of headers in HTTP request or response that will be handled. If client or server sends request or response with the number of headers greater than specified, the connection will be dropped. The default value is 64.

max-requests

Specifies the number of requests that the system accepts on a per-connection basis. The default value is 0 (zero), which means the system does not limit the number of requests per connection.

oversize-client-headers

Specifies the pass-through behavior when max-header-size is exceeded by the client. The default is disabled which rejects the connection.

oversize-server-headers

Specifies the pass-through behavior when max-header-size is exceeded by the server. The default is disabled which rejects the connection.

pipeline

Enables or disables HTTP/1.1 pipelining. If pass-through is chosen, then the HTTP filter will switch to pass through mode (and be disabled) if pipelined data is seen. The default value is allow, which means that clients can make requests even when prior requests have not received a response. In order for this to succeed, however, destination servers must include support for pipelining.

to-folder

http profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

truncated-redirects

Specifies the pass-through behavior when a redirect lacking the trailing carriage-return and line feed pair at the end of the headers is parsed. The default is disabled, which will silently drop the invalid HTTP.

unknown-method

Specifies the behavior (allow, reject, or pass-through) when an unknown HTTP method is parsed. The default is to allow unknown methods.

fallback-host

Specifies an HTTP fallback host. The default value is none.

With HTTP redirection, you can redirect HTTP traffic to another protocol identifier, host name, port number, or URI path. For example, if all members of a targeted pool are unavailable (that is, the members are disabled, marked as down, or have exceeded their connection limit), the system can redirect the HTTP request to the fallback host, with the HTTP reply Status Code 302 Found.

fallback-status-codes

Specifies one or more three-digit status codes that can be returned by an HTTP server. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

header-erase

Specifies the header string that you want to erase from an HTTP request. The default value is none.

header-insert

Specifies a quoted header string that you want to insert into an HTTP request. The default value is none.

The HTTP header being inserted can include a client IP address. Including a client IP address in an HTTP header is useful when a connection goes through a secure network address translation (SNAT) and you need to preserve the original client IP address. When you assign the configured HTTP profile to a virtual server, the system then inserts the header specified by the profile into any HTTP request that the system sends to a pool or pool member.

insert-xforwarded-for

Enables or disables insertion of an X-Forwarded-For header. The default value is disabled.

When using connection pooling, which allows clients to make use of other client requests' server connections, you can insert the X-Forwarded-For header and specify a client IP address.

lws-separator

Specifies the linear white space separator that the system uses between HTTP headers when a header exceeds the maximum width specified in the lws-width option. The valid value should be none, or, any combination of cr(carriage return), lf(line feed), or sp(space). The default value is none.

lws-width

Specifies the maximum number of columns that a header that is inserted into an HTTP request can have. The default value is 80.

name Specifies a unique name for the component. This option is required for the commands create, delete, and

modify.

oneconnect-transformations

Specifies whether the system performs HTTP header transformations for the purpose of keeping server-side connections open. The default value is enabled. This feature requires configuration of a OneConnect(tm) profile.

oneconnect-status-reuse

Specifies the 2xx and 4xx HTTP status codes that permit a server-side connection to be reused by OneConnect. The default value is "200 206". This feature requires configuration of a OneConnect(tm) profile.

partition

Displays the partition within which the component resides.

redirect-rewrite

Specifies which of the application HTTP redirects the system rewrites to HTTPS. The options are:

all Specifies to rewrite all application redirects to HTTPS.

matching

Specifies to rewrite to HTTPS only application redirects that match the original URI exactly.

nodes

If the URI contains a node IP address, instead of a host name, specifies that the system rewrites the node IP address to the virtual server IP address.

none Specifies that the system does not rewrite to HTTPS any application HTTP redirects. This is the default value.

Use this feature when an application is generating HTTP redirects that send the client to HTTP (a non-secure channel) when you want the client to continue accessing the application using HTTPS (a secure channel). This is a common occurrence when using client SSL processing on a BIG-IP system.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

request-chunking

Specifies how to handle chunked and unchunked requests. The default value is sustain. The options are described under response-chunking.

response-chunking

Specifies how to handle chunked and unchunked responses. The default value is sustain. The options are:

unchunk

If the response is chunked, this option unchunks the response, processes the HTTP content, and passes the response on as unchunked. The Keep-Alive value for the Connection header is not supported, and therefore the system sets the value of the header to close.

If the response is unchunked, the LTM system processes the HTTP content and passes the response on untouched.

rechunk

If the request or response is chunked, the system unchunks the request or response, processes the HTTP content, re-adds the chunk trailer headers, and then passes on the request or response as chunked. Any chunk extensions are lost.

If the request or response is unchunked, the system adds transfer encoding and chunking headers on egress.

sustain

Preserve request or response chunking unless there is a command to modify the body. If the request or response is chunked: unchunk the HTTP content, process the data, re-add chunking headers on egress. Chunk extensions will be lost. When the response is chunked, it can be rechunked on egress to the client.

response-headers-permitted

Specifies headers that the BIG-IP system allows in an HTTP response. The default value is none.

explicit-proxy

Specifies explicit settings for the HTTP profile:

enabled

Specifies whether the explicit proxy service is enabled or disabled. The default is no.

dns-resolver

Specifies the dns-resolver object that will be used to resolve hostnames in proxy requests. The default is dns-resolver.

ipv6 Specifies the relative order of IPv4 and IPv6 DNS resolutions for URIs. The default is no, which will try a IPv4 lookup before a IPv6.

tunnel-name

Specifies the tunnel that will be used for outbound proxy requests. This enables other virtual servers to receive connections initiated by the proxy service. The default is http-tunnel.

route-domain

Specifies the route-domain that will be used for outbound proxy requests. The default is 0.

default-connect-handling

Specifies the behavior of the proxy service for CONNECT requests. If set to deny, CONNECT requests will only be honored if there is another virtual server listening for the requested outbound connection. If set to allow outbound connections will be made regardless of other virtual servers. The default is deny.

tunnel-on-any-request

Specifies that the tunnel will be used for non-CONNECT requests. If set to yes, virtual servers listening on a tunnel will be able to receive any requests and default-connect-handling option effect will be extended to all outbound proxy requests. The default is no.

host-names

Specifies the which host names are to be treated as local. Proxy requests made for those hosts will be treated as regular HTTP requests and will be sent to the configured default pool.

connect-error-message

Specifies the error message that will be returned to the browser when a proxy request can't be completed because of a failure to establish the outbound connection.

dns-error-message

Specifies the error message that will be returned to the browser when a proxy request can't be completed because of a failure to resolve the hostname in the request.

bad-request-message

Specifies the error message that will be returned to the browser when a proxy request can't be completed because the request was malformed.

bad-response-message

Specifies the error message that will be returned to the browser when a proxy request can't be completed because the response was malformed.

sflow

Specifies sFlow settings for the HTTP profile:

poll-interval

Specifies the maximum interval in seconds between two pollings. The default value is 0. To enable this setting, you must also set the poll-interval-global setting to no.

poll-interval-global

Specifies whether the global HTTP poll-interval setting, which is available under sys sflow global-settings module, overrides the object-level poll-interval setting. The default value is yes.

The available values are:

no Specifies to use the object-level poll-interval setting.

yes Specifies to use the global HTTP poll-interval setting.

sampling-rate

Specifies the ratio of packets observed to the samples generated. For example, a sampling rate of 2000 specifies that 1 sample will be randomly generated for every 2000 packets observed. The default value is 0. To enable this setting, you must also set the sampling-rate-global setting to no.

sampling-rate-global

Specifies whether the global HTTP sampling-rate setting, which is available under sys sflow global-settings module, overrides the object-level sampling-rate setting. The default value is yes.

The available values are:

no Specifies to use the object-level sampling-rate setting.

yes Specifies to use the global HTTP sampling-rate setting.

via-host-name

Specifies the hostname that will be used in the Via: HTTP header. See via-request and via-response for how the Via: header will be handled. If either via-request or via-response are set to append, then this is required.

via-request

Specifies how you want to process Via: HTTP header in requests sent to OWS. The default setting is remove. The available values are:

append

The value from via-host-name is appended to the Via: HTTP header.

preserve

Via: HTTP header is preserved without changes.

remove

Via: HTTP header is removed from the request.

via-response

Specifies how you want to process Via: HTTP header in responses sent to clients. The default setting is

remove. The available values are the same as in `via-request`.

`server-agent-name`

Specifies the string used as the server name in traffic generated by LTM. The default value is `BigIP`.

`alternative-xff-names`

Specifies alternative XFF headers instead of the default `X-forwarded-for` header.

`hsts` Specifies HSTS settings for the HTTP profile:

`mode` Specifies if the HSTS settings are enabled or disabled. The default is disabled.

`maximum-age`

Specifies the maximum age to be sent in the HSTS header. The default is 16070400.

`include-subdomains`

Specifies if the `includeSubdomains` directive is sent in the HSTS header. The default is enabled.

`preload`

Specifies if the `preload` directive is sent in the HSTS header. The default is disabled.

`global`

DELETE
delete http2 [name]

DESCRIPTION

You can use the http2 component to create, modify, display, or delete a HTTP/2 profile.

The BIG-IP(r) system installation includes the following default HTTP/2-type profiles:

http2

The default HTTP/2 profile contains values for properties related to managing HTTP/2 traffic.

You can create a new HTTP/2-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

create http2 my_http2_profile defaults-from http2

OPTIONS

activation-modes

Specifies what will cause a connection to be treated as a HTTP/2 connection. The value alpn specifies that the TLS application-layer-protocol-negotiation will be used to determine whether HTTP/2 should be activated. Clients that use TLS, but only support HTTP will work as-if HTTP/2 is not present. The value always specifies that all connections are assumed to be HTTP/2 connections. The default value is { alpn }.

concurrent-streams-per-connection

Specifies how many concurrent requests are allowed to be outstanding on a single HTTP/2 connection.

connection-idle-timeout

Specifies how many seconds a HTTP/2 connection is left open idly before it is shutdown.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is http2.

description

User defined description.

frame-size

Specifies the size of the data frames, in bytes, that HTTP/2 will send to the client. Larger frame sizes will improve network utilization, but may affect concurrency. The default value is 2048.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

insert-header

Specifies whether an HTTP header that indicates the use of HTTP/2 should be inserted in the request going to the back-end server. The default value is disabled.

insert-header-name

Specifies the name of the HTTP header controlled by insert-header. The default value is "X-HTTP2".

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

receive-window

Specifies the receive window, in KB. The receive window is a mechanism used by HTTP/2 to perform flow control. The receive window allows HTTP/2 to stall individual upload streams when needed. This mechanism is available only for HTTP/2 version 3. The default value is 32.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

write-size

Specifies the total size of combined data frames, in bytes, HTTP/2 will send in a single write. This controls the size of the TLS records when HTTP/2 is used over SSL. A large write size will cause HTTP/2 to buffer more data, but will improve network utilization. The default value is 16384.

header-table-size

Specifies the size of the header table, in bytes. The HTTP/2 protocol compresses http headers to save bandwidth. A larger table will allow better compression, at the cost of more memory usage. The default value is 4096 bytes.

enforce-tls-requirements

Specifies whether the TLS connection requirements, as specified in the HTTP/2 protocol specification, will be enforced. The default value is enabled.

DELETE

delete http3 [name]

DESCRIPTION

You can use the http3 component to create, modify, display, or delete a HTTP/3 profile.

The BIG-IP(r) system installation includes the following default HTTP/3-type profiles:

http3

The default HTTP/3 profile contains values for properties related to managing HTTP/3 traffic.

You can create a new HTTP/3-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

create http3 my_http3_profile defaults-from http3

OPTIONS

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is http3.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

header-table-size

Specifies the size of the header table, in bytes. The HTTP/3 protocol compresses http headers to save bandwidth. A larger table will allow better compression, at the cost of more memory usage. The default value is 4096 bytes.

show httprouter

show httprouter [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

DELETE

delete httprouter [name]

DESCRIPTION

You can use the httprouter component to manage a HTTP router profile.

EXAMPLES

create httprouter my_router_profile defaults-from httprouter

Creates a HTTP router profile named my_router_profile using the system defaults.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is router.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

one-line
partition

show icap

show icap [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

DELETE
delete icap [name]

DESCRIPTION
You can use the icap component to manage an Internet Content Adaptation Protocol profile.

EXAMPLES
create icap my_icap defaults-from icap

Creates an internet content adaptation protocol profile named my_icap using the system defaults.

create icap my_icap { uri icap://mycompany.com/ad_insertion/ }

Creates an internet content adaptation protocol profile named my_icap that uses icap://mycompany.com/ad_insertion/ as the ICAP URI.

mv icap /Common/my_icap_profile to-folder /Common/my_folder

Moves a custom icap profile named my_icap_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is icap.

description
User defined description.

header-from
Specifies the header-from attribute to use in the ICAP header. Please refer to RFC 3507 section 4.3.2.

host Specifies the host attribute to use the in the ICAP header. Please refer to RFC 3507 section 4.3.2i.

preview-length
Specifies the ICAP data preview size. Please refer to RFC 3507 section 4.5.

referer
Specifies the referer attribute to use in the ICAP header. Please refer to RFC 3507 section 4.3.2.

to-folder
icap profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

uri Specifies the ICAP URI to use in the ICAP header. Please refer to RFC 3507 section 4.2. Macro expansion has been implemented for all attributes values in the ICAP header. If an ICAP header attribute value contains \${SERVER_IP}, the macro will be replaced with the IP address of the ICAP server selected from the internal virtual server's pool. If an ICAP header attribute contains \${SERVER_PORT}, the macro will be replaced with the port of the ICAP server selected from the internal virtual server's pool. For example, the URI attribute in an ICAP profile could be set to icap://\${SERVER_IP}:\${SERVER_PORT}/videoOptimization.

user-agent
Specifies the user-agent attribute to use in the ICAP header. Please refer to RFC 3507 section 4.3.2.

SEE ALSO

ltm profile iiop

NAME
iiop - Configures an Internet Inter-Orb Protocol (IIOP) profile.

MODULE
ltm profile

SYNTAX

Configure the iiop component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create iiop [name]

modify iiop [name]

options:

abort-on-timeout [disabled | enabled]

app-service [[string] | none]

defaults-from [name]

description [string]

persist-object-key [disabled | enabled]

persist-request-id [disabled | enabled]

timeout [integer]

edit iiop [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

reset-stats iiop

reset-stats iiop [name]

DISPLAY

list iiop

list iiop [[[name] | [glob] | [regex]] ...]

show running-config iiop

show running-config iiop [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

show iiop

show iiop [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

global

DELETE

delete iiop [name]

DESCRIPTION

You can use the iiop component to manage IIOP network traffic. The system parses the incoming TCP stream, disaggregates it into IIOP messages, and performs load balancing and persistence based on the parameters you set.

EXAMPLES

```
create iiop my_iiop_profile defaults-from iiop
```

Creates an IIOP profile named my_iiop_profile that inherits its settings from the system default IIOP profile named iiop.

```
list iiop all-properties
```

Displays all properties for all IIOP profiles.

OPTIONS

abort-on-timeout

Specifies whether the system aborts the connection if there is no response received within the time specified in the timeout option. The default value is disabled.

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is iiop.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which this profile resides.

persist-object-key

Specifies whether to persist connections based on the object key in the IIOP request. The default value is disabled.

persist-request-id

Specifies whether to persist connections based on the request ID in the IIOp request. The default value is enabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the request timeout. The system uses this value when the abort-on-timeout option is enabled. The default value is 30 seconds.

SEE ALSO

ltm profile ilx

NAME

ilx - Configures an ILX profile.

MODULE

ltm profile

SYNTAX

Configure the ilx component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create ilx [name]

modify ilx [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

plugin [string]

edit ilx [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list ilx

list ilx [[[name] | [glob] | [regex]] ...]

show running-config ilx

show running-config ilx [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete ilx [name]

DESCRIPTION

You can use the ilx component to create, modify, display, or delete an ILX profile. An ILX profile is used to associate an ILX Plugin (see ilx plugin) with a virtual server. When a client connects to a virtual server the data from the client and server will be routed to the ILX plugin allowing the plugin to inspect and manage traffic. An ILX profile is compatible with the following virtual server profiles: clientssl, http, http-compression, serverssl, stream, tcp and web-acceleration. A plugin may be associated with at most one ILX profile. An ILX profile may be associated with multiple virtual servers.

The BIG-IP(r) system installation includes the following default ILX profiles:

ilx

EXAMPLES

create ilx my_ilx_profile defaults-from ilx

Creates a custom ILX profile named `my_ilx_profile` that inherits its settings from the system default ILX profile.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is `ilx`.

`description`

User defined description.

`mpi-channel`

Displays the communication channel used by the TMM and Node.js process.

`partition`

Displays the administrative partition within which the profile resides.

`plugin`

The name of an ILX Plugin, see also `ilx plugin`.

STATS

`Connections`

The number of current active connections

`Connections Max Active`

The maximum number of active connections at one time

`Connection Aborts`

The number of aborted connections (due to plugin error)

`Connection Rejects`

The number of aborted connections (due to TMM error)

`Backlogged Messages`

Messages queued to be sent from TMM to plugin

`Backlogged Bytes`

Bytes queued to be sent from TMM to plugin

`Received Message Count`

Messages received by TMM from plugin

`Transmitted Message Count`

Messages sent from TMM to plugin

`Received Payload Bytes`

Payload bytes received by TMM from plugin

`Transmitted Payload Bytes`

Payload bytes sent from TMM to plugin

SEE ALSO

ltm profile imap

NAME

`imap` - Configures an IMAP profile.

MODULE

`ltm profile`

SYNTAX

Configure the `imap` component within the `ltm profile` module using the syntax shown in the following sections.

CREATE/MODIFY
create imap [name]
modify imap [name]
options:
 app-service [[string] | none]
 defaults-from [[name] | none]
 description [string]
 activation-mode [none | allow | require]

edit imap [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list imap
list imap [[[name] | [glob] | [regex]] ...]
show running-config imap
show running-config imap [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DELETE
delete imap [name]

DESCRIPTION

You can use the imap component to create, modify, display, or delete an IMAP profile with which you can manage IMAP traffic.

EXAMPLES

```
create imap my_imap_profile defaults-from imap
```

Creates a custom IMAP profile named my_imap_profile that inherits its settings from the system default IMAP profile.

```
list imap
```

Displays the properties of all IMAP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is imap.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

activation-mode

Sets the activation-mode STARTTLS. The options are NONE, ALLOW, or REQUIRE. The default value is REQUIRE.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, sys provision, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2017. All rights reserved.

BIG-IP 2017-08-23 ltm profile imap(1)

Itm profile ipother

NAME

ipother - Configures a generic IP profile for non-TCP and non-UDP traffic.

MODULE

Itm profile

SYNTAX

Configure the ipother component within the Itm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create ipother [name]
modify ipother [name]
options:
  app-service [[string] | none]
  defaults-from [[name] | none]
  description [string]
  idle-timeout [immediate | indefinite | integer]

edit ipother [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

reset-stats ipother
reset-stats ipother [ [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list ipother
list ipother [ [ [name] | [glob] | [regex] ] ... ]
show running-config ipother
show running-config ipother
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show ipother
show ipother [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

DELETE

```
delete ipother [name]
```

DESCRIPTION

You can use the ipother component to manage non-TCP and non-UDP network traffic. If you want to manage TCP or UDP traffic, then use the appropriate TCP or UDP LTM profiles.

EXAMPLES

```
create ipother my_ipother_profile defaults-from ipother
```

This creates a custom IP-OTHER profile that is named my_ipother_profile which inherits its settings from the system default IP-OTHER profile.

```
list ipother all-properties
```

Displays all properties for all IP-OTHER profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is ipother.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

idle-timeout

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 60 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and

modify.

partition

Displays the administrative partition within which the profile resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, ltm profile, ltm virtual, modify, show, regex, reset-stats, tmsh

COPYRIGHT

BIG-IP 2015-07-22 ltm profile ipother(1)

Itm profile ipsecalg

NAME

ipsecalg - Configures a IPsecALG profile.

MODULE

ltm profile

SYNTAX

Configure the ipsecalg component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create ipsecalg [name]

modify ipsecalg [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

idle-timeout [integer]

pending-ike-connection-limit [integer]

initial-connection-timeout [integer]

log-publisher [log publisher name | none]

log-profile [log profile name | none]

mv ipsecalg [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

edit ipsecalg [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list ipsecalg

list ipsecalg [[[name] | [glob] | [regex]] ...]

show running-config ipsecalg

show running-config ipsecalg [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete ipsecalg [name]

DESCRIPTION

Use this command to create, modify, display, or delete an IPsecALG profile with which you can manage IPsecALG traffic.

EXAMPLES

create ipsecalg my_ipsecalg_profile defaults-from ipsecalg

Creates a custom IPsecALG profile named my_ipsecalg_profile that inherits its settings from the system default IPsecALG profile.

list ipsecalg

Displays the properties of all IPsecALG profiles.

mv ipsecalg /Common/my_ipsecalg_profile to-folder /Common/my_folder

Moves a custom IPsecALG profile named my_ipsecalg_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is ipsecalg.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

to-folder

ipsecalg profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

idle-timeout

Specifies an idle timeout in seconds. This setting specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 3600 seconds.

pending-ike-connection-limit

Specifies the the maximum number of unacknowledged IKE connections a client can have before being denied further requests to prevent a single client from flooding all the connections trying to establish the connections. The default value is 5 connections per client.

initial-connection-timeout

Specifies an initial connection timeout in seconds. This is the max number of seconds to wait for a response from the server for the IKE/IPsec request. The default value is 3 seconds.

log-publisher

Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile

Specify the name of the ALG log profile which controls the logging of ALG events. See help ltm alg-log-profile for more details on the logging profile sub-system. Use the "ltm alg-log-profile profile" component to set up an ALG log profile.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, mv, regex, reset-stats, show, tmsh

BIG-IP 2017-01-20 ltm profile ipsecalg(1)

ltm profile mapt

NAME

map-t - Configures a MAP-T tunnel profile.

MODULE

net tunnels

SYNTAX

Configure the map-t component within the ltm profile module using the syntax in the following sections.

CREATE/MODIFY

create map-t [name]

modify map-t [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

ip6-prefix [ipv6 address/netmask]

ip4-prefix [ipv4 address/netmask]

ea-bits-length [integer]

port-offset [integer]

br-prefix [ipv6 address/netmask]

edit map-t [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list map-t

list map-t [[[name] | [glob] | [regex]] ...]

show running-config map-t

show running-config map-t [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE

delete map-t [all | [name]]

DESCRIPTION

You can use the map-t component to create a MAP-T profile that you associate with an LTM Virtual. A map-t profile allows you to define NAT parameters which will allow legacy IPV4 servers to connect to an IPV6 network.

EXAMPLES

create map-t my_map

Creates a MAP-T profile called my_map.

list map-t all-properties

Displays all the properties of all the MAP-T profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is map-t.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ip6-prefix

Specifies the Rule IPv6 Prefix and netmask using CIDR notation, such as 2014::/48. The default prefix length is 48.

ip4-prefix

Specifies the Rule IPv4 Prefix and netmask using CIDR notation, such as 192.0.0.0/8. The default prefix length is 8.

ea-bits-length

Specifies the Rule EA (Embedded Address) Length of the MAP-T domain. The default is 40 (IPv4 32 bits + PSID 8 bits).

port-offset

Specifies the port offset bits length of the MAP-T domain. The default is 6.

br-prefix

Specifies the BR (Border Relay) IPv6 prefix and netmask using CIDR notation, such as 2023::/96. The default prefix length is 96.

psid Specify PSID value for MAPT. The default is zero.

draft-mode

Allow BIGIP to work with non rfc compliant CE devices which map BR prefix at a wrong offset. The default is to disable draft mode.

br-pfx-ignore

Allow BIGIP to work with non rfc compliant CE devices which ignore BR prefix lengths. The default is to disable.

SEE ALSO

Itm profile mblb

NAME

mblb - Configures an MBLB profile (experimental).

MODULE

ltm profile

SYNTAX

Configure the mblb component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create mblb [name]

modify mblb [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

isolate-abort [disabled | enabled]

isolate-expire [disabled | enabled]

isolate-server [disabled | enabled]

isolate-client [disabled | enabled]

egress-high [# of messages]

egress-low [# of messages]

ingress-high [# of messages]

ingress-low [# of messages]

min-conn [# of connections]

tag-ttl [# of seconds]

shutdown-timeout [# of seconds]

edit mblb [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list mblb

list mblb [[[name] | [glob] | [regex]] ...]

show running-config mblb

show running-config mblb [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DELETE

delete mblb [name]

DESCRIPTION

Use this command to create, modify, display, or delete an MBLB profile with which you can customize MBLB behavior.

EXAMPLES

create mblb my_mblb_profile defaults-from mblb

Creates a custom MBLB profile named my_mblb_profile that inherits its settings from the system default MBLB profile.

list mblb

Displays the properties of all MBLB profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is mblb.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

isolate-abort

Specify whether to isolate abort event propagation.

isolate-expire

Specify whether to isolate expiration event propagation.

isolate-server

Specify whether to isolate serverside shutdown event propagation. This also dominate serverside abort/expiration event propagation.

isolate-client

Specify whether to isolate clientside shutdown event propagation. This also dominate clientside abort/expiration event propagation.

egress-high

Specify the high water mark for egress message queue. The default value is 50.

egress-low

Specify the low water mark for egress message queue. The default value is 5.

ingress-high

Specify the high water mark for ingress message queue. The default value is 50.

ingress-low

Specify the low water mark for ingress message queue. The default value is 5.

min-conn

Specify the minimum number of serverside connections. The default value is 0.

tag-ttl

Specify the TTL (time to live) for message TAG. The default value is 60.

shutdown-timeout

Delays sending FIN when BIGIP receives the first FIN packet from either the client or the server. Value of 0 means send FIN immediately otherwise the minimum of tcp idle timeout and shutdown timeout is used. The default value is 5 seconds

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

global

DELETE

delete mqtt [name]

DESCRIPTION

You can use the mqtt component to create, modify, display, or delete an MQTT profile.

The BIG-IP(r) system installation includes the following default MQTT-type profiles:

mqtt

The default MQTT profile contains values for properties related to managing MQTT traffic.

You can create a new MQTT-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

create mqtt my_mqtt_profile defaults-from mqtt

Creates a custom MQTT profile named my_mqtt_profile that inherits its settings from the system default MQTT profile.

mv mqtt /Common/my_mqtt_profile to-folder /Common/my_folder

Moves a custom MQTT profile named my_mqtt_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

Please refer to the mv manual page for examples on how to use the mv command.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

SEE ALSO

ltm profile mssql

NAME

mssql - Configures a profile to manage mssql(tds) database traffic.

MODULE

ltm profile

SYNTAX

Configure the mssql component within the ltm profile module using the syntax in the following sections.

CREATE/MODIFY

```
create mssql [name]
modify mssql [name]
options:
  app-service [[string] | none]
  defaults-from [name]
  description [[string] | none]
  read-pool [string]
  read-write-split-by-user [disabled | enabled]
  read-write-split-by-command [disabled | enabled]
  user-can-write-by-default [true | false]
  user-list [add | delete | none | replace-all-with] {
    [user names...]
  }
  write-persist-timer [number]
  write-pool [string]
```

```
edit mssql [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
non-default-properties
```

```
reset-stats mssql
```

```
reset-stats mssql [ [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list mssql
```

```
list mssql [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config mssql
```

```
show running-config mssql [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
non-default-properties
one-line
partition
```

```
show mssql
```

```
show mssql [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global
```

DELETE

```
delete mssql [name]
```

DESCRIPTION

You can use the mssql component to configure a profile to manage mssql(tds) database traffic.

EXAMPLES

```
create mssql my_mssql_profile defaults-from mssql
```

Creates a mssql profile named my_mssql_profile that inherits its settings from the system default mssql profile.

list mssql

Displays the properties of all mssql profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is mssql.

partition

Displays the administrative partition within which the profile resides.

read-pool

Specifies the pool of MS SQL database servers to which the system sends ready-only requests.

read-write-split-by-command

When enabled, the system decides which pool to send the client requests the by the content in the message. It can only be enabled when read-write-split-by-user is disabled.

read-write-split-by-user

When enabled, the system decides which pool to send the client requests the by user name. It can only be enabled when read-write-split-by-command is disabled.

user-can-write-by-default

Specifies whether users have write access by default. When set to true, all users have write access, except those added to the users list.

user-list

Specifies the users who have read-only access to the MS SQL if user-can-write-by-default is true, or the users who have write access to the MS SQL database if user-can-write-by-default is false.

write_persist_timer

Specify how many minimum time in milliseconds the connection will be persisted to write-pool after connection switch to write pool.

write-pool

Specifies the pool of MS SQL database servers to which the system sends requests that are not read-only.

Itm profile netflow

NAME

netflow - Configures a NETFLOW profile.

MODULE

ltm profile

SYNTAX

Configure the netflow component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create netflow [name]

modify netflow [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

netflow-version [enumerated]

edit netflow [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

mv netflow [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

reset-stats netflow

reset-stats netflow [[[name] | [glob] | [regex]] ...]

DISPLAY

list netflow

list netflow [[[name] | [glob] | [regex]] ...]

show running-config netflow

show running-config netflow [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

show netflow

show netflow [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

DELETE

delete netflow [name]

DESCRIPTION

You can use the netflow component to manage a NETFLOW profile.

EXAMPLES

create netflow my_netflow_profile defaults-from netflow

Creates a NETFLOW profile named my_netflow_profile using the system defaults.

create netflow my_netflow_profile { netflow-version version-5 }

Creates a NETFLOW profile named my_netflow_profile that specifies the maximum number of messages that can be held in the ingress queue is 1000.

mv netflow /Common/my_netflow_profile to-folder /Common/my_folder

Moves a custom netflow profile named my_netflow_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is netflow.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

netflow-version

Specifies the expected netflow version for a profile.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, mv, regex, reset-stats, show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

ltm profile ntlm

NAME

ntlm - Configures a Microsoft(r) Windows(r) NT Local Area Network (LAN) manager profile.

MODULE

ltm profile

SYNTAX

Configure the ntlm component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create ntlm [name]

modify ntlm [name]

options:

app-service [[string] | none]

defaults-from [name]

description [string]

insert-cookie-domain [domain]

insert-cookie-name [cookie name]

insert-cookie-passphrase [passphrase]

key-by-cookie [disabled | enabled]

key-by-cookie-name [cookie name]

key-by-domain [disabled | enabled]

key-by-ip-address [disabled | enabled]

key-by-target [disabled | enabled]

key-by-user [disabled | enabled]

key-by-workstation [disabled | enabled]

edit ntlm [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list ntlm

list ntlm [[[name] | [glob] | [regex]] ...]

show running-config ntlm

show running-config ntlm [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete ntlm [name]

DESCRIPTION

You can use the ntlm component to create a Microsoft Windows NT LAN manager (NTLM) profile to manage servers on the LAN that are running Windows NT.

EXAMPLES

create ntlm my_ntlm_profile defaults-from ntlm

Creates a Microsoft Windows NT LAN manager profile named my_ntlm_profile that inherits its settings from the system default NTLM profile named ntlm.

list ntlm all-properties

Displays all properties for all NTLM profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is ntlm.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

insert-cookie-domain
Specifies an optional domain for the inserted cookie. The default is none, which causes no domain to be configured for the inserted cookie.

insert-cookie-name
Specifies a cookie name that the system inserts in the cookie. The default value is NTLMconnpool.

insert-cookie-passphrase
Specifies a cookie passphrase that the system inserts in the cookie. The default value is mypassphrase.

key-by-cookie
Specifies whether the system uses the existing cookie as the key. The default value is disabled.

key-by-cookie-name
Specifies whether the system uses the value of the insert-cookie-name option as the key. The default value is mycookie.

key-by-domain
Specifies whether the system uses the NTLM domain as the key. The default value is disabled.

key-by-ip-address
Specifies whether the system uses the client IP address as the key. The default value is disabled.

key-by-target
Specifies whether the system uses the NTLM target as the key. The default value is disabled.

key-by-user
Specifies whether the system uses the NTLM user as the key. The default value is enabled.

key-by-workstation
Specifies whether the system uses the NTLM workstation as the key. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

Itm profile ocsdp

NAME

ocsp - Configures a OCSP profile.

MODULE

itm profile

SYNTAX

Configure the ocsp component within the itm profile module using the syntax in the following sections.

CREATE/MODIFY

create ocsp [name]

modify ocsp [name]

options:

defaults-from [[name] | none]

max-age [integer]

nonce [enabled | disabled]

edit ocsp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

mv ocsp [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

DISPLAY

list ocsp

list ocsp [[[name] | [glob] | [regex]] ...]

show running-config ocsp

show running-config ocsp

[[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete ocsp [all | [name]]

options:

recursive

DESCRIPTION

You can use the ocsp component to manage a OCSP profile.

OCSP profile enables the traffic management system to respond to OCSP requests from clients. You can implement this type of profile by using the default profile, or by creating a custom profile based on the OCSP profile template and modifying its settings.

EXAMPLES

create ocsp my_ocsp_profile defaults-from ocsp

Creates a custom OCSP profile named my_ocsp_profile that inherits its settings from the system default profile ocsp.

list ocsp all-properties

Displays all properties for all OCSP profiles.

mv ocsp /Common/my_ocsp_profile to-folder /Common/my_folder

Moves a custom ocsp profile named my_ocsp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is ocsp.

max-age

Specifies the value for HTTP Response cache control header max-age. The max-age header sent to client is the lesser of the configured value and validity of OCSP response. Default value is 604800 seconds.

nonce

Specifies whether OCSP Nonce Request Extension is supported by the OCSP profile. Default value is enabled.

partition

Displays the administrative partition within which the component resides.

SEE ALSO

create, delete, edit, glob, list, ltm profile client-ssl, ltm virtual, modify, mv, regex, show, tmsh

ltm profile one-connect

NAME

one-connect - Configures a OneConnect(tm) profile.

MODULE

ltm profile

SYNTAX

Configure the one-connect component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create one-connect [name]

modify one-connect [name]

options:

app-service [[string] | none]

defaults-from [name]

description [string]

idle-timeout-override [disabled | enabled]

share-pools [disabled | enabled]

max-age [integer]

max-reuse [integer]

max-size [integer]

source-mask [ip address]

limit-type [none|idle|strict]

edit one-connect [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

mv one-connect [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

reset-stats one-connect

reset-stats one-connect[[[name] | [glob] | [regex]] ...]

DISPLAY

list one-connect

list one-connect [[[name] | [glob] | [regex]] ...]

show running-config one-connect

show running-config one-connect [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

show one-connect

show one-connect [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

global

DELETE

delete one-connect [name]

DESCRIPTION

You can use the one-connect component to create a OneConnect profile that optimizes connections by improving client performance and increasing server capacity.

EXAMPLES

create one-connect my_OC_profile defaults-from oneconnect

Creates a OneConnect profile named my_OC_profile that inherits its settings from the system default OneConnect profile named oneconnect.

list one-connect all-properties

Displays all properties for all OneConnect profiles.

mv one-connect /Common/my_oneconnect_profile to-folder /Common/my_folder

Moves a custom one-connect profile named my_oneconnect_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is oneconnect.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

idle-timeout-override

Specifies the number of seconds that a connection is idle before the connection flow is eligible for deletion. The default value is disabled.

share-pools

Indicates that connections may be shared not only within a virtual server, but also among similar virtual servers (e.g. those that differ only in destination address). When enabled, all virtual servers that use the same One Connect and other internal network profiles can share connections.

max-age

Specifies the maximum age, in number of seconds, of a connection in the connection reuse pool. For any connection with an age higher than this value, the system removes that connection from the reuse pool. The default value is 86400.

max-reuse

Specifies the maximum number of times that a server connection can be reused. The default value is 1000.

max-size

Specifies the maximum number of connections that the system holds in the connection reuse pool. If the pool is already full, then the server connection closes after the response is completed. The default value is 10000.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

source-mask

Specifies a source IP mask. The default value is 0.0.0.0.

The system applies the value of this option to the source address to determine its eligibility for reuse. A mask of 0.0.0.0 causes the system to share reused connections across all clients. A host mask (all 1's in binary), causes the system to share only those reused connections originating from the same client IP address.

limit-type

Connection limits with OneConnect are different from straight TCP connection limits. Three options are supported: "none" (the default), "idle", and "strict". When the limit is "none", simultaneous in-flight requests and responses over TCP connections to a pool member are counted toward the limit (this being the historical handling). There may be more TCP connections open to support new requests than there can be simultaneous in-flight requests and responses. This is particularly true when SNAT pools and narrow source address masks are used. When the limit is "idle", idle connections will be dropped as the TCP connection limit is reached. For short intervals, during the overlap of the idle connection being dropped and the new connection being established, the TCP connection limit may be exceeded. When the limit is "strict", the TCP connection limit is honored with no exceptions. This means that idle connections will prevent new TCP connections from being made until they expire, even if they could otherwise be reused. This is not a recommended configuration except in very special cases with short expiration timeouts.

to-folder

one-connect profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

field-fmt

DELETE

delete pcp [name]

DESCRIPTION

You can use the pcp component to specify Port Control Protocol attributes for a profile that can be used in an LSN pool.

EXAMPLES

create pcp my_pcp_profile defaults-from pcp

Creates a custom PCP profile named my_pcp_profile that inherits its settings from the system default pcp profile.

list pcg all-properties

Displays all properties for all PCP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is pcg, a profile that is shipped in the software.

description

User defined description.

announce-after-failover

Specifies that the BIG-IP software should send an unsolicited ANNOUNCE response to all PCP clients when there is a failover. The unsolicited ANNOUNCE response goes over a link-local multi-cast address, and it contains a new EPOCH time. This signals to the PCP clients that they should renew all of their active mappings.

announce-multicast

Whenever the BIG-IP system reboots, or if there is any possibility that the system lost its PCP-mapping state, it sends an unsolicited ANNOUNCE response to all of its PCP clients. It sends the response over a link-local multi-cast address, and it contains a new EPOCH time. The PCP clients react by renewing all of their active IP mappings. To compensate for possible packet loss (since the multi-cast address is link-local), you can use this property to set the number of multi-cast re-sends. Default is 10 re-sends.

map-filter-limit

A PCP client can request a "filter" for a mapping entry, where the filter limits the number of external endpoints that can use the IP map. The filter request contains the particular IP address and port for the endpoint (or subnet of endpoints), as well as a prefix length. Enter the maximum number of filters (allowed subnets) that clients are allowed to set for each PCP mapping. Default is 1.

map-limit-per-client

Specifies the maximum number of PCP mappings per client. Default is 65535 (unlimited).

Use run util lsndb to see the currently-active set of PCP mappings on the system. See "util lsndb" for details on the LSN DB utility.

map-recycle-delay

After a IP mapping times out (that is, its lifetime expires), there is a further delay before the public-side address and port can be used by another PCP client. Use this property to set the recycle delay. Default is 60 (seconds).

Use run util lsndb to see the currently-active set of PCP mappings on the system. See "util lsndb" for details on the LSN DB utility.

max-mapping-lifetime

When a PCP client requests an IP mapping from a BIG IP system, it also requests a "lifetime" for the mapping. The mapping expires at the end of that lifetime. This property is the maximum number of seconds allowed for a mapping lifetime. Default is 86400 (seconds), or 1 day.

Use run util lsndb to see the currently-active set of PCP mappings on the system. See "util lsndb" for details on the LSN DB utility.

min-mapping-lifetime

Specifies the minimum number of seconds allowed for a mapping lifetime. Default is 600 (seconds), or 10 minutes.

Use run util lsndb to see the currently-active set of PCP mappings on the system. See "util lsndb" for details on the LSN DB utility.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex (regex) for a description of regular expression syntax.

rule Specifies the iRule that is associated with this pcg profile. An iRule can read packets and possibly filter them based on whatever programming logic you design. For example, an iRule could reject all PCP mapping requests using a specific port, or pass an ANNOUNCE request through a specific port. An iRule gives you the flexibility to filter, process, or log the PCP packets that fit this profile.

Select an iRule from the menu of existing iRules. To create a new one, use the create ltm rule command (see "ltm rule").

third-party-allowed-subnets

Specifies the PCP clients that can make MAP requests on behalf of other clients. Enter a collection of IP prefixes (IPv4 or IPv6) with their prefix lengths. If a PCP client outside of any of these subnets attempts a PCP mapping, the BIG-IP software rejects the mapping.

You can shorten any IPv6 addresses as defined in RFC 2373 (see).

This list is only used if the third-party-option is also enabled.

If the list is empty and the third-party-option is enabled, any PCP client can create mappings for third parties.

third-party-option

Allows PCP clients to make MAP requests on behalf of other clients, using the THIRD_PARTY flag in the PCP request. You can set this property to enabled or disabled. If you enable this property, we recommend using the third-party-subnets option to limit the clients that can use the THIRD_PARTY flag; it is a potential security risk. The default is disabled.

DELETE

delete pop3 [name]

DESCRIPTION

You can use the pop3 component to create, modify, display, or delete a POP3 profile with which you can manage POP3 traffic.

EXAMPLES

create pop3 my_pop3_profile defaults-from pop3

Creates a custom POP3 profile named my_pop3_profile that inherits its settings from the system default POP3 profile.

list pop3

Displays the properties of all POP3 profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is pop3.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

activation-mode

Sets the activation-mode for STARTTLS. The options are NONE, ALLOW, or REQUIRE. The default value is REQUIRE.

DELETE
delete pptp [name]

DESCRIPTION
You can use the pptp component to manage a PPTP profile.

EXAMPLES
create pptp my_pptp_profile defaults-from pptp
Creates a PPTP profile named my_pptp_profile using the system defaults.
create pptp my_pptp_profile { log-server-ip disabled }
Creates a PPTP profile named my_pptp_profile with server address logging disables.
modify pptp my_pptp_profile description "This is a PPTP Profile"
Modifies the description attribute of a PPTP profile named my_pptp_profile.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none.
defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is pptp.
description
User defined description.
glob
Displays the items that match the glob expression. See help glob for a description of glob expression syntax.
publisher-name
Specifies the name of the log publisher for PPTP events.
include-destination-ip
Specifies whether the log messages for call establishment/disconnect include the server's ip address. The default value is disabled. When disabled the ip address will be displayed as 0.0.0.0.
csv-format
When enabled, use CSV log format for log entries. The default value is disabled.
name
Specifies a unique name for the component. This option is required for the commands create, delete, and modify.
partition
Displays the administrative partition within which the component resides.
regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ltm profile qoe

NAME
qoe - Deprecated since v15.0.0. Configures a Quality of Experience (QoE) Monitoring profile.

MODULE
ltm profile

SYNTAX
Configure the qoe component within the ltm profile module using the syntax shown in the following sections.

```
CREATE/MODIFY
create qoe [name]
modify qoe [name]
options:
  app-service [[string] | none]
  defaults-from [name]
  description [[string] | none]
  video [true | false]

reset-stats qoe
reset-stats qoe [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list qoe
list qoe [ [ [name] | [glob] | [regex] ] ... ]
show running-config qoe
show running-config qoe [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show qoe
show qoe [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete qoe [name]

DESCRIPTION
  You can use the qoe component to monitor Video Quality of Experience.

EXAMPLES
  create qoe my_qoe defaults-from qoe

  Creates an quality of experience profile named my_qoe.

  create qoe my_qoe { video true }

  video
  Specifies to monitor the QoE MOS score of video streams with the format of MP4 or FLV.

SEE ALSO
  create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, tmsh, ltm profile qoe

COPYRIGHT
  No part of this program may be reproduced or transmitted in any form or by any means, electronic or
  mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose
  other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP      2018-10-31      ltm profile qoe(1)
```

Itm profile quic

```
NAME
  quic - Configures a Quic profile.

MODULE
  ltm profile

SYNTAX
  Configure the quic component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create quic [name]
modify quic [name]
options:
  defaults-from [[name] | none]
  description [string]
  bidi-concurrent-streams-per-connection [integer]
  uni-concurrent-streams-per-connection [integer]

edit quic [ [ [name] | [glob] | [regex] ] ... ]
```

options:
all-properties
non-default-properties

mv quic [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]
options:
to-folder

reset-stats quic
reset-stats quic [[[name] | [glob] | [regex]] ...]

DISPLAY
list quic
list quic [[[name] | [glob] | [regex]] ...]
show running-config quic
show running-config quic
[[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

show quic
show quic [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global

DELETE
delete quic [name]

DESCRIPTION
You can use the quic component to manage Quic network traffic.

EXAMPLES
create quic my_quic_profile defaults-from quic

Creates a custom Quic profile named my_quic_profile that inherits its settings from the system default Quic profile.

list quic all-properties

Displays all properties for all Quic profiles.

mv quic /Common/my_quic_profile to-folder /Common/my_folder

Moves a custom Quic profile named my_quic_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS
app-service
Specifies the name of the application service to which the profile belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is quic.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

bidi-concurrent-streams-per-connection
Specifies how many bidirectional concurrent streams are allowed to be outstanding on a single QUIC connection.

uni-concurrent-streams-per-connection
Specifies how many unidirectional concurrent streams are allowed to be outstanding on a single QUIC connection.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the profile resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

to-folder

quic profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

SEE ALSO

ltm profile radius

NAME

radius - Configures a RADIUS profile for network traffic load balancing.

MODULE

ltm profile

SYNTAX

Configure the radius component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create radius [name]

modify radius [name]

options:

app-service [[string] | none]

clients [add | delete | modify | replace-all-with] {
[ip address] ...
}

clients none

defaults-from [name]

description [string]

persist-avp [[string] | [integer] | none]

pem-protocol-profile-radius [[pem_protocol_profile_radius_name] | none]

subscriber-discovery [disabled | enabled]

mv radius [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

edit radius [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

reset-stats radius

reset-stats radius [[[name] | [glob] | [regex]] ...]

DISPLAY

show running-config radius

show running-config radius [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

show radius

show radius [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

global

DELETE

delete radius [name]

DESCRIPTION

You can use the radius component to manage RADIUS network traffic.

EXAMPLES

create radius my_radius_server

Creates a RADIUS profile named `my_radius_server` that inherits its settings from the system default RADIUS profile.

`delete radius my_radius_server`

Deletes the RADIUS profile named `my_radius_server`.

`mv radius /Common/my_radius_profile to-folder /Common/my_folder`

Moves a custom radius profile named `my_radius_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`clients`

Specifies host and network addresses from which clients can connect. The default value is none, which indicates that any client can connect.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is `radiusLB`.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`

Displays the administrative partition within which the component resides.

`pem-protocol-profile-radius`

Specifies PEM protocol profile to be used when subscriber discovery is enabled. PEM protocol profile defines mapping of RADIUS AVPs to subscriber ID and other PEM subscriber session attributes.

`persist-avp`

Specifies the name of the RADIUS attribute on which traffic persists. Acceptable values are ASCII strings from section 5 of RFC 2865 or numeric codes (1-255). The default value is none, which indicates that persistence is disabled.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an `@` sign (`@{regular expression}`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`subscriber-discovery`

Specifies whether to enable PEM subscriber discovery based on the content of RADIUS packets. The options are `disabled` and `enabled`. The default value is `disabled`, which indicates that it will not extract subscriber information from RADIUS packets.

`to-folder`

radius profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

SEE ALSO

`create`, `delete`, `edit`, `glob`, `list`, `ltm virtual`, `modify`, `mv`, `regex`, `reset-stats`, `show`, `tmsh`

BIG-IP 2016-03-14 ltm profile radius(1)

ltm profile ramcache

NAME

`ramcache` - Manages the BIG-IP(r) system RAM cache.

MODULE
lrm profile

SYNTAX
Configure the ramcache component within the lrm profile module using the syntax shown in the following sections.

DISPLAY
show ramcache
show ramcache [[[name] | [glob] | [regex]] ...]
options:
exact
host [string]
max-response [integer]
uri [string]

DELETE
delete ramcache [name]

DESCRIPTION
You can use the ramcache component to delete the entries in or show information about the BIG-IP(r) system RAM cache.

EXAMPLES
show ramcache

Displays information about the entries in the BIG-IP system RAM cache.

delete ramcache

Deletes the entries in the BIG-IP system RAM cache.

OPTIONS
exact
Displays the exact number of entries in the RAM cache.

host Displays the host from which the entry was cached.

max-response
Displays the maximum number of entries in the RAM cache. The default value is 0 (zero), which is equivalent with no max-response value being specified. Without the max-response option the system will limit the number of entries to 10 per Traffic Management Microkernel (TMM).

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

uri Displays the URI from which the entry was cached.

SEE ALSO
delete, show, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-10-10 lrm profile ramcache(1)

lrm profile request-adapt

NAME
request-adapt - Configures a HTTP request adaptation profile.

MODULE
lrm profile

SYNTAX
Configure the request-adapt component within the lrm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create request-adapt [name]
modify request-adapt [name]
options:
defaults-from [[name] | none]

```

enabled [ yes | no ]
internal-virtual [ [name] | none]
preview-size [integer]
service-down-action [ ignore | reset | drop ]
timeout [integer]
allow-http-10 [ yes | no ]

edit request-adapt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

mv request-adapt [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]] ]
options:
  to-folder

reset-stats request-adapt
reset-stats request-adapt [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list request-adapt
list request-adapt [ [ [name] | [glob] | [regex] ] ... ]
show running-config request-adapt
show running-config request-adapt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show request-adapt
show request-adapt [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete request-adapt [name]

```

DESCRIPTION

You can use the request-adapt component to manage a HTTP request adaptation profile.

EXAMPLES

```
create request-adapt my_req_adapt defaults-from request-adapt
```

Creates a HTTP request adaptation profile named my_req_adapt using the system defaults.

```
create request-adapt my_req_adapt { enabled yes }
```

Creates a HTTP request adaptation profile named my_req_adapt that is enabled for adapting HTTP requests.

```
mv request-adapt /Common/my_requestadapt_profile to-folder /Common/my_folder
```

Moves a custom request-adapt profile named my_requestadapt_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is requestadapt.

enabled

Enables adaptation of HTTP requests. If set to yes, HTTP requests will be forwarded to the specified internal virtual server for adaptation. The default value is yes.

internal-virtual

Specifies the name of the internal virtual server to use for adapting the HTTP request.

preview-size

Specifies the maximum size of the preview buffer. The preview buffer is used to hold a copy of the HTTP request header and data sent to the internal virtual server in case the adaptation server reports that it does not need to adapt the HTTP request. Setting the preview-size to 0, disables buffering the request and should only be done if the adaptation server will always return with a modified HTTP request or the original HTTP request. The default value is 1024.

service-down-action

Specifies the action to take if the internal virtual server does not exist or returns an error. The default value is ignore.

The options are:

ignore

Ignore the error and send the unmodified HTTP request to a HTTP server selected from this virtual server's pool.

drop Drop the connection.

reset

Reset the connection.

timeout

Specifies a timeout in milliseconds. If the internal virtual server does not return a result within the specified time, a timeout error will occur. If preview-size is 0, the countdown will start after the entire content has been sent for adaptation. A 0 value disables the timeout. The default value is 0.

to-folder

request-adapt profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

allow-http-10

Specifies whether to forward HTTP version 1.0 requests for adaptation. By default only HTTP version 1.1 requests are forwarded. Version 1.0 is not supported. While it should work in most cases, it might be necessary to restrict adaptation on a site-specific basis. The default value is no.

response-log-error-protocol [TCP | UDP | none]

response-log-error-template [string]

response-log-pool [[pool_name] | none]

response-log-protocol [TCP | UDP | none]

response-log-template [string]

response-logging [disabled | enabled]

edit request-log [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

mv request-log [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

DISPLAY

```
list request-log
list request-log [ [ [name] | [glob] | [regex] ] ... ]
show running-config request-log
show running-config request-log
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show request-log
show request-log [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

```
DELETE
delete request-log [name]
```

DESCRIPTION

You can use the request-log component to manage request-log network traffic.

EXAMPLES

```
create request-log my_reqlog_profile defaults-from request-log
```

Creates a custom request-log profile named my_reqlog_profile that inherits its settings from the system default request-log profile.

```
list request-log all-properties
```

Displays all properties for all request-log profiles.

```
mv request-log /Common/my_requestlog_profile to-folder /Common/my_folder
```

Moves a custom request-log profile named my_requestlog_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the default values from this profile.

description

User defined description.

log-request-logging-errors

Enables secondary logging should the primary lack sufficient available bandwidth. This mechanism is best used to send an alert to a completely separate destination.

log-response-by-default

Indicates if response logging may be overridden via iRule. This field determines the default response action.

log-response-logging-errors

Enables secondary logging should the primary lack sufficient available bandwidth. This mechanism is best used to send an alert to a completely separate destination.

partition

Displays the administrative partition within which the profile resides.

proxy-close-on-error

Specifies, if enabled, that the logging profile will close the connection after sending its proxy-response.

proxy-respond-on-logging-error

Specifies that the logging profile respond directly (for example, with an HTTP 502) if the logging fails.

proxy-response

Specifies the response to send on logging errors.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

request-log-error-pool

Specifies the name of the pool from which to select log servers.

request-log-error-protocol

Specifies the HighSpeedLogging protocol to use when logging.

request-log-error-template

Specifies the template to use when generating log messages. Shell style escapes (for example, \$foo and/or \${foo}) are used to import transaction-specific values.

request-log-pool

Specifies the name of the pool from which to select log servers.

request-log-protocol

Specifies the HighSpeedLogging protocol to use when logging.

request-log-template

Specifies the template to use when generating log messages. Shell style escapes (for example, \$foo and/or \${foo}) are used to import transaction-specific values.

request-logging

Enables or disables logging before the response is returned to the client.

response-log-error-pool

Specifies the name of the pool from which to select log servers.

response-log-error-protocol

Specifies the HighSpeedLogging protocol to use when logging.

response-log-error-template

Specifies the template to use when generating log messages. Shell style escapes (for example, \$foo and/or \${foo}) are used to import transaction-specific values.

response-log-pool

Specifies the name of the pool from which to select log servers.

response-log-protocol

Specifies the HighSpeedLogging protocol to use when logging.

response-log-template

Specifies the template to use when generating log messages. Shell style escapes (for example, \$foo and/or \${foo}) are used to import transaction-specific values.

response-logging

Enables or disables logging before the response is returned to the client.

to-folder

request-log profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

SEE ALSO

DELETE

delete response-adapt [name]

DESCRIPTION

You can use the response-adapt component to manage a HTTP response adaptation profile.

EXAMPLES

create response-adapt my_req_adapt defaults-from response-adapt

Creates a HTTP response adaptation profile named my_req_adapt using the system defaults.

create response-adapt my_req_adapt { enabled yes }

Creates a HTTP response adaptation profile named my_req_adapt that is enabled for adapting HTTP responses.

mv response-adapt /Common/my_responseadapt_profile to-folder /Common/my_folder

Moves a custom responseadapt profile named my_responseadapt_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is responseadapt.

enabled

Enables adaptation of HTTP responses. If set to yes, HTTP responses will be forwarded to the specified internal virtual server for adaptation. The default value is yes.

internal-virtual

Specifies the name of the internal virtual server to use for adapting the HTTP response.

preview-size

Specifies the maximum size of the preview buffer. The preview buffer is used to hold a copy of the HTTP response header and data sent to the internal virtual server in case the adaptation server reports that it does not need to adapt the HTTP response. Setting the preview-size to 0, disables buffering the response and should only be done if the adaptation server will always return with a modified HTTP response or the original HTTP response. The default value is 1024.

service-down-action

Specifies the action to take if the internal virtual server does not exist or returns an error. The default value is ignore.

The options are:

ignore

Ignore the error and send the unmodified HTTP response to a HTTP server selected from this virtual server's pool.

drop Drop the connection.

reset

Reset the connection.

timeout

Specifies a timeout in milliseconds. If the internal virtual server does not return a result within the specified time, a timeout error will occur. If preview-size is 0, the countdown will start after the entire content has been sent for adaptation. A 0 value disables the timeout. The default value is 0.

to-folder

response-adapt profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

allow-http-10

Specifies whether to forward HTTP version 1.0 responses for adaptation. By default only HTTP version 1.1 responses are forwarded. Version 1.0 is not supported. While it should work in most cases, it might be necessary to restrict adaptation on a site-specific basis. The default value is no.

  non-default-properties

```

```

DELETE
delete rewrite [name]

```

DESCRIPTION

Use the rewrite component to configure a Rewrite Profile in URI Translation or Portal (Access) mode.

EXAMPLES

URI Translation Mode

Create a profile

```
create my_uri_rewrite rewrite-mode uri-translation
```

Add a rule to rewrite URIs

```
modify my_uri_rewrite uri-rules add { my_rule { client { path /client/ } server { path /server/ } } }
```

```
modify my_uri_rewrite uri-rules add { my_rule { client { scheme http host www.client.com path / }
server { scheme http host www.server.com path / } } }
```

Add a rule to rewrite Set-Cookie headers

```
modify my_uri_rewrite set-cookie-rules add { my_rule { client { domain client.com path / } server {
domain server.com path / } } }
```

Portal (Access) Mode

Create a profile

```
create my_portal_rewrite rewrite-mode portal
```

Configure the client to cache all files

```
modify my_portal_rewrite client-caching-type cache-all
```

Set the rewrite list and bypass list

```
modify my_portal_rewrite rewrite-list add { *://www.myportal.com/* http://abc*.com/* } bypass-list add
{ *://external_web.com/* }
```

Configure split-tunneling

```
modify my_portal_rewrite split-tunneling true
```

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

bypass-list

Specifies a list of URIs that are bypassed inside a web page when the page is accessed using Portal Access. The default is none.

client-caching-type

Specifies one of four options for client caching. When the Client Cache setting for a web application resource is set to default, the system uses the setting configured in the Rewrite profile. If the Client Cache option is configured for any other setting, the web application resource item caching configuration overwrites the setting in the Rewrite profile. The default is cache-css-js. The options are:

cache-all

Do not modify cache headers on backend servers.

cache-css-js

Cache only the CSS file and Java Script.

cache-img-css-js

Cache only images, the CSS file and Java Script.

no-cache

Eliminate caching.

defaults-from

Specifies the profile from which the Rewrite profile inherits properties. Explicitly specified properties override inherited properties.

java-ca-file

Specifies a CA against which to verify signed Java applets signatures. The default value is ca-bundle.crt.

java-crl

Specifies a CRL against which to verify signed Java applets signature certificates. The default value is none.

java-sign-key

Specifies a private key for re-signing of signed Java applets after patching. The default value is default.key.

java-sign-key-passphrase

Specifies a passphrase for the private key to be encrypted with. The default value is none. Note: your passphrase will be encrypted and displayed under the label java-sign-key-passphrase-encrypted.

java-signer

Specifies a certificate to use for re-signing of signed Java applets after patching. The default value is default.crt.

location-specific

Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location. The default value is none.

rewrite-list

Specifies a list of URIs that are rewritten inside a web page when the page is accessed using Portal Access. The default value is none.

rewrite-mode

Specifies the mode of rewriting. uri-translation is a rules-based rewrite mode. portal is for use with Portal Access.

set-cookie-rules

Used with uri-translation mode. Specifies the rules for rewriting HTTP Set-Cookie headers. Each rule has a name and a client and server domain and path. The name may be any alphanumeric string and must be unique. The path must be an absolute directory path and not a relative path or a file path. If the domain and path of the Set-Cookie header in the HTTP response match the domain and path of the server side of a rule, they will be rewritten to the domain and path of client side of that rule. Set-Cookie rules take precedence over URI rules when rewriting Set-Cookie headers.

split-tunneling

Specifies whether the profile provides for split tunneling. The default is false.

uri-rules

Used with uri-translation mode. Specifies the rules for rewriting request and response headers and response bodies. These rules affect the following.

request headers

URI, Host, Referer

response headers

Content-Location, Link, Location, Refresh, Set-Cookie

response body

HTML, CSS

Each rule has a name, a type, and a client and server URI. The name may be any alphanumeric string and must be unique. The type may be "request", "response", or "both": "request" rules affect request headers only, "response" rules affect response headers and bodies only, and "both" rules affect both. URIs must include a path; scheme, host, and port are optional. If a URI must contain a scheme or host, it must include both. If it must include a port, it must also include a scheme and host. Paths may be absolute directory paths only. They may not be relative paths or file paths. If a URI in a request header matches the client side URI of a rule, it will be rewritten to the server side URI of that rule. If a URI in a response header or body matches the server side URI of a rule, it will be rewritten to the client side URI of that rule. When rewriting Set-Cookie headers, the host and path of the server side URI are used to match the domain and path of the header. The client side host and path replace that header's domain and path if a match is found. Set-Cookie rules take precedence over URI rules when rewriting Set-Cookie headers.

Itm profile rtsp

NAME

rtsp - Configures an RTSP (realtime streaming protocol) profile.

MODULE

Itm profile

SYNTAX

Configure the rtsp component within the Itm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create rtsp [name]

modify rtsp [name]

options:

app-service [[string] | none]

check-source [disabled | enabled]

defaults-from [name]

description [string]

idle-timeout [integer]

max-header-size [integer]

max-queued-data [integer]

multicast-redirect [disabled | enabled]

proxy [external | internal | none]

proxy-header [[name] | none]

real-http-persistence [disabled | enabled]

rtcp-port [number]

rtp-port [number]

session-reconnect [disabled | enabled]

unicast-redirect [disabled | enabled]

log-publisher [log publisher name | none]

log-profile [log profile name | none]

edit rtsp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

mv rtsp [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

reset-stats rtsp

reset-stats rtsp [[[name] | [glob] | [regex]] ...]

DISPLAY

list rtsp

list rtsp [[[name] | [glob] | [regex]] ...]

show running-config rtsp

show running-config rtsp

field-fmt

global

DELETE

delete rtsp [name]

DESCRIPTION

You can use the rtsp component to manage a profile that you use to control RTSP traffic.

EXAMPLES

create rtsp my_rtsp_profile defaults-from rtsp

Creates a custom RTSP profile named my_rtsp_profile that inherits its settings from the system default RTSP profile.

list rtsp all-properties

Displays all properties for all RTSP profiles.

mv rtsp /Common/my_rtsp_profile to-folder /Common/my_folder

Moves a custom rtsp profile named my_rtsp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

check-source

When enabled the system uses the source attribute in the transport header to establish the target address of the RTP stream, and before the response is forwarded to the client, updates the value of the source attribute to be the virtual address of the BIG-IP system. When disabled the system does not change the source attribute. The default value is enabled.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is rtsp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

idle-timeout

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 300 seconds.

max-header-size

Specifies the maximum size of an RTSP request or response header that the RTSP filter accepts before dropping the connection. The default value is 4096 bytes.

max-queued-data

Specifies the maximum amount of data that the RTSP filter buffers before dropping the connection. The default value is 32768 bytes.

multicast-redirect

Specifies whether to enable or disable multicast redirect. When enabled, the client can select the destination to which to stream data. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

proxy

Specifies whether the RTSP filter is associated with an RTSP proxy configuration. The default value is none.

proxy-header

When the proxy option is set, specifies the name of the header in the RTSP proxy configuration that is passed from the client-side virtual server to the server-side virtual server. Note that the name of the header must begin with X-. The default value is none.

To use the proxy-header option, you must specify a value for the proxy option.

real-http-persistence

Specifies whether to enable or disable real HTTP persistence. When enabled, the RTSP filter automatically persists Real Networks RTSP over HTTP using the RTSP port. The default value is enabled. If you disable this parameter, you can override the default behavior with an iRule.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rtcp-port

Specifies the number of the port to use for the Real Time Control Protocol (RTCP) service. The default value is 0 (zero). RTCP allows monitoring of real-time data delivery.

rtp-port

Specifies the number of the port to use for the RTP service. The default value is 0 (zero).

session-reconnect

Specifies whether to enable or disable session reconnect. When enabled, the RTSP filter persists the control connection, which is being resumed, to the correct server. The default value is disabled.

to-folder

rtsp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

unicast-redirect

Specifies whether to enable or disable unicast redirect. When enabled, the client can select the destination to which to stream data. The default value is disabled.

log-publisher

Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile

Specify the name of the ALG log profile which controls the logging of ALG . See help Itm alg-log-profile for more details on the logging profile sub-system. Use the "Itm alg-log-profile profile" component to set up a ALG log profile.

  field-fmt
  global
```

```
DELETE
delete sctp [name]
```

DESCRIPTION

You can use the sctp component to manage a profile for SCTP traffic.

EXAMPLES

```
create sctp my_sctp_profile defaults-from sctp
```

Creates a custom SCTP profile named my_sctp_profile that inherits its settings from the system default SCTP profile.

```
list sctp all-properties
```

Displays all properties for all SCTP profiles.

```
mv sctp /Common/my_sctp_profile to-folder /Common/my_folder
```

Moves a custom sctp profile named my_sctp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

cookie-expiration

Specifies how many seconds the cookie is valid. The default value is 60 seconds.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is sctp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

heartbeat-interval

Specifies the number of seconds to wait before sending a heartbeat chunk. The default value is 30 seconds.

heartbeat-max-burst

Specifies the number of heartbeat packets to be sent in a single burst. The default value is 1.

idle-timeout

Specifies the number of seconds without traffic before a connection is eligible for deletion. The default value is 300 seconds.

in-streams

Specifies the number of inbound streams to advertise on new connections. The default value is 1.

init-max-retries

Specifies the maximum number of retries to establish a connection. The default value is 4.

ip-tos

Specifies the Type of Service (ToS) that is set in packets sent to the peer. The default value is 0.

link-qos

Specifies the Link Quality of Service (QoS) that is set in sent packets. The default value is 0.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

out-streams

Specifies the number of outbound streams. The default value is 2.

partition

Displays the administrative partition within which the component resides.

proxy-buffer-high

Specifies the proxy buffer level after which the system closes the receive window. The default value is 16384.

proxy-buffer-low

Specifies the proxy buffer level after which the system opens the receive window. The default value is 4096.

receive-chunks

Specifies the size (in chunks) of the rx_chunk buffer. The default value is 256.

receive-ordered

When enabled, the default, the system delivers messages to the application layer in order.

receive-window-size

Specifies the size (in bytes) of the receive window. Prorate this value to the receive-chunks value. The default value is 65535.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout

When enabled, the default, the system resets the connection when the connection times out.

rto-initial

Specifies the number of milliseconds for the initial value of retransmission timeout. The default value is 3000 milliseconds.

rto-max

Specifies the number of milliseconds for the maximum value of retransmission timeout. The default value is 60000 milliseconds.

rto-min

Specifies the number of milliseconds for the minimum value of retransmission timeout. The default value is 1000 milliseconds.

sack-timeout

Specifies the number of milliseconds for the delayed selective acknowledgement timeout. The default value is 200 milliseconds.

secret

Specifies the internal secret string used for HTTP Message Authenticated Code (HMAC) cookies.

send-buffer-size

Specifies the size in bytes of the buffer. The default value is 65536.

max-burst

Specifies the maximum number of data packets to send in a single burst. The default value is 4.

send-max-retries

Specifies the maximum number of time the system tries again to send the data. The default value is 8.

send-partial

When enabled, the default, the system accepts partial application data.

tcp-shutdown

When enabled, the system emulates the closing of a TCP connection. The default value is enabled.

to-folder

sctp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

transmit-chunks

Specifies the size of the tx_chunk buffer. The default value is 256.

SEE ALSO

non-default-properties

DELETE

delete server-ldap [name]

DESCRIPTION

You can use the server-ldap component to create, modify, display, or delete an Server LDAP profile with which you can manage Server LDAP traffic.

EXAMPLES

create server-ldap my_serverldap_profile defaults-from serverldap

Creates a custom Server LDAP profile named my_serverldap_profile that inherits its settings from the system default Server LDAP profile.

list server-ldap

Displays the properties of all Server LDAP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is smtp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

activation-mode

Sets the activation-mode for STARTTLS. The options are NONE, ALLOW, or REQUIRE. The default value is

NONE.

DESCRIPTION

You can use the server-ssl component to manage a server SSL profile.

Server-side profiles enable the traffic management system to handle encryption tasks for any SSL connection being sent from a local traffic management system to a target server. A server-side SSL profile is acts as a client by presenting certificate credentials to a server when authentication of the local traffic management system is required. You implement this type of profile by using the default profile, or by creating a custom profile based on the Server SSL profile template and modifying its settings.

EXAMPLES

create server-ssl my_serverssl_profile defaults-from serverssl

Creates a custom Server SSL profile named my_serverssl_profile that inherits its settings from the system default profile serverssl.

list server-ssl all-properties

Displays all properties for all Server SSL profiles.

mv server-ssl /Common/my_serverssl_profile to-folder /Common/my_folder

Moves a custom server-ssl profile named my_serverssl_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

alert-timeout

Specifies the maximum time period in seconds to keep the SSL session active after alert message is sent, or indefinite. The default value is indefinite.

allow-expired-crl

Use the specified CRL file even if it has expired. The default value is disabled.

authenticate

Specifies the frequency of authentication. The default value is once. Note that if this is set to always session cache and session ticket will be disabled.

authenticate-depth

Specifies the client certificate chain maximum traversal depth. The default value is 9.

authenticate-name

Specifies a Common Name (CN) that is embedded in a server certificate. The system authenticates a server based on the specified CN. The default value is none.

bypass-on-client-cert-fail

Enables or disables SSL forward proxy bypass on failing to get client certificate that server asks for. When enabled and the SSL handshake cannot be completed because of failure to get the client certificate, SSL traffic bypasses the BIG-IP system untouched, without decryption/encryption. The default value is disabled. Conversely, you can specify enabled to use this feature.

bypass-on-handshake-alert

Enables or disables SSL forward proxy bypass on receiving handshake_failure, protocol_version or unsupported_extension alert message during the serverside SSL handshake. When enabled and there is an SSL handshake_failure, protocol_version or unsupported_extension alert during the serverside SSL handshake, SSL traffic bypasses the BIG-IP system untouched, without decryption/encryption. The default value is disabled. Conversely, you can specify enabled to use this feature.

c3d-ca-cert

Specifies the name of the certificate file that is used as the certification authority certificate when SSL client certificate constrained delegation is enabled. The certificate should be generated and installed by you on the system. When selecting this option, type a certificate file name.

c3d-ca-key

Specifies the name of the key file that is used as the certification authority key when SSL client certificate constrained delegation is enabled. The key should be generated and installed by you on the system. When selecting this option, type a key file name.

c3d-ca-passphrase

Specifies the passphrase of the key file that is used as the certification authority key when SSL client certificate constrained delegation is enabled. When selecting this option, type the passphrase corresponding to the selected c3d-ca-key.

c3d-cert-extension-custom-oids

Specifies the custom extension OID of the client certificates to be included in the generated certificates using SSL client certificate constrained delegation.

c3d-cert-extension-includes

Specifies the extensions of the client certificates to be included in the generated certificates using SSL client certificate constrained delegation. For example, { basic-constraints }. The default value is { basic-constraints extended-key-usage key-usage subject-alternative-name }. The extensions are:

basic-constraints

Basic constraints are used to indicate whether the certificate belongs to a CA.

extended-key-usage

Extended Key Usage is used, typically on a leaf certificate, to indicate the purpose of the public key contained in the certificate.

key-usage

Key Usage provides a bitmap specifying the cryptographic operations which may be performed using the public key contained in the certificate; for example, it could indicate that the key should be used for signature but not for encipherment.

subject-alternative-name

Subject Alternative Name allows identities to be bound to the subject of the certificate. These identities may be included in addition to or in place of the identity in the subject field of the certificate.

c3d-cert-lifespan

Specifies the lifespan of the certificate generated using the SSL client certificate constrained delegation. The default value is 24.

ca-file

Specifies the certificate authority file name. Configures certificate verification by specifying a list of client or server CAs that the traffic management system trusts. The default value is none.

cache-size

Specifies the SSL session cache size. For client profiles only, you can configure timeout and size values for the SSL session cache. Because each profile maintains a separate SSL session cache, you can configure the values on a per-profile basis. The default value is 262144.

cache-timeout

Specifies the SSL session cache timeout value, which is the usable lifetime seconds of negotiated SSL session IDs. The default value is 3600 seconds. Acceptable values are integers greater than or equal to 0 and less than or equal to 86400.

cert Specifies the name of the certificate installed on the traffic management system for the purpose of terminating or initiating an SSL connection. The default value is none.

chain
Specifies or builds a certificate chain file that a client can use to authenticate the profile. The default value is none.

cipher-group
Specifies a cipher group. If the cipher group is not blank or none, the ciphers string will be used.

ciphers
Specifies a cipher name. The default value is DEFAULT.

crl Specifies the name of crl validator for validating status of server certificate. Specifying none disables crl validation of server certificate. The default value is none.

crl-file
Specifies the certificate revocation list file name. The default value is none.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is serverssl.

description
User defined description.

expire-cert-response-control
Specifies the BIGIP action when the server certificate has expired. The default value is drop, which causes the connection to be dropped. Conversely, you can specify ignore to cause the connection to ignore the error and continue or you can specify mask in case of SSL forward proxy to mask server certificate errors and continue with handshake and forge a good certificate on client-side.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

handshake-timeout
Specifies the handshake timeout in seconds. The default value is 10.

key Specifies the key file name. Specifies the name of the key installed on the traffic management system for the purpose of terminating or initiating an SSL connection. The default value is none.

mod-ssl-methods
Enables or disables ModSSL methods. The default value is disabled.

Enable this option when OpenSSL methods are inadequate. For example, you can enable ModSSL method emulation when you want to use SSL compression over TLSv1.

mode Enables or disables SSL processing. The default value is enabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

ocsp Specifies the name of ocsp profile for purpose of validating status of server certificate. Specifying none disables ocsp validation of server certificate. The default value is none.

options
Enables options, including some industry-related workarounds. Enter options inside braces, for example, { dont-insert-empty-fragments}. The default value is dont-insert-empty-fragments no-tlsv1.3.

dont-insert-empty-fragments
Disables a countermeasure against a SSL 3.0/TLS 1.0 protocol vulnerability affecting CBC ciphers. These ciphers cannot be handled by certain broken SSL implementations. This option has no effect for connections using other ciphers.

max-active-handshakes
Specifies the maximum number allowed SSL active handshakes. The default value is 0.

no-session-resumption-on-renegotiation
When performing renegotiation as an SSL server, this option always starts a new session (that is, session resumption requests are accepted only in the initial handshake). The system ignores this option for server-side SSL.

gmssl1.1
Enable GMSSLv1.1 protocol.

no-ssl
Do not use any version of the SSL protocol.

no-ssl3
Do not use the SSLv3 protocol.

no-tls
Do not use any version of the TLS protocol.

`no-tls1`
Do not use the TLSv1.0 protocol.

`no-tls1.1`
Do not use the TLSv1.1 protocol.

`no-tls1.2`
Do not use the TLSv1.2 protocol.

`no-tls1.3`
Do not use the TLSv1.3 protocol. Note that this is for future expansion. Currently TLSv1.3 has not been implemented for server side SSL, so removing this will have no effect and log a warning message.

`no-dtls`
Do not use any version of the DTLS protocol.

`no-dtls1.0`
Do not use the DTLSv1.0 protocol.

`no-dtls1.2`
Do not use the DTLSv1.2 protocol.

`passive-close`
Specifies how to handle passive closes.

`none` Disables all workarounds. Note that F5 Networks does not recommend this option.

`single-dh-use`
Creates a new key when using temporary/ephemeral DH parameters. This option must be used to prevent small subgroup attacks, when the DH parameters were not generated using strong primes (for example, when using DSA-parameters). If strong primes were used, it is not strictly necessary to generate a new DH key during each handshake, but F5 Networks recommends it. Enable the Single DH Use option whenever temporary or ephemeral DH parameters are used.

`tls-rollback-bug`
Disables version rollback attack detection. During the client key exchange, the client must send the same information about acceptable SSL/TLS protocol levels as it sends during the first hello. Some clients violate this rule by adapting to the server's answer. For example, the client sends an SSLv2 hello and accepts up to SSLv3.1 (TLSv1), but the server only processes up to SSLv3. In this case, the client must still use the same SSLv3.1 (TLSv1) announcement. Some clients step down to SSLv3 with respect to the server's answer and violate the version rollback protection. The system ignores this option for server-side SSL.

`partition`
Displays the administrative partition within which the component resides.

`passphrase`
Specifies the key passphrase, if required. The default value is none.

`peer-cert-mode`
Specifies the peer certificate mode. The default value is ignore.

`proxy-ssl`
Enabling this option requires a corresponding client ssl profile with proxy-ssl enabled to perform transparent SSL decryption. This feature allows further modification of application traffic within an SSL tunnel while still allowing the server to perform necessary authorization, authentication, auditing steps.

`proxy-ssl-passthrough`
Enabling this option requires a corresponding client ssl profile with proxy-ssl-passthrough enabled. This allows Proxy SSL to passthrough the traffic when ciphersuite negotiated between the client and server is not supported. The default option is disabled.

`regex`
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

`renegotiate-period`
Specifies the number of seconds from the initial connect time after which the system renegotiates an SSL session. The default value is indefinite, which means that you do not want the system to renegotiate SSL sessions.

Each time the session renegotiation is successful, a new connection is started. Therefore, the system attempts to renegotiate the session again, in the specified amount of time following a successful session renegotiation. For example, setting the renegotiate-period option to 3600 seconds triggers session renegotiation at least once an hour.

`renegotiate-size`
Specifies a throughput size, in megabytes, of SSL renegotiation. This option forces the traffic management system to renegotiate an SSL session based on the size, in megabytes, of application data that is transmitted over the secure channel. The default value is indefinite, which specifies that you do not want a throughput size.

`renegotiation`

Specifies whether renegotiations are enabled. The default value is enabled. When renegotiations are disabled, the system is acting as an SSL server, and a COMPAT or NATIVE cipher is negotiated, the system will abort the connection. Additionally, when renegotiations are disabled and the system is acting as an SSL client, the system will ignore the server's HelloRequest messages.

retain-certificate

APM module requires storing certificate in SSL session. When set to false, certificate will not be stored in SSL session. The default value is true.

revoked-cert-status-response-control

Specifies the BIGIP action when the server certificate status is revoked. The default value is drop, which causes the connection to be dropped. You can specify ignore to cause the connection to ignore the error and continue handshake. You can specify mask in case of SSL forward proxy to mask server certificate status error and continue handshake.

generic-alert

Enables or disables generic-alert. The default option is enabled, which causes the SSL profile to use generic alert number. Conversely, you can specify disabled to cause SSL profile to use alert number defined in RFC5246/RFC6066 strictly.

secure-renegotiation

Specifies the secure renegotiation mode. The default value is require-strict. When secure renegotiation is set to require, any connection to an unpatched server will be aborted. For server-ssl, there is no difference between require and require-strict secure renegotiation. When secure renegotiation is set to request, connections to unpatched servers will be permitted. This setting is NOT recommended however, as it is subject to active man-in-the-middle attacks.

server-name

Specifies the server name to be included in SNI (server name indication) extension during SSL handshake in ClientHello.

session-mirroring

Enables or disables the mirroring of sessions to high availability peer. By default, this setting is disabled, which causes the system to not mirror ssl sessions.

session-ticket

Enables or disables session-ticket. The default option is disabled, which causes the SSL profile not to use session ticket per RFC 5077. Conversely, you can specify enabled to cause SSL profile to use session ticket per RFC 5077.

sni-default

When true, this profile is the default SSL profile when the server name in a client connection does not match any configured server names, or a client connection does not specify any server name at all.

sni-require

When this option is enabled, connections to a server that does not support SNI extension will be rejected.

ssl-c3d

Enables or disables SSL Client certificate constrained delegation. The default option is disabled. Conversely, you can specify enabled to use the SSL client certificate constrained delegation.

ssl-forward-proxy

Enables or disables ssl-forward-proxy feature. The default option is disabled. Conversely, you can specify enabled to use the SSL Forward Proxy Feature.

ssl-sign-hash

Specifies SSL sign hash algorithm which is used to sign and verify SSL Server Key Exchange and Certificate Verify messages for the specified SSL profiles. The default value is sha1.

ssl-forward-proxy-bypass

Enables or disables ssl-forward-proxy-bypass feature. The default option is disabled. Conversely, you can specify enabled to use the SSL Forward Proxy Bypass Feature.

ssl-forward-proxy-verified-handshake

Specifies, when enabled, that in SSL forward proxy mode, the system should always do a TLS handshake with the server first before doing the client handshake. When disabled, the system will do the server handshake first only if it has not previously forged and cached the server certificate; once the server certificate is ready, the system will always handshake first with the client. The default value is disabled.

strict-resume

Enables or disables the resumption of SSL sessions after an unclean shutdown. The default value is disabled, which indicates that the SSL profile refuses to resume SSL sessions after an unclean shutdown.

to-folder

server-ssl profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

unclean-shutdown

Specifies, when enabled, that the SSL profile performs unclean shutdowns of all SSL connections, which means that underlying TCP connections are closed without exchanging the required SSL shutdown alerts. If you want to force the SSL profile to perform a clean shutdown of all SSL connections, you can disable this option.

unknown-cert-status-response-control

Specifies the BIGIP action when the server certificate status is unknown. The default value is ignore,

which causes the connection to ignore the error and continue handshake. You can specify drop which causes the connection to be dropped. You can specify mask in case of SSL forward proxy to mask server certificate status error and continue handshake.

untrusted-cert-response-control

Specifies the BIGIP action when the server certificate has untrusted CA. The default value is drop, which causes the connection to be dropped. Conversely, you can specify ignore to cause the connection to ignore the error and continue or you can specify mask in case of SSL forward proxy to mask server certificate errors and continue with handshake and forge a good certificate on client-side.

data-0rtt

Specifies if TLSv1.3 should send 0-RTT early data when available. The default value is disabled.

ltm profile sip

NAME

sip - Configures a Session Initiation Protocol (SIP) profile.

MODULE

ltm profile

SYNTAX

Configure the sip component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create sip [name]

modify sip [name]

options:

alg-enable [disabled | enabled]

app-service [[string] | none]

community [[community name] | none]

defaults-from [[name] | none]

description [string]

dialog-aware [disabled | enabled]

dialog-establishment-timeout [integer]

enable-sip-firewall [no | yes]

insert-record-route-header [disabled | enabled]

insert-via-header [disabled | enabled]

max-media-sessions [integer]

max-registrations [integer]

max-sessions-per-registration [integer]

max-size [integer]

registration-timeout [integer]

rtp-proxy-style [symmetric | restricted-by-ip-address | any-location]

secure-via-header [disabled | enabled]

security [disabled | enabled]

sip-session-timeout [integer]

terminate-on-bye [disabled | enabled]

user-via-header [[via-header] | none]

log-publisher [log publisher name | none]

log-profile [log profile name | none]

edit sip [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

mv sip [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

reset-stats sip

reset-stats sip [[[name] | [glob] | [regex]] ...]

DISPLAY

list sip

list sip [[[name] | [glob] | [regex]] ...]

```
show running-config sip
show running-config sip [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show sip
show sip [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

```
DELETE
delete sip [name]
```

DESCRIPTION
You can use the sip component to manage a SIP profile.

EXAMPLES

```
create sip my_sip_profile defaults-from sip
```

Creates a SIP profile named my_sip_profile using the system defaults.

```
create sip my_sip_profile { terminate-by disabled }
```

Creates a SIP profile named my_sip_profile that leaves a connection open following the completion of a BYE transaction.

```
mv sip /Common/my_sip_profile to-folder /Common/my_folder
```

Moves a custom sip profile named my_sip_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

alg-enable
Enables or disables the SIP ALG (Application Level Gateway) feature. The default value is disabled. Note: for a SIP profile with ALG enabled to function correctly, the virtual which uses the profile must have destination and mask set to 0.0.0.0 for IPv4, or :: for IPv6. Additionally, the virtual must have source-address-translation enabled.

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

community
Specifies the community to which you want to assign the virtual server that you associate with this profile. The default value is none.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is sip.

description
User defined description.

dialog-aware
Enables or disables the ability for the system to be aware of unauthorized use of the SIP dialog. The default value is disabled.

dialog-establishment-timeout
Indicates the timeout value for dialog establishment in a sip session. The default value is 10 seconds.

enable-sip-firewall
Indicates whether to enable SIP firewall functionality or not. Default value is no.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

insert-record-route-header
Enables or disables the insertion of a Record-Route header, which indicates the next hop for the following SIP request messages. The default value is disabled.

insert-via-header
Enables or disables the insertion of a Via header, which indicates where the message originated. The response message uses this routing information. The default value is disabled.

max-media-sessions
Indicates the maximum number of SDP media sessions that the BIG-IP system accepts. The default value is 6.

max-registrations
Indicates the maximum number of registrations, the maximum allowable REGISTER messages can be recorded that the BIG-IP system accepts. The default value is 100.

max-sessions-per-registration

Indicates the maximum number of calls or sessions can be made by a user for a single registration that the BIG-IP system accepts. The default value is 50.

max-size

Specifies the maximum SIP message size that the BIG-IP system accepts. The default value is 65535 bytes.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

registration-timeout

Indicates the timeout value for a sip registration. The default value is 3600 seconds.

rtp-proxy-style

Indicates the style in which the RTP will proxy the data. When a dialog is established, the necessary SDP data needs to know where the RTP flows are directed. The default value is symmetric. The options available are:

symmetric

Indicates the use of a bidirectional related flow.

restricted-by-ip-address

Indicates the use of ephemeral listeners to support fixed client IP, listener is restricted to connections coming from a particular source.

any-location

Indicates the use of ephemeral listeners to support wildcard, connections are allowed to come from anyway.

secure-via-header

Enables or disables the insertion of a Secure Via header, which indicates where the message originated. When you are using SSL/TLS (over TCP) to create a secure channel with the server node, use this setting to configure the system to insert a Secure Via header into SIP requests. The default value is disabled.

security

Enables or disables security for the SIP profile. The default value is disabled.

sip-session-timeout

Indicates the timeout value for a sip session. The default value is 300 seconds.

terminate-on-bye

Enables or disables the termination of a connection when a BYE transaction finishes. Use this parameter with UDP connections only, not with TCP connections. The default value is enabled.

to-folder

sip profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

user-via-header

Enables or disables the insertion of a Via header specified by a system administrator. The default value is none.

log-publisher

Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile

Specify the name of the ALG log profile which controls the logging of ALG . See help ltm alg-log-profile for more details on the logging profile sub-system. Use the "ltm alg-log-profile profile" component to set up a ALG log profile.

Itm profile smtp

NAME

smtp - Configures an SMTP profile.

MODULE

itm profile

SYNTAX

Configure the smtp component within the Itm profile module using the syntax shown in the following sections. The smtp profile is available when the asm module is enabled. You enable the asm module via provisioning commands, which are described in help sys provision.

CREATE/MODIFY

create smtp [name]

modify smtp [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

security [disabled | enabled]

edit smtp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list smtp

list smtp [[[name] | [glob] | [regex]] ...]

show running-config smtp

show running-config smtp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DELETE

delete smtp [name]

DESCRIPTION

You can use the smtp component to create, modify, display, or delete an SMTP profile with which you can manage SMTP traffic.

EXAMPLES

create smtp my_smtp_profile defaults-from smtp

Creates a custom SMTP profile named my_smtp_profile that inherits its settings from the system default SMTP profile.

list smtp

Displays the properties of all SMTP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is smtp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

security

Enables or disables secure SMTP traffic for the BIG-IP(r) Application Security Manager. The default value is disabled.

SEE ALSO

create, delete, edit, glob, list, Itm virtual, modify, regex, reset-stats, show, sys provision, tmsh

BIG-IP 2013-11-06 ltm profile smtp(1)

ltm profile smtps

NAME

smtps - Configures an SMTPs profile.

MODULE

ltm profile

SYNTAX

Configure the smtps component within the ltm profile module using the syntax shown in the following sections. The smtps profile is available when the asm module is enabled. You enable the asm module via provisioning commands, which are described in help sys provision.

CREATE/MODIFY

create smtps [name]

modify smtps [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

activation-mode [none | allow | require]

edit smtps [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list smtps

list smtps [[[name] | [glob] | [regex]] ...]

show running-config smtps

show running-config smtps [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DELETE

delete smtps [name]

DESCRIPTION

You can use the smtps component to create, modify, display, or delete an SMTPs profile with which you can manage SMTPs traffic.

EXAMPLES

create smtps my_smtps_profile defaults-from smtps

Creates a custom SMTPs profile named my_smtps_profile that inherits its settings from the system default SMTPs profile.

list smtps

Displays the properties of all SMTPs profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is smtp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

activation-mode
Sets the activation-mode for STARTTLS. The options are NONE, ALLOW, or REQUIRE. The default value is NONE.

SEE ALSO

ltm profile socks

NAME

socks - Configures a SOCKS profile.

MODULE

ltm profile

SYNTAX

Configure the socks component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create socks [name]

modify socks [name]

options:

protocol-versions {
 [[socks4] | [socks4a] | [socks5]] ... }

dns-resolver [dns-resolver]

ipv6 [no | yes]

tunnel-name [tunnel]

route-domain [route-domain]

default-connect-handling [deny | allow]

edit socks [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

reset-stats socks

reset-stats socks [[[name] | [glob] | [regex]] ...]

DISPLAY

list socks

list socks [[[name] | [glob] | [regex]] ...]

show running-config socks

show running-config socks [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

show socks

show socks [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

global

DELETE

delete socks [name]

DESCRIPTION

You can use the socks component to create, modify, display, or delete an SOCKS profile.

The BIG-IP(r) system installation includes the following default SOCKS-type profiles:

socks

The default SOCKS profile contains values for properties related to managing SOCKS traffic.

You can create a new SOCKS-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

create socks my_socks_profile defaults-from socks

Creates a custom SOCKS profile named my_socks_profile that inherits its settings from the system default SOCKS profile.

OPTIONS

protocols-versions

Specifies the SOCKS protocol versions that are supported. The value is one or more off:

socks4

Specifies protocol support for SOCKS version 4.

socks4a

Specifies protocol support for SOCKS version 4A (like version 4, but with hostname support).

socks5

Specifies protocol support for SOCKS version 5 (with hostname and IPv6 support).

The default value specifies all available protocols.

dns-resolver

Specifies the dns-resolver object that will be used to resolve hostnames in connect requests. The default is dns-resolver.

ipv6 Specifies the relative order of IPv4 and IPv6 DNS resolutions for URIs. The default is no, which will try a IPv4 lookup before a IPv6.

tunnel-name

Specifies the tunnel that will be used for outbound connect requests. This enables other virtual servers to receive connections initiated by the proxy service. The default is socks-tunnel.

route-domain

Specifies the route-domain that will be used for outbound connect requests. The default is 0.

default-connect-handling

Specifies the behavior of the proxy service for connect requests. If set to deny, connect requests will only be honored if there is another virtual server listening for the requested outbound connection. If set to allow outbound connections will be made regardless of other virtual servers. The default is deny.

ltm profile splitsessionclient

NAME

splitsessionclient - Configures a Splitsessionclient profile.

MODULE

splitsessionclient profile

SYNTAX

Configure the splitsessionclient component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create splitsessionclient [name]

modify splitsessionclient [name]

options:

peer-ip
peer-port
http-header
local-peer
session-lookup-type

DISPLAY

list splitsessionclient
list splitsessionclient [[[name] | [glob] | [regex]] ...]
show running-config splitsessionclient
show running-config splitsessionclient [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

show splitsessionclient
show splitsessionclient [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global

DELETE

delete splitsessionclient [name]

DESCRIPTION

Use this command to create, modify, display, or delete a Splitsessionclient profile.

EXAMPLES

create splitsessionclient my_splitsessionclient_profile defaults-from splitsessionclient

OPTIONS

peer-ip

Specifies the IP address of the Splitsession peer that the Out-of-band connection is made to if the splitsession peer (server) is remote. There is no default value for this field. If the peer is remote, splitsession-default-serverssl and splitsession-default-tcp profiles are used by the Splitsession client for the encrypted Out-of-band channel. If the splitsession peer is local, this value must be any.

peer-port

Specifies the port of the Splitsession peer that the Out-of-band connection is made to if the peer is remote. There is no default value for this field. If the peer is remote, splitsession-default-serverssl and splitsession-default-tcp profiles are used by the Splitsession client for the encrypted Out-of-band channel. If the splitsession peer is local, this value must be 0.

http-header

Specifies the HTTP header for signaling between the splitsession client and server. The default value is none.

local-peer

Specifies if the splitsession peer is local or remote. The default value is remote.

session-lookup-type

Specifies the session DB lookup method type, including flow, session-flow and http-header. Lookup type flow uses the 5-tuple flow key as the index to lookup the session DB, session-flow uses 5-tuple flow key plus the splitsessionclient profile name, and http-header depends on an HTTP header value. The default value is flow.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is none.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, ltm profile fasthttp, ltm virtual, modify, regex, reset-stats, show, tmsh

COPYRIGHT

non-default-properties

one-line

partition

show splitsessionserver

show splitsessionserver [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

global

DELETE

delete splitsessionserver [name]

DESCRIPTION

Use this command to create, modify, display, or delete a Splitsessionserver profile.

EXAMPLES

create splitsessionserver my_splitsessionserver_profile defaults-from splitsessionserver

OPTIONS

listen-ip

Specifies the IP address that the Splitsession server listens on for the Out-of-band connection if the splitsession client is remote. There is no default value for this field. If the peer is remote, splitsession-default-clientssl and splitsession-default-tcp profiles are used by the Splitsession server for the encrypted Out-of-band channel. If the splitsession peer is local, this value must be any.

listen-port

Specifies the port that the Splitsession server listens on for the Out-of-band connection if the splitsession client is remote. There is no default value for this field. If the peer is remote, splitsession-default-clientssl and splitsession-default-tcp profiles are used by the Splitsession server for the encrypted Out-of-band channel. If the splitsession peer is local, this value must be 0.

http-header

Specifies the HTTP header for signaling between the splitsession client and server. The default value is none.

local-peer

Specifies if the splitsession peer is local or remote. The default value is remote.

splitsessionclient

Specifies splitsessionclient profile associated with this splitsessionserver in local deployment.

session-lookup-type

Specifies the session DB lookup method type, including flow, session-flow and http-header. Lookup type flow uses the 5-tuple flow key as the index to lookup the session DB, session-flow uses 5-tuple flow key plus the splitsessionclient profile name, and http-header depends on an HTTP header value. The default

value is flow.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is none.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

  non-default-properties

mv statistics [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]] ]
options:
  to-folder

reset-stats statistics
reset-stats statistics [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list statistics
list statistics [ [ [name] | [glob] | [regex] ] ... ]
show running-config statistics
show running-config statistics
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show statistics
show statistics [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete statistics [all | name]

```

DESCRIPTION

You can use the statistics component to create, modify, display, or delete a Statistics profile that provides user-defined statistical counters.

EXAMPLES

```
create statistics my_stats_profile defaults-from stats
```

Creates a Statistics profile name `my_stats_profile` that inherits all settings and values from the profile `stats`.

```
list statistics my_stats
```

Displays the configuration of the profile `my_stats`.

```
list statistics my_stats field1 total_users field2 current_users field3 max_users
```

Creates a Statistics profile named `my_stats` with a total users counter in Field 1 and a current users counter in Field 2. You can then write an iRule to count the total number of connections, and record the current number of connections.

For more information about writing and using iRules(r), see the F5 Networks DevCentral web site at <https://devcentral.f5.com/>.

```
mv statistics /Common/my_statistics_profile to-folder /Common/my_folder
```

Moves a custom statistics profile named `my_statistics_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `stats`.

description

User defined description.

field1 ... field32

Specifies the name of a counter. You can specify a counter for up to 32 fields. The default value for each field is none.

You can then write an iRule that uses the counter names to gather statistics about the traffic the system is processing.

glob Displays the items that match the glob expression. See help `glob` for a description of glob expression

syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

to-folder
statistics profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

ltm profile stream

NAME

stream - Configures a Stream profile.

MODULE

ltm profile

SYNTAX

Configure the stream component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create stream [name]

modify stream [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

source [none | [string]]

target [none | [string]]

chunking-enabled [disabled | enabled]

chunk-size [integer]

edit stream [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

mv stream [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

reset-stats stream

reset-stats stream [[[name] | [glob] | [regex]] ...]

DISPLAY

list stream

list stream [[[name] | [glob] | [regex]] ...]

show running-config stream

show running-config stream

[[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

show stream

show stream [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global

DELETE
delete stream [name]

DESCRIPTION

You can use the stream component to search and replace strings within a data stream, such as a TCP connection.

EXAMPLES

create stream my_stream_profile defaults-from stream

Creates a custom Stream profile named my_stream_profile that inherits its settings from the system default stream profile.

list stream all-properties

Displays all properties for all Stream profiles.

mv stream /Common/my_stream_profile to-folder /Common/my_folder

Moves a custom stream profile named my_stream_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is stream.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

source

Specifies the string that you want to rewrite. The default value is none.

target

Specifies the new string, to replace the source string. The default value is none.

chunking

Specifies that the stream processor should parse incoming data in chunks. This restricts the maximum amount of additional memory needed by the stream processor. It also limits the maximum length of the value that can be matched to the chunk-size. The default value is disabled.

chunk-size

The maximum size of the parsed chunk.

to-folder

stream profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

show tcp-analytics [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global

DELETE

delete tcp-analytics [name]

DESCRIPTION

You can use the tcp-analytics component to generate detailed TCP statistics for virtuals that have a TCP or FastL4 profile, if AVR is provisioned. The options specify where the data is collected and stored, and which connection identifiers ("entities") users can query the data with.

In general, storing more entities increases the ability to drill down to specific connections. However, if AVR hits its memory limits it will begin to aggregate new connections and reduce this resolution. If a virtual serves a very high number of IP addresses, for example, it is best to store data using collect-remote-host-subnet, or use the TCP::analytics iRule to enhance collection for a set of IP addresses of interest.

The system installation includes the default profile tcp-analytics. You can modify the settings of this profile, or create new TCP analytics profiles using it as a parent profile.

EXAMPLES

create Itm profile tcp-analytics my_tcpanalytics_profile defaults-from tcp-analytics

Creates a custom TCP profile named my_tcpanalytics_profile that inherits its settings from the system default tcp-analytics profile.

list Itm profile tcp-analytics all-properties

Displays all properties for all TCP profiles

OPTIONS

collected-by-client-side

When enabled, client side connections collect TCP analytics data unless directed otherwise by iRule. If false, client side connections only collect data if directed by iRule. The default value is enabled.

collected-by-server-side

When enabled, server side connections collect TCP analytics data unless directed otherwise by iRule. If false, server side connections only collect data if directed by iRule. The default value is disabled.

collected-stats-external-logging

When enabled, TCP statistics are logged on a remote machine determined by external-logging-publisher. The default value is disabled.

collected-stats-internal-logging

When enabled, TCP statistics are logged on the local BIG-IP. The default value is enabled.

collect-city

When enabled, AVR stores the city (from the GeoIP database) for the remote IP address of the connection with TCP statistics. See SOL11176 on support.f5.com for more on GeoIP. The default value is disabled.

collect-continent

When enabled, AVR stores the continent (from the GeoIP database) for the remote IP address of the connection with TCP statistics. See SOL11176 on support.f5.com for more on GeoIP. The default value is enabled.

collect-country

When enabled, AVR stores the country (from the GeoIP database) for the remote IP address of the connection with TCP statistics. See SOL11176 on support.f5.com for more on GeoIP. The default value is enabled.

collect-nexthop

When enabled, AVR stores the nexthop ethernet address of the connection with TCP statistics. The default value is disabled.

collect-post-code

When enabled, AVR stores the postcode (from the GeoIP database) for the remote IP address of the connection with TCP statistics. See SOL11176 on support.f5.com for more on GeoIP. The default value is disabled.

collect-region

When enabled, AVR stores the region (from the GeoIP database) for the remote IP address of the connection with TCP statistics. See SOL11176 on support.f5.com for more on GeoIP. The default value is disabled.

collect-remote-host-ip

When enabled, AVR stores the remote host IP address with TCP statistics. The default value is disabled.

collect-remote-host-subnet

When enabled, AVR stores the remote host IP subnet (24-bit) with TCP statistics. The default value is enabled.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is tcp-analytics.

description

User defined description.

external-logging-publisher

The name of the publisher to accept external logging.

DESCRIPTION

You can use the tcp component to manage TCP network traffic. Many of the options are standard SYSCTL-types of options, while others are unique to the traffic management system. For most of the options, the default values usually meet your needs. The specific options that you might want to change are: reset-on-timeout, idle-timeout, ip-tos-to-client, and link-qos-to-client.

The system installation includes these default TCP-type profiles: tc, tcp-cell-optimized, tcp-lan-optimized, and tcp-wan-optimized. You can modify the settings of these profiles, or create new TCP-type profiles using any of these existing profiles as parent profiles.

EXAMPLES

```
create tcp my_tcp_profile defaults-from tcp
```

Creates a custom TCP profile named my_tcp_profile that inherits its settings from the system default tcp profile.

```
list tcp all-properties
```

Displays all properties for all TCP profiles

OPTIONS

abc When enabled, increases the congestion window by basing the increase amount on the number of previously unacknowledged bytes that each acknowledgement code (ACK) includes. The default value is enabled.

ack-on-push

When enabled, significantly improves performance to Microsoft(r) Windows(r) and MacOS peers, who are writing out on a very small send buffer. The default value is enabled.

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

auto-proxy-buffer-size

Specifies, when enabled, that the system uses the network measurements to set the optimal proxy buffer size. The default value is disabled.

auto-receive-window-size

Specifies, when enabled, that the system uses the network measurements to set the optimal receive window size. The default value is disabled.

auto-send-buffer-size

Specifies, when enabled, that the system uses the network measurements to set the optimal send buffer size. The default value is disabled.

close-wait-timeout

Specifies the number of seconds that a connection remains in a LAST-ACK (last acknowledgement code) state before quitting. A value of 0 (zero) represents a term of forever (or until the maxrtx of the FIN state). The default value is 5 seconds.

cmetrics-cache

Specifies, when enabled, the default value, that the system uses a cache for storing congestion metrics.

cmetrics-cache-timeout

Specifies the time, in seconds, for which entries in the congestion metrics cache are valid. The default

value is 0, which defers to the sys db variable route.metrics.timeout.

congestion-control

Specifies the algorithm to use to share network resources among competing users to reduce congestion. The default value is high-speed.

The options are:

bbr Specifies that the system uses an implementation of the BBR congestion control algorithm, which uses connection's maximum delivery rate (bottleneck bandwidth) and minimum round trip time to avoid growing buffers and path delay.

cdg Specifies that the system use a Caia Delay-Gradient congestion control algorithm, where congestion inferences are made based on a gradient of RTT over time. Improves inferences made about packet loss and whether they are due to congestion or other factors. The use of a shadow window improves coexistence with loss-based TCP flows.

chd Specifies that the system use a Caia-Hamilton delay-based congestion control algorithm, where delay-based congestion window operations are performed only once per RTT. Tolerates packet losses that are likely to be unrelated to congestion. Uses a shadow window to help regain lost transmission opportunities when competing with loss-based TCP flows.

cubic Specifies that the system uses a component optimized for high latency, high bandwidth connections as the TCP congestion control algorithm.

high-speed

Specifies that the system uses a more aggressive, loss-based algorithm.

illinois

Specifies that the system uses a hybrid of both delay and loss as the TCP congestion control algorithm.

new-reno

Specifies that the system uses a modification to the Reno algorithm that responds to partial acknowledgements when SACKs are unavailable.

none

Specifies that the system does not use a network-congestion-control mechanism, even when congestion occurs.

reno

Specifies that the system uses an implementation of the TCP Fast Recovery algorithm, which is based on the implementation in the BSD Reno release.

scalable

Specifies that the system uses a TCP algorithm modification that adds a scalable, delay-based and loss-based component into the Reno algorithm.

vegas

Specifies that the system uses a delay-based component as the TCP congestion control algorithm.

westwood

Specifies that the system uses the Westwood+ bandwidth estimation component as the TCP congestion control algorithm.

woodside

Specifies that the system uses a hybrid of both delay and loss as the TCP congestion control algorithm.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is tcp.

deferred-accept

Specifies, when enabled, that the system defers allocation of the connection chain context until the system has received the payload from the client. This option is useful for dealing with 3-way handshake denial-of-service (DOS) attacks. The default value is disabled.

delay-window-control

When enabled, the system uses an estimate of queueing delay as a measure of congestion, in addition to the normal loss-based control, to control the amount of data sent. The default value is disabled.

delayed-acks

Specifies, when enabled, the default value, that the traffic management system allows coalescing of multiple acknowledgement (ACK) responses.

description

User defined description.

dsack

When enabled, specifies the use of the SACK option to acknowledge duplicate segments. The default is disabled.

early-retransmit

Specifies, when enabled, that the system uses early retransmit recovery (as specified in RFC 5827) to reduce the recovery time for connections that are receive-buffer or user-data limited. The default value is enabled.

ecn

Specifies, when enabled, that the system uses the TCP flags CWR and ECE to notify its peer of congestion and congestion counter-measures. The default value is enabled.

enhanced-loss-recovery

Specifies whether the system uses enhanced loss recovery to recover from random packet losses more effectively. The default value is enabled.

fast-open

Specifies, when enabled, that the system supports TCP Fast Open, which allows a client to include the first packet of data with the SYN to reduce latency. The default value is enabled. This option has no effect on server-side TCP profiles.

fast-open-cookie-expiration

Specifies the number of seconds that a "Fast Open Cookie" delivered to a client is valid for SYN packets from that client. The default value is 21600 seconds (6 hours). A value of 0 (zero) means use the default. The maximum value is 1000000 seconds.

fin-wait-timeout

Specifies the number of seconds that a connection is in the FIN-WAIT-1 or closing state before quitting. The default value is 5 seconds. A value of 0 (zero) represents a term of forever (or until the maxrtx of the FIN state).

fin-wait-2-timeout

Specifies the number of seconds that a connection is in the FIN-WAIT-2 state before quitting. The default value is 300 seconds. A value of 0 (zero) represents a term of forever (or until the maxrtx of the FIN state).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hardware-syn-cookie

This option is deprecated in version 13.0.0 and is replaced by syn-cookie-enable. Specifies whether or not to use hardware SYN Cookie when cross system limit. The default value is enabled.

idle-timeout

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 300 seconds.

init-cwnd

Specifies the initial congestion window size for connections to this destination. The actual window size is this value multiplied by the MSS (Maximum Segment Size) for the same connection. The default value is 10. The range is from 0 to 64.

init-rwnd

Specifies the initial receive window size for connections to this destination. The actual window size is this value multiplied by the MSS (Maximum Segment Size) for the same connection. The default value is 10. The range is from 0 to 64.

ip-df-mode

Describe the IP Header Don't Fragment (DF) bit setting in the outgoing TCP packet. The available settings are: Pmtu: Set the outgoing IP Header DF bit based on IP pmtu setting(tm.pathmtudiscovery). Preserve: Set the outgoing Packet's IP Header DF bit to be same as incoming IP Header DF bit. Set: Set the outgoing packet's IP Header DF bit. Clear: Clear the outgoing packet's IP Header DF bit. The default setting is Pmtu.

ip-ttl-mode

Describe the outgoing TCP packet's IP Header TTL mode. The available Modes are: Proxy: Set the outgoing IP Header TTL value to 255/64 for ipv4/ipv6 respectively. Preserve: Set the outgoing IP Header TTL value to be same as the incoming IP Header TTL value. Decrement: Set the outgoing IP Header TTL value to be one less than the incoming TTL value. Set: Set the outgoing IP Header TTL value to a specific value(as specified by ip-ttl-v[4|6]). The default mode is Proxy.

ip-ttl-v4

Specify the outgoing packet's IP Header TTL value for IPv4 traffic. Maximum TTL value that can be specified is 255. The default is 255.

ip-ttl-v6

Specify the outgoing packet's IP Header TTL value for IPv6 traffic. Maximum TTL value that can be specified is 255. The default is 64.

ip-tos-to-client

Specifies the Type of Service (ToS) level that the traffic management system assigns to TCP packets when sending them to clients. The default value is 0 (zero).

keep-alive-interval

Specifies the keep-alive probe interval, in seconds. The default value is 1800 seconds.

limited-transmit

Specifies, when enabled, the default value, that the system uses limited transmit recovery revisions for fast retransmits (as specified in RFC 3042) to reduce the recovery time for connections on a lossy network.

link-qos-to-client

Specifies the Link Quality of Service (QoS) level that the system assigns to TCP packets when sending them to clients. The default value is 0 (zero).

max-retrans

Specifies the maximum number of retransmissions of data segments that the system allows. The default value is 8.

max-segment-size

Specifies the largest amount of data that the system can receive in a single TCP segment, not including the TCP and IP headers. If the value is 0 (zero), the system calculates the value from the MTU. The default value is 1460 bytes.

md5-signature

Specifies, when enabled, that the system uses RFC2385 TCP-MD5 signatures to protect TCP traffic against intermediate tampering. The default value is disabled.

md5-signature-passphrase

Specifies a plain text passphrase which may be between 1 and 80 characters in length, and is used in a shared-secret scheme to implement the spoof-prevention parts of RFC2385. The default value is none.

minimum-rto

Specifies the minimum TCP retransmission timeout in milliseconds. The default value is 1000 milliseconds.

mptcp

Specifies, when enabled, that the system will accept MPTCP connections. When passthrough MPTCP connections are not terminated by this virtual. The default value is disabled.

mptcp-csum

Specifies, when enabled, that the system will calculate the checksum for MPTCP connections. The default value is disabled.

mptcp-csum-verify

Specifies, when enabled, that the system verifies checksum for MPTCP connections. The default value is disabled.

mptcp-debug

This option is DEPRECATED v12.0.0 onwards and is maintained here for backward compatibility reasons. Specifies, when enabled, that the system provides debug logs and statistics for MPTCP connections. The default value is disabled.

mptcp-fallback

Specifies, MPTCP fallback mode. The default value is reset.

The options are:

accept

Specifies accept on fallback.

active-accept

Specifies active accept on fallback.

reset

Specifies that the connection is reset on fallback.

retransmit

Specifies retransmit on fallback.

mptcp-join-max

Specifies the max number of MPTCP connections that can join to given one. The default value is 5.

mptcp-nojoindssack

Specifies, when enabled, no DSS option is sent on the JOIN ACK. The default value is disabled.

mptcp-rtomax

Specifies, the number of RTOs before declaring subflow dead. The default value is 5.

mptcp-rxmitmin

Specifies the minimum value (in msec) of the retransmission timer for these MPTCP flows. The default value is 1000.

mptcp-subflowmax

Specifies the maximum number of MPTCP subflows for a single flow. The default value is 6.

mptcp-makeafterbreak

Specifies, when enabled, that make-after-break functionality is supported, allowing for long-lived MPTCP sessions. The default value is disabled.

mptcp-timeout

Specifies, the timeout value to discard long-lived sessions that do not have an active flow, in seconds. The default value is 3600.

mptcp-fastjoin

Specifies, when enabled, FAST join, allowing data to be sent on the MP_JOIN SYN, which can allow a server response to occur in parallel with the JOIN. The default value is disabled.

nagle

Specifies, when enabled, that the system applies Nagle's algorithm to reduce the number of short segments on the network. The default value is disabled. When auto, the use of Nagle's algorithm is decided based on network conditions.

Note that for interactive protocols such as Telnet, rlogin, or SSH, F5 Networks recommends disabling this setting on high-latency networks, to improve application responsiveness.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the profile resides.

pkt-loss-ignore-burst
Specifies the probability of performing congestion control when multiple packets in a row are lost, even if the pkt-loss-ignore-rate was not exceeded. Valid values are 0 (zero) through 32. The default value is 0 (zero), which means that the system performs congestion control, if any packets are lost. Higher values decrease the chance of performing congestion control.

pkt-loss-ignore-rate
Specifies the threshold of packets lost per million at which the system should perform congestion control. Valid values are 0 (zero) through 1,000,000. The default value is 0 (zero), which means that the system performs congestion control, if any packet loss occurs. If you set the ignore rate to 10 and packet loss for a TCP connection is greater than 10 per million, congestion control occurs.

proxy-buffer-high
Specifies the highest level at which the receive window is closed. The default value is 131072.

proxy-buffer-low
Specifies the lowest level at which the receive window is closed. The default value is 98304.

proxy-mss
Specifies, when enabled, that the system advertises the same TCP maximum segment size to the server as was negotiated with the client. The setting is ignored when MRF routing (e.g., httprouter, siprouter, diameterrouter, mqttrouter, messagerouter) is used. The default value is enabled.

proxy-options
Specifies, when enabled, that the system advertises an option, such as a time-stamp to the server only if it was negotiated with the client. The setting is ignored when MRF routing (e.g., httprouter, siprouter, diameterrouter, mqttrouter, messagerouter) is used. The default value is disabled.

push-flag
When default, specifies that the system sets PUSH flag when sending the last segment in the send buffer. When none, specifies that the system never sets PUSH flag for TCP packets. When one, specifies that the system sets one PUSH flag for the FIN segment. When auto, specifies that the system sets PUSH flag based on the application/network conditions. The default value is default.

rate-pace
Specifies, when enabled, that the system will rate pace TCP data transmissions. The default value is enabled.

rate-pace-max-rate
If not 0, sets the maximum rate in bytes per second that TCP data transmission will be paced to. If set to 0, no maximum is enforced. The default value is 0.

receive-window-size
Specifies the size of the receive window, in bytes. The default value is 65535 bytes.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout
Specifies whether to reset connections on timeout. The default value is enabled.

rexmt-thresh
Specifies the number of duplicate ACKs (retransmit threshold) to start fast recovery. The default value is 3. The range is from 3 to 255.

selective-acks
Specifies, when enabled, the default value, that the system negotiates RFC2018-compliant Selective Acknowledgements with peers.

selective-nack
Specifies whether Selective Negative Acknowledgment is enabled or disabled. The default value is disabled.

send-buffer-size
Specifies the size of the buffer, in bytes. The default value is 131072 bytes.

slow-start
Specifies, when enabled, the default value, that the system uses larger initial window sizes (as specified in RFC 3390) to help reduce round trip times. Note that disabling this attribute causes the setting for cmetrics-cache to be ignored.

syn-cookie-enable
Specifies the default (if no DoS profile is associated) number of embryonic connections that are allowed on any virtual server, before SYN Cookie challenges are enabled for that virtual server. The default is enabled.

syn-cookie-whitelist
Specifies whether or not to use a SYN Cookie WhiteList when doing software SYN Cookies. This means not doing a SYN Cookie for the same src IP address if it has been done already in the previous

tm.flowstate.timeout (30) seconds. The default value is disabled.

syn-max-retrans

Specifies the maximum number of retransmissions of SYN segments that the system allows. The default value is 3.

syn-rto-base

Specifies the initial RTO (Retransmission TimeOut) base multiplier for SYN retransmission, in milliseconds. This value is modified by the exponential backoff table to select the interval for subsequent retransmissions. The default value is 3000.

tail-loss-probe

Specifies whether the system uses tail loss probe to reduce the number of retransmission timeouts. The default value is enabled.

tcp-options

Specifies the option numbers that will be accessible from iRules (TCP::option) for the flow. The format of each entry should be: "{

ltm profile tftp

NAME

tftp - Configures a TFTP profile.

MODULE

ltm profile

SYNTAX

Configure the tftp component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create tftp [name]

modify tftp [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

idle-timeout [integer]

log-publisher [log publisher name | none]

log-profile [log profile name | none]

mv tftp [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

edit tftp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list tftp

list tftp [[[name] | [glob] | [regex]] ...]

show running-config tftp

show running-config tftp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete tftp [name]

DESCRIPTION

Use this command to create, modify, display, or delete an TFTP profile with which you can manage TFTP traffic.

EXAMPLES

create tftp my_tftp_profile defaults-from tftp

Creates a custom TFTP profile named my_tftp_profile that inherits its settings from the system default TFTP profile.

list tftp

Displays the properties of all TFTP profiles.

mv tftp /Common/my_tftp_profile to-folder /Common/my_folder

Moves a custom tftp profile named `my_tftp_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `tftp`.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an `@` sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`to-folder`

tftp profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

`idle-timeout`

Specifies an idle timeout in seconds. This setting specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 300 seconds.

`log-publisher`

Specify the name of the log publisher which logs translation events. See help `sys log-config` for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

`log-profile`

Specify the name of the ALG log profile which controls the logging of ALG events. See help `ltm alg-log-profile` for more details on the logging profile sub-system. Use the "ltm alg-log-profile profile" component to set up an ALG log profile.

DELETE
delete traffic-acceleration [name]

DESCRIPTION

You can use this component to create, modify, display, or delete a Traffic Acceleration profile.

Any changes you make to an active Traffic Acceleration profile (one that is in use by a virtual server) take effect after the value of the idle-timeout option has passed. That means new connections are affected by the profile change immediately. However, for the new values to take effect, old connections need to be either aged out or closed.

EXAMPLES

create traffic-acceleration my_profile defaults-from traffic-acceleration

Creates a custom Traffic Acceleration profile named my_profile that inherits its settings from the system default Traffic Acceleration profile.

show traffic-acceleration

Displays statistics for all Traffic Acceleration profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is traffic-acceleration.

description

User defined description.

idle-timeout

Specifies the number of milliseconds that a connection is idle before the connection is eligible for deletion. The default value is five minutes or 300000 milliseconds. Minimum is 0 meaning the connection does not timeout. The maximum is 2147483647 (0x7FFFFFFF) milliseconds.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

tcp-handshake-timeout

Specifies a TCP handshake timeout in milliseconds. The default value is 5000 milliseconds. Minimum is 0 meaning there is no timeout. The maximum is 65535 milliseconds.

time-wait-timeout

Specifies a TCP time_wait timeout in milliseconds. The default value is 2000 milliseconds. The minimum is 1 millisecond. The maximum is 65535 milliseconds.

DELETE

delete udp [name]

DESCRIPTION

You can use the udp component to manage UDP network traffic.

EXAMPLES

create udp my_udp_profile defaults-from udp

Creates a custom UDP profile named `my_udp_profile` that inherits its settings from the system default UDP profile.

`list udp all-properties`

Displays all properties for all UDP profiles.

`mv udp /Common/my_udp_profile to-folder /Common/my_folder`

Moves a custom udp profile named `my_udp_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`allow-no-payload`

Provides the ability to allow the passage of datagrams that contain header information, but no essential data. The default is disabled.

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`buffer-max-bytes`

Specifies ingress buffer byte limit. The default value is 655350. Maximum allowed value is 16777215.

`buffer-max-packets`

Specifies ingress buffer packet limit. The default value is 0. Maximum allowed value is 255.

`datagram-load-balancing`

Provides the ability to load balance UDP datagram by datagram. The default is disabled.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is `udp`.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`idle-timeout`

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 60 seconds.

`ip-tos-to-client`

Specifies the Type of Service level that the traffic management system assigns to UDP packets when sending them to clients. The default value is 0 (zero).

`ip-ttl-mode`

Describe the outgoing UDP packet's TTL mode. Modes are: Proxy: Set the IP TTL of ipv4 to the default value of 255 and ipv6 to the default value of 64. Preserve: Set the IP TTL to the original packet TTL value. Decrement: Set the IP TTL to the original packet TTL value minus 1. Set: Set the IP TTL with the specified values in `ip-ttl-v4` and `ip-ttl-v6` values in the same profile.

`ip-df-mode`

Describe the Don't Fragment (DF) bit setting in the outgoing UDP packet. Pmtu: Set the outgoing UDP packet DF big based on the ip pmtu setting. Preserve: Preserve the incoming UDP packet Don't Fragment bit. Set: Set the outgoing UDP packet DF bit. Clear: Clear the outgoing UDP packet DF bit.

`link-qos-to-client`

Specifies the Quality of Service level that the system assigns to UDP packets when sending them to clients. The default value is 0 (zero).

`name` Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

`no-checksum`

Enables or disables checksum processing. Note that if the datagram is IPv6, the system always performs checksum processing. The default value is disabled.

`partition`

Displays the administrative partition within which the profile resides.

`proxy-mss`

Specifies, when enabled, that the system advertises the same mss to the server as was negotiated with the client. The default value is disabled.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an `@` sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`send-buffer-size`

Specifies send buffer byte limit. The default value is 655350. The range is from 536 to 16777215.

to-folder
udp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

```

```

DELETE
delete web-acceleration [name]

```

DESCRIPTION

You can use the web-acceleration component to create, modify, display, or delete an Web Acceleration profile.

The BIG-IP(r) system installation includes the following default Web Acceleration-type profiles:

```

web-acceleration
optimized-caching
optimized-acceleration

```

The default Web Acceleration profile contains values for properties related to managing WA Cache.

You can create a new Web Acceleration-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

```
create web-acceleration my_wa_profile defaults-from web-acceleration
```

Creates a custom Web Acceleration profile named my_wa_profile that inherits its settings from the system default Web Acceleration profile.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

cache-aging-rate

Specifies how quickly the system ages a cache entry. The aging rate ranges from 0 (slowest aging) to 10 (fastest aging). The default value is 9.

cache-client-cache-control-mode

Specifies which cache disabling headers sent by clients the system ignores. The default value is all.

cache-insert-age-header

When enabled, inserts Age and Date headers in the response. The default value is enabled.

cache-max-age

Specifies how long the system considers the cached content to be valid. The default value is 3600 seconds.

cache-max-entries

Specifies the maximum number of entries that can be in the WA cache. The default value is 10000.

cache-object-max-size

Specifies the largest object that the system considers eligible for caching. The default value is 50000 bytes.

cache-object-min-size

Specifies the smallest object that the system considers eligible for caching. The default value is 500 bytes.

cache-size

Specifies the maximum size, in megabytes, for the WA cache. When the cache reaches the maximum size, the system starts removing the oldest entries. The default value is 100 megabytes.

cache-uri-exclude

Configures a list of Uniform Resource Identifiers (URIs) to exclude from the WA Cache. The default value is none and specifies that no URI will be excluded.

cache-uri-include

Configures a list of URIs that are cacheable. The default value is .* and specifies that all URIs are cacheable.

cache-uri-include-override

Configures a list of URIs that should be cached in the WA cache even though they would normally not be cached due to constraints defined by cache-object-max-size or others. The default value is none. URIs on the cache-uri-include-override list are cacheable even if they are not on the cache-uri-include list.

cache-uri-pinned

Configures a list of URIs that are kept in the WA cache regardless their max-age or expiry settings. The default value is none. URIs on the cache-uri-pinned list are cacheable even if they are not on the cache-uri-include list.

defaults-from

Configures the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is webacceleration.

description

User defined description.

partition

Displays the administrative partition within which the profile resides.

Itm profile websocket

NAME

websocket - Configures a WebSocket protocol profile.

MODULE

websocket profile

SYNTAX

Configure the websocket component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create websocket [name]
modify websocket [name]
options:
masking [preserve | unmask | remask | selective]
compress-mode [preserved | typed]
compression [enabled | disabled]

window-bits [integer]
no-delay [enabled | disabled]

edit websocket [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

mv websocket [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-
folder [folder-name]]]
options:
to-folder

reset-stats websocket
reset-stats websocket [[[name] | [glob] | [regex]] ...]

DISPLAY
list websocket
list websocket [[[name] | [glob] | [regex]] ...]
show running-config websocket
show running-config websocket [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

show websocket
show websocket [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global

DELETE
delete websocket [name]

DESCRIPTION
Use this command to create, modify, display, or delete a WebSocket profile.

EXAMPLES
create websocket my_websocket_profile defaults-from websocket

OPTIONS
masking
Specifies the masking operation for WebSocket frames.

preserve
Maintains the mask of the packet received from the client.

unmask
Removes the mask from the packet and remasks it using the same mask when sending the traffic to the server.

remask
Removes the mask received from the client and the system generates a new, random mask when sending the traffic to the server.

selective
Preserves the mask of the packet received, and makes no changes unless an Application Security Policy is associated with the virtual server.

compress-mode
Specifies the mode that controls what compression operations are performed. The default value is preserved.

preserved
No compression or decompression operations are performed in this mode.

typed
The compression parameter controls whether compression is negotiated with the endpoint. Compressed data received from the endpoint is decompressed thereby enabling security policies to take actions on cleartext data. Data maybe recompressed before being masked and sent on the wire.

= over 5

compression
Specifies whether compression will be negotiated with the endpoint. The default value is enabled.

window-bits
Specifies the maximum sliding window for compression negotiated with the endpoint. The default value is 10.

no-delay
Specifies whether data should be buffered for efficient compression, or compressed without delay. The default value is enabled.

= back

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is none.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression

syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, ltm profile fasthttp, ltm virtual, modify, regex, reset-stats, show, tmsh

ltm profile xml

NAME

xml - Configures an XML profile.

MODULE

ltm profile

SYNTAX

Configure the xml component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create xml [name]

modify xml [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

namespace-mappings [[none] |

[{ { mapping-namespace namespace1 mapping-prefix prefix1 } }]

xpath-queries [none |

[add | delete | replace_all_with { queries }]]

multiple-query-matches [enabled | disabled]

edit xml [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

mv xml [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]

options:

to-folder

DISPLAY

list xml

list xml [[[name] | [glob] | [regex]] ...]

show running-config xml

show running-config xml [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete xml [name]

DESCRIPTION

Use this command to create, modify, display, or delete an XML profile with which you can use XML functionality.

EXAMPLES

create xml my_xml_profile defaults-from xml

Creates a custom XML profile named my_xml_profile that inherits its settings from the system default XML profile.

list xml

Displays the properties of all XML profiles.

mv xml /Common/my_xml_profile to-folder /Common/my_folder

Moves a custom xml profile named my_xml_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is xml.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

namespace-mappings

Specifies a list of mappings between namespaces and prefixes to be used in the XPath queries of the profile.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

to-folder

xml profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

xpath-queries

Specifies the list of XPath queries that are used by the profile. A match of any of the queries will trigger the XML_CONTENT_BASED_ROUTING iRule event.

multiple-query-matches

Enables or disables multiple matches for a single XPath query.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, mv, regex, reset-stats, show, tmsh

BIG-IP 2014-01-07 ltm profile xml(1)

ltm rule-profiler

MODULE

ltm

SYNTAX

Configure the rule-profiler component within the ltm module using the syntax shown in the following sections.

```
CREATE/MODIFY
create rule-profiler [name]
modify rule-profiler [ [name] ... ]
```

```
DISPLAY
list rule-profiler
list rule-profiler [ [ [name] | [glob] | [regex] ] ... ]
```

```
DELETE
delete rule-profiler [name]
```

```
HELP help rule-profiler
```

DESCRIPTION

You can use the rule-profiler component to configure execution tracing of iRules attached to virtual servers. A rule-profiler comprises a set of matching filters that help limit the profiling information output, a log publisher that directs the output to the intended destination and properties for controlling the state of the profiler and the amount of time the profiler will be active for.

EXAMPLES

```
list rule-profiler
```

Displays all iRule Profiler objects.

```
delete rule-profiler my_profiler
```

Deletes the iRule Profiler named my_profiler.

```
rule-profiler my_profiler {
vs-filter { vs_test }
rule-filter { rl_http }
event-filter { HTTP_REQUEST }
```

```
period 1000
publisher my_tracer_pub
occ-mask 30
state disabled
}
```

Creates an iRule Profiler named my_profiler.

```
modify rule-profiler my_profiler state enabled
```

Enables the rule-profiler causing matching profiling occurrences to be published by the publisher associated with the rule-profiler.

OPTIONS

```
description
User defined description.
```

```
period
Specifies the period (in milliseconds) that a rule-profiler can be active for. When set to 0, the profiler is disabled. Default value is 0.
```

```
state
Specifies the state of the rule-profiler. When set to enabled and the profiler consequently started, matching occurrence records are emitted via the configured log publisher. Default value is disabled.
```

```
start
Start profiling. After this command, at the point of the first filter match, profiling and timer counting start.
```

```
stop
Stop profiling. After this command, the profiling stops.
```

```
vs-filter
Specifies the name of virtual server(s) for which occurrence records can be emitted. If this property is left empty, all virtual servers will be considered a match. Default is empty list.
```

```
rule-filter
Specifies the name of iRule(s) for which occurrence records can be emitted. If this property is left empty, all executing iRules will be considered a match. Default is empty list.
```

```
event-filter
Specifies the name of iRule Events for which occurrence records can be emitted. If this property is left empty, all iRule Events will be considered a match. Default is empty list.
```

```
occ-mask
Specifies the types of occurrences of interest to the user. This is a value set comprised by adding the desired occurrence type. The types are defined as follows:
```

```
Â· event
```

Specifies that profiling information is emitted at the entry point to the TCL subsystem, as close as possible to the occurrence of the external event, and at completion of the execution, just before the TCL subsystem returns to the LTM profile/filter code.

Â· rule

Specifies that profiling information is emitted at the entry point to the execution of a single iRule handler for the event, and once the TCL VM completes execution of the single event handler. This bit is useful when there are multiple rules handling the same event.

Â· rule-vm

Specifies that profiling information is emitted once the TCL VM is about to execute the byte code for an iRule script, and once it completed executing the byte code.

Â· cmd-vm

Specifies that profiling information is emitted when the TCL VM is beginning the internal setup preceding the invocation of a TCL command (eg. HTTP::uri) and once the internal setup is being torn down.

Â· cmd

Specifies that profiling information is emitted once the TCL VM is about to invoke a TCL command (eg. HTTP::uri) and once the command execution completes.

Â· var-mod

Specifies that profiling information is emitted when the TCL VM is changing the value of an iRule variable.

Â· bytecode

Specifies that profiling information is emitted when the TCL VM is executing a byte code instruction.

SEE ALSO

create, delete, list, modify, tmsh

BIG-IP 2017-05-12 Itm rule-profiler(1)

Itm rule

NAME

rule - Configures an iRule for traffic management system configuration.

MODULE

itm

SYNTAX

Configure the rule component within the Itm module using the syntax shown in the following sections.

CREATE/MODIFY

create rule [name]

edit rule [name]

modify rule [[[name] | [glob] | [regex]] ...]

Note: When using tmsh, you can only create iRules using the editor, which starts when you use the create or edit commands. You cannot create an iRule directly on the command line. The vim editor applies the autoindent and smartindent options. You can toggle on/off paste mode using the F12 key.

Note: You can also edit user metadata associated with an iRule. See the example section for more information.

DISPLAY

list rule

list rule [[[name] | [glob] | [regex]] ...]

show running-config rule

show running-config rule [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

show rule

show rule [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

```
mv rule [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]] ]
options:
  to-folder
```

DELETE
delete rule [name]

GENERATE
generate rule [name]
options:
 checksum
 signature

HELP help rule help rule [command | event | namespace] [name]
DESCRIPTION

You cannot edit the system rules that come with the BIG-IP system. However, you can open a system rule in the editor and use it as a template to create a new rule.

To create a new rule using a system rule as a template:

1. Enter the command sequence edit rule [system rule name].
tmsh opens the system rule in an editor.
 2. Change the name of the rule in the editor.
 3. Edit the rule and exit the editor.
- tmsh checks for syntax errors, and if there are none, it saves the new rule.

For more information about iRules(r), see <http://devcentral.f5.com/>.

EXAMPLES

list rule

Displays all iRules.

delete rule my_irule

Deletes the iRule named my_irule.

```
rule my_irule {
when RULE_INIT {
}
priority 1

when SERVER_CONNECTED {
}
timing on
check strict
}
```

Creates an iRule named my_irule.

generate rule my_irule checksum

Generates a checksum for the rule definition and adds the checksum to the rule.

generate rule my_irule signature signing-key my_key

Generates a signature for the rule definition using the specified private key and adds the signature to the rule.

Note: For a rule that includes a checksum or signature to successfully load, the rule definition contents must match the stored checksum or signature. To modify the rule definition and still retain the checksum or signature, the ignore-verification attribute must be set to true. This is done by editing the rule and adding the ignore-verification attribute, which allows the modified rule to load and changes the verification status to Not Verified:

```
rule my_irule {
when RULE_INIT {}
definition-checksum 7c0dba9aa53e8959042c6cfe041d3d11
ignore-verification true }
```

Modifies an existing iRule named my_irule by adding a new metadata and modifying an existing metadata:

```
modify rule my_irule {
when RULE_INIT {}
definition-checksum 7c0dba9aa53e8959042c6cfe041d3d11
metadata replace-all-with {
  my_meta { _persist false
    value "hello"
  }
  my_meta2 { _persist false
    value "hello 2"
  }
}
```

The metadata attribute is the user defined key/value pair. Metadata has the following format:

```
metadata
[add | delete | modify] {
  [metadata_name] {
    value [ "value content" ]
    persist [ true | false ]
  } }>
```

Deletes a metadata from an iRule:

```
modify rule my_irule {
when RULE_INIT {}
definition-checksum 7c0dba9aa53e8959042c6cfe041d3d11
metadata delete { my_meta } }
```

```
mv /ltm rule /Common/my_rule to-folder /Common/some_folder
```

Moves an iRule named my_rule to the folder named some_folder, where some_folder has already been created under /Common.

Note: Please note that you may not move an iRule that has an explicit usage of a configuration object, such as a pool.

OPTIONS

checksum

Generates a checksum for the rule definition and adds the checksum to the rule. This option is used only with the generate command.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the create, delete, and modify commands.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

signature

Generates a signature for the rule definition using the specified private key and adds the signature to the rule as a property. This option is used only with the generate command.

signing-key

Specifies the private key to use for signing the rule. This is used only with the signature option.

meta-data

Specifies the user-defined key/value pair associated with the rule. See the example section for usage format.

app-project

Specifies the dev plugin this rule belongs to. This is a read-only attribute.

SEE ALSO

ltm snat-translation

NAME

snat-translation - Configures an explicit secure network address translation (SNAT) translation address.

MODULE

ltm

SYNTAX

Configure the snat-translation component within the ltm module using the syntax shown in the following sections.

CREATE/MODIFY

```

create snat-translation [all | [name] ]
modify snat-translation [all | [name] ]
options:
  address [ip address]
  arp [disabled | enabled]
  app-service [[string] | none]
  connection-limit [integer]
  description [string]
  [disabled | enabled]
  ip-idle-timeout [indefinite | [integer] ]
  tcp-idle-timeout [indefinite | [integer] ]
  udp-idle-timeout [indefinite | [integer] ]
  traffic-group [[string] | default | non-default | none]

edit snat-translation [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list snat-translation
list snat-translation [ [ [name] | [glob] | [regex] ] ... ]
show running-config snat-translation
show running-config snat-translation [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

show snat-translation
show snat-translation [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

```

```

DELETE
delete snat-translation [all | [name] ]

```

DESCRIPTION
 Explicitly defines the properties of a SNAT translation address.

EXAMPLES
 modify snat-translation all arp disabled
 Disables Address Resolution Protocol (ARP) on all SNAT translation addresses.
 list snat-translation all-properties
 Displays all properties of all SNAT translation addresses.

OPTIONS

address
 The translation IP address.

arp Indicates whether the system responds to ARP requests or sends gratuitous ARPs. The default value is enabled.

app-service
 Specifies the name of the application service to which this object belongs. The default value is none.
 Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

connection-limit
 Specifies the number of connections a translation address must reach before it no longer initiates a connection. The default value of 0 (zero) indicates that the option is disabled.

description
 User defined description.

disabled
 Disables SNAT translation.

enabled
 Enables SNAT translation. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

traffic-acceleration-status
 Displays the current traffic-acceleration status. Indicates whether the SNAT address is (indirectly via a SNAT pool) in-use by or dedicated to a virtual server that uses a traffic-acceleration profile.

ip-idle-timeout
 Specifies the number of seconds that IP connections initiated using a SNAT address are allowed to remain idle before being automatically disconnected. The default value is indefinite.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

tcp-idle-timeout

Specifies the number of seconds that TCP connections initiated using a SNAT address are allowed to remain idle before being automatically disconnected. The default value is indefinite.

udp-idle-timeout

Specifies the number of seconds that UDP connections initiated using a SNAT address are allowed to remain idle before being automatically disconnected. The default value is indefinite.

unit Read-only property that specifies the unit in a redundant system. Derived from traffic-group.

traffic-group

Specifies the traffic group of the failover device group on which the SNAT is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

SEE ALSO

create, delete, edit, glob, list, modify, ltm snat, ltm snatpool, regex, show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

DELETE
delete snat [name]

DESCRIPTION

You can use the snat component to configure a SNAT. A SNAT defines the relationship between an externally visible IP address, SNAT IP address, or translated address, and a group of internal IP addresses, or originating addresses, of individual servers at your site.

EXAMPLES

create snat my_snat origins add { 10.1.1.3 } translation mySnatTranslation

Creates the SNAT my_snat that translates the address of connections that originate from the address 10.1.1.3 to the translation address mySnatTranslation.

list snat all-properties

Displays all properties for all SNATs.

OPTIONS

automap

Specifies that the system translates the source IP address to an available self IP address when establishing connections through the virtual server. You can use this option only if you do not use the snatpool and translation options.

Note that when you use the edit command to create a new snat, by default automap is enabled. If you do not want to use automap, you must turn this feature off by using the none option.

app-service

Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

mirror

Enables or disables mirroring of SNAT connections. The default value is none.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

origins

Specifies a set of IP addresses and subnets from which connections originate. This option is required.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

snatpool

Specifies the name of a SNAT pool. You can only use this option if you do not use the automap and translation options.

source-port

Specifies whether the system preserves the source port of the connection. The default value is preserve.

The options are:

change

Use this setting to obfuscate internal network addresses.

preserve

Specifies to preserve the source port of the connection.

preserve-strict

Use this value only for UDP under very special circumstances such as nPath or transparent (that is, no translation of any other L3/L4 field), where there is a 1:1 relationship between virtual IP

addresses and node addresses, or when clustered multi-processing (CMP) is disabled.

translation

Specifies the name of a translated IP address. Note that translated addresses are outside the traffic management system. You can use this option only if you do not use the automap and snatpool options.

vlan

Specifies the name of the VLAN to which you want to assign the SNAT. The default value is none.

vlan-disabled

Disables the SNAT for all specified VLANs. When the "vlan" value is set to "none", the "vlan-disabled" option enables the SNAT on all VLANs.

vlan-enabled

Enables the SNAT for all specified VLANs. When the "vlan" value is set to "none", the "vlan-enabled" option disables the SNAT on all VLANs.

metadata

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

detail

field-fmt

DELETE
delete snatpool [name]

DESCRIPTION

A SNAT pool is a pool of translation addresses that you can map to one or more original IP addresses. Translation addresses in a SNAT pool are not self-IP addresses. You can simply create a SNAT pool and then assign it as a resource directly to a virtual server. This eliminates the need for you to explicitly define original IP addresses to which to map translation addresses.

EXAMPLES

```
create snatpool my_snat_pool1 members add { 11.12.11.24 11.12.11.25 }
```

Creates the SNAT pool my_snat_pool1 that contains the translation addresses (members) 11.12.11.24 and 11.12.11.25.

```
delete snatpool my_snat_pool1
```

Deletes the SNAT pool named my_snat_pool1.

OPTIONS

app-service

Specifies the name of the application service to which this object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

traffic-acceleration-status

Displays the current traffic-acceleration status. Indicates whether the SNAT pool is in-use by or dedicated to a virtual server that uses a traffic-acceleration profile.

members

Specifies translation IP addresses of the pools in the SNAT pool.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

BIG-IP 2016-10-07 ltm snatpool(1)

ltm tacdb customdb-file

NAME

customdb-file - Manages a custom TACDB file

MODULE

ltm tacdb

SYNTAX

List the customdb-file component within the ltm tacdb module using the syntax in the following sections.

CREATE

```
create customdb-file [name]
```

options:

source-path [string]

app-service [name]

DEPRECATED: Though this command is visible, this is not meant to be used by the users. The daemons use it internally.

DISPLAY

list customdb-file [[name] | all | [property]]

options:

- all-properties
- one-line
- partition

DELETE

delete customdb-file [[name] | all]

DEPRECATED: Though this command is visible, this is not meant to be used by the users. The daemons use it internally.

DESCRIPTION

The customdb-file is created internally using the URI specified in `ltm tacdb customdb`.

EXAMPLES

create customdb-file new { source-path file:/shared/images/new.txt }

Creates a new customdb file object, "new" from the source file /shared/images/new.txt

list customdb-file [fileobj-name]

Lists the attributes of customdb file object, "new" from the source file /shared/images/new.txt

OPTIONS

create

Creates a new file object for custom tacdb.

delete

Deletes the file object that you specify next.

source-path

Specifies the location from where the TACDB file object sources the file.

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description for this customdb file object.

partition

Displays the administrative partition within which the component resides.

SEE ALSO

edit, list, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-05-12 ltm tacdb customdb-file(1)

ltm tacdb customdb

NAME

customdb - Configures a custom tacdb to be used for file loads. A customdb includes a URL (including local file paths) from where TACDB files are loaded. These files contain TAC code information.

MODULE

ltm tacdb

SYNTAX

Configure the customdb component within the ltm tacdb module using the syntax in the following sections.

CREATE/MODIFY

create customdb [name]

modify customdb [[name] | all]

options:

- url [string]
- poll-interval [integer]
- user [string]
- password [string]

priority [high | low]
app-service [name]
description [string]

DISPLAY

list customdb [[name] | all | [property]]

options:

all-properties
non-default-properties
one-line
partition
recursive

DELETE

delete customdb [[name] | all]

LOAD load customdb [name]

DESCRIPTION

You can use the customdb component to define a custom tacdb

EXAMPLES

create customdb new { url file:/shared/images/new.txt }

Creates a new custom tacdb, "new" with TAC code information in the file specified by url.

delete customdb new

Deletes the custom tacdb that has been specified.

load customdb new

Trigger a manual download of the custom tacdb from the location pointed to and load it into memory.

OPTIONS

url Specifies the url to fetch the file containing the TACDB information.

poll-interval

Specifies the time interval in seconds at which the URL needs to be polled. The initial default value 0 disables polling. The literal "default" value is 300 seconds (5 minutes).

priority

Specifies the priority whether the customdb is higher or lower than built-in/licensed TACDB.

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description for this customdb.

partition

Displays the administrative partition within which the component resides.

SEE ALSO

edit, list, modify, tmsh

COPYRIGHT

F5 Networks and BIG-IP (c) Copyright 2008, 2012-2016. All rights reserved.

BIG-IP 2017-05-17 Itm tacdb customdb(1)

Itm tacdb licenseddb

NAME

licenseddb - Configures a licensed tacdb to be used for file loads.

MODULE

Itm tacdb

SYNTAX

Configure the licenseddb component within the Itm tacdb module using the syntax in the following sections.

MODIFY

modify licenseddb [licensed-tacdb | all]

options:
poll-interval [integer]

LOAD
load licenseddb [licensed-tacdb]

DISPLAY
list licenseddb [licensed-tacdb | all | [property]]
options:
all-properties
non-default-properties
one-line
recursive

DESCRIPTION
You can use the licenseddb component to define polling interval of downloading licensed tacdb

EXAMPLES
modify licenseddb licensed-tacdb poll-interval 2

Modifies polling interval, "2" means two weeks.

load licenseddb licensed-tacdb

Triggers a manual download of the licensed tac-db from the built-in location in the F5 servers and loads it into memory.

OPTIONS
poll-interval
Specifies the time interval in weeks at which the licensed tacdb needs to be polled

SEE ALSO
edit, list, modify, tmsh

ltm tacdb query

NAME
query - Displays the device type and OS to which a TAC code belongs

MODULE
ltm tacdb

SYNTAX
Use the query component within the ltm tacdb module to query the device type and OS the TAC code belongs to.

DISPLAY
show ltm tacdb query [integer]

DESCRIPTION
You can use the query component to query the device type and OS a url belongs to

EXAMPLES
show ltm tacdb query 35333303

Displays the device type and OS "35333303" belongs to.

OPTIONS
integer
Specify the TAC code.

SEE ALSO
show, tmsh

COPYRIGHT

Itm traffic-class

NAME

traffic-class - Configures a traffic class.

MODULE

Itm

SYNTAX

Configure the traffic-class component within the Itm module using the syntax shown in the following sections.

CREATE/MODIFY

create traffic-class [name]

modify traffic-class [name]

options:

app-service [[string] | none]

classification [string]

description [string]

destination-address [[ip address] | none]

destination-mask [[ip address] | none]

destination-port [[integer] | [port name]]

protocol [any | [protocol]]

source-address [[ip address] | none]

source-mask [[ip address] | none]

source-port [[integer] | [port name]]

edit traffic-class [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DISPLAY

list traffic-class

list traffic-class [[[name] | [glob] | [regex]] ...]

show running-config traffic-class

show running-config traffic-class [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DELETE

delete traffic-class [name]

DESCRIPTION

You can use the traffic-class component to configure a traffic class, which is a named group of ports, machines, and subnets. You can then assign this traffic class to a virtual server in order to configure the virtual server to achieve specific Quality of Service (QoS) standards.

EXAMPLES

create traffic-class my_traffic_class classification "My traffic class."

Creates a traffic class named my_traffic_class, which tags matching flows with the tag My traffic class.

list traffic-class all-properties

Displays all of the properties of all of the traffic classes.

delete traffic-class my_traffic_class

Deletes the traffic class named my_traffic_class.

OPTIONS

app-service

Specifies the name of the application service to which the traffic class belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the traffic class. Only the application service can modify or delete the traffic class.

classification

Specifies the actual textual tag to be associated with the flow if the traffic class is matched. This option is required.

description

User defined description.

destination-address

Specifies destination IP addresses for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is none.

destination-mask

Specifies a destination IP address mask for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is none.

destination-port

Specifies a destination port for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is 0 (zero).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

protocol

Specifies a protocol for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is any.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

source-address

Specifies source IP addresses for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is none.

source-mask

Specifies a source IP address mask for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is none.

source-port

Specifies a source port for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is 0 (zero).

SEE ALSO

BIG-IP 2016-03-14 ltm traffic-class(1)

ltm traffic-matching-criteria

NAME

traffic-matching-criteria - Configures a virtual server matching object that defines how traffic is steered towards the virtual server object for the Local Traffic Manager.

MODULE

ltm

SYNTAX

Configure the traffic-matching-criteria component within the ltm module using the syntax shown in the following sections.

CREATE/MODIFY

create traffic-matching-criteria [name]

modify traffic-matching-criteria [name]

options:

all

description [string]

destination-address-list [[addr_list_name] | none]

destination-address-inline [[address] | none]

destination-port-list [[port_list_name] | none]

destination-port-inline [port]

source-address-list [[addr_list_name] | none]

source-address-inline [address]

source-port-inline [port]

edit traffic-matching-criteria [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list traffic-matching-criteria

list traffic-matching-criteria [[[name] | [glob] | [regex]] ...]

show running-config traffic-matching-criteria

show running-config traffic-matching-criteria [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

show traffic-matching-criteria

show traffic-matching-criteria [name]

options:

hours

minutes

seconds

DELETE

delete traffic-matching-criteria [name]

Note: You must remove all references to a traffic-matching-criteria before you can delete the traffic-matching-criteria.

DESCRIPTION

You can use this traffic-matching-criteria component to configure the virtual server matching definitions on the Local Traffic Manager. This defines the criteria used for matching destination and source address/ports for a virtual server.

EXAMPLES

```
create traffic-matching-criteria my_traffic_matching_criteria destination-address-list dst_addr_list
destination-port-list dst_port_list
```

Creates a Local Traffic Manager traffic-matching-criteria named my_traffic_matching_criteria with dst_addr_list and the dst_port_list for destination matching, from any source.

```
create traffic-matching-criteria my_traffic_matching_criteria source-address-list src_addr_list source-port-
list src_port_list
```

Creates a Local Traffic Manager traffic-matching-criteria named my_traffic_matching_criteria with src_addr_list and the port-list for source matching, to any destination.

```
create traffic-matching-criteria my_traffic_matching_criteria destination-address-list dst_addr_list
destination-port-list dst_port_list source-address-list src_addr_list1 source-port-list src_port_list1
```

Creates a Local Traffic Manager traffic-matching-criteria named my_traffic_matching_criteria with src_addr_list and the src_port-list for source matching, and dst_addr_list and dst_port_list for destination matching.

```
delete traffic-matching-criteria my_traffic_matching_criteria
```

Deletes the traffic_matching_criteria named my_traffic_matching_criteria.

```
show traffic-matching-criteria
```

Displays status for all Local Traffic Manager traffic-matching-criteria objects in the system configuration.

```
show traffic-matching-criteria all-properties
```

Displays status for all Local Traffic Manager traffic-matching-criteria objects in the system configuration.

```
list traffic-matching-criteria my_traffic_matching_criteria
```

Displays properties of the traffic-matching-criteria named my_traffic_matching_criteria.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

destination-address-list

Specifies the name of destination address list for this virtual server matching object i.e. the addresses on which the virtual server referencing this object will listen for connections. The default value is any.

destination-address-inline

Specifies a single destination address for this virtual server matching object i.e. the address on which the virtual server referencing this object will listen for connections. The default value is none.

destination-port-list

Specifies the name of destination port list for this virtual server matching object i.e. the ports on which the virtual server referencing this object will listen for connections. The default value is any.

destination-port-inline

Specifies a single destination port for this virtual server matching object i.e. the port on which the virtual server referencing this object will listen for connections. The default value is none.

source-address-list

Specifies the source address list for this virtual server matching object i.e. the addresses from which the virtual server referencing this object will accept traffic. The default value is any.

source-address-inline

Specifies a single source address list for this virtual server matching object i.e. the address from which the virtual server referencing this object will accept traffic. The default value is none.

source-port-list

Specifies the source port list for this virtual server matching object i.e. the ports from which the virtual server referencing this object will accept traffic. The default value is any.

source-port-inline

Specifies a single source port for this virtual server matching object i.e. the port from which the virtual server referencing this object will accept traffic. The default value is none.

description

User defined description.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

DELETE
delete virtual-address [all | [name]]

DESCRIPTION

You can use the virtual-address component to enable, disable, display, and delete virtual addresses. You can also list the virtual address configuration, and view statistics for a specific virtual address.

Note that tmsh only displays virtual addresses when you explicitly request them. For example:

To display the properties of virtual addresses or a specific virtual address from the ltm module, use the command sequences list virtual-address and list virtual-address [name], respectively.

To display statistics for virtual addresses or a specific virtual address from the ltm module, use the command sequence show virtual-address and show virtual-address [name], respectively.

EXAMPLES

create virtual-address myVirtualAddr address 10.10.10.20 enabled yes

Creates a virtual address 10.10.10.20, with a name of myVirtualAddr.

create virtual-address myVirtualAddr address 10.10.10.20 enabled yes traffic-group /Common/traffic-group-1

Creates a virtual address 10.10.10.20, with a name of myVirtualAddr, that is assigned to traffic-group-1.

modify virtual-address myVirtualAddr enabled no

Disables the virtual address myVirtualAddr.

delete virtual-address myVirtualAddr

Deletes the virtual address myVirtualAddr.

list virtual-address myVirtualAddr all-properties

Lists the configuration information for the virtual address, myVirtualAddr.

show virtual-address myVirtualAddr

Displays statistics and status for the virtual-address myVirtualAddr.

show virtual-address myVirtualAddr all-properties

Displays statistics and status for the virtual named myVirtualAddr.

Note that if the system includes Packet Velocity(r) ASIC (PVA) and PVA Assist capabilities, this command displays status and statistics for that feature.

mv /ltm virtual-address /Common/10.10.10.20 to-folder /Common/all_virtual_addresses

Moves the virtual-address 10.10.10.20 to a folder named all_virtual_addresses.

Note: If you wish to change the name of the virtual-address, you must use the configured IP Address or a name that does not represent a different IP Address than the one configured.

Please refer to the mv manual page for additional examples on how to use the mv command.

OPTIONS

address

The virtual IP address.

arp Enables or disables ARP for the specified virtual address. The default value is enabled.

app-service

Specifies the name of the application service to which the virtual address belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the virtual address. Only the application service can modify or delete the virtual address.

auto-delete

Indicates if the virtual address will be deleted automatically on deletion of the last associated virtual server or not. The default value is true.

connection-limit

Sets a concurrent connection limit for one or more virtual servers. The default value is 0, meaning "no limit."

description

User defined description.

enabled

Specifies whether the specified virtual address is enabled. The default value is yes.

floating

Read-only property derived from traffic-group. A floating virtual address is a virtual address for a VLAN that serves as a shared address by all devices of a BIG-IP traffic-group.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

icmp-echo

Specifies whether the virtual address should reply to ICMP echo requests. The default value is enabled.

enabled or always

ICMP echo reply will be sent in response to ICMP echo requests.

disabled

ICMP echo reply will not be sent in response to ICMP echo requests.

selective

ICMP echo reply will be sent in response to ICMP echo requests, when availability status is true.

any ICMP echo reply will be sent in response to ICMP echo requests, when any of the contributing virtual server is available.

all ICMP echo reply will be sent in response to ICMP echo requests when all of the contributing virtual server is available.

mask Sets the netmask for one or more network virtual servers only. This setting is required for network virtual servers. The default value is 255.255.255.255.

partition

Displays the administrative partition within which the virtual address resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

route-advertisement

Specifies the route advertisement setting for the virtual address. The default value is disabled.

enabled or selective

Route is advertised when virtual-address is available.

disabled

Route is not advertised.

always

Route is advertised regardless of the availability status.

any Route is advertised when any of the contributing virtual server is available.

all Route is advertised when all of the contributing virtual server is available.

server-scope

Specifies when the virtual address is considered available. When a virtual address is available and Route Advertisement is enabled or selective, the BIG-IP system advertises the route for the virtual address. The default value is any.

any When any virtual server is available: Advertises the route when any virtual server is available.

all When all virtual servers are available: Advertises the route when all virtual servers are available.

none Always advertises the route regardless of the virtual servers available.

spanning

Enables or disables spanning for the specified virtual address. The default value is disabled.

unit Read-only property that specifies the unit in a redundant system. Based on traffic-group.

traffic-group

Specifies the traffic group on which the virtual address is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

metadata

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

SEE ALSO

DELETE

delete virtual [name]

DESCRIPTION

You can use the virtual component to create, delete, modify properties on, and display information about virtual servers. Virtual servers are externally visible IP addresses that receive client requests. Rather than sending the requests directly to the destination IP address specified in the packet header, it sends the requests to any of several content servers that make up a load balancing pool. Virtual servers also apply various behavioral settings to multiple traffic types, enable persistence for multiple traffic types, and direct traffic according to user-written iRules(r).

Note: After you configure a Global Traffic Manager listener, when you use the tab completion feature within the ltm module, the listener displays as one of the virtual servers in the Configuration Items section.

EXAMPLES

```
create virtual myV2 { destination 11.11.11.12:any persist replace-all-with { source_addr } } pool myPool}
```

Creates a virtual server named myV2, which uses the source address persistence method.

```
modify virtual vs_f14_http4 profiles replace-all-with { profile-udp }
```

Replaces the profile associated with the virtual server vs_f14_http4.

Note: To replace the profile associated with a virtual server, you must enclose the name of the new profile in curly brackets.

```
delete virtual myV4 myV5 myV6
```

Deletes the virtual servers named myV4, myV5, and myV6.

```
show virtual myV4
```

Displays statistics and status for the virtual named myV4.

```
show virtual myV4 all-properties
```

Displays statistics and status for the virtual named myV4.

Note: If the system includes Packet Velocity(r) ASIC (PVA) and PVA Assist capabilities, this command displays status and statistics for that feature.

```
mv /ltm virtual /Common/my_vip to-folder /Common/some_folder
```

Moves a virtual server named my_vip to the folder named some_folder, where some_folder has already been created under /Common.

Note: Please note that you may not move a virtual server that is associated with CGNAT configuration items, such as LSN pools.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

address-status

Specifies whether the virtual will contribute to the operational status of the associated virtual-address. The default value is 'yes'.

app-service

Specifies the name of the application service to which the virtual server belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the virtual server. Only the application service can modify or delete the virtual server.

auth Specifies a list of authentication profile names, separated by spaces, that the virtual server uses to manage authentication.

auto-discovery

Enable or disable security protected objects (virtual server) auto discovery functionality. The default value is disabled.

clone-pools

Specifies a pool or list of pools that the virtual server uses to replicate either client or server traffic. You must specify a value of either clientside or serverside for the context option for each clone pool. Typically, this option is used for intrusion detection.

cmp-enabled

Enables or disables clustered multi-processor (CMP) acceleration. This feature applies to certain platforms only. The default value is yes.

connection-limit

Specifies the maximum number of concurrent connections you want to allow for the virtual server. The default value of 0 (zero) allows for an unlimited number of concurrent connections.

context

Specifies that the pool is either a clientside or serverside clone pool.

Note: Because validation occurs outside of TMSH, you will receive an error when you modify the context for profiles in a virtual server.

dhcp-relay

Specifies a virtual server that relays all received dhcp requests to all pool members. If there is no pool, the received request get dropped. If you specify the dhcp-relay option, you cannot use the ip-forward or l2-forward or reject options.

description

User defined description.

destination

Specifies the name of the virtual address and service on which the virtual server listens for connections.

The format for "ipv4" is a.b.c.d[:port]. The format for an "ipv6" address is a:b:c:d:e:f:g:h[:port].

The default value is any:any.

(enabled | disabled)

Specifies the state of the virtual server. The default value is enabled.

Note: When you disable a virtual server, the virtual server no longer accepts new connection requests. However, it allows current connections to finish processing before going to a down state.

eviction-protected

Enables or disables protection for the virtual server from the aggressive sweeper. The default is disabled.

fallback-persistence

Specifies a fallback persistence profile for the virtual server to use when the default persistence profile is not available. The default value is none.

flow-eviction-policy

Specifies a flow eviction policy for the virtual server to use, to select which flows to terminate when the number of connections approaches the connection limit on the virtual server. The default value is none.

fw-enforced-policy

Specifies an enforced firewall policy. fw-enforced-policy rules are enforced on a virtual server.

fw-enforced-policy-rules

Specifies firewall rules enforced on ltm virtual via referenced fw-enforced-policy.

fw-staged-policy

Specifies a staged firewall policy. fw-staged-policy rules are not enforced while all the visibility aspects namely statistics, reporting and logging function as if the fw-staged-policy rules were enforced on a virtual server.

fw-staged-policy-rules

Specifies firewall rules staged on ltm virtual via referenced fw-staged-policy.

security-nat-rules

Specifies security nat rules associated with ltm virtual via referenced security-nat-policy.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

gtm-score

Specifies a score that is associated with the virtual server. Global Traffic Manager (GTM) can rely on this value to load balance traffic in a proportional manner.

traffic-acceleration-status

Displays the current traffic-acceleration status. The virtual server is considered traffic-acceleration-dedicated if it uses a traffic-acceleration profile.

ip-forward

Specifies a virtual server that has no pool members to load balance, but instead, forwards the packet directly to the destination IP address specified in the client request. If you specify the ip-forward option, you cannot use the l2-forward or reject options. The destination, mask, translate-address, translate-port, vlans, vlans-disabled and vlans-enabled attributes are set by the system, any attempt to change them will have no effect.

ip-protocol

Specifies the IP protocol for which you want the virtual server to direct traffic. Sample protocol names

are TCP and UDP. The default value is any.

Note: You do not use this setting when creating an HTTP class virtual server.

internal

Specifies an internal virtual server that handles requests for a parent virtual server, such as content adaptation. Internal virtual servers do not receive external connections, instead they are specified by name by profiles in the parent virtual server (see `itm profile request-adapt` and `itm profile response-adapt`). Since internal virtual servers do not listen for external connections, not all attributes are used for internal virtual servers. The `destination`, `mask`, `translate-address`, `translate-port`, `vlangs`, `vlangs-disabled` and `vlangs-enabled` attributes are set by the system, any attempt to change them will have no effect.

l2-forward

Specifies a virtual server that shares the same IP address as a node in an associated VLAN. You create this type of virtual server when you want to create a VLAN group. If you specify the `l2-forward` option, you cannot use the `ip-forward` or `reject` options.

last-hop-pool

Specifies the name of the last hop pool that you want the virtual server to use to direct reply traffic to the last hop router. The default value is none.

`mask` Specifies the netmask for a network virtual server only. This setting is required for a network virtual server.

The netmask clarifies whether the host bit is an actual zero or a wildcard representation. The default value is 255.255.255.255 for IPv4 or ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff for IPv6.

mirror

Enables or disables mirroring. You can use mirroring to maintain the same state information in the standby unit that is in the active unit, allowing transactions such as FTP file transfers to continue as though uninterrupted. The default value is none.

mobile-app-tunnel

Deprecated since v13.1.0.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

nat64

Enable or disable NAT64. The default value is disabled. NAT64 is a service that automatically translate IPv6 traffic into IPv4.

partition

Displays the name of the administrative partition within which the virtual server resides.

per-flow-request-access-policy

Specifies the name of the per-request access policy to be used with the virtual server. The default value is none.

persist

Specifies a list of profiles separated by spaces that the virtual server uses to manage connection persistence. The default value is none.

To enable persistence, typically you specify a single profile. However, you can specify multiple profiles in conjunction with `iRules(r)` that define a persistence strategy based on incoming traffic. In the case of multiple profiles, the default option specifies which profile you want the virtual server to use if an `iRule` does not specify a persistence method. When you specify multiple profiles, the default value of the default property is no. You can set the value of the default property to yes for only one of the profiles.

policies

Manage LTM Policies applied to the virtual server. LTM Policies define a set of conditions and actions that can be used to inspect, modify, direct traffic, and enable/disable features on the fly, similar to `iRules`. LTM Policies do not require programming. See also `itm policy`.

`pool` Specifies a default pool to which you want the virtual server to automatically direct traffic. The default value is none.

port-misuse

Used to show or reset port misuse policy statistics for the virtual server.

fw-context-stat

Used to show or reset firewall statistics for the virtual server.

profiles

Specifies a list of profiles for the virtual server to use to direct and manage traffic. The default value is `fastL4`.

rate-class

Specifies the name of an existing rate class that you want the virtual server to use to enforce a throughput policy for incoming network traffic. The default value is none.

rate-limit

Specifies the maximum number of connections per second allowed for a virtual server. The default value is 'disabled'.

rate-limit-mode

Indicates whether the rate limit is applied per virtual object, per source address, per destination address, or some combination thereof. The default value is 'object', which does not use the source or destination address as part of the key.

rate-limit-dst-mask

Specifies a mask, in bits, to be applied to the destination address as part of the rate limiting. The default value is '0', which is equivalent to using the entire address - '32' in IPv4, or '128' in IPv6.

rate-limit-src-mask

Specifies a mask, in bits, to be applied to the source address as part of the rate limiting. The default value is '0', which is equivalent to using the entire address - '32' in IPv4, or '128' in IPv6.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

related-rules

Specifies a list of iRules, separated by spaces, that customize the behavior of secondary channels (for instance the data channel on FTP) opened on behalf of the virtual server. The default value is none.

reject

Specifies that the BIG-IP(r) system rejects any traffic destined for the virtual server IP address. If you specify the reject option, you cannot use the ip-forward or l2-forward options.

rules

Specifies a list of iRules, separated by spaces, that customize the virtual server to direct and manage traffic. The default value is none.

security-nat-policy

Configures the following options to specify which Security NAT Policy is to be used to match the incoming traffic and perform source/destination translation (address/port) using the first-match rule criteria:

policy

Specifies the name of the Security NAT Policy to be used (see security nat policy).

use-route-domain-policy

Specifies whether to use the virtual server's route domain context's Security NAT policy. If enabled AND the virtual server does not have a NAT policy configured, route domain's security NAT policy is used.

use-device-policy

Specifies whether to use the security device context NAT policy (see security device-context). If enabled AND both virtual server as well as route domain do not have a NAT policy configured, NAT policy configured at security device (a.k.a global) level is used.

serverssl-use-sni

When multiple server-ssl profiles are attached to a virtual, setting this allows one to be chosen based on the SNI extension from the ClientHello if a client-ssl profile is also attached to the virtual.

service-down-immediate-action

Specifies the immediate action the BIG-IP system should respond with upon the receipt of the initial client's SYN packet if the availability status of the virtual server is Offline or Unavailable. This is supported for the virtual server of Standard type and TCP protocol. The default value is none.

service-policy

Specifies a service policy for the virtual server. If set, it will enforce the service policy for incoming network traffic. The service policy can be used to validate if incoming traffic conforms to a set of application protocols.

snat Specifies whether SNAT automap is enabled for the virtual server. The default value is none. This attribute is DEPRECATED. Use source-address-translation { type (automap / none) }

snatpool

Specifies the name of an existing SNAT pool that you want the virtual server to use to implement selective and intelligent SNATs. This attribute is DEPRECATED. Use source-address-translation { type snatpool pool pool_name }

source

Specifies an IP address or network from which the virtual server will accept traffic.

The format for an "ipv4" address is a.b.c.d[/prefixlen]. The format for an "ipv6" address is a:b:c:d:e:f:g:h[/prefixlen].

source-address-translation

Specifies the type of source address translation enabled for the virtual server as well as the pool that the source address translation will use.

pool Specifies the name of a LSN or SNAT pool used by the specified virtual server.

type Specifies the type of source address translation associated with the specified virtual server.

The options are:

automap

Specifies the use of self IP addresses for virtual server source address translation.

lsn Specifies the use of a LSN pool of translation addresses for virtual server source address translation.

none Specifies no source address translation to be used by the virtual server.

snat Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

source-port
Specifies whether the system preserves the source port of the connection. The default value is preserve.

The options are:

change
Obfuscates internal network addresses.

preserve
Preserves the source port of the connection.

preserve-strict
Use this value only for UDP under very special circumstances, such as nPath or transparent (that is, no translation of any other L3/L4 field), where there is a 1:1 relationship between virtual IP addresses and node addresses, or when clustered multi-processing (CMP) is disabled.

traffic-classes
Specifies a list of traffic classes that are associated with the virtual server. The default value is none.

translate-address
Enables or disables address translation for the virtual server. Disable address translation for a virtual server if you want to use the virtual server to load balance connections to any address. This option is useful when the system is load balancing devices that have the same IP address. The default value is disabled.

translate-port
Enables or disables port translation. Disable port translation for a virtual server, if you want to use the virtual server to load balance connections to any service. The default value is disabled.

transparent-nexthop
Specifies the egress interface for traffic and enables layer 2 (MAC) address preservation. Layer 2 address preservation disables layer 3 (IP/IPv6) address translation.

vlan
Specifies a list of VLANs on which the virtual server is either enabled or disabled. The default value is none. The options vlans-disabled and vlans-enabled indicate whether the virtual server is disabled or enabled on the list of specified VLANs.

vlans-disabled
Disables the virtual server on the VLANs specified in the vlans option. This is the default setting.

vlans-enabled
Enables the virtual server on the VLANs specified in the vlans option.

vs-index
Displays a unique index assigned to this virtual server.

metadata
Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

ip-intelligence-categories
Used to show/ reset statistics on IP intelligence white/ black lists categories.

mgmt shared settings api-status availability

NAME

availability - Configures the accessibility of the elements that have one of the specified API lifecycle states.

MODULE

mgmt shared settings api-status

SYNTAX

Configure the availability component within the mgmt shared settings api-status module using the syntax shown in the following sections.

MODIFY

modify availability

options:

deprecatedApiAllowed [true | false]
earlyAccessApiAllowed [true | false]
testOnlyApiAllowed [true | false]

DISPLAY

list availability

options:

deprecatedApiAllowed
earlyAccessApiAllowed
testOnlyApiAllowed

DESCRIPTION

There are six F5 API lifecycle states namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states are described at the end of this page. For the commands, command properties in deprecated, earlyAccess and testOnly states the availability can be configured by the user.

The availability settings indicate if the commands or properties within a command are accessible to the user. For example: if the deprecatedApiAllowed property is set to false; then it implies that the commands and properties with deprecated status are not available to user. i.e. These elements will not be available for create, modify, delete commands. For list action, the elements will not displayed at the command line.

Warnings will be generated at stderr and /var/log/ltm based on the mgmt::shared::settings::api-status::log::resource and resource-property settings.

If these settings are modified in the tmsh interactive mode then, the user has to exit the tmsh interactive mode and re-enter for the settings to be effective.

OPTIONS

deprecatedApiAllowed

Determines the accessibility of commands, properties in deprecated state. The default value is true.

earlyAccessApiAllowed

Determines the accessibility of commands, properties in earlyAccess state. The default value is true.

testOnlyApiAllowed

Determines the accessibility of commands, properties in testOnly state. The default value is false.

The remaining properties are read-only and are not user modifiable.

F5 API lifecycle policy

The F5 API lifecycle consists of five states, namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states can be described as follows:

internal

Internal routing not exposed through public interface

testOnly

Enabled only when test variable configured. Used internally for test cases that require special-case workers to complete functional testing for features not exposed in public API.

earlyAccess

Experimental and susceptible to change in future releases. Used for new features that haven't had time to be solidified.

generalAccess

API that satisfies the API general access release policy.

deprecated

Resource still exists in the API but indicates that there is an preferred alternative or that it may be removed in the future based on deprecation policy.

noStatus

For backward compatibility for APIs not categorized. At some point this status will be disallowed and build time break will occur if resource not categorized with appropriate flag.

In the write-up above the terms command, command::properties are used in place of API to describe the behavior of the mgmt::shared::settings::api-status::availability settings.

SEE ALSO

mgmt shared settings api-status log resource, mgmt shared setting api-status log resource-property

COPYRIGHT

BIG-IP 2017-06-19 mgmt shared settings api-status availability(1)

mgmt shared settings api-status log resource-property

NAME

resource-property - Configures the logging of api-status message for the properties that have one of the specified API lifecycle states.

MODULE

mgmt shared settings api-status log

SYNTAX

Configure the resource-property component within the mgmt shared settings api-status log module using the syntax shown in the following sections.

MODIFY

modify resource-property

options:

deprecatedApiAllowed [true | false]

earlyAccessApiAllowed [true | false]

testOnlyApiAllowed [true | false]

DISPLAY

list resource-property

options:

deprecatedApiAllowed

earlyAccessApiAllowed

testOnlyApiAllowed

DESCRIPTION

There are six F5 API lifecycle states namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states are described at the end of this page. For the properties in deprecated, earlyAccess and testOnly states the log::resource-property can be configured by the user.

The resource settings indicate if the user attempt to access the command would generate a [api-status-warning]. These warning will be generated at stderr and /var/log/ltm. For example: if the deprecatedApiAllowed property is set to true; then it implies that the accessing the command with deprecated status will generate an [api-status-warning].

Warnings will always be generated regardless of the log::resource-property setting if the property is not available as per the mgmt::shared::settings::api-status::log::availability setting

If these settings are modified in the tmsh interactive mode then, the user has to exit the tmsh interactive mode and re-enter for the settings to be effective.

OPTIONS

deprecatedApiAllowed

Determines if the [api-status-warning] messages will be generated for the properties with deprecated state. The default value is true.

earlyAccessApiAllowed

Determines if the [api-status-warning] messages will be generated for the properties with earlyAccess state. The default value is true.

testOnlyApiAllowed

Determines if the [api-status-warning] messages will be generated for the properties with testOnly state. The default value is true.

The remaining properties are read-only and are not user modifiable.

F5 API lifecycle policy

The F5 API lifecycle consists of five states, namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states can be described as follows:

internal

Internal routing not exposed through public interface

testOnly

Enabled only when test variable configured. Used internally for test cases that require special-case workers to complete functional testing for features not exposed in public API.

earlyAccess

Experimental and susceptible to change in future releases. Used for new features that haven't had time to be solidified.

generalAccess

API that satisfies the API general access release policy.

deprecated

Resource still exists in the API but indicates that there is an preferred alternative or that it may be removed in the future based on deprecation policy.

noStatus

For backward compatibility for APIs not categorized. At some point this status will be disallowed and build time break will occur if resource not categorized with appropriate flag.

In the write-up above the term property is used in place of API to describe the behavior of the mgmt::shared::settings::api-status::log::resource-property settings.

DESCRIPTION

There are six F5 API lifecycle states namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states are described at the end of this page. For the commands, command properties in deprecated, earlyAccess and testOnly states the resource can be configured by the user.

The resource settings indicate if the user attempt to access the command would generate a [api-status-warning]. These warning will be generated at stderr and /var/log/ltm. For example: if the deprecatedApiAllowed property is set to true; then it implies that the accessing the command with deprecated status will generate an [api-status-warning].

Warnings will always be generated regardless of the log resource setting if the command is not available as per the mgmt::shared::settings::api-status::log::availability setting

If these settings are modified in the tmsh interactive mode then, the user has to exit the tmsh interactive mode and re-enter for the settings to be effective.

OPTIONS

deprecatedApiAllowed

Determines if the [api-status-warning] messages will be generated for the commands with deprecated state. The default value is true.

earlyAccessApiAllowed

Determines if the [api-status-warning] messages will be generated for the commands with earlyAccess state. The default value is true.

testOnlyApiAllowed
Determines if the [api-status-warning] messages will be generated for the commands with testOnly state. The default value is true.

The remaining properties are read-only and are not user modifiable.

F5 API lifecycle policy

The F5 API lifecycle consists of five states, namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states can be described as follows:

internal
Internal routing not exposed through public interface

testOnly
Enabled only when test variable configured. Used internally for test cases that require special-case workers to complete functional testing for features not exposed in public API.

earlyAccess
Experimental and susceptible to change in future releases. Used for new features that haven't had time to be solidified.

generalAccess
API that satisfies the API general access release policy.

deprecated
Resource still exists in the API but indicates that there is an preferred alternative or that it may be removed in the future based on deprecation policy.

noStatus
For backward compatibility for APIs not categorized. At some point this status will be disallowed and build time break will occur if resource not categorized with appropriate flag.

In the write-up above the terms command is used in place of API to describe the behavior of the mgmt::shared::settings::api-status::log::resource settings.

net

net address-list

NAME
address-list - An address-list is a list of IP addresses.

MODULE
net

SYNTAX
CREATE/MODIFY
create address-list [name]
modify address-list [[name] | all]
options:
addresses [add | delete | modify | replace-all-with] {
 [[ip address]]
}
app-service [name]
description [string]

edit address-list [[name] | all]
options:
 all-properties
 non-default-properties

DISPLAY
list address-list [[name] | all | [property]]

DELETE
delete address-list [[name] | all]

DESCRIPTION

You can use the address-list component to define reusable lists of addresses.

EXAMPLES

```
create address-list alist1 addresses add { 10.10.1.1 10.10.1.2 192.168.24.0/24 }
```

Creates a new address list, "alist1," with two IPv4 addresses and one IPv4 subnet.

```
modify address-list alist1 addresses modify { 10.10.1.1 { description "management IP at wwmed site3" } }
```

Modifies the above address list with a description for the first address.

```
modify address-list alist1 addresses add { 2001:DB8:a::/64 }
```

Modifies the same address list by adding an IPv6 subnet.

```
list address-list alist1
net address-list alist1 {
  addresses {
    10.10.1.1 {
      description "management IP at wwmed site3"
    }
    10.10.1.2 { }
    192.168.24.0/24 { }
    2001:db8:a::/64 { }
  }
}
```

Shows the modified address list.

OPTIONS

addresses

Specifies a list of individual IP addresses and/or subnets. The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:ca90:ff00:0042:8329" to "2001:db7:3f4a:9dd:ca90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:23ff:678" to "2001::c34a:0:23ff:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

The next keyword specifies the action to take with the addresses (add, delete, modify, or replace the current set of addresses).

add Creates a new address list, which you specify next with IP addresses and/or prefixes in curly braces ({}).

delete

Deletes the address(es) that you specify next, in curly braces ({}).

modify

Makes it possible to replace the optional description(s) for the address(es). You can specify a description in a nested set of curly braces after each address.

replace-all-with

Replaces the current set of IP addresses with the address(es) that you specify next, in curly braces ({}).

app-service

Associates this address list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers.

description

Is your description for this address list.

BIG-IP 2019-04-25 net address-list(1)

net arp

NAME

arp - Manages entries in the Address Resolution Protocol (ARP) table.

MODULE

net

SYNTAX

Configure the arp component within the net module using the syntax in the following sections.

CREATE/MODIFY

create arp [name]

options:

description [string]

ip-address [ip address ... ip address]

mac-address [mac address]

modify arp [name]

options:

description [string]

mac-address [mac address]

edit arp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list arp

list arp [[[name] | [glob] | [regex]] ...]

show running-config arp

show running-config arp

[[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

show arp

show arp [[[name] | [glob] | [regex]] ...]

options:

(dynamic | static)

DELETE

delete arp [name]

DESCRIPTION

You can use the arp component to add entries to or delete entries from the ARP table.

You can create static ARP entries for IPv4 addresses to link-layer addresses, such as Ethernet media access control (MAC) addresses. You can view and delete static and dynamic ARP entries.

Note that you can use the db component in the sys module to configure how the system handles ARP entries for dynamic timeout, maximum dynamic entries, add reciprocal, and maximum retries. For more information, see sys db.

EXAMPLES

create arp myARP ip-address 10.10.10.20 mac-address 00:0b:09:88:00:9a

Creates an arp mapping of the IP address 10.10.10.20 to the MAC address 00:0b:09:88:00:9a, and the name of this entry is myARP. Alternatively, the address can be used as the name, like the following example.

create arp 10.10.10.20 mac-address 00:0b:09::88:00:9a

Creates an arp mapping of IP address 10.10.10.20 to the MAC address 00:0b:09:88:00:9a.

modify arp 10.10.10.20 mac-address 00:0b:09:88:00:9b

Modifies the ARP mapping of the ARP entry named 10.10.10.20 to the MAC address 00:0b:09:88:00:9b.

show arp

Displays ARP status and statistics for the system.

show arp any%2

Displays ARP status and statistics for all IP addresses in route domain 2. A glob expression displays the same result: show arp *%2.

list arp all-properties

Displays all properties for all ARP entries for the system.

list arp non-default-properties

Displays all non-default properties for all ARP entries for the system.

delete arp all

Deletes all ARP entries for the system.

delete arp myARP

Deletes the ARP entry named myARP.

OPTIONS

description

User defined description.

dynamic

Displays the status of dynamic ARP entries.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ip address

Specifies the IP address, in one of the following formats, for which you want to configure an ARP entry:

IPv4 address in dotted-quad notation, for example, 10.10.10.1

host name, for example, www.f5.com

You can also specify a list of IP addresses separated by a single space. For example, this list contains three IP addresses: 10.10.10.20 10.10.10.21 10.10.10.22.

ip-address

The IP address to be mapped. This is optional, and if not present, the name needs to be a string that represents a valid IP address.

mac-address

Specifies a 6-byte ethernet address in not case-sensitive hexadecimal colon notation, for example, 00:0b:09:88:00:9a. You must specify a MAC address when you create an ARP entry.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

static

Displays the status of static ARP entries.

SEE ALSO

net bwc policy

NAME

policy - Configures a bandwidth control policy for traffic flow.

MODULE

net bwc

SYNTAX

Configure the policy component within the net bwc module using the syntax in the following sections.

CREATE/MODIFY

create policy [name]

modify policy [name]

options:

app-service [[string] | none]

description [string]

dynamic [enabled]

max-rate [integer]

max-user-rate [integer]

max-user-rate-pps [integer]

ip-tos [integer | pass-through]

```

link-qos [integer | pass-through]
measure [ disabled ]
log-publisher [[string] | none]
log-period [integer]
categories [none] {
    max-cat-rate [integer]
    max-cat-rate-percentage [integer]
    ip-tos [ integer | pass-through]
    link-qos [integer | pass-through]
    traffic-priority-map [string]
}
traffic-priority-map [string]

edit policy [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list policy
list policy [ [ [name] | [glob] | [regex] ] ... ]
show running-config net policy
show running-config net policy [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line

DELETE
delete net policy [all | [name] ]

```

DESCRIPTION

You can use the net bwc policy to create a bandwidth control policy to handle traffic flow, and then associate it with other components such as packet filter, iRule and virtual server. For details on packet filter, virtual server, please refer to the respective documentation.

EXAMPLES

```
create net bwc policy
```

Creates a bwc policy (see below).

```
list net bwc policy all-properties
```

Displays all of the properties of all of the bwc policies.

```
delete net bwc policy
```

Deletes a policy (see below).

Example for static policy:

```
net bwc policy silver_static_policy {
    max-rate 120mbps
}
```

Example for dynamic policy:

```
net bwc policy gold-dynamic-policy {
    categories {
        web {
            description "This is a web test category."
            max-cat-rate 600kbps
            ip-tos 7
            link-qos 5
        }
    }
    description "This is a test."
    dynamic enabled
    max-rate 40gbps
    max-user-rate 1gbps
}
```

Example for dynamic policy with measure enabled:

```
net bwc policy gold-dynamic-policy {
    categories {
        web {
            description "This is a web test category."
            max-cat-rate 600kbps
            ip-tos 7
            link-qos 5
        }
    }
    description "This is a test."
    dynamic enabled
    measure enabled
    log_publisher /Common/my_log_publisher
}
```

```

log-period 2048
max-rate 40gbps
max-user-rate 1gbps
}

```

Example for BWC using packet filter:

```

net bwc policy bwc {
    max-rate 1mbps
}

```

Define packet filter with bwc on it:

```

net packet-filter pfilter {
    action continue
    bwc policy bwc
    logging enabled
    order 2
    rule ip
}

```

Example for BWC association with virtual server:

```

ltm virtual l2-for-virtual {
    destination 0.0.0.0:any
    l2-forward
    mask any
    profiles {
        fastL4 { }
    }
    rules {
        bwc_test
    }
    translate-address disabled
    translate-port disabled
    vlans {
        lan
        wan
    }
    vlans-enabled
}
ltm virtual tcp-passthrough {
    destination 0.0.0.0:http
    ip-protocol tcp
    mask any
    profiles {
        tcp { }
    }
    rules {
        bwc_test
    }
    translate-address disabled
    vlans-disabled
}

```

Example for Delete bwc policy:

```

net bwc policy silver_static_policy

```

Example for bwc policy traffic map:

```

net bwc policy bwc-policy-105 {
    categories {
        cat1 {
            max-cat-rate 10mbps
            traffic-priority-map tc1->cat1
        }
        cat2 {
            max-cat-rate 10mbps
            traffic-priority-map tc1->cat2
        }
    }
    dynamic enabled
    max-rate 100mbps
    max-user-rate 10mbps
}

```

Notes: Only static policies are supported for association with packet filter or virtual server components.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies a unique name for the policy. This option is required for the commands create, delete, and modify.

description

User defined description.

max-rate

Specifies the maximum bandwidth that traffic is allowed using the policy associated. The range is from 1Mbps to 320Gbps.

Valid units: bps(default), gbps, kbps, mbps.

max-user-rate

Specifies the maximum bandwidth that traffic is allowed using the policy associated. The range is from 5kbps to 2Gbps.

Valid units: bps(default), gbps, kbps, mbps.

max-user-rate-pps

Specifies the limiter in packets per second that traffic is allowed using the associated policy. This does not allocate any fairshare bandwidth. When configured this acts purely as a simple packet limiter. It is packet size and protocol agnostic. It can be configured only on a dynamic policy. When configured along with mbps values, whichever lower limit pps vs mbps is applied. When configured, both need to pass for packets to go through. The default value is 0 (not configured).

traffic-priority-map

Specifies the bwc priority-group to use during congestion. This is optional and to be configured only as needed. A bwc priority-group can be shared and amongst categories of the same bwc policy but not across bwc policies. When configured on policy or category, the max-user-rate or max-cat-rate as configured would be additionally applied. Thus the lower of all values for max. rates would take effect.

max-cat-rate

Specifies the maximum bandwidth that traffic is allowed using this category with associated policy. The range is from 5Kbps to max-user-rate.

Valid units: bps(default), gbps, kbps, mbps.

max-cat-rate-percentage

Specifies the percentage of the value of the max-cat-rate option of the category, which is associated with the net bwc policy component to which this shaping policy is associated, that is available for this traffic flow. It is the maximum bandwidth as percentage of that traffic is allowed using this category with associated policy. The range is from 1 to 100.

dynamic

Specifies the type for policy to be dynamic type. This option is optional for the commands create, delete, and modify. The default valid is disabled. When dynamic is disabled, the policy type is said to be static, where the maximum rate is enforced for combined traffic using the policy and no fairness bandwidth guarantee for each of the traffic respectively. The default value is: disabled. Note: policy type change modification is a disallowed configuration.

By enabling this option, the policy is dynamic type and requires you to configure max-user-rate-range. This type of policy enforces fairness for all the traffic associated with the policy and also for each traffic within the policy.

ip-tos

Specifies an IP ToS number for the traffic using the net bwc policy. This option specifies the ToS level that the traffic management system assigns to UDP packets when sending them. The default value is pass-through, which indicates, do not modify UDP packets. The valid range for IP ToS value that can be specified is 0 to 63.

Note: If this is specified, bandwidth policy is not enforced. The packets are just marked for a downstream system to process.

link-qos

Specifies a Link QoS (VLAN priority) for the traffic using the net bwc policy. This option specifies the QoS level that the system assigns to UDP packets when sending. The default value is pass-through, which indicates, do not modify UDP packets. The valid range for QoS value is 0 to 7.

Note: If this is specified, bandwidth policy is not enforced. The packets are just marked for a downstream system to process.

measure

Enables or disables bandwidth measurement on all the future instances of bwc policy. Users can override this setting using iRules. If enabling measurement on all instances is not desired then users can keep this setting disabled and use iRules to enable measurement on specific instances of bwc policy.

log_publisher

Specifies the name of the log publisher configured in the system. Bandwidth measurement results will be sent to this log publisher.

log_period

Time interval in milliseconds representing the frequency of generation of bandwidth measurement logs.

categories

This specifies the categories under policy. Note: policy need to be enabled as dynamic to configure categories. Up to a maximum of 32 categories can be configured. All the categories under the dynamic policy share the bandwidth as specified for the category, up to a maximum of max-user-rate. Specify the maximum bandwidth for the category of traffic using max-cat-rate or by max-cat-rate-percentage as a percentage of the maximum user rate. Either only the range or absolute value is required.

Example to configure a dynamic bandwidth policy category using tmsh:

```
root@(localhost)(cfg-sync
Standalone)(Active)/(Common)(tmsh.net.bwc policy.gold-dynamic-policy)# categories add { web { max-cat-rate 600kbps } }

net bwc policy gold-dynamic-policy {
categories {
  web {
max-cat-rate 600kbps
  }
}
dynamic enabled
max-rate 40gbps
max-user-rate 1gbps
}
```

The parameters for dynamic policy and categories:

```
net bwc policy test-policy {
app-service none
categories {
  web {
app-service none
description "This is a web test cat"
max-cat-rate 600kbps
max-cat-rate-percentage 0
ip-tos 6
  }
}
description "This is a test"
dynamic enabled
ip-tos pass-through
link-qos pass-through
max-rate 40gbps
max-user-rate 1gbps
measure enabled
log-publisher /Common/my_log_publisher
log-period 2048
partition Common
}
```

Few Examples using iRule:

Please refer to iRule documentation for complete list of bwc commands. Below are few examples and do not cover all cases.

Example to associate static bwc policy using iRule:

```
when CLIENT_ACCEPTED {
  BWC::policy attach silver_static_policy
}
```

Example to associate dynamic bwc policy using iRule:

```
when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]
  BWC::policy attach gold-dynamic-policy $mycookie
}
```

Example for bwc policy to mark traffic flows using iRule:

```
BWC::mark > >
```

So to assign a policy, color, and mark here is an example rule

```
when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::color set gold_user p2p
  BWC::mark set gold_user tos 8 qos 4
}
```

Example for using bwc policy category to color a flow using iRule:

After a flow has been assigned a policy, at some later time when the traffic is classified the user can assign an application to this flow. This uses the bwc config to create a bwc policy with the categories keyword: for example, p2p category below:

```
tmsh create net bwc policy gold_user categories add { p2p { max-cat-rate 8mbps } } max-rate 10mbps max-user-rate 10mbps dynamic enabled
```

The rule args

```
BWC::color
```

So to assign a policy and color here is an example rule

```

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::color set gold_user p2p
}

```

Example for bwc policy rate change using iRule:

After a policy is created, irule can modify the rate for a session or category

The rule args

```
BWC::rate
```

```
BWC::rate
```

So to modify the rate

```

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::color set gold_user p2p
  BWC::mark set gold_user tos 8 qos 4
  BWC::rate $mycookie p2p 1000000bps
}

```

Example for bwc policy to measure the bandwidth using iRule:

```

BWC::measure << | | >
[session_str]>

```

To start the bandwidth measurement for BWC policy

```

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::measure start session
}

```

The above iRule will start the measurement of bandwidth on the gold_user policy instance. The results will be published to the destination specified in the log_publisher setting for the gold_user bwc policy. The measurement results will be logged every 'log_period' amount of time, which is also specified in the policy settings for gold_user.

Note: Attaching a BWC policy is a pre-requisite for all 'BWC::measure.' iRules. Failing to do so will result in the iRule execution failure which in turn will abort the connection.

To start the bandwidth measurement for a flow inside a BWC policy and tag the results.

```

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::measure identifier MYFLOW flow
  BWC::measure start flow
}

```

The above iRule will start the measurement of bandwidth on the current flow or the flow over which the current iRule is running. The results will be published to the destination specified in the log_publisher setting for the gold_user bwc policy. The measurement results will be logged every 'log_period' amount of time, which is also specified in the policy settings for gold_user. Every log message containing the bandwidth result will carry the tag 'MYFLOW'. This helps identify different types of bandwidth results when analyzing the bandwidth measurement results.

To start the bandwidth measurement for a BWC session and get the periodic results.

```

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  set measureID "MYSESSION"
  BWC::policy attach gold_user $mycookie
  BWC::measure identifier $measureID session
  BWC::measure start session
}

```

```

when SERVER_CONNECTED {
  TCP::collect
  set count 0
}

```

```

when SERVER_DATA {
  if {$count >= 1000 } {
    set rate [BWC::measure get rate session]
    set bytes [BWC::measure get bytes session]

```

```

log local0. "Rate $rate/sec : Bytes $bytes : for address $mycookie"
set count 0
}
TCP::release

```

```
TCP::collect
incr count
}
```

The above example creates an instance of BWC policy `gold_user` and enables measurement on it upon the `iRule` event `CLIENT_ACCEPTED`. It also starts collecting so that it keeps getting notified upon the data arrival. For every 1000 packets a measurement of bandwidth is logged. This is an example that illustrates how to measure bandwidth periodically using `iRules`. Note that the bandwidth measurement results are still sent to configured `log_publisher` at every `log_period` interval.

An example log message that is sent to a log publisher.

```
Apr 2 16:29:04 MYSESSION BWC Measurement: Moving average - 539277 bytes/sec. Total bytes - 7305051
```

Example for `bwc` policy using `pps`:

```
BWC::pps

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::pps 100
}
```

net bwc priority-group

NAME

`priority-group` - Configures a bandwidth control policy for traffic flow.

MODULE

`net bwc`

SYNTAX

Configure the `priority-group` component within the `net bwc` module using the syntax in the following sections.

CREATE/MODIFY

```
create priority-group [name]
modify priority-group [name]
options:
  app-service [[string] | none]
  description [string]
  priority-classes [none] {
    description [string]
    weight-percentage [integer]
  }
}
```

```
edit priority-group [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
  all-properties
  non-default-properties
```

DISPLAY

```
list priority-group
list priority-group [ [ [name] | [glob] | [regex] ] ... ]
show running-config net bwc priority-group
show running-config net bwc priority-group [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete net bwc priority-group [all | [name] ]
```

DESCRIPTION

You can use the `net bwc priority-group` to create a bandwidth traffic group policy to handle traffic flow, and then associate it with `bwc` component such as `bwc policy/category`.

EXAMPLES

create net bwc priority-group

Creates a bwc policy (see below).

list net bwc priority-group all-properties

Displays all of the properties of all of the bwc policies.

delete net bwc priority-group

Deletes a bwc traffic group (see below).

Example for dynamic policy:

```
net bwc priority-group tc-GOLD {
  priority-classes {
    tc-BLUE {
      weight-percentage 30
    }
    tc-RED {
      weight-percentage 20
    }
  }
}
```

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies a unique name for the policy. This option is required for the commands create, delete, and modify.

description

User defined description.

weight-percentage

Specifies the percentage of maximum bandwidth that traffic is allowed during congestion using the traffic class associated. The valid range is 5-100.

iRule

Please refer to iRule documentation for iRule to use bandwidth control policy.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

COPYRIGHT

BIG-IP 2016-05-18 net bwc priority-group(1)

net bwc traffic-group

NAME

traffic-group - Configures a bandwidth control policy for traffic flow.

MODULE

net bwc

SYNTAX

Configure the traffic-group component within the net bwc module using the syntax in the following sections.

CREATE/MODIFY

```
create traffic-group [name]
modify traffic-group [name]
options:
  app-service [[string] | none]
  description [string]
  dynamic [ enabled ]
  priority-classes [none] {
    weight-percentage [integer]
  }
```

edit traffic-group [[[name] | [glob] | [regex]] ...]

options:

- all-properties
- non-default-properties

DISPLAY

list traffic-group

list traffic-group [[[name] | [glob] | [regex]] ...]

show running-config net bwc traffic-group

show running-config net bwc traffic-group [[[name] | [glob] | [regex]] ...]

options:

- all-properties
- non-default-properties
- one-line

DELETE

delete net bwc traffic-group [all | [name]]

DESCRIPTION

You can use the net bwc traffic-group to create a bandwidth traffic group policy to handle traffic flow, and then associate it with bwc component such as bwc policy/category.

EXAMPLES

create net bwc traffic-group

Creates a bwc policy (see below).

list net bwc traffic-group all-properties

Displays all of the properties of all of the bwc policies.

delete net bwc traffic-group

Deletes a bwc traffic group (see below).

Example for dynamic policy:

net bwc traffic-group tc-GOLD {

priority-classes {

tc-BLUE {

weight-percentage 30

}

tc-RED {

weight-percentage 20

}

}

}

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies a unique name for the policy. This option is required for the commands create, delete, and modify.

description

User defined description.

weight-percentage

Specifies the maximum bandwidth that traffic is allowed during congestion using the traffic class associated. The range is from 1Mbps to 320Gbps.

Valid units: bps(default), gbps, kbps, mbps.

dynamic

Specifies the type for traffic group to be dynamic type. This option is optional for the commands create, delete, and modify. The default valid is disabled. When dynamic is disabled, the traffic group type is said to be static. The type of traffic group should match with be bwc policy that would be mapped. Note: policy type change modification is a disallowed configuration.

iRule

Please refer to iRule documentation for iRule to use bandwidth control policy.

net clone-stats

NAME

clone-stats - Display and Reset Clone Statistics.

MODULE

net

SYNTAX

Display and Reset the clone-stats component within the net module using the syntax in the following section.

MODIFY

reset-stats clone-stats

DISPLAY

show clone-stats

options:

(default | field-fmt)

DESCRIPTION

You can use the clone-stats component to display and reset clone statistics. This will help to debug the clone feature.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

reset-stats, show, tmsh

net cmetrics

NAME

cmetrics - Displays and deletes entries in the route metrics table on the BIG-IP(r) system.

MODULE

net

SYNTAX

Use the cmetrics component within the net module to view route metrics or delete a route metric entry using the following syntax.

DISPLAY

show cmetrics

option:

bandwidth

dest-addr [ip address]

hwaddress

mtu

rtt

rttvar

ssthresh

tmm

DELETE

delete cmetrics

option:

dest-addr [IP address]

DESCRIPTION

You can use the cmetrics component to display entries in the route metrics table on the BIG-IP system. Additionally, you can delete a specified route metric entry from the table. The options are display-only values and cannot be used for filtering.

Note: You can delete only entries that have no connection references.

EXAMPLES

show cmetrics

Displays all the entries in the route metrics table.

delete cmetrics dest-addr 10.10.1.11

Deletes the entry with destination IP address 10.10.1.11 from the route metrics table.

OPTIONS

bandwidth

Displays the size of the channel in kbps. Computed as cwnd/rtt.

dest-addr

Specifies the destination IP address of the entry that you want to display or delete. You can enter this address in either IPv4 or IPv6 format.

hwaddress

Displays the Media Access Control (MAC) address for the route.

mtu Displays the maximum transmit unit size (in bytes) on the route.

rtt Displays the round-trip time on the route in units of 100ns.

rttvar

Displays the variation in the round-trip time in units of 100ns.

ssthresh

Displays the cached slow-start threshold in bytes.

tmm Displays the identifying number of the tmm (Traffic Management Microkernel).

SEE ALSO

delete, show, tmsh

COPYRIGHT

BIG-IP 2015-10-08 net cmetrics(1)

net cos global-settings

NAME

global-settings - Configures the global configuration for class of service (CoS).

MODULE

net cos

SYNTAX

Modify the global-settings component within the net cos module using the syntax shown in the following sections.

CREATE/MODIFY

modify global-settings

options:

feature-enabled

feature-disabled

precedence [dscp-only, 8021p-only]

default-map-dscp

[add | delete | modify | replace-all-with] {

[map-dscp-name] ...

}

default-map-8021p

[add | delete | modify | replace-all-with] {

[map-8021p-name] ...

}

default-traffic-priority [traffic-priority-name]

DISPLAY

list global-settings

options:

all-properties

non-default-properties

one-line
show global-settings

DESCRIPTION

You can use the global-settings component to configure and view information about the global settings of all CoS behavior.

show keyword displays an analysis of the relative weights of the associated traffic-priority objects.

EXAMPLES

modify global-settings default-traffic-priority NORMAL_PRIORITY

Replace the default traffic-priority with traffic-priority NORMAL_PRIORITY.

modify global-settings default-map-8021p add { VOIP }

Add the VOIP 802.1p mapping. The VOIP object specifies the 802.1p field value and associated traffic priority.

OPTIONS

feature-enabled

Enable 8 hardware egress CoS queue feature.

feature-disabled

Disable 8 hardware egress CoS queue feature.

precedence

Specifies the precedence between handling of DSCP and 802.1p. Currently, provided options are dscp-only and 8021p-only.

default-map-dscp

Enables adding and removal of mappings between DSCP field values and traffic priorities. See net cos traffic-priority and net cos map-dscp.

default-map-8021p

Enables adding and removal of mappings between 802.1p field values and traffic priorities.

default-traffic-priority

Specifies the default traffic-priority which is applied to all traffic that does not match a specified DSCP/802.1p field value. This allows the user to specify only the mappings which do not match the default.

SEE ALSO

net cos traffic-priority, net cos map-dscp

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 net cos global-settings(1)

net cos map-8021p

NAME

map-8021p - Configures vlan 8021.p tag to traffic priority mapping.

MODULE

net cos

SYNTAX

Modify the map-8021p component within the net cos module using the syntax shown in the following sections.

CREATE/MODIFY

create map-8021p [name]

modify map-8021p [name]

options:

value [0..7]

traffic-priority [name]

edit map-8021p [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list map-8021p

list map-8021p [[[name] | [glob] | [regex]] ...]

```
show map-8021p
show map-8021p [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

```
DELETE
delete map-8021p [name]
```

DESCRIPTION

The map-8021p object allows users to associate 802.1p field values to relative traffic priority. These objects are associated with active system configuration via net cos global-settings.

EXAMPLES

```
create map-8021p VOIP value 4 traffic-priority HIGH_PRIORITY
```

Create the map-8021p named VOIP that associates 802.1p value 4 traffic with traffic-priority named HIGH_PRIORITY.

```
delete map-8021p VOIP
```

Delete the map-8021p named VOIP.

OPTIONS

value
Specifies the 802.1p field value.

traffic-priority
Specifies the traffic-priority object associated with traffic matching value.

SEE ALSO

create, delete, edit, glob, list, net cos global-settings, modify, net cos traffic-priority, net cos map-dscp, regex, show, tmsh

COPYRIGHT

BIG-IP 2013-07-01 net cos map-8021p(1)

net cos map-dscp

NAME

map-dscp - Configures IP DSCP field to traffic priority mapping.

MODULE

net cos

SYNTAX

Modify the map-dscp component within the net cos module using the syntax shown in the following sections.

```
CREATE/MODIFY
create map-dscp [name]
modify map-dscp [name]
options:
  value [0..7]
  traffic-priority [name]
```

```
edit map-dscp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list map-dscp
list map-dscp [ [ [name] | [glob] | [regex] ] ... ]
```

```
show map-dscp
show map-dscp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

DELETE
delete map-dscp [name]

DESCRIPTION
The map-dscp object allows users to associate DSCP field values to relative traffic priority. These objects are associated with active system configuration via net cos global-settings.

EXAMPLES
create map-dscp VOIP value 4 traffic-priority HIGH_PRIORITY

Create the map-dscp named VOIP that associates DSCP value 4 traffic with traffic-priority named HIGH_PRIORITY.

delete map-dscp VOIP

Delete the map-dscp named VOIP.

OPTIONS
value
Specifies the DSCP field value.

traffic-priority
Specifies the traffic-priority object associated with traffic matching value.

SEE ALSO
create, delete, edit, glob, list, net cos global-settings, modify, net cos traffic-priority, net cos map-dscp, regex, show, tmsh

COPYRIGHT

BIG-IP 2013-07-01 net cos map-dscp(1)

net cos traffic-priority

NAME
traffic-priority - Configures a traffic priority object.

MODULE
net cos

SYNTAX
Modify the traffic-priority component within the net cos module using the syntax shown in the following sections.

CREATE/MODIFY
create traffic-priority [name]
modify traffic-priority [name]
options:
 weight [1..127]
 buffer [1..127]

edit traffic-priority [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list traffic-priority
list traffic-priority [[[name] | [glob] | [regex]] ...]

show traffic-priority
show traffic-priority [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
 field-fmt

DELETE
delete traffic-priority [name]

DESCRIPTION
The traffic-priority object allows users to assign relative scheduling and buffer weightings. These objects are associated to specific traffic with net cos map-dscp and net cos map-8021p. There can be at most 8 traffic-priorities defined in the system. The DEFAULT_PRIORITY priority may be deleted or modified as desired.

EXAMPLES

```
create traffic-priority HIGH_PRIORITY weight 127
```

Create the traffic-priority HIGH_PRIORITY that has a weight of 127.

```
delete traffic-priority HIGH_PRIORITY
```

Delete the traffic-priority named HIGH_PRIORITY.

OPTIONS

weight

Specifies the egress buffer weight. This value is used relative to other egress traffic-priority objects typical of weighted round-robin behavior.

buffer

Specifies the relative buffer weight where available egress buffer space is distributed with consistent relative weight.

SEE ALSO

create, delete, edit, glob, list, net cos global-settings, modify, net cos map-dscp, net cos map-8021p, regex, show, tmsb

BIG-IP 2016-03-14 net cos traffic-priority(1)

net dag-globals

NAME

dag-globals - configure global disaggregation settings.

MODULE

net

SYNTAX

Configure the dag-globals component within the net module using the syntax shown in the following sections.

MODIFY

modify dag-globals

options:

round-robin-mode [global | local]

dag-ipv6-prefix-len [integer]

icmp-hash [icmp | ipicmp]

icmp-monitor-priority [high | normal]

edit dag-globals

options:

all-properties

non-default-properties

DISPLAY

list dag-globals

show running-config dag-globals

options:

all-properties

non-default-properties

one-line

DESCRIPTION

Provides the ability to configure global disaggregation settings.

round-robin-mode

Specifies whether the round robin disaggregator (DAG) on a blade can disaggregate packets to all the TMMs in the system or only to the TMMs local to the blade.

dag-ipv6-prefix-len

Specifies whether SPDAG or IPv6 prefix DAG should be used to disaggregate IPv6 traffic when vlan cmp hash is set to src-ip or dst-ip. The default value is 128, using SPDAG.

icmp-hash

Specifies ICMP hash for ICMP echo request and ICMP echo reply in SW DAG. ICMP echo request and ICMP echo reply can be disaggregated based on ICMP id or ICMP id and IP addresses. The default ICMP hash is ICMP id.

icmp-monitor-priority
Specifies the priority for ICMP monitor traffic. The default value is normal.

SEE ALSO
list, modify, show, tmsh

BIG-IP 2018-05-09 net dag-globals(1)

net dns-resolver

NAME
resolver - Configures a DNS resolver on the BIG-IP(r) system.

MODULE
net dns-resolver

SYNTAX
Configure the DNS resolver component using the syntax in the following sections.

CREATE/MODIFY
create [name]
modify [name]
options:
 answer-default-zones [yes | no]
 app-service [[string] | none]
 cache-size [integer]
 description [string]
 forward-zones [add | delete | modify | replace-all-with] {
 [[zone-name]] {
options:
 nameservers [add | delete | replace-all-with] {
 [[IPv4address:port] | [IPv6address.port]]
 }
 nameservers none
 }
 forward-zones none
 randomize-query-name-case [yes | no]
 route-domain [name]
 use-ipv4 [yes | no]
 use-ipv6 [yes | no]
 use-tcp [yes | no]
 use-udp [yes | no]

DISPLAY
list
list [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line
show [name]
reset-stats

DELETE
delete [name]

DESCRIPTION
You can use the dns-resolver component to configure and view information about a DNS Resolver object. A DNS resolver performs recursive resolution to fill its cache.

Important: When sizing caches, consider the total amount of memory available and how you wish to allocate memory for DNS caching. Note that cache sizing values are per-TMM process; therefore, a platform with eight TMMs consumes the amount of memory set for the Resolver object times eight.

Important: DNS Resolver objects use the DNS root nameservers published by InterNIC.

EXAMPLES
list

Displays the properties of the DNS Resolver myRes.

OPTIONS

answer-default-zones

Specifies whether the resolver answers queries for default zones: localhost, reverse 127.0.0.1 and ::1, and AS112 zones. The default value is no.

app-service

Specifies the name of the application service to which this dns-resolver belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this dns-resolver. Only the application service can modify or delete this dns-resolver.

cache-size

Specifies the maximum cache size in bytes of the DNS Resolver object. The default value is 5767168.

The BIG-IP system caches the supporting records in a DNS response in the resource record cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

description

User defined description.

forward-zones

Adds, deletes, modifies, or replaces a set of forward zones on a DNS Resolver, by specifying zone name(s). A given zone name should only use the symbols allowed for a fully qualified domain name (FQDN), namely ASCII letters a through z, digits 0 through 9, hyphen -, and period .. For example site.example.com would be a valid zone name.

A DNS Resolver configured with a forward zone will forward any queries that resulted in a cache-miss (the answer was not available in the cache) and which also match a configured zone name, to the nameserver specified on the zone. If no nameservers are specified on the zone, an automatic SERVFAIL is returned. When a forward zone's nameserver returns a valid response to the DNS Cache, that response is cached and then returned to the requestor.

nameservers

Adds, deletes, modifies, or replaces a set of nameservers in a forward zone on a DNS Resolver. A nameserver is represented by an IPaddress and port in the format [IPv4:port] or [IPv6.port], for example 10.10.10.10:53 or 2001::1:ff:53, respectively.

If more than one nameserver is listed for a given forward zone, a matching query will be sent to the nameserver that is currently deemed the most responsive (based on RTTs). If no response is received within a certain window of time, the DNS Resolver will resend the query to another nameserver with an increased wait window, until a response is received.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

randomize-query-name-case

Specifies whether the resolver randomizes the case of query names. The default value is yes.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

route-domain

Specifies the route domain the resolver uses for outbound traffic. The default value is the default route domain.

use-ipv4

Specifies whether the resolver sends DNS queries to IPv4 addresses. The default value is yes.

use-ipv6

Specifies whether the resolver sends DNS queries to IPv6 addresses. The default value is yes.

use-tcp

Specifies whether the resolver can send queries over the TCP protocol. The default value is yes.

use-udp

Specifies whether the resolver can send queries over the UDP protocol. The default value is yes.

SEE ALSO

create, delete, edit, glob, list, show, modify, regex, tmsh

net f5optics

NAME
f5optics - Manage f5optics package.

MODULE
net

SYNTAX
Manage net f5optics using the syntax in the following section.

INSTALL
install f5optics
options:
recovery
slot [[slot number] | all]

SHOW
show f5optics

DESCRIPTION
The f5optics package specifies the supported optical PHY modules and their tuning parameters for network interfaces. You can use the f5optics component to manage the f5optics package. The install command will install f5optics with the latest f5optics package under /shared/f5optics/images. Additionally, for a cluster, you can use the slot option to specify either a specific slot or all slots to install the f5optics package.

Notice that the installation will cause network interfaces to be re-initialized on the affected slot(s), hence a temporary traffic interruption.

The show command will display the version information of the installed f5optics package on the appliance, or all the slots in a cluster.

EXAMPLES
install net f5optics

Install the f5optics package on the appliance, or all the slots in a cluster.

install net f5optics slot all

Install the f5optics package on all the slots in a cluster.

install net f5optics recovery slot all

Install the f5optics package on all the slots in a cluster, even if it is not newer than the installed package.

install net f5optics slot 2

Install the f5optics package on slot 2.

show net f5optics

Show the f5optics package on the appliance, or all the slots in a cluster.

OPTIONS
recovery
Always install the latest f5optics package, even if it is not newer than the installed package. This is for recovery purposes.

slot [[slot number] | all]
Install the f5optics package on either a specific slot or all slots in a cluster, without changing the active volume of the slot(s).

This option is only available in a clustered environment.

net fdb tunnel

NAME

tunnel - Manages tunnel entries in the Layer 2 Forwarding table.

MODULE

net fdb

SYNTAX

Configure the tunnel component within the net fdb module using the syntax in the following sections.

MODIFY

```
modify tunnel [tunnel name]
options:
  app-service [ [string] | none]
  records [add | delete | modify | replace-all-with] {
    [MAC address] {
  app-service [[string] | none]
  description [string]
  endpoint [IP address]
  endpoints [add | delete | modify | replace-all-with] {
    [IP address(es)]
  }
  replicators [add | delete | modify | replace-all-with] {
    [IP address(es)]
  }
}
}
records none
```

DISPLAY

```
list tunnel
list tunnel [ [ [tunnel name] | [glob] | [regex] ] ... ]
show tunnel
show tunnel [ [ [tunnel name] | [glob] | [regex] ] ... ]
options:
  all-records
  dynamic
  field-fmt
  static
```

DELETE

```
delete tunnel [tunnel name]
options:
  all-records
  dynamic
  static
```

DESCRIPTION

You can use the tunnel component to manage tunnel entries in the Layer 2 Forwarding table.

EXAMPLES

```
modify tunnel t1 records add { 00:01:02:03:04:05 { endpoint 10.10.0.2 } }
```

Creates a tunnel entry for the specified tunnel in the Layer 2 Forwarding table.

```
modify tunnel t1 records none
```

Deletes all configured tunnel entries for the specified tunnel in the Layer 2 Forwarding table.

```
modify tunnel t1 records add { ff:ff:ff:ff:ff:ff { endpoints add { 10.10.0.2 10.10.0.3 10.10.0.4 } } }
```

Creates a set of endpoints for the specified tunnel in the Layer 2 Forwarding table.

```
list tunnel
```

Displays all configured tunnel entries in the Layer 2 Forwarding table.

```
show tunnel
```

Displays all dynamic and static tunnel entries in the Layer 2 Forwarding table.

```
delete tunnel t1 all-records
```

Deletes all dynamic and static tunnel entries in the Layer 2 Forwarding table.

OPTIONS

all-records

Applies the command to all dynamic and static tunnel entries in the Layer 2 Forwarding table.

dynamic

Applies the command to all dynamic tunnel entries in the Layer 2 Forwarding table.

static

Applies the command to all static tunnel entries in the Layer 2 Forwarding table.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

glob, net tunnels, regex, show, tmsh

non-default-properties

one-line

partition

records

show vlan

show vlan [[[vlan name] | [glob] | [regex]] ...]

options:

dynamic

field-fmt

static

DELETE

delete vlan

delete vlan [all | [vlan name]]

options:

all-records

dynamic

static

DESCRIPTION

You can use the vlan component to manage entries in VLAN Layer 2 Forwarding tables.

EXAMPLES

modify vlan internal records add { 00:0b:09:88:00:9a { interface 1.2 } }

Creates a mapping of the MAC address 00:0b:09:88:00:9a to interface 1.2 on VLAN internal.

modify vlan internal records modify { 00:0b:09:88:00:9a { interface 1.1 } }

Modifies the mapping of the MAC address 00:0b:09:88:00:9a to interface 1.1 on VLAN internal.

show vlan

Displays all dynamic and static entries in the Layer 2 Forwarding table.

list vlan all-properties

Displays all properties for all static entries in the Layer 2 Forwarding table.

list vlan non-default-properties

Displays all non-default properties for all static entries in the Layer 2 Forwarding table.

delete vlan all

Deletes all entries in all VLAN Layer 2 Forwarding tables.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

all-records

Deletes, from the specified VLAN, all dynamic and static records.

description

User defined description.

dynamic

Displays or deletes all dynamic entries in the Layer 2 Forwarding table.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interface

Specifies an interface to which you want to map a MAC address. You must specify either an interface or a trunk when you create an entry in the Layer 2 Forwarding table.

MAC address

Specifies a 6-byte ethernet address in not case-sensitive hexadecimal colon notation, for example, 00:0b:09:88:00:9a. You must specify a MAC address when you create an entry in the Layer 2 Forwarding table.

partition

Displays the administrative partition in which the VLAN resides.

records

Specifies MAC addresses for the VLAN Layer 2 Forwarding table. Specifies MAC addresses that you want to add to, delete from, modify, or replace in the VLAN Layer 2 Forwarding table.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

static

Displays or deletes all static entries in the Layer 2 Forwarding table.

trunk

Specifies a trunk to which you want to map a MAC address. You must specify either an interface or a trunk when you create an entry in the Layer 2 Forwarding table.

SEE ALSO

net interface-cos

NAME

interface-cos - Displays and resets COS (Class of Service) related statistics for the interfaces.

MODULE

net

SYNTAX

Display cos related statistics within the net module using the following syntax.

MODIFY

reset-stats interface-cos

DISPLAY

show interface-cos

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

global

DESCRIPTION

You can use the interface-cos component to display COS related statistics, including pkts out and bits out for all 8 COS queue.

EXAMPLES

show interface-cos

Displays interface COS related statistics for the system.

For information about the command reset-stats, see help reset-stats.

SEE ALSO

reset-stats, show,

show interface

show interface [[[name] | [glob] | [regex]] ...]
options:
all-properties
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

DESCRIPTION

You can use the interface component to enable or disable an interface, and to display and set media options, duplex mode, and status for an interface. In addition, you can specify whether the interface participates in the spanning tree protocol (STP) configuration, and set per-interface STP parameters such as link type, edge port status, and automatic edge port detection.

EXAMPLES

modify interface 1.1 enabled

Enables the interface named 1.1.

modify interface 1.2 disabled

Disables the interface named 1.2.

modify interface 1.1 1.2 1.3 stp disable

Disables STP on the interfaces named 1.1, 1.2, and 1.3.

modify interface 1.1 1.2 1.3 stp-auto-edge-port enabled

Sets auto edge detection for STP on the interfaces named 1.1, 1.2, and 1.3.

modify interface 1.1 1.2 1.3 stp-edge-port true

Sets the edge port attribute for STP on the interfaces named 1.1, 1.2, and 1.3.

OPTIONS

description

User defined description.

[disabled | enabled]

Enables or disables the specified interface. The default value is enabled.

flow-control

Specifies how the system controls the sending of PAUSE frames for flow control. The default value is tx-rx.

none Disables flow control.

rx Specifies that the interface honors pause frames from its partner, but does not generate pause frames.

tx Specifies that the interface ignores pause frames from its partner, and generates pause frames when necessary.

tx-rx

Specifies that the interface honors pause frames from its partner, and also generates pause frames when necessary.

force-gigabit-fiber

Enables or disables forcing of gigabit fiber media. If this is enabled for a gigabit fiber interface, the media setting will be forced, and no auto-negotiation will be performed. If it is disabled, auto-negotiation will be performed with just a single gigabit fiber option advertised.

forward-error-correction

Enables or disables IEEE 802.3bm Clause 91 Reed-Solomon Forward Error Correction (RS-FEC) on 100G interfaces. This setting is not valid for LR4 media. This setting must be the same on both ends of the link.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

if-index

Displays the index assigned to this interface. It is a unique identifier assigned for all objects displayed in the SNMP IF-MIB.

mac-address

Displays the 6-byte ethernet address in not case-sensitive hexadecimal colon notation, for example, 00:0b:09:88:00:9a.

media

Specifies the settings for the interface. The possible values are: 10baseT-full, 10baseT-half, 10GbaseER-full, 10GbaseLR-full, 10GbaseSR-full, 10GbaseT-full, 10SFP+Cu-full, 40GbaseSR4-full, 40GbaseLR4-full, 100baseTX-half, 100baseTX-full, 1000baseLX full, 1000baseCX-full, 1000baseT-full, 1000baseT-half, 1000baseSX-full, auto, and no-phy.

When you set the media option, the system automatically sets either the media-sfp or media-fixed option, based on whether the interface supports small form factor pluggable (SFP) interfaces, or for combo ports whether SFP is the preferred port.

media-active

Displays the current media setting for the interface.

media-fixed

Specifies the settings for a fixed (non-pluggable) interface. Use this option only with a combo port to specify the media type for the fixed interface, when it is not the preferred port.

media-max

Displays the maximum media value for the interface.

media-sfp

Specifies the settings for an SFP (pluggable) interface. Note that you use this option only with a combo port to specify the media type for the SFP interface, when it is not the preferred port.

module-description

Displays an optics module description about the interface. It is only available on a SFP/SFP+/XFP/QSFP+/QSFP28 unit.

transmitter-technology

Displays the transmitter technology of the pluggable unit on an interface. It is only available on a QSFP+/QSFP28 unit.

mtu Displays the Maximum Transmission Unit (MTU) of the interface, which is the maximum number of bytes in a frame without IP fragmentation.

name Specifies an interface name, for example 3.1, where 3 is the physical slot number holding the network interface hardware and 1 is the physical port number of that interface on that hardware. Another example is mgmt, the name given to the management interface.

no-mgmt

Ensures that no changes are made to the mgmt interfaces when all is specified. This is especially convenient when disabling all traffic interfaces using the disabled command.

[pending | not-pending]

Pending indicates that the slot with which the interface is associated does not contain a blade. Not-pending indicates that the slot with which the interface is associated is not a cluster member. The default value is pending.

port-fwd-mode

Specifies the port forwarding mode. The default value is I3.

The options are:

I3 Specifies to use the I3 mode. This is the traditional mode of operation of BIGIP, wherein BIGIP forwards traffic between 2 VLANs.

passive

Specifies to use the passive mode. Use this mode to enable the BIGIP to process out of band traffic. In this mode, the BIGIP assumes the received traffic is a copy of real inline traffic, and while it processes it like regular traffic, traffic received on such an interface is never forwarded out.

virtual-wire

Specifies to use the virtual-wire mode. Use this mode to enable the BIGIP to operate like a L2 switch - transparent to the neighboring devices. Packets received on a virtual-wire interface can only be forwarded to another virtual-wire-configured interface. Such traffic retains the L2 header and is forwarded to the same VLAN.

prefer-port

Indicates which side of a combo port the interface uses, if both sides of the port have the potential for external links. The default value is sfp. Do not use this option for non-combo ports.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

sflow

Specifies sFlow settings for the interface:

poll-interval

Specifies the maximum interval in seconds between two pollings. The default value is 0. To enable this setting, you must also set the poll-interval-global setting to no.

poll-interval-global

Specifies whether the global interface poll-interval setting, which is available under sys sflow global-settings module, overrides the object-level poll-interval setting. The default value is yes.

The available values are:

no Specifies to use the object-level poll-interval setting.

yes Specifies to use the global interface poll-interval setting.

serial

Displays the serial number of the pluggable unit on an interface. It is only available on a SFP/SFP+/XFP/QSFP+/QSFP28 unit.

stp Enables or disables STP. If you disable STP, no STP, RSTP, or MSTP packets are transmitted or received on the interface or trunk, and spanning tree has no control over forwarding or learning on the port or the trunk. The default value is enabled.

stp-auto-edge-port
Sets the STP automatic edge port detection for the interface. The default value is enabled. When STP automatic edge port detection is set to enabled on an interface, the system monitors the interface for incoming STP, RSTP, or MSTP packets. If no such packets are received for a sufficient period of time (about three seconds), the interface is automatically given edge port status. When automatic edge port detection is set to disabled on an interface, the system does not automatically give the interface the edge port status. Any STP setting set on a per-interface basis applies to all spanning tree instances.

stp-edge-port
Sets STP edge port detection. The default value is true.

stp-link-type
Specifies the STP link type for the interface. The default value is auto.

The spanning tree system includes important optimizations that can only be used on point-to-point links. That is, on links that connect just two bridges. If these optimizations are used on shared links, incorrect or unstable behavior may result. By default, the implementation assumes that full-duplex links are point-to-point and that half-duplex links are shared.

The options are:

auto Specifies that the system determines the spanning tree link type, which is based on the duplex setting.

p2p Specifies that the system uses the optimizations for point-to-point spanning tree links. Point-to-point links connect only two spanning tree bridges.

shared
Specifies that the system uses the optimizations for shared spanning tree links. Shared links connect two or more spanning tree bridges.

stp-reset
Resets STP, which forces a migration check.

qinq-ethertype
Specifies the ether-type value used for the packets handled on this port when it is a member in a QinQ vlan. The ether-type can be set to any string containing a valid hexadecimal 16 bits number, or any of the well known ether-types: 0x8100, 0x9100, 0x88a8. Default value is set to 0x8100.

bundle
Sets the bundle capability on the port.

bundle-speed
Sets the bundle-speed on the port when bundle capability is enabled.

if-index
Displays the index assigned to this interface. It is a unique identifier assigned for all objects displayed in the SNMP IF-MIB.

vendor
Displays the name of the vendor of the pluggable unit on an interface. It is only available on a SFP/SFP+/XFP/QSFP+/QSFP28 unit.

vendor-partnum
Displays the part number programmed by the vendor of the pluggable unit on an interface. It is only available on a SFP/SFP+/XFP/QSFP+/QSFP28 unit.

vendor-oui
Displays the vendor OUI of the pluggable unit on an interface. It is only available on a SFP/SFP+/XFP/QSFP+/QSFP28 unit.

vendor-revision
Displays the vendor revision of the pluggable unit on an interface. It is only available on a SFP/SFP+/XFP/QSFP+/QSFP28 unit.

net ipsec-stat

NAME

action - Displays and resets IPsec statistics.

MODULE

ipsec-stat

SYNTAX

Display statistics for the action component within the IPsec module using the syntax in the following section.

DISPLAY

show action

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the action component to display IPsec statistics. The statistics details are described below:

Cmd Id

Specifies the CPU id for IPsec.

Mode

Specifies the IPsec mode (TRANSPORT/TUNNEL).

Proto

Specifies the Ipsec Protocol (ESP/AH)..

Packets In

Specifies the number of incoming IPsec packets.

Bytes In

Specifies the number of incoming IPsec bytes.

Packets Out

Specifies the number of outgoing IPsec packets.

Bytes Out

Specifies the number of outgoing IPsec bytes.

EXAMPLES

show action

Displays IPsec statistics.

reset-stats action

Resets the IPsec statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

BIG-IP 2017-03-02 net ipsec-stat(1)

net ipsec ike-daemon

NAME

ike-daemon - Configures the Internet Key Exchange (ISAKMP) daemon.

MODULE

net ipsec

SYNTAX

Configure the ike-daemon component within the net ipsec module using the syntax in the following sections.

MODIFY

modify ike-daemon

options:
description [string]
isakmp-natt-port [port number]
isakmp-port [port number]
log-level [error|warning|notify|info|debug|debug2]
natt-keep-alive [seconds]
log-publisher [string]

DISPLAY
list
list ike-daemon
show running-config ike-daemon
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use the ike-daemon component to configure global settings for the IKE agent.

EXAMPLES
modify ike-daemon isakmp-port 500

Sets the isakmp port to 500.

OPTIONS
description
User defined description.

isakmp-natt-port
Specifies the port that the IKE daemon uses to accept ISAKMP messages when NAT-Traversal is detected. This is also the port number used to accept UDP-encapsulated ESP traffic for NAT-Traversal. Only 4500 is currently supported.

isakmp-port
Specifies the port that the IKE daemon uses to accept ISAKMP messages. Only 500 is currently supported.

log-level
Specifies the logging level of the IKE daemon. The log file is located at /var/log/racoon.log.

natt-keep-alive
Specifies the interval between sending NAT-Traversal keep-alive packets. The default value is 20 seconds. Set to 0 to disable keep-alive packets.

log-publisher
Specifies the logging publisher. A new log-publisher object can be created via TMSH command tmsh create sys log-config publisher.

SEE ALSO
list, net ipsec ike-peer, tmsh

DESCRIPTION

You can use the ike-peer component to modify the IKE phase 1 parameters for each remote IKE peer. The setting in the default anonymous ike-peer will apply to any peer that does not match a more specific ike-peer directive.

EXAMPLES

```
create ike-peer SanJose { remote-address 1.2.3.4 preshared-key abc phase1-auth-method pre-shared-key }
```

Creates an ike-peer named SanJose that has the IP address of 1.2.3.4 using preshared key as the authentication method.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

ca-cert-file

Specifies the file name, which contains the certificates of the trusted root and intermediate certificate authorities.

crl-file

Specifies the file name of the Certificate Revocation List.

description

User-defined description.

dpd-delay

This option activates the Dead Peer Detection (DPD) and sets the time (in seconds) allowed between two proofs of liveness requests. The default value is 30. When the value is set to 0, it means to disable DPD monitoring, but still negotiate DPD support.

generate_policy

This directive is for the responder. To use it, set passive to true so the IKE peer is only a responder.

If the responder does not have any policy in the Security Policy Database (SPD) during phase 2 negotiation, and the directive is set to on, then the racoon daemon chooses the first proposal in the Security Association (SA) payload from the initiator, and generates policy entries from the proposal. It is useful to negotiate with clients whose IP address is allocated dynamically. If an inappropriate policy

is installed into the responder's SPD by the initiator, other communications might fail due to a policy mismatch between the initiator and the responder. The initiator ignores this directive. The default value is off.

lifetime

Specifies the lifetime of an IKE SA that will be proposed in the phase 1 negotiations.

mode Specifies the exchange mode for phase 1 when racoon is the initiator, or the acceptable exchange mode when racoon is the responder.

my-cert-file

Specifies the name of my certificate file. The certificate type must match the phase1-auth-method value. Note that there are no default certificates for DSS and ECDSA authentication methods.

my-cert-key-file

Specifies the name of my certificate key file. The certificate key type must match the phase1-auth-method value. Note that there are no default keys for DSS and ECDSA authentication methods.

my-cert-key-passphrase

Specifies the passphrase of the key used for my-cert-key-file. Note that only IKEv2 supports passphrase.

my-id-type

Specifies the identifier type sent to the remote host to use in the phase 1 negotiation.

my-id-value

Specifies the identifier value sent to the remote host to use in the phase 1 negotiation.

nat-traversal

Enables use of the NAT-Traversal IPsec extension (NAT-T). NAT-T allows one or both peers to reside behind a NAT gateway (that is, performing address- or port-translation). The presence of NAT gateways along the path is discovered during the phase 1 handshake, and if found, NAT-T is negotiated. When NAT-T is in charge, all ESP and AH packets of a given connection are encapsulated into UDP datagrams (port 4500, by default). The options are:

force

NAT-T is used regardless of whether NAT is detected between the peers.

off NAT-T is not proposed/accepted. This is the default.

on NAT-T is used when a NAT gateway is detected between the peers.

passive

Specify true if you do not want to be the initiator of the IKE negotiation with this ike-peer.

peers-cert-file

Specifies the peer's certificate for authentication. Deprecated in IKEv2 configuration.

peers-cert-type

Specifies that the only peers-cert-type supported is certfile. Deprecated in IKEv2 configuration.

peers-id-type

Specifies that address, fqdn, asn1dn, user-fqdn, or keyid-tag can be used as peers-id-type.

peers-id-value

Specifies the peer's identifier to be received. If it is not defined, then the IKE agent will not verify the peer's identifier in the ID payload transmitted from the peer. The usage of peers-id-type and peers-id-value is the same as my-id-type and my-id-value except that the individual component values of an asn1dn identifier may be specified as * to match any value (for example, "C=XX, O=MyOrg, OU=*, CN=Mine").

phase1-auth-method

Defines the authentication method used for the phase 1 negotiation. Possible values are: pre-shared-key if using preshared-key, and rsa-signature, dss, ecdsa-256, ecdsa-384 or ecdsa-521 if using X.509 certificate-based authentication. Note that dss, ecdsa certificates are supported in IKEv2 only."

phase1-encrypt-algorithm

Specifies the encryption algorithm used for the ISAKMP phase 1 negotiation. This directive must be defined. Possible value is one of following: des, 3des, blowfish, cast128, aes, or camellia for Oakley.

phase1-hash-algorithm

Defines the hash algorithm used for the ISAKMP phase 1 negotiation. This directive must be defined. The algorithm should be one of following: md5, sha1, sha256, sha384, or sha512 for Oakley.

phase1-perfect-forward-secrecy

Defines the Diffie-Hellman group for key exchange to provide perfect forward secrecy. This directive must be defined in one of Diffie-Hellman groups: modp768, modp1024, modp1536, modp2048, modp3072, modp4096, modp6144 and modp8192, or one of Elliptic-Curve Diffie-Hellman groups: ecp256, ecp384 and ecp521. Note that ECDH is supported in IKEv2 only.

preshared-key

Specifies the preshared key for ISAKMP SAs. This field is valid only when phase1-auth-method is pre-shared-key.

preshared-key-encrypted

Specifies the preshared key for ISAKMP SAs. This field is valid only when phase1-auth-method is pre-shared-key. Stores preshared-key in encrypted form.

prf Specifies the pseudo-random function to derive keying material for all cryptographic operations.

proxy-support

If this value is enabled, both values of ID payloads in the phase 2 exchange are used as the addresses of end-point of IPsec-SAs. This attribute must be enabled, which is the default value. This field is used only for IKEv1.

remote-address

Specifies the IP address of the IKE remote node. The format required for specifying a route domain ID in an IP address is A.B.C.D%ID. For example, A.B.C.D%2, where the IP address A.B.C.D pertains to route domain 2. The route domain id should be same as the route domain id specified in the source/destination address of the traffic selector associated with this remote node.

replay-window-size

Specifies the replay window size of the IPsec SAs negotiated with the IKE remote node. This window limits the number of out-of-order IPsec packets that can be received relative to the packet with the highest sequence number that has been authenticated so far. Packets with older sequence numbers that are outside this range are rejected. The default value is 64. The valid range is from 4 to 255.

state

Enables or disables this IKE remote node.

traffic-selector

Specifies the names of the traffic-selector objects associated with this ike-peer.

verify-cert

If set to true, the identifier sent by the remote host (as specified in its my_identifier statement) is compared with the credentials in the certificate as follows: Type asn1dn: the entire certificate subject name is compared with the identifier, e.g. \"C=XX, O=YY, ...\". Type address, fqdn, or user_fqdn: The certificate's subjectAltName is compared with the identifier. If the two do not match, the negotiation will fail. The default value is false, which is not to verify the identifier using the peer's certificate.

version

Specifies which version of IKE to be used. The default value is v1. The following versions are available:

v1 Specifies version IKEv1 will be used.

v2 Specifies version IKEv2 will be used.

net ipsec ike-sa

NAME

ike-sa - Displays IKE security associations on the BIG-IP(r) system.

MODULE

net ipsec

SYNTAX

Use the ike-sa component within the ipsec module to manage IKE security associations using the following syntax.

DISPLAY

show ike-sa

option:

all-properties

peer-ip [IP address]

peer-name [name]

route-domain [integer]

traffic-selector [name]

DESCRIPTION

You can use the ike-sa component to display information about IKE security associations in the system.

EXAMPLES

show ike-sa all-properties

Display detail information about IKE security associations.

OPTIONS

peer-ip

Specifies the peer IP address of the security associations that you want to display.

peer-name

Specifies the peer name of the security associations that you want to display.

route-domain

Specifies route domain used for traffic that you want to display. The default value is the default route domain.

traffic-selector

Specifies the name of the traffic-selector associated with the security associations that you want to display.

show running-config ipsec-policy

show running-config ipsec-policy [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

partition

DESCRIPTION

An ipsec-policy indicates the ipsec rule and action to be applied to the packets matched by the traffic-selector associated with this ipsec-policy.

EXAMPLES

```
create ipsec ipsec-policy tunnel_policy_sjc_sea { description "ipsec policy for the sjc-sea ipsec tunnel" mode
tunnel tunnel-local-address 1.1.1.1 tunnel-remote-address 2.2.2.2 }
```

Creates the tunnel mode ipsec-policy tunnel_policy_sjc_sea.

```
delete ipsec ipsec-policy tunnel_policy_sjc_sea
```

Deletes the ipsec-policy tunnel_policy_sjc_sea.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

ike-phase2-auth-algorithm
Specifies a payload authentication algorithm for ESP. This attribute is only valid when IKE is used to negotiate Security Associations. The possible options are: aes-gcm128, aes-gcm192, aes-gcm256, aes-gmac128, aes-gmac192, aes-gmac256, sha256, sha384, sha512 and sha1. The default value is aes-gcm128.

Note: Because aes-gcm and aes-gmac are authenticated encryption algorithms, when ike-phase2-auth-algorithm is set to aes-gcm or aes-gmac, ike-phase2-encrypt-algorithm has to be set to the identical algorithm with the same key length. sha256, sha384, sha512 and sha1 can only be used with an encryption algorithm that is NOT an authenticated encryption algorithm.

ike-phase2-encrypt-algorithm
Specifies an encryption algorithm for ESP. This attribute is only valid when IKE is used to negotiate security associations. The default value is aes-gcm128.

Note: Because aes-gcm and aes-gmac are authenticated encryption algorithms, when ike-phase2-encrypt-algorithm is set to one of these algorithms, ike-phase2-auth-algorithm has to be set to the identical algorithm with the same key length.

ike-phase2-lifetime
Specifies the lifetime duration in minutes, for the dynamically-negotiated security associations (SA). This attribute is only valid when IKE is used to negotiate security associations.

ike-phase2-lifetime-kilobytes
Specifies the lifetime duration in kilobytes, for the dynamically-negotiated security associations (SA). This attribute is only valid when IKE is used to negotiate security associations. A value of '0' means the SA will not re-key based on the number of bytes encrypted/decrypted. The minimum recommended value is 1000 kilobytes. This value is not negotiated between peers."

ike-phase2-perfect-forward-secrecy
Defines the group of Diffie-Hellman exponentiations. This attribute is only valid when IKE is used to negotiate Security Associations. The value 'none' indicates that the PFS is disabled for phase2 SA negotiations.

mode Specifies a security protocol mode for use. The options are:

transport
IPsec transport mode is used.

tunnel
IPsec tunnel mode is used.

interface
IPsec interface mode is used.

protocol
Specifies the IPsec protocol: Encapsulating Security Payload (ESP) or Authentication Header (AH).

ipcomp
Specifies the compression algorithm for IPComp. The following codec are available:

none Disable IPComp

deflate
Packets will be encapsulated with IPComp header and Deflate compression algorithm will be applied to the data.

null
Packets will be encapsulated with IPComp header but no compression algorithm will be applied to the data.

tunnel-local-address
Specifies the IP address of the local IPsec tunnel endpoint. This option is only valid when mode is tunnel. The format required for specifying a route domain ID in an IP address is A.B.C.D%ID. For example, A.B.C.D%2, where the IP address A.B.C.D pertains to route domain 2.

tunnel-remote-address
Specifies the IP address of the remote IPsec tunnel endpoint. This option is only valid when mode is tunnel. The format required for specifying a route domain ID in an IP address is A.B.C.D%ID. For example, A.B.C.D%2, where the IP address A.B.C.D pertains to route domain 2.

net ipsec ipsec-sa

NAME

ipsec-sa - Displays IPsec security associations on the BIG-IP(r) system.

MODULE

net ipsec

SYNTAX

Use the ipsec-sa component within the ipsec module to manage IPsec security associations using the following syntax.

DISPLAY

show ipsec-sa

option:

all-properties

src-addr [IP address]

dst-addr [IP address]

route-domain [integer]

spi [integer]

traffic-selector [name]

DESCRIPTION

You can use the ipsec-sa component to display information about IPsec security associations in the system.

EXAMPLES

show ipsec-sa all-properties

Display detail information about IPsec security associations.

OPTIONS

src-addr

Specifies the source IP address of the security associations that you want to display.

dst-addr

Specifies the destination IP address of the security associations that you want to display.

route-domain

Specifies route domain used for traffic that you want to display. The default value is the default route domain.

spi Specifies the SPI of the security associations that you want to display.

traffic-selector

Specifies the name of the traffic-selector object associated with the security associations that you want to display.

SEE ALSO

show, net ipsec traffic-selector, net ipsec ipsec-policy, tmsh

BIG-IP 2015-01-21 net ipsec ipsec-sa(1)

net ipsec manual-security-association

NAME

manual-security-association - Configures the IPsec manual-security-association.

MODULE

net ipsec

SYNTAX

Configure the manual-security-association component within the net ipsec module using the syntax in the following sections.

CREATE/MODIFY

create manual-security-association
modify manual-security-association
options:
 app-service [[string] | none]
 description [string]
 auth-algorithm [sha1]
 auth-key [key]
 destination-address [ip address]
 encrypt-algorithm [3des|aes128|aes192|aes256|null]
 encrypt-key [key]
 ipsec-policy [name]
 protocol [esp]
 source-address [ip address]
 spi [number]

DISPLAY
list manual-security-association
show running-config manual-security-association
options:
 app-service
 all-properties
 non-default-properties
 one-line

DELETE
delete manual-security-association [name]

DESCRIPTION

Manually configures Security Association Database(SAD) entries. Because each SA provides data protection only for unidirectional traffic, you must configure a manual-security-association for traffic in each direction to establish a bidirectional IPsec tunnel.

EXAMPLES

```
create ipsec manual-security-association msa_on_dut2_transport_in { auth-key test description "manual security association on dut2 for dut1 - transport" destination-address 7.7.7.7 encrypt-key test ipsec-policy transport_policy_on_dut2 source-address 2.2.2.2 spi 1025 }
```

Creates a manual-security-association object named msa_on_dut2_transport_in to use IPsec to protect traffic from 2.2.2.2 to 7.7.7.7 with the authentication key test and the encryption key test. The ipsec-policy object named transport_policy_on_dut2 is associated with this manually configured security association.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auth-algorithm

Specifies an authentication algorithm.

auth-key

Specifies the key for the authentication algorithm.

auth-key-encrypted

Displays the encrypted auth-key.

description

User-defined description.

destination-address

Specifies the destination of the security association.

encrypt-algorithm

Specifies an encryption algorithm.

encrypt-key

Specifies the key for the encryption algorithm.

encrypt-key-encrypted

Display the encrypted encrypt-key.

ipsec-policy

Specifies the ipsec-policy associated with this manual-security-association.

protocol

Specifies the IPsec protocol: Encapsulating Security Payload (ESP) or Authentication Header (AH).

source-address

Specifies the source address of the security association.

spi Specifies the Security Parameters Index. If this is the Security Association(SA) for the outbound traffic, make sure it matches the SPI of the inbound SA configured on the remote site and vice versa. SPI values between 0 and 255 are reserved for the future use by IANA and cannot be used.

SEE ALSO

net ipsec traffic-selector

NAME

traffic-selector - Configures a traffic selector for IPsec.

MODULE

net ipsec

SYNTAX

Configure the traffic-selector component within the net ipsec module using the syntax in the following sections.

CREATE/MODIFY

create traffic-selector [name]

modify traffic-selector [name]

options:

action [protect]

app-service [[string] | none]

description [string]

destination-address [ip address/netmask]

destination-port [port number]

direction [both | in | out]

ipsec-policy [name]

ip-protocol [protocol number]

order [integer]

source-address [ip address/netmask]

source-port [port number]

DISPLAY

list traffic-selector

list traffic-selector [name]

show traffic-selector

show traffic-selector [name]

DELETE

delete traffic-selector

delete traffic-selector [name]

DESCRIPTION

You can use the traffic-selector component to specify which incoming traffic you want the system to protect with IPsec.

EXAMPLES

```
create traffic-selector sjc2sea { source-address 10.10.10.0/24 destination address 20.20.20.0/24 direction
both ipsec-policy my_policy }
```

Creates a traffic-selector named sjc2sea, which has the IP address of 10.10.10.0/24 using ipsec-policy named my_policy.

OPTIONS

action

Specifies how the system handles traffic that matches the criteria in the traffic selector. Only protect is currently supported.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

destination-address

Specifies the destination IP address of the traffic to be matched. The format required for specifying a route domain ID in an IP address is A.B.C.D%ID. For example, A.B.C.D%2, where the IP address A.B.C.D pertains to route domain 2.

destination-port

Specifies the destination port number of the traffic to be matched.

direction

Specifies the direction of traffic to be protected with IPsec. If the direction is both, use source-address and destination-address with respect to the outbound direction. The default value is both.

ip-protocol

Specifies the IP protocol of the traffic to be matched.

ipsec-policy

Specifies the name of the IPsec policy to be enforced on the matched traffic.

order

Specifies the order in which traffic is matched, if traffic can be matched to multiple traffic selectors. Traffic is matched to the traffic selector with the highest priority (lowest order number).

source-address

Specifies the source IP address of the traffic to be matched. The format required for specifying a route domain ID in an IP address is A.B.C.D%ID. For example, A.B.C.D%2, where the IP address A.B.C.D pertains to route domain 2.

source-port

Specifies the source port number of the traffic to be matched.

net ipv6-subscriber-prefix-length

NAME

ipv6-subscriber-prefix-length - Configure global IPV6 Subscriber Prefix Length.

MODULE

net

SYNTAX

Configure the ipv6-subscriber-prefix-length component within the net module using the syntax shown in the following sections.

MODIFY

```
modify ipv6-subscriber-prefix-length
options:
  value [1 - 128, only multiples of 8]
```

```
edit ipv6-subscriber-prefix-length
```

```
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list ipv6-subscriber-prefix-length
show running-config ipv6-subscriber-prefix-length
options:
  all-properties
  non-default-properties
  one-line
```

DESCRIPTION

Provides the ability to configure global IPV6 Subscriber Prefix Length.

value

Specifies the Prefix Length value between 1 and 128 (Only multiples of 8 are allowed).

DESCRIPTION

Provides the ability to configure global LLDP settings.

[disabled | enabled]

To disable or enable LLDP feature on BIGIP.

max-neighbors-per-port

Specifies maximum neighbors per port BIGIP LLDP feature supports.

reinit-delay

Specifies time delay, in seconds, from when LLDP ports is disabled to a new LLDP initialization.

tx-delay

Specifies the minimum time delay, in seconds, between successive LLDP frame transmissions.

tx-hold

Specifies the multiplier to use to calculate the TTL of transmitted LLDP frame.

tx-interval

Specifies the time interval, in seconds, between LLDP frame transmission to its neighbors.

SEE ALSO

net lldp-neighbors

NAME

lldp-neighbors - show lldp neighbors information.

MODULE
net

SYNTAX
show lldp-neighbors information within the net module using the syntax shown in the following sections.

DISPLAY
show lldp-neighbors
options:
all
all-properties

DESCRIPTION
show lldp neighbor information.

SEE ALSO
modify, show, tmsh

COPYRIGHT

net mroute

NAME
mroute - Displays the multicast routes in the BIG-IP(r) system.

MODULE
net

SYNTAX
Display multicast route (mroute) entries within the net module using the syntax given below.

DISPLAY
show net mroute
options:
source [IP address]
group [multicast group address]

DESCRIPTION
Use the mroute component to display all the multicast routes in the BIG-IP(r) system. Results can be filtered using source option, group option, or both.

EXAMPLES
show net mroute

Displays all the multicast routes in the system.

show net mroute source 10.10.10.1

Displays all the multicast routes in the system whose source IP address is 10.10.10.1.

show net mroute group 224.1.0.13

Displays all the multicast routes in the system whose group multicast address is 224.1.0.13.

show net mroute source 10.10.10.1 group 224.1.0.13

Displays all the multicast routes in the system whose source IP address is 10.10.10.1 and group multicast address is 224.1.0.13.

OPTIONS
source
Specifies the source IP address of the multicast routes that you want to display.

group
Specifies the multicast group address to display. Only a single group may be specified with the group option.

SEE ALSO
show, tmsh

net multicast-globals

NAME

multicast-globals - Global IP multicast configuration options

MODULE

net

SYNTAX

Configure the multicast-globals component within the net module using the syntax shown in the following sections.

MODIFY

modify multicast-globals

options:

route-lookup-timeout [integer value: 0 ~ 2147483647]
max-pending-routes [integer value: 0 ~ 2147483647]
max-pending-packets [integer value: 0 ~ 2147483647]
rate-limit [disabled | enabled]

edit multicast-globals

options:

all-properties
non-default-properties

DISPLAY

list multicast-globals

show running-config multicast-globals

options:

all-properties
non-default-properties
one-line

DESCRIPTION

Configure global options related to IP multicast traffic processing.

EXAMPLES

modify multicast-globals route-lookup-timeout 2

Specifies the maximum lifetime, in seconds, of an incomplete MFC entry. The default value is 2.

modify multicast-globals max-pending-routes 256

Specifies the maximum number of incomplete MFC entries any TMM instance can have at one time. The default value is 256.

modify multicast-globals max-pending-packets 16

Specifies the maximum number of packets queued on behalf of a single incomplete MFC entry. The default value is 16.

modify multicast-globals rate-limit enabled

When enabled, the packet rate limit configured in the DB variable switchboard.maxmcastrate is enforced. Otherwise multicast packets are not rate limited. The default value is enabled.

net ndp

NAME

ndp - Configures IPv6-to-Ethernet neighbor discovery display and control.

MODULE

net

SYNTAX

Configure the ndp component within the net module using the syntax in the following sections.

CREATE/MODIFY

create ndp [name]

options:

description [string]

ip-address [ip address]

mac-address [MAC address]

modify ndp [name]

options:

description [string]

mac-address [MAC address]

edit ndp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list ndp

list ndp [[[name] | [glob] | [regex]] ...]

show running-config ndp

show running-config ndp

[[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

show ndp

show ndp [[[name] | [glob] | [regex]] ...]

options:

[all | dynamic | field-fmt | static]

DELETE

delete ndp [[all] | [name]...]

DESCRIPTION

Configures the IPv6-to-Ethernet address translation tables used by the IPv6 neighbor discovery protocol.

EXAMPLES

create ndp myNdp ip-address fec0:f515::c001 mac-address 00:0B:DB:3F:F6:57

Maps the IPv6 address, fec0:f515::c001, to the MAC address, 00:0B:DB:3F:F6:57, and the name of this entry is myNdp. Alternatively, the address can be used as the name, like the following example.

create ndp fec0:f515::c001 mac-address 00:0B:DB:3F:F6:57

Maps the IPv6 address, fec0:f515::c001, to the MAC address, 00:0B:DB:3F:F6:57.

show ndp

Displays all static and dynamic IPv6 address-to-MAC address mappings.

OPTIONS

ip-address

The IP address that is to be mapped. This is optional, and if not present, the name needs to be a string that represents a valid IP address.

description

User defined description.

dynamic

Displays dynamic IPv6 address-to-MAC address mapping.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ip-address

The IP address that is to be mapped. This is optional, and if not present, the name needs to be a string that represents a valid IP address.

mac-address

Specifies a 6-byte Ethernet address in hexadecimal colon notation that is not case-sensitive, for example, 00:0b:09:88:00:9a.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

static

Displays static IPv6 address-to-MAC address mapping.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsb

net packet-filter-trusted

NAME

packet-filter-trusted - Modifies or displays trusted allow lists for packet filters.

MODULE

net

SYNTAX

Configure the packet-filter-trusted component within the net module using the syntax in the following sections.

MODIFY

modify packet-filter-trusted

options:

description [string]

ip-addresses none

ip-addresses

[add | delete | replace-all-with] {

[ip address ...]

}

mac-addresses none

mac-addresses

[add | delete | replace-all-with] {

[MAC address ...]

}

vlan none

vlan

[add | delete | replace-all-with] {

[vlan name ...]

}

edit packet-filter-trusted

DISPLAY

list packet-filter-trusted

show running-config packet-filter-trusted

options:

all-properties

non-default-properties

one-line

DESCRIPTION

Use the packet-filter-trusted component to create a layer of security for the traffic management system using trusted allow lists.

Trusted allow lists are lists of IP addresses, MAC addresses, and VLANs that are exempt from packet filter rules.

Important: By default, packet filtering is disabled. You must enable packet filtering using the Configuration utility. For more information, see the TMOS(r) Management Guide for BIG-IP(r) Systems.

EXAMPLE

Creates a trusted allow list that allows anything listed to bypass the packet filter.

In the following example, you have an administrative laptop that you want to have unrestricted access to the traffic management system. This is a laptop, and therefore it might have a different IP address from time to time. One way to solve the problem is to add a trusted MAC address. This trusted allow list example shows the laptop MAC address as 00:02:3F:3E:2F:FE. Now the laptop can access the traffic management system regardless of what address it boots with or to which VLAN it is connected, as long as it is on the same physical segment as the traffic management system.

Also in this example, the traffic management system is configured for basic firewalling of the private/internal network. This example shows a way to filter incoming traffic and allow outgoing traffic to be unrestricted. To do this, you add trusted VLANs that represent all traffic that originated on the internal network. Another way to do this is to use trusted IP addresses instead, for example, 192.168.26.0/24.

```
modify packet-filter-trusted {
  vlans add { internal1 internal2 }
  mac-addresses add { 00:02:3F:3E:2F:FE }
}
```

OPTIONS

description
User defined description.

ip-addresses
Specifies a list of source IP addresses. Any traffic matching a source IP address in the list is automatically allowed. This simplifies configuration of the packet filter to allow trusted internal traffic to be passed from VLAN to VLAN without a filter rule, including out to the Internet. Processing of traffic by this option occurs before rule list evaluation, making it impossible to override this option and mask out (block) certain types of traffic with a packet filter rule. This option is empty by default.

mac-addresses
Specifies a list of MAC addresses. The system allows any traffic matching a MAC address in the source address list. This simplifies configuration of the packet filter to allow trusted internal traffic to be passed from VLAN to VLAN without a filter rule, including out to the Internet. Processing of traffic by this option occurs before rule list evaluation, making it impossible to override this option and mask out (block) certain types of traffic with a packet filter rule. This option is empty by default.

vlans
Specifies a list of ingress VLANs. Any traffic received on a VLAN that is on the ingress VLAN list is automatically allowed. This simplifies configuration of the packet filter to allow trusted internal traffic to be passed from VLAN to VLAN without a filter rule, including out to the Internet. Processing of traffic by this option occurs before rule list evaluation, making it impossible to override this option and mask out (block) certain types of traffic with a packet filter rule. This option is empty by default.

```

DESCRIPTION

You can use the packet-filter component to create a layer of security for the traffic management system using packet filter rules.

The BIG-IP(r) system packet filters are based on the Berkeley Software Design Packet Filter (BPF) architecture. Packet filter rules are composed of four mandatory attributes and three optional attributes. The mandatory attributes are name, order, action, and rule. The optional attributes are vlan, logging, and rate-class. The rule attribute you choose defines the BPF script to match for the rule.

Important: By default, packet filtering is disabled. You must enable packet filtering using the Configuration utility. For more information, see the TMOS(r) Management Guide for BIG-IP(r) Systems.

EXAMPLES

You can create a set of rules that specify what incoming traffic you want the system to accept and how to accept it. See the examples following.

Example 1: Block spoofed addresses

This example prevents private IP addresses from being accepted on a public VLAN. This is a way of ensuring that no one can spoof private IP addresses through the external VLAN of the system. In this example, the system logs when this happens:

```
create packet-filter spoof_blocker {
order 5
action discard
vlan external
logging enabled
rule " (src net 172.19.255.0/24) "
```

Example 2: Allow restricted management access

You can provide restricted SSH and HTTPS access to the traffic management system for management purposes, and keep a log of that access. Note: This not the same management access you can get through the management port/interface (mgmt); that interface is not affected by any packet filter configuration, and if that is the only way you want to allow access to your system, this configuration is not necessary.

In the first rule shown below, SSH is allowed access from a single fixed-address administrative workstation, and each access is logged. In the subsequent rule, browser-based Configuration utility access is allowed from two fixed-address administrative workstations; however, access is not logged.

```
create packet-filter management_ssh {
order 10
action accept
logging enabled
rule " (proto TCP) and (src host 172.19.254.10) and
(dst port 22) "
```

```
create packet-filter management_gui {
order 15
action accept
rule " (proto TCP) and (src host 172.19.254.2 or
src host 172.19.254.10) and (dst port 443) "
```

Example 3: Allow access to all virtual servers

In this final example, you can verify that all of the virtual servers in your configuration are reachable

from the public network. This is critical if you have decided to use a default-deny policy. This example also shows how to rate shape all traffic to the virtual server IP address with a default rate class (that can be overridden by individual virtual servers or iRules(r) later).

Note: This example has a single virtual server IP, and it does not matter what port traffic is destined for. If you want to be more specific, you can specify each service port, as well (for example, HTTP, FTP, telnet).

```
create packet-filter virtuals {
order 20
action accept
vlan external
rate class root
rule " ( dst host 172.19.254.80 ) "
}
```

OPTIONS

You can use these options with the packet-filter component to create packet filter rules:

action

Specifies how the system handles a packet that matches the criteria in the packet filter rule. There is no default; you must specify a value when you create a packet filter rule.

The possible values are:

accept

Indicates that the system accepts the packet, and stops processing additional packet filter rules, if there are any.

continue

Indicates that the system acknowledges the packet for logging or statistical purposes, but makes no decision on how to handle the packet. The system continues to evaluate traffic matching a rule with the Continue action, starting with the next packet filter rule in the list.

discard

Indicates that the system drops the packet, and stops processing additional packet filter rules, if there are any.

reject

Indicates that the system drops the packet, and also sends a reject packet to the sender, indicating that the packet was refused.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

logging

Enables or disables packet filter logging. If you omit this value, no logging is performed.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

order

Specifies a sort order greater than 0 (zero). No two rules may have the same sort order. There is a single, global list of rules. Each rule in the list has a relative integer order. The system first evaluates the rule with the lowest order value, and then evaluates all other rules based on ascent of the order value assigned to each rule.

For example, if there are 5 rules, numbered 500, 100, 300, 200, 201; the rule evaluation order is 100, 200, 201, 300, 500.

The system compares each packet to be filtered against the list of rules in sequence, starting with the first. Evaluation of the rule list stops on the first match that has an action of accept, discard or reject. A match on a rule with an action of none does not stop further evaluation of the rule list; the system updates the statistics count and generates a log if the rule indicates it, but otherwise rule processing continues with the next rule in the list.

F5 Networks recommends that you sequence rules for effect and efficiency; generally this means:

-- Assign the lowest order to more specific rules, so that the system will evaluate those rules first.

-- The system evaluates one expression with multiple criteria more efficiently than multiple expressions each with a single criterion.

This option is required.

rate-class

Specifies the name of a rate class. The value is the name of any existing rate class. If omitted, no rate filter is applied.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rule Specifies the BPF expression to match. The rule is mandatory, however you can leave it empty. If empty, the packet filter rule matches all packets.

vlan Specifies the VLAN to which the packet filter rule applies. The value for this option is any VLAN name currently in existence. If you omit this value, the rule applies to all VLANs. If you do not provide a VLAN name when you create a packet-filter, the rule applies to all VLANs.

BIG-IP 2013-10-25 net packet-filter(1)

net packet-tester security

NAME

packet-tester - Shows if packet with given parameters passes through data path , which AFM policies and rules will be applied to the packet, if it will be dropped or not. This is shown for Dos in global and Virtual server context, IP Intelligence and ACL in global, route domain and listener context. You can only use the show command with this component.

MODULE

net

SYNTAX

```
show packet-tester security
  dest-addr [IP address]
  source-addr [IP address]
  dest-port [TCP/UDP port]
  source-port [TCP/UDP port]
  protocol [protocol]
  src-vlan [source vlan name]
  check-staged[enable/disable]
  trigger-log[enable/disable]
  ttl[1 to 255]
  syn[SYN TCP FLAG]
  ack[ACK TCP FLAG]
  rst[RST TCP FLAG]
  fin[FIN TCP FLAG]
  push[PUSH TCP FLAG]
  urg[URG TCP FLAG]
```

DESCRIPTION

With user provided VLAN, source/destination IP addresses, TCP/UDP ports and protocol, the command will craft a packet and insert into data path to match these parameters against user configured DOS, ACL rules and IP intelligence global, route domain, VIP/SelfIP context, and return which policies, rules applied and the final action taken on packet. Both IPv4 and IPv6 addresses and IP/UDP/TCP/SCTP protocols are supported. Detail option with provide which specific policy and rule will be applied to such a packet. This command can be used as a diagnostic tool to trouble-shoot BigIP AFM configuration problem. It provides a faster way to identify which AFM config will have impact to the specified packet stream.

EXAMPLES

```
[root@bigip208:Active:Standalone] rpm # tmsh -s -m show net packet-tester security dst-addr 41.41.41.41 dst-
port 80 src-addr 8.8.8.1 src-port 99 protocol udp src-vlan /Common/internal detail

net port-list

NAME
port-list - A port list is a list of IP ports.

MODULE
net

SYNTAX
CREATE/MODIFY
create port-list [name]
modify port-list [[name] | all]
options:
ports [add | delete | modify | replace-all-with] {
[[port]]
}
app-service [name]
description [string]

edit port-list [[name] | all]
options:
all-properties
non-default-properties

DISPLAY
list port-list [[name] | all | [property]]
show running-config port-list [[name] | all | [property]]

DELETE
delete port-list [[name] | all]

DESCRIPTION
You can use the port-list component to define reusable lists of ports.

EXAMPLES
create port-list plist1 ports add { 80 443 }

Creates a new port list, "plist1," with two ports.

modify port-list plist1 description "my port list"

Modifies the above port list with a description.

modify port-list plist1 ports add { 999 }

Modifies the same port list by adding port 999 to it.

```
list port-list plist1
net port-list plist1 {
  ports {
    description "my port list"
    999 { }
    http { }
    https { }
  }
}
```

Shows the modified port list.

OPTIONS
ports
Specifies a list of IP ports.

The next keyword specifies the action to take with the ports (add, delete, modify, or replace the current set of ports).

add Creates a new port list.

delete

Deletes the port(s) that you specify next, in curly braces ({}).

modify

Makes it possible to replace the optional description(s) for the port(s). You can specify a description in a nested set of curly braces after each port.

replace-all-with

Replaces the current set of IP ports with the port(s) that you specify next, in curly braces ({}).

app-service

Associates this port list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers.

description

Is your description for this port list.

SEE ALSO

edit, list, modify, ltm virtual, tmsh

BIG-IP 2017-12-04 net port-list(1)

net port-mirror

NAME

port-mirror - Configures interface (port) mirroring.

MODULE

net

SYNTAX

Configure the port-mirror component within the net module using the syntax in the following sections.

CREATE/MODIFY

create port-mirror [interface_name]

modify port-mirror [interface_name]

options:

app-service [[string] | none]

interfaces

[add | delete | replace-all-with] {

[interface_name ...]

}

interfaces [default | none]

edit port-mirror [[[interface_name] | [glob] | [regex]] ...]

options:

all-properties

DISPLAY

list port-mirror

list port-mirror

[[[interface_name] | [glob] | [regex]] ...]

show running-config port-mirror

show running-config port-mirror

[[[interface_name] | [glob] | [regex]] ...]

options:

one-line

DELETE

delete port-mirror [interface_name]

DESCRIPTION

You can use the port-mirror component to mirror traffic from interfaces on a blade to other interfaces on the same blade or another blade.

EXAMPLES

create port-mirror 1/1.1 interfaces add 1/1.2 1/1.3 1/1.4

Creates a port mirror from interface 1.1 on blade 1 to interfaces 1.2, 1.3, 1.4 on the same blade. The system mirrors traffic from interfaces 1.2, 1.3, and 1.4 on blade 1 to the interface 1.1 on the same blade.

modify port-mirror 1/1.1 interfaces delete 1/1.3 1/1.4

Deletes interfaces 1.3 and 1.4 on blade 1 from the existing port mirror 1/1.1 on the same blade.

OPTION

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interface_name

Specifies the name of the interface, for example, 1/1.1.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

DELETE

delete class [all | [name]]

DESCRIPTION

You can use the class component to create a rate class. A rate class lets you specify shaping properties for a specific type of traffic, such as Layer 3 traffic that specifies a certain source, destination, or service. Specifically, a rate class defines the number of bits per second that the system accepts per flow and the number of packets in a queue.

You configure rate shaping by creating a class and then assigning the class to a packet filter, a virtual server, or from within an iRule. When you configure a class, you can associate another class with the class you are configuring using the parent option.

You can also associate drop policies, shaping policies, and queues with a class using the drop-policy, shaping-policy, and queue options of the class component. You can associate pre-configured drop policies and queues with the class, or you can create custom drop policies, queues, and shaping policies, and then associate them with the class.

Note that if you specify a value for the shaping-policy option of the class, the system automatically changes the ceiling-percentage, drop-policy, max-burst, queue, and rate-percentage options of the class to match the values in the specified shaping policy.

EXAMPLES

```
create class my_class rate 10
```

Creates a class named my_class with a rate of 10.

```
list class all-properties
```

Displays all of the properties of all of the classes.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

ceiling

Specifies (in bps) how far beyond the value specified for the rate option that traffic can flow. This number sets an absolute limit. No traffic can exceed this rate. The rate class might limit traffic throughput to the value of the rate option when there is high contention among siblings of a parent-child class hierarchy. The default value is the value of the rate option. The minimum value is 296 bps.

ceiling-percentage

Specifies the ceiling of the rate class as a percentage of the ceiling of the associated parent class. This option applies only to rate classes with an associated parent rate class. The default value is 0 (zero), which indicates that the class uses the value of the ceiling option.

description

User defined description.

direction

Specifies the direction of traffic to which the class is applied. The default value is any.

drop-policy

Specifies the name of a drop policy. You can use one of the pre-configured drop policies, or you can create a customized drop policy using the drop-policy component.

The default value is tail, which is the simplest drop policy. The pre-configured drop policies are:

fred Specifies that the system uses Flow-based Random Early Detection to decide whether to drop packets based on the aggressiveness of each flow.

red Specifies that the system uses Random Early Detection to determine whether to drop packets to maintain the average queue length within the specified range.

tail Specifies that the system drops all incoming packets when the queue is full.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

max-burst

Specifies the maximum number of bytes that traffic can burst beyond the value of the rate option. The traffic may not burst higher than the value of the ceiling option. The default value is 0 (zero).

name Specifies a unique name for the component. This option is required for the commands create, delete, and

modify.

parent

Associates another class with this class. The class you are configuring (which when you configure a parent class for it becomes a child class) can borrow bandwidth from the parent class. The parent class can use any of the unused bandwidth of the child class.

queue

Specifies the queuing method. The default value is sfq. The pre-configured options are:

pfifo

The Priority FIFO queuing method queues all traffic under a set of five sub-queues based on the Type of Service (TOS) field of the traffic. Four of the sub-queues correspond to the four possible TOS values (Minimum delay, Maximum throughput, Maximum reliability, and Minimum cost). The fifth sub-queue represents traffic with no TOS value. The Priority FIFO method processes these five sub-queues in a way that preserves the meaning of the TOS value as much as possible. For example, a packet with the TOS value of Minimum cost might yield dequeuing to a packet with the TOS value of Minimum delay.

sfq Stochastic Fair Queuing is a queuing method that further queues packets under a set of many FIFO sub-queues. Selecting a specific sub-queue is based on a hash of the flow address information. SFQ dequeues packets from the set of sub-queues in a Round Robin fashion. The overall effect is that fairness of dequeuing is achieved, because packets from one flow cannot occupy the queues at the exclusion of those of another flow.

Note that if you assign a shaping policy to the class, then the queuing discipline of the class becomes that specified in the shaping policy. If you do not assign a shaping policy to the class, the default queue is sfq.

rate Specifies the guaranteed throughput rate of the traffic handled by this rate class, in bits per second (bps).

rate-percentage

Specifies the rate of the rate class as a percentage of the ceiling of the associated parent class. This option applies only to rate classes with an associated parent rate class. The default value is 0 (zero), which specifies that the system uses the value of the rate option.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

shaping-policy

Specifies the name of a shaping policy. The default value is none.

Note that the system automatically changes the ceiling-percentage, drop-policy, max-burst, queue, and rate-percentage options of this class to match the values in the specified shaping policy.

BIG-IP 2016-03-14 net rate-shaping class(1)

net rate-shaping color-policer

NAME

color-policer - Configures a policer, which can be applied to other configuration entities to meter or rate-shape traffic using color based classification of packets.

MODULE

net rate-shaping

SYNTAX

Configure the color-policer component within the net rate-shaping module using the syntax in the following sections.

CREATE

create color-policer [name]

modify color-policer [name]

options:

action [action]

app-service [[string] | none]

committed-burst-size [integer]
description [string]
committed-information-rate [integer]
excess-burst-size [integer]

DISPLAY

list color-policer

options:

all-properties

DELETE

delete color-policer [name]

DESCRIPTION

You can use a color-policer to create a metering/policing configuration to be applied to other configuration entities. For instance, to limit or track out of profile network traffic to a vCMP guest, a color-policer can be added to a vcmp traffic-profile and be applied to any number of vcmp guest objects.

Based on the configuration of color-policer attributes a packet may be counted as either green, yellow, or red. These categories can be tracked for accounting purposes, as well as allowing for out of profile (Red) traffic to be dropped as a rate-shaping or DOS protection technique.

EXAMPLES

list net color-policer

Lists the current configuration of all color-policers.

create net color-policer fiftyMbpsLimiter action drop-red committed-information-rate 50mbps committed-burst-size 10mb excess-burst-size 10mb

Configures a policer with a committed information rate (CIR) of 50 mbps committed burst size (CBS) of 10 mb, and excess burst size (EBS) of 10 mb. See individual descriptions of options below for more detailed semantics.

OPTIONS

action

One of drop-red or default. Drop-red means that a packet which exceeds the excess burst rate of the policer, and is marked red should be dropped immediately before even attempting to enqueue the packet to/from the guest. Default means that the default behavior for the resulting color packets should be taken, which may vary depending on additional system configuration, and load. For instance, a Red colored packet may be considered lowest priority with respect to QOS queues associated with the guest. Thus, allowing as much traffic through as is available, but increasing the drop probability for packets out of profile in the case that the system is under high enough data-plane traffic load.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

committed-burst-size

When the data rate exceeds the committed-information-rate then the committed-burst-size (by default specified in bytes) is the burst size below which a packet is marked green, and above which it may be marked yellow, or red.

committed-information-rate

The committed rate of data transfer that is to be given to a metered entity that the policer is associated with. Traffic is marked green as long as it stays below this rate or if bursts above this rate are smaller than the committed-burst-size.

description

User defined description.

excess-burst-size

An additional data burst size to be used on top of the committed-burst-size. A packet is marked yellow if it exceeds the committed-burst-size but not the additional excess-burst-size, and red if it exceeds the excess-burst-size.

net rate-shaping drop-policy

NAME

drop-policy - Configures a custom drop policy for use in rate shaping.

MODULE

net rate-shaping

SYNTAX

Configure the drop-policy component within the net rate-shaping module using the syntax in the following sections.

CREATE/MODIFY

create drop-policy [name]

modify drop-policy [name]

options:

app-service [[string] | none]
average-packet-size [integer]
description [string]
fred-max-active [integer]
fred-max-drop [integer]
fred-min-drop [integer]
inverse-weight [integer]
max-probability [integer]
max-threshold [integer]
min-threshold [integer]
red-hard-limit [integer]
type [fred | red | tail]

edit drop-policy [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

DISPLAY

list drop-policy

list drop-policy [[[name] | [glob] | [regex]] ...]

show running-config drop-policy

show running-config drop-policy [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties
one-line

DELETE

delete drop-policy [all | [name]]

DESCRIPTION

A drop policy tells the system when and how to drop packets when the traffic handling queue is full, if required. The system comes with three pre-configured drop policies: fred, red, and tail.

You can use the drop-policy component to create a custom drop policy, and then associate it with a class using the drop-policy option of the class component. For more information, see `net rate-shaping class`.

You can also associate a custom drop policy with a shaping policy using the drop-policy option of the shaping-policy component. For more information, see `net rate-shaping shaping-policy`.

EXAMPLES

create drop-policy my_dp

Creates a custom drop policy named my_dp.

list drop-policy all-properties

Displays all of the properties of all of the drop policies.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

average-packet-size

Specifies the average MTU (maximum transmission unit) size in the range of 0 to 10000 bytes. The default value is 0 (zero).

description

User defined description.

fred-max-active

Specifies the maximum number of flows that can be active for each queue. The range is 0 to 10000. The default value is 0 (zero), which disables active flow limitation.

fred-max-drop

Specifies a hard drop limit in the range of 0 to 400. The default value is 0 (zero). Setting this to a small value does not change the hard drop limit, but a higher number increases the limit.

fred-min-drop

Specifies a hard no drop limit in the range of 0 to 100. The default value is 0 (zero). Setting this to a large value prevents packets from being dropped.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

inverse-weight

Specifies the weight used to calculate the average queue length. Valid values are 0, 64, 128, 256, 512, and 1024. The default value is 0 (zero).

max-probability

Specifies the maximum percentage probability in the range of 0 to 100 according to which packets are dropped when the average queue length is between the minimum and maximum thresholds. The default value is 0 (zero).

max-threshold

Specifies the queue length above which the system drops packets. The default value is 0 (zero).

min-threshold

Specifies the queue length below which the system does not drop packets. The default value is 0 (zero).

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

red-hard-limit

Specifies the maximum queue size in bytes. Additional packets are dropped. The default value is 0 (zero).

This option applies only when the value of the type option is red.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

type Specifies the type of drop policy. The default value is tail.

The options are:

fred Specifies that the system uses Flow-based Random Early Detection to decide whether to drop packets based on the aggressiveness of each flow.

red Specifies that the system uses Random Early Detection to determine whether to drop packets to maintain the average queue length within the specified range.

tail Specifies that the system drops all incoming packets when the queue is full. This is the simplest drop policy.

Note that although you could create a drop policy based on tail, that is already the default value of the drop-policy option in both the shaping-policy and class components.

BIG-IP 2016-03-14 net rate-shaping drop-policy(1)

net rate-shaping queue

NAME

queue - Configures a custom queuing method.

MODULE

net rate-shaping

SYNTAX

Configure the queue component within the net rate-shaping module using the syntax in the following sections.

CREATE/MODIFY

create queue [pfifo | sfq]

modify queue [all | pfifo | sfq]

options:
app-service [[string] | none]
description [string]
pfifo-max-size [integer]
pfifo-min-size [integer]
sfq-bucket-count [integer]
sfq-bucket-size [integer]
sfq-perturbation [integer]
type [pfifo | sfq]

edit queue [[[all | pfifo | sfq] | [glob] | [regex]] ...]

options:
all-properties
non-default-properties

DISPLAY

list queue

list queue [[[all | pfifo | sfq] | [glob] | [regex]] ...]

show running-config queue

show running-config queue

[[[all | pfifo | sfq] | [glob] | [regex]] ...]

options:
all-properties
non-default-properties
one-line

DELETE

delete queue [all | [name]]

DESCRIPTION

You can use the queue component to configure a custom queuing method.

EXAMPLES

create queue my_q type pfifo

Creates a pfifo type queue name my_q.

list queue all-properties

Displays all of the properties of all of the queue.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

pfifo-max-size

Specifies the size of the largest queue for the pfifo type only. The default value is 0 (zero). Valid units are bytes(default), eb, gb, k, kb, mb, pb, and tb.

pfifo-min-size

Specifies the size of the smallest queue for the pfifo type only. The default value is 0 (zero). Valid units are bytes(default), eb, gb, k, kb, mb, pb, and tb.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

sfq-bucket-count

Specifies the number of buckets into which the queue is divided when you are configuring the sfq type. Valid values are 0, 16, 32, 64, 128, 256, 512, and 1024. The default value is 0 (zero).

sfq-bucket-size

Specifies the bucket size for the sfq type. The default value is 0 (zero). Valid units are bytes(default), eb, gb, k, kb, mb, pb, and tb.

sfq-perturbation

Specifies the interval in seconds at which the system reconfigures the SFQ hash function. This option applies only to the sfq type. The default value is 0 (zero).

type Specifies the queue discipline this custom queue uses. The options are:

pfifo

The Priority FIFO queuing method queues all traffic under a set of five sub-queues based on the Type of Service (TOS) field of the traffic. Four of the sub-queues correspond to the four possible TOS values (Minimum delay, Maximum throughput, Maximum reliability, and Minimum cost). The fifth sub-

queue represents traffic with no TOS value. The Priority FIFO method processes these five sub-queues in a way that preserves the meaning of the TOS value as much as possible. For example, a packet with the TOS value of Minimum cost might yield dequeuing to a packet with the TOS value of Minimum delay.

sfq Stochastic Fair Queuing is a queuing method that further queues packets under a set of many FIFO sub-queues. Selecting a specific sub-queue is based on a hash of the flow address information. SFQ dequeues packets from the set of sub-queues in a Round Robin fashion. The overall effect is that fairness of dequeuing is achieved, because packets from one flow cannot occupy the queues at the exclusion of those of another flow.

BIG-IP 2013-04-12 net rate-shaping queue(1)

net rate-shaping shaping-policy

NAME

shaping-policy - Configures a custom rate shaping policy for traffic flow.

MODULE

net rate-shaping

SYNTAX

Configure the shaping-policy component within the net rate-shaping module using the syntax in the following sections.

CREATE/MODIFY

```
create shaping-policy [name]
modify shaping-policy [name]
options:
  app-service [[string] | none]
  ceiling-percentage [integer]
  description [string]
  drop-policy [ [name] | none]
  max-burst [integer]
  queue [ [name] | none]
  rate-percentage [integer]
```

```
edit shaping-policy [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list shaping-policy
list shaping-policy [ [ [name] | [glob] | [regex] ] ... ]
show running-config shaping-policy
show running-config shaping-policy [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete shaping-policy [all | [name] ]
```

DESCRIPTION

You can use the shaping-policy component to create a custom rate shaping policy to handle traffic flow, and then associate the shaping policy with a class.

Note that if you specify a value for the shaping-policy option of a class, the system automatically changes the ceiling-percentage, drop-policy, max-burst, queue, and rate-percentage options of that class to match the values in the shaping policy.

EXAMPLES

```
create shaping-policy my_sp
```

Creates a shaping policy named my_sp.

```
list shaping policies all-properties
```

Displays all of the properties of all of the shaping policies.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

ceiling-percentage

Specifies the percentage of the value of the ceiling option specified for the parent associated with the class component to which this shaping policy is associated. The default value is 0 (zero).

description

User defined description.

drop-policy

Specifies the name of a drop policy for this traffic flow. The default value is none.

You can use one of the pre-configured drop policies, or you can create a customized drop-policy using the drop-policy component.

The pre-configured drop policies are:

fred Specifies that the system uses Flow-based Random Early Detection to decide whether to drop packets based on the aggressiveness of each flow.

red Specifies that the system uses Random Early Detection to determine whether to drop packets to maintain the average queue length within the specified range.

tail Specifies that the system drops all incoming packets when the queue is full. This is the simplest drop policy.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

max-burst

Specifies the maximum number of bytes that traffic is allowed to burst beyond the value of the rate option of the class component to which this shaping policy is associated. The default value is 0 (zero).

Valid units are byte, bytes(default), eb, gb, k, kb, mb, pb, and tb.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

queue

Specifies the queuing method for this traffic flow. The default value is none. You can create a customized queuing method using the queue component. For more information, see net rate-shaping queue.

The preconfigured queues are:

pfifo

The Priority FIFO queuing method queues all traffic under a set of five sub-queues based on the Type of Service (TOS) field of the traffic. Four of the sub-queues correspond to the four possible TOS values (Minimum delay, Maximum throughput, Maximum reliability, and Minimum cost). The fifth sub-queue represents traffic with no TOS value. The Priority FIFO method processes these five sub-queues in a way that preserves the meaning of the TOS value as much as possible. For example, a packet with the TOS value of Minimum cost might yield dequeuing to a packet with the TOS value of Minimum delay.

sfq Stochastic Fair Queuing is a queuing method that further queues packets under a set of many FIFO sub-queues. Selecting a specific sub-queue is based on a hash of the flow address information. SFQ dequeues packets from the set of sub-queues in a Round Robin fashion. The overall effect is that fairness of dequeuing is achieved, because packets from one flow cannot occupy the queues at the exclusion of those of another flow.

rate-percentage

Specifies the percentage of the value of the rate option of the parent, which is associated with the class component to which this shaping policy is associated, that is available for this traffic flow. The default value is 0 (zero).

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

```

DESCRIPTION

Using route domains, you can assign the same IP address to more than one device on a network, as long as each instance of the IP address resides in a separate routing domain.

EXAMPLES

```
create route-domain myRouteDomain id 1 vlans add { my_vlan }
```

Creates a route domain named myRouteDomain with an ID of 1 that includes my_vlan.

list route-domain all-properties

Displays all properties of all route domains.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

bwc-policy

Configures the bandwidth control policy for the route-domain. If set, it will enforce a throughput policy for incoming network traffic.

connection-limit

Configures the connection limit for the route domain. If set to a value other than zero, this specifies the total number of open connections allowed on this route domain. The default value is 0, unlimited.

description

User defined description.

id Specifies a unique numeric identifier for the route-domain. This option is required during creation; it may not be modified once set.

flow-eviction-policy

Specifies a flow eviction policy for the route domain to use, to select which flows to evict when the number of connections approaches the connection limit on the route domain. The default value is none.

fw-enforced-policy

Specifies an enforced firewall policy. fw-enforced-policy rules are enforced on a route-domain.

fw-enforced-policy-rules

Specifies firewall rules enforced on net route-domain via referenced fw-enforced-policy.

fw-staged-policy

Specifies a staged firewall policy. fw-staged-policy rules are not enforced while all the visibility aspects namely statistics, reporting and logging function as if the fw-staged-policy rules were enforced on a route-domain.

fw-staged-policy-rules

Specifies firewall rules staged on net route-domain via referenced fw-staged-policy.

security-nat-rules

Specifies security nat rules associated with net route-domain via referenced security-nat-policy.

parent

Specifies the route domain the system searches when it cannot find a route in the configured domain. The default value is None.

If you specify a parent, during route table lookup, if the system cannot find a route in the current route domain, the system searches routes in the parent route domain. If no route is found in the parent route domain, the system searches the parent route domain's parent, and so on, until the system finds either a match or a parent with a value of None. For example, if rd_1 has a parent of rd_0 (in this example, route domain rd_0 has a parent of None), and you include vlan_a in rd_1, when requests arrive for vlan_a, the system looks in rd_1 for a route for the specified destination. If no route is found, the system searches route domain 0. If it still cannot find a route, the request for vlan_a fails. If, using the same example, you set the parent to None, under the same conditions, the system looks in rd_1, and if it cannot find a matching route, the system refrains from searching any other route domain, the request for vlan_a fails.

port-misuse

Used to show or reset port misuse policy statistics for the route domain.

fw-context-stat

Used to show or reset firewall statistics for the route domain.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

security-nat-policy

Configures the Security NAT Policy (see security nat policy). If specified, this is the NAT policy used to perform first-match classification for incoming traffic to a virtual server if 'the virtual server itself does not have a NAT policy configured AND security-nat-policy.use-route-domain-policy is enabled on the virtual'.

service-policy

Configures the service policy for the route-domain. If set, it will enforce the service policy for incoming network traffic. The service policy can be used to set specific policy based configurations like flow timers, which applies to the flows that matches the policy specification.

strict

Specifies whether the system allows a connection to span route domains. The default value is enabled.

Note: When you enable this option, the system may find invalid iRules(r) that passed validation.

routing-protocol

Specifies routing protocols, by name, for the system to use in the route domain. The default value is none. Dynamic routing must be licensed to use this option.

vlan

Specifies VLANs, by name, for the system to use in the route domain. The default value is none.

ip-intelligence-categories

Used to show/ reset statistics on IP intelligence white/ black lists categories.

net route

NAME

route - Configures a route for traffic management.

MODULE

net

SYNTAX

Configure the route component within the net module using the syntax in the following sections.

CREATE/MODIFY

create route [name | ip address/netmask | default | default-inet6]

modify route [name | ip address/netmask | default | default-inet6]

options:

blackhole

description [string]

gw [ip address]

interface [name]

mtu [integer]

network [ip address/netmask]

pool [name]

edit route

[[name | ip address/netmask | default | default-inet6] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list route

list route

[[name | ip address/netmask | default | default-inet6] | [glob] | [regex]] ...]

show running-config route

show running-config route

[[name | ip address/netmask | default | default-inet6] | [glob] | [regex]] ...]

options:

all-properties

mtu

non-default-properties

one-line

partition

show route

show route

[[name | ip address/netmask | default | default-inet6] | [glob] | [regex]] ...]

options:

connected

dynamic

field-fmt

lookup [ip address]

static

DELETE

delete route [name | ip address/netmask | default | default-inet6]

DESCRIPTION

You can configure routes for the system, including default routes.

Note that when you use the command edit to create a new route, by default the gw (gateway) option is set. If you do not want to use the gw option, remove that line of syntax in the editor.

EXAMPLES

create route myRoute3 network 12.12.4.0/24 interface external

Sets the route myRoute3 to the address 12.12.4.0/24 on the interface named external.

create route 12.12.3.0/24 gw 10.10.10.254

Sets the route to the subnet 12.12.3.0/24 whose gateway IP address is 10.10.10.254.

create route default gw 10.10.10.254

Sets the default gateway IP address to 10.10.10.254.

show route lookup myRoute

Displays the route that the system uses to reach the IP address 12.12.3.0.

OPTIONS

Note: The options blackhole, gw, interface, and pool are mutually exclusive. You can use only one of these options at a time, and you must specify at least one of these options when configuring a route.

blackhole

Specifies that the system drops traffic that is addressed to the specified destination.

connected

Displays connected routes.

description

User defined description.

dynamic

Displays dynamic routes.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

gw Specifies a gateway address for the system.

interface

Specifies the tunnel, VLAN or VLAN group to which the system sends traffic.

ip address/netmask

Specifies the destination subnet and mask using CIDR notation, such as 12.12.3.0/24. You can also specify the keyword default or default-inet6.

lookup

Displays the route that the system uses to reach the specified IP address. You can specify only a single IP address with the lookup option.

mtu Sets a specific maximum transition unit (MTU). If you set this option to 0 (zero), the system selects the appropriate MTU for the route, and does not display the MTUs.

network

Specifies the destination subnet and mask using CIDR notation, such as 12.12.3.0/24. You can also specify the keyword default or default-inet6.

partition

Displays the administrative partition within which the route resides.

pool Specifies a pool to which the system sends traffic. This allows the system to send traffic to multiple, load-balanced gateways.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

static

Displays static routes.

SEE ALSO

net router-advertisement

NAME

router-advertisement - Configures IPv6 prefixes for router advertisement on a VLAN.

MODULE

net

SYNTAX

Modify the router-advertisement component within the net module using the syntax shown in the following sections.

CREATE/MODIFY

```
create router-advertisement [name]
modify router-advertisement [name]
options:
  app-service [[string] | none]
  current-hop-limit [integer]
  description [string]
  disabled | enabled
  max-interval [integer]
  min-interval [integer]
  mtu [integer]
  no-other-config | other-config
  prefixes
    [add | delete | modify | replace-all-with] {
[name] ... {
  app-service [[string] | none]
  autonomous | not-autonomous
  description [string]
  on-link | not-on-link
  preferred-lifetime [integer]
  prefix [ip address]
  prefix-length [integer]
  valid-lifetime [integer]
}
}
  reachable-time [integer]
  retransmit-timer [integer]
  router-lifetime [integer]
  unmanaged | managed
  vlan [name]
```

```
edit router-advertisement [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list router-advertisement
list router-advertisement [ [ [name] | [glob] | [regex] ] ... ]
show running-config router-advertisement
show running-config router-advertisement
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete router-advertisement [name]
```

DESCRIPTION

Router advertisements are part of the configuration of BIG-IP(r) network components. When creating a router advertisement, you must specify a VLAN on the command line.

EXAMPLES

```
create router-advertisement my_ra vlan my_vlan
```

Creates the router advertisement my_ra that includes the VLAN my_vlan.

```
delete router-advertisement my_ra
```

Deletes the router advertisement named my_ra and all associated prefixes.

OPTIONS

Note the following information regarding options for the router-advertisement component:

- The options disabled and enabled are mutually exclusive.
- The options no-other-config and other-config are mutually exclusive.
- The options unmanaged and managed are mutually exclusive.
- The options autonomous and not-autonomous are mutually exclusive.
- The options on-link and not-on-link are mutually exclusive.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

autonomous

Indicates that the Autonomous Flag field in the prefix information option be set to 1. The default value is 1.

current-hop-limit

Defines the hop limit sent in the router advertisement. The default value is 0 (zero).

description

User defined description.

disabled

Disables router advertisement for the VLAN. This is the default.

enabled

Enables router advertisement for the VLAN.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

managed

Indicates that the Managed address configuration flag field in the router advertisement be set to 1.

max-interval

Specifies the maximum time allowed between sending unsolicited multicast Router Advertisements from the interface, in seconds. The default value is 600.

min-interval

Specifies, in seconds, the minimum time allowed between sending unsolicited multicast Router Advertisements from the interface. The default value is 200.

mtu Sets a specific maximum transition unit (MTU) for the VLAN. The default value is 0 (zero).

name Specifies a unique name for the component. This option is required for the create, delete, and modify commands.

no-other-config

Indicates that the Other Configuration flag field in the router advertisement be set to 0 (zero). The default value is 0 zero.

not-autonomous

Indicates that the Autonomous flag field in the prefix information option be set to 0 (zero).

not-on-link

Indicates that the on-link flag field in the prefix information option be set to 0 (zero).

on-link

Indicates that the on-link flag field in the prefix information option be set to 1. The default value is 1.

other-config

Indicates that the Other Configuration flag field in the router advertisement be set to 1.

preferred-lifetime

Specifies, in seconds, the value for the Preferred Lifetime field in the prefix information option. The default value is 604800.

prefix

Specifies the prefix for the prefix information option.

prefix-length

Specifies the length of the prefix for the prefix information option.

prefixes

Specifies the objects that hold the prefix specific information for the router advertisement.

reachable-time

Specifies the value to be used for the Reachable Time field in the Router Advertisement. The default value is 0 (zero).

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

retransmit-timer

Specifies the value to be used for the Retransmit Timer field in the Router Advertisement. The default value is 0 (zero).

router

Specifies that the router advertisement acts as a router for the VLAN.

router-lifetime

Specifies the value to be used for the Router Lifetime field in the Router Advertisement. The default value is 1800.

unmanaged

Specifies that the Managed address configuration flag field in the router advertisement be set to 0 (zero). The default value is 0 (zero).

valid-lifetime

Specifies, in seconds, the value for the Valid Lifetime field in the prefix information option. The default value is 2592000.

DISPLAY

DELETE delete bgp [name]

DESCRIPTION None

EXAMPLES

OPTIONS

allow-infinite-hold-time

BGP timer disallow-infinite-hold-time. (default: True)

always-compare-med

option to compare the Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems. (default: False)

bestpath

as-path-ignore

prevent the router from considering the autonomous system (AS) path length as a factor in the algorithm for choosing a best path route.

compare-confed-aspath

allow comparing of the confederation AS path length.

compare-originator-id

change the default bestpath selection by not comparing an originator-ID for an identical EBGp path. (default: True)

compare-routerid

compare router IDs for identical eBGP paths.

med

confed

Compare MED among confederation paths.

missing-as-worst

Treat missing MED as the least preferred one.

remove-recv-med

To remove rcvd MED attribute.

remove-send-med

To remove send MED attribute.

tie-break-on-age

always select a preferred older route even when the bestpath.compare-routerid is enabled. (default: True)

client-to-client-reflection

Configure client-to-client route reflection. (default: True)

cluster-id

Route-reflector cluster-id in IP address or 32-bit quantity format.

confederation

identifier

Set routing domain confederation AS.

peers

AS numbers of eBGP peers that are in the same confederation.

dampening
reachability-half-life
Reachability half-life time for the penalty(minutes).

reuse
Value to start reusing a route.

route-map
Route-map to specify the criteria for dampening.

state
Enable route-flap dampening.

suppress
Value to start suppressing a route.

suppress-max
Maximum duration to suppress a stable route(minutes).

unreachability-half-life
Un-reachability half-life time for the penalty(minutes).

default-local-preference
Configure default local preference value (higher=more preferred). (default: 100)

description
deterministic-med
Pick the best-MED path among paths advertised from the neighboring AS. (default: False)

enabled
enforce-first-as
Enforce the first AS for EBGp routes.

fast-external-failover
Immediately reset session if a link to a directly connected external peer goes down. (default: True)

graceful-restart
graceful-reset
Graceful reset capability.

restart-time
Max time needed for neighbor(s) to restart (seconds).

stalepath-time
Max time to retain stale paths from restarting Neighbor(s) (seconds).

graceful-shutdown
capable
Set router as g-shut capable. (default: False)

local-preference
Set local preference to use during g-shut. (default: 0)

mode Gracefully shutdown this router. (default: False)

hold-time
Globally set or reset the holdtime value for all of the neighbors. (default: 90)

keep-alive
Globally set or reset the keepalive value for all of the neighbors. (default: 30)

local-as
log-neighbor-changes
Log neighbor up/down and reset reason. (default: False)

profile
route-domain
router-id
Manually override current router identifier (peers will reset).

scan-time
Configure background scan interval (sec). (default: 60)

synchronization
Enable IGP synchronization of internal BGP (iBGP) learned routes. (default: False)

update-delay
Max time to defer initial route-selection (sec). (default: 120)

view BGP view name.

address-family
auto-summary
enable sending summarized routes by a BGP speaker to its peers. (default: False)

distance

external

Define administrative distance for routes external to the AS. (default: 20)

internal

Define administrative distance for routes internal to the AS. (default: 200)

local

Define administrative distance for local routes. (default: 200)

network-synchronization

Enable IGP synchronization on network routes.

aggregate-address

as-set

summary-only

redistribute

route-map

distance

access-list

distance

neighbor

advertisement-interval

Minimum interval between sending BGP routing updates.

allow-infinite-hold-time

BGP per neighbor allow-infinite-hold-time. (default: True)

as-origination-interval

Minimum interval between sending AS-origination routing updates.

capability

dynamic

Advertise dynamic capability to this neighbor. (default: False)

route-refresh

Advertise route-refresh capability to this neighbor. (default: True)

capability-negotiate

override

Override capability negotiation result. (default: False)

state

Perform capability negotiation. (default: True)

strict-match

Strict capability negotiation match. (default: False)

collide-established

Include Neighbor in Established State for Collision Detection.

connect-timer

BGP connect timer. (default: 0)

description

User defined description..

ebgp-multihop

Allow EBGp neighbors not on directly connected networks. (default: 1)

enabled

enforce-multihop

Enforce EBGp neighbors to perform multihop. (default: False)

fall-over

Fall-over detection - Bidirectional Forwarding Detection (BFD) or BFD Multihop.

graceful-shutdown

mode Gracefully shut down this neighbor. (default: False)

timer

Max time needed for Neighbor to shutdown. (default: 60)

hold-time

Holdtime. (default: 90)

keep-alive

Keepalive interval. (default: 30)

local-as

Specify AS number to use with BGP neighbor.

passive

Don't send open messages to this neighbor. (default: False)

password

Set password to the neighbor.

peer-group
port Neighbor's BGP port. (default: 179)

remote-as
Specify AS number of BGP neighbor.

restart-time
Max time needed for Neighbor to restart. (default: 0)

update-source
Source of routing updates.

version
Set the BGP version to match a neighbor. (default: 4)

vlan
address-family
activate
Enable the address family for this neighbor. (default: True)

allow-as-in
Accept as-path with my AS present in it.

as-override
Override AS path.

attribute-unchanged
as-path
BGP attribute, as-path, is propagated unchanged to this neighbor.

med BGP attribute, med, is propagated unchanged to this neighbor.

next-hop
BGP attribute, next-hop, is propagated unchanged to this neighbor.

capability
graceful-restart
The graceful-restart capability. (default: True)

orf
prefix-list
Advertise ORF capability to peer. (default: disabled)

default-originate
route-map
Route-map to specify criteria to originate default.

state
Originate default route to this neighbor. (default: False)

distribute-list
in Filter updates to/from this neighbor.

out Filter updates to/from this neighbor.

filter-list
in Establish BGP filters.

out Establish BGP filters.

maximum-prefix
threshold
Maximum number of prefix threshold value. (default: 0)

value
Maximum number of prefix accept from this peer. (default: 0)

warning-only
Only give a warning message when the maximum-prefix.threshold limit is exceeded. (default: True)

next-hop-self
Disable the next hop calculation for this neighbor. (default: False)

prefix-list
in Filter updates to/from this neighbor.

out Filter updates to/from this neighbor.

remove-private-as
Remove private AS number from outbound updates. (default: False)

route-map
in Apply route map to neighbor.

out Apply route map to neighbor.

route-reflector-client
Configure a neighbor as Route Reflector client. (default: False)

route-server-client
Configure a neighbor as Route Server client. (default: False)

send-community
Send community attribute to this neighbor. (default: both)

soft-reconfiguration-inbound
(default: False)

unsuppress-map
Route-map to selectively unsuppress suppressed routes.

weight
Set default weight for routes from this neighbor.

network
backdoor
route-map
peer-group
advertisement-interval
Minimum interval between sending BGP routing updates.

allow-infinite-hold-time
BGP per neighbor allow-infinite-hold-time. (default: True)

as-origination-interval
Minimum interval between sending AS-origination routing updates.

capability
dynamic
Advertise dynamic capability to this neighbor. (default: False)

route-refresh
Advertise route-refresh capability to this neighbor. (default: True)

capability-negotiate
override
Override capability negotiation result. (default: False)

state
Perform capability negotiation. (default: True)

strict-match
Strict capability negotiation match. (default: False)

collide-established
Include Neighbor in Established State for Collision Detection.

connect-timer
BGP connect timer. (default: 0)

description
User defined description..

ebgp-multihop
Allow EBGp neighbors not on directly connected networks. (default: 1)

enabled
enforce-multihop
Enforce EBGp neighbors to perform multihop. (default: False)

fall-over
Fall-over detection - Bidirectional Forwarding Detection (BFD) or BFD Multihop.

graceful-shutdown
mode Gracefully shut down this neighbor. (default: False)

timer
Max time needed for Neighbor to shutdown. (default: 60)

hold-time
Holdtime. (default: 90)

keep-alive
Keepalive interval. (default: 30)

local-as
Specify AS number to use with BGP neighbor.

passive
Don't send open messages to this neighbor. (default: False)

password
Set password to the neighbor.

port Neighbor's BGP port. (default: 179)

remote-as
Specify AS number of BGP neighbor.

restart-time
Max time needed for Neighbor to restart. (default: 0)

update-source
Source of routing updates.

version
Set the BGP version to match a neighbor. (default: 4)

address-family
activate
 Enable the address family for this neighbor. (default: True)

allow-as-in
 Accept as-path with my AS present in it.

as-override
 Override AS path.

attribute-unchanged
 as-path
 BGP attribute, as-path, is propagated unchanged to this neighbor.

 med
 BGP attribute, med, is propagated unchanged to this neighbor.

 next-hop
 BGP attribute, next-hop, is propagated unchanged to this neighbor.

capability
 graceful-restart
 The graceful-restart capability. (default: True)

 orf
 prefix-list
 Advertise ORF capability to peer. (default: disabled)

default-originate
 route-map
 Route-map to specify criteria to originate default.

 state
 Originate default route to this neighbor. (default: False)

distribute-list
 in Filter updates to/from this neighbor.

 out Filter updates to/from this neighbor.

filter-list
 in Establish BGP filters.

 out Establish BGP filters.

maximum-prefix
 threshold
 Maximum number of prefix threshold value. (default: 0)

 value
 Maximum number of prefix accept from this peer. (default: 0)

 warning-only
 Only give a warning message when the maximum-prefix.threshold limit is exceeded. (default: True)

next-hop-self
 Disable the next hop calculation for this neighbor. (default: False)

prefix-list
 in Filter updates to/from this neighbor.

 out Filter updates to/from this neighbor.

remove-private-as
 Remove private AS number from outbound updates. (default: False)

route-map
 in Apply route map to neighbor.

 out Apply route map to neighbor.

route-reflector-client

Configure a neighbor as Route Reflector client. (default: False)

route-server-client

Configure a neighbor as Route Server client. (default: False)

send-community

Send community attribute to this neighbor. (default: both)

soft-reconfiguration-inbound

(default: False)

unsuppress-map

Route-map to selectively unsuppress suppressed routes.

weight

Set default weight for routes from this neighbor.

EXAMPLES

OPTIONS

```

description
route-domain
entries

```

action

match

as-path

Define a BGP AS path access list.

community

exact-match

Do exact matching of communities. (default: False)

list Match BGP ecommunity list.

extcommunity

exact-match

Do exact matching of extcommunities. (default: False)

list Match BGP ecommunity list.

ipv4

address

access-list

Match entries of IPv4 access-lists.

prefix-list

Match entries of IPv4 prefix-lists.

next-hop

access-list

Match entries of IPv4 access-lists.

prefix-list

Match entries of IPv4 prefix-lists.

peer

access-list

Match entries of IPv4 access-lists.

ipv6

address

access-list

Match entries of IPv6 access-lists.

prefix-list

Match entries of IPv6 prefix-lists.

next-hop

access-list

Match entries of IPv6 access-lists.

prefix-list

Match entries of IPv6 prefix-lists.

peer
access-list
Match entries of IPv6 access-lists.

metric
Match metric of route.

origin
Match BGP origin code.

route-type
Match route type.

tag Match tag.

vlan Match first hop interface of route.

set
aggregator
address
set BGP aggregator IP address.

as set BGP aggregator attribute.

as-path-prepend
Prepend string for a BGP AS-path attribute.

atomic-aggregate
BGP atomic aggregate attribute.

community
additive
Add to the existing community.

exact-set
Do exact setting of communities. (default: False)

value
set community number, either in AA:NNO format, or number..

dampening
reachability-half-life
Reachability half-life time for the penalty(minutes). (default: 15)

reuse
Value to start reusing a route. (default: 750)

suppress
Value to start suppressing a route. (default: 2000)

suppress-max
Maximum duration to suppress a stable route(minutes). (default: 60)

unreachability-half-life
Un-reachability half-life time for the penalty(minutes). (default: 1)

extcommunity
rt VPN extended community.

soo Site-of-Origin extended community.

ip
next-hop
address
IP address of next-hop.

ipv6
next-hop
address
IPv6 local address.

local
IPv6 local address.

level
IP address of next-hop.

local-preference
BGP local preference path attribute.

metric
type Metric value.

value
origin
set BGP origin code.

originator-id
set IP address of originator.

tag set tag.

weight
set BGP weight for routing table.

net rst-cause

NAME

rst-cause - Displays and Reset TCP/IP Reset Cause Statistics

MODULE

net

SYNTAX

Display and Reset the rst-cause component within the net module using the syntax in the following section.

MODIFY

reset-stats rst-cause

DISPLAY

show rst-cause

options:

(default | field-fmt)

DESCRIPTION

You can use the rst-cause component to display and reset TCP/IP reset cause statistics. This will help to debug the reason for TCP/IP reset.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

reset-stats, show, tmsh

COPYRIGHT

BIG-IP 2011-01-24 net rst-cause(1)

net self-allow

NAME

self-allow - Configures the default "allow list" for all self IP addresses on the BIG-IP(r) system when the option allow-service of the component self is set to default.

MODULE

net

SYNTAX

Modify the self-allow component within the net module using the syntax shown in the following sections.

MODIFY

```
modify self-allow
options:
  defaults [all | none]
  defaults
    [add | delete | replace-all-with] {
      [protocol:port] ...
    }
}
```

```
edit self-allow
options:
  all-properties
```

```
DISPLAY
list self-allow
show running-config self-allow
options:
  all-properties
  defaults
  one-line
```

```
DELETE
You cannot delete the default allow list.
```

DESCRIPTION

You can use the self-allow component to modify or display the default allow list for all self IP addresses on the BIG-IP system when the option allow-service of the component self is set to default. The default allow list displays which service and protocol ports allow connections from outside the system. The system refuses connections made to a service or protocol port that is not on the list.

EXAMPLES

```
modify self-allow defaults all
```

Sets the default allow list to all. Then, if the value of the option allow-service of the net self component is default, the system accepts traffic from all protocol port combinations.

```
modify self-allow default replace-all-with { tcp:55 }
```

Sets the default "allow list" for all self IP addresses on the system to TCP on port 55.

```
list self-allow defaults
```

Displays the default "allow list" for all self IP addresses on the system.

OPTIONS

defaults
Specifies to set the default allow list to one of the following:

all Specifies that all protocols and services allow connections from outside the system. Use this option to open the system to complete access.

none Specifies that no protocols or services allow connections from outside the system.

protocol:port
Specifies a list of protocols/services that allow connections from outside the system.

replace-all-with
Specifies to replace the current protocols and services that allow connections from outside the system with the specified protocols and services.

DELETE

delete self [name]

DESCRIPTION

A self IP address is an IP address that is assigned to the system. Self IP addresses are part of the configuration of the BIG-IP(r) network components. You must define at least one self IP address for each VLAN.

EXAMPLES

```
create self mySelf address 10.10.10.24/16 vlan internal
```

Adds the self IP address 10.10.10.24 to the VLAN named internal. This entry is named mySelf. Alternatively, the name can encompass the IP address and mask fields, like the following example.

```
create self 10.10.10.24/16 vlan internal
```

Adds the self IP address 10.10.10.24 to the VLAN named internal.

```
modify self 10.1.1.1/16 vlan external traffic-group /Common/traffic-group-1
```

Enables a floating IP address on the external VLAN. The traffic-group option makes this virtual address available to whichever device is active on the given traffic-group. In other words, when the standby device becomes the active device for that traffic-group, it uses this virtual address. Only one of the devices in the traffic-group can use the IP address at any given time.

```
mv /net self /Common/10.10.10.15/24 /Common/myselfIP2
```

Moves/Renames the Self IP from 10.10.10.15/24 to myselfIP2.

Note: If you wish to change the name of the self IP, you may use a name that is the same as the IP Address or a name that does not represent a different IP Address than the one configured. If using prefix-length adornment on the name, it must match the existing prefix-length/netmask for the self IP.

Please refer to the mv manual page for additional examples on how to use the mv command.

Options

allow-service

Specifies the type of protocol/service that the VLAN handles. If you use this property to allow SSH, HTTP, and/or HTTPS service, administrators can use this self-IP address to log into the BIG-IP system; this makes the current self-IP available as a management-IP address on the VLAN.

The options are:

add Adds the specified protocol/service to the VLAN.

all Specifies that the VLAN handles all protocols/services.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

default

Specifies that the system uses a pre-defined set of network protocols/services that are commonly required for BIG-IP deployment. You can customize this set of services with the self-allow component.

This is not the default for the allow-service property; none, described below, is the actual default.

delete

Removes the specified protocol/service from the VLAN.

none Specifies that the VLAN handles no protocols/services. This is the default setting for a self IP address.

replace-all-with

Replaces the current protocol/service that the VLAN handles with the specified protocol/service.

address

Specifies the IP address and netmask to be assigned to the system. This is an optional field. If not specified, the name of the entry must appear in the format [ip address/mask].

address-source

Specifies the source of the self IP. This is an optional field. If not specified, the default value of from-user is used.

The options are:

from-management

Assigns the self IP with the management IP rather than the provided address or entry name.

from-user

Assigns the self IP with the provided address or entry name.

fw-context-stat

Used to show or reset firewall statistics for the self IP.

description

User-defined description.

floating

Read-only property based on the traffic-group. A floating self IP address is a self IP address for a VLAN that serves as a shared address by all devices of a BIG-IP traffic-group.

fw-enforced-policy

Specifies an enforced firewall policy. fw-enforced-policy rules are enforced on a self IP address.

fw-enforced-policy-rules

Specifies firewall rules enforced on net self via referenced fw-enforced-policy.

fw-staged-policy

Specifies a staged firewall policy. fw-staged-policy rules are not enforced while all the visibility aspects namely statistics, reporting and logging function as if the fw-staged-policy rules were enforced on a self IP address.

service-policy

Configures the service policy for the self IP address. If set, it will enforce the service policy for incoming network traffic. The service policy can be used to set specific policy based configurations like flow timers, which applies to the flows that matches the policy specification.

fw-staged-policy-rules

Specifies firewall rules staged on net self via referenced fw-staged-policy.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for

a description of regular expression syntax.

unit Read-only property that specifies the unit in a redundant system. Based on traffic-group.

traffic-group

Specifies the traffic group of the self IP address. The default traffic group is traffic-group-local-only, the non-floating traffic-group.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

vlan Specifies the VLAN for which you are setting a self IP address. This option is required.

BIG-IP 2017-09-06 net self(1)

net service-policy

NAME

service-policy - Configures the service policy.

MODULE

net

SYNTAX

Modify the service policy component within the net module using the syntax shown in the following sections.

CREATE/MODIFY

create service-policy [name]

modify service-policy [name]

options:

description [string]

port-misuse-policy [[port misuse policy name] | [none]]

timer-policy [[timer policy name] | [none]]

edit service-policy [[name] | all]

options:

all-properties

non-default-properties

DISPLAY

list service-policy

show running-config service-policy

options:

all-properties

non-default-properties

one-line

DESCRIPTION

service-policy configuration allows one to specify certain properties that would apply to a flow. Service policy consists of other policy objects like timer policy and port misuse policy objects. The policy can be applied at different contexts, like Global context, virtual server context, route domain context, self-ip context, or a firewall rule. When a service policy is configured both at a context level, as well as on a firewall rule, and a flow matches the rule, the more specific service-policy configuration in the rule will override the service policy setting at the context level. You can use the service-policy component to configure a shareable and reusable set of network service policies which can be associated with a number of configuration objects of the following types: net self, net route-domain, security firewall policy rules, security firewall rule-list rules, ltm virtual. Port misuse policy object is not effective with net self context.

EXAMPLES

create net service-policy flow-policy timer-policy idle-flow-policy

list service-policy

net service-policy flow-policy {

timer-policy idle-flow-policy

}

Creates service policy and associates a timer policy configuration object. (see "net timer-policy").

modify net service-policy flow-policy port-misuse-policy tcp-port-policy

```
list service-policy
net service-policy flow-policy {
    timer-policy idle-flow-policy
    port-misuse-policy tcp-port-policy
}
```

Associates a port misuse policy with service policy. (see "security firewall port-misuse-policy").

list service-policy

Displays the current service policy configuration.

OPTIONS

description
User defined description.

port-misuse-policy
Specify service port misuse policy.

timer-policy
Specify service timer policy.

SEE ALSO

net sfc-stats

NAME

sfc-stats - Display and Reset SFC Statistics.

MODULE

net

SYNTAX

Display and Reset the sfc-stats component within the net module using the syntax in the following section.

MODIFY

reset-stats sfc-stats

DISPLAY

show sfc-stats
options:
(default | field-fmt)

DESCRIPTION

You can use the sfc-stats component to display and reset SFC statistics. This will help to debug the SFC feature.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

reset-stats, show, tmsh

COPYRIGHT

BIG-IP 2017-03-09 net sfc-stats(1)

net sfc chain

NAME

chain - Defines a service function chain in the Service Function Chaining (SFC) architecture.

MODULE

net sfc

SYNTAX

Define a SFC chain.

CREATE

```
create chain [name]
options:
  app-service [[string] | none]
  description [[string] | none]
  hops
    [add | delete ] {
[name] ... {
  app-service [[string] | none]
  description [[string] | none]
  hopkey [service-index | interface]
  [nexthop-endpoint-ip [ip-address] | nexthop-service [string] | nexthop-terminate]
  service-index [integer]
  source-interface [[string] | none]
}
  path-id [integer]
```

DISPLAY

```
list chain
list chain [ [ [name] | [glob] | [regex] ] ... ]
show running-config net sfc chain
show running-config net sfc chain [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete net sfc chain [all | [name] ]
```

DESCRIPTION

You can use the net sfc chain to create a n ordered set of abstract service functions and ordering constraints that must be applied to packets and/or frames and/or flows selected as the result of classification.

There is no modify for net sfc chain. Any modification needs to be done by deleting the chain and then creating it.

EXAMPLES

```
create net sfc chain SC
```

Creates a service function chain named SC. (See below).

```
list net sfc chain SC all-properties
```

Displays all of the properties of a service function chain.

```
delete net sfc chain
```

Deletes a service function chain (see below).

Example :

```
list net sfc chain chain1 net sfc chain chain1 {
hops {
  1 {
    nexthop-service sf2-1
    service-index 255
  }
  2 {
    nexthop-terminate
    service-index 254
  }
}
path-id 678 }
```

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies a unique name for the chain. This option is required for the commands create and delete.

description
User defined description.

hops The list of next-hops.

name Specifies a unique name for the hop. This option is required for the commands create and delete.

hopkey Specifies the type of hop, service-index or interface. The default is service-index.

nexthop-endpoint-ip
If nexthop-endpoint-ip is specified then it is assumed the next hop is NSH enabled. Only one of nexthop-endpoint-ip, nexthop-service, nexthop-terminate may be specified.

nexthop-service
The service function (SF) name of the next hop. Only one of nexthop-endpoint-ip, nexthop-service, nexthop-terminate may be specified.

nexthop-terminate
If nexthop-terminate is specified then the chain is terminated and the NSH header is removed. Only one of nexthop-endpoint-ip, nexthop-service, nexthop-terminate may be specified.

service-index
The service-index is required when hopkey is service-index.

source-interface
Specifies the interface name, a tunnel or vlan, to match on ingress for this hop. The source-interface is required when hopkey is interface.

path-id
The service path identifier that uniquely identifies the service function path.

SEE ALSO
create, delete, edit, glob, list, modify, regex, show, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

net sfc hop

NAME
hop - A Service Function Chain (SFC) hop object for showing statistics.

MODULE
net sfc

SYNTAX
Display the statistics for the net sfc hop objects.

DISPLAY
show running-config net sfc hop
show running-config net sfc hop [[[name] | [glob] | [regex]] ...]

DESCRIPTION
Display the statistics for the net sfc hop objects.

EXAMPLE
show net sfc hop

```
-----  
Net: SFC Hop Statistics  
Hop Name Chain Name Fwd Packets In Fwd Packets Out Fwd Bytes In ...  
-----  
2 chain1 0 0 0  
1 chain1 0 0 0
```

SEE ALSO

BIG-IP 2018-07-21 net sfc hop(1)

net sfc sf

NAME

sf - Service Function (SF)

MODULE

net sfc

SYNTAX

Configure a sf definition within the net sfc using the syntax in the following sections.

CREATE/MODIFY

create sf [name]

modify sf [name]

options:

app-service [[string] | none]

description [string]

egress-interface [[string] | none]

ingress-interface [[string] | none]

ip-address [[ip address] | none]

nsh-aware [disabled | enabled]

pool-name [[pool_name] | none]

virtual-name [[virtual_name] | none]

edit sf [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list sf

list sf [[[name] | [glob] | [regex]] ...]

show running-config net sfc sf

show running-config net sfc sf [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DELETE

delete net sfc sf [all | [name]]

DESCRIPTION

You can use the net sfc sf to define a service function (SF) to be referenced by a net sfc chain.

EXAMPLES

create net sfc sf

Creates a sfc sf (see below).

list net sfc sf all-properties

Displays all of the properties of all of the sfc sf.

delete net sfc sf

Deletes a sfc sf (see below).

Example:

```
net sfc sf sf2-1 {  
ip-address any  
virtual-name __f5_sfc_app__ }
```

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies a unique name for the sf. This option is required for the commands create, delete, and modify.

description

User defined description.

egress-interface
Egress interface.

ingress-interface
Ingress interface.

ip-address
IP address of the SF. Only one of ip-address, pool-name, virtual-name may be specified.

nsh-aware
Indicate if the SF is capable of network service header (NSH) packets.

pool-name
Only one of ip-address, pool-name, virtual-name may be specified. If specified, both ingress and egress interface, vlan name, need to be specified and of the same type. If nsh-aware is enabled, then ingress and egress VXLAN-GPE tunnel names can be the same or different.

virtual-name
Only one of ip-address, pool-name, virtual-name may be specified. If specified, then no ingress or egress interface should be specified. nsh-aware cannot be specified with virtual-name defined.

net stp-globals

NAME

stp-globals - Configures spanning tree protocols on the system.

MODULE

net

SYNTAX

Configure the stp-globals component within the net module using the syntax shown in the following sections.

MODIFY

modify stp-globals

options:

config-name [configuration name]
config-revision [integer]
description [string]
fwd-delay [integer]
hello-time [integer]
max-age [integer]
max-hops [integer]
mode [disabled | mstp | passthru | rstp | stp]
transmit-hold [integer]

edit stp-globals

options:

all-properties
non-default-properties

DISPLAY

list stp-globals

show running-config stp-globals

options:

all-properties
non-default-properties
one-line

DESCRIPTION

Provides the ability to configure spanning tree protocols for the traffic management system. Spanning tree protocols are Layer 2 protocols for preventing bridging loops. The system supports multiple spanning tree protocol (MSTP), rapid spanning tree protocol (RSTP), and spanning tree protocol (STP).

EXAMPLES

modify stp-globals mode passthru

Sets the STP mode to passthru. Passthru mode forwards spanning tree bridge protocol data units (BPDUs)

received on any interface to all other interfaces.

modify stp-globals mode disabled

Sets the STP mode to disabled. No MSTP, RSTP, or STP packets are transmitted or received on the interface or trunk, and the spanning tree algorithm exerts no control over forwarding or learning on the port or the trunk.

OPTIONS

config-name

Specifies the configuration name (1 - 32 characters in length) only when the spanning tree mode is MSTP. The default configuration name is a string representation of a globally unique MAC address belonging to the traffic management system.

The MSTP standard introduces the concept of spanning tree regions, which are groups of adjacent bridges with identical configuration names, configuration revision levels, and assignments of VLANs to spanning tree instances.

Note: The system default configuration name is a string representation of the globally unique MAC address of the traffic management system in which hyphens replace the colons in the standard MAC address. For example, the default configuration name 00-01-D7-68-11-80, represents the MAC address 00:01:D7:68:11:80.

config-revision

Specifies the revision level of the MSTP configuration only when the value of the mode option is mstp. The specified number must be in the range 0 through 65535. The default value is 0 (zero).

description

User defined description.

fwd-delay

In the original STP, the forward delay parameter controlled the number of seconds for which an interface was blocked from forwarding network traffic after a reconfiguration of the spanning tree topology. This parameter has no effect when RSTP or MSTP are used, as long as all bridges in the spanning tree use the RSTP or MSTP protocol. If any legacy STP bridges are present, then neighboring bridges must fall back to the old protocol, whose reconfiguration time is affected by the value of the fwd-delay option. The default value is 15 seconds, and the valid range is 4 to 30.

hello-time

Specifies the time interval in seconds between the periodic transmissions that communicate spanning tree information to the adjacent bridges in the network. The default value is 2 seconds, and the valid range is 1 - 10. The default value is optimal in virtually all cases. F5 Networks recommends that you do not change the value of the hello-time option.

max-age

Specifies the number of seconds for which spanning tree information received from other bridges is considered valid. The default value is 20 seconds, and the valid range is 6-40 seconds.

max-hops

Specifies the maximum number of hops an MSTP packet can travel before it is discarded. Use this option only when the value of the mode option is mstp. The number of hops must be in the range of 1 to 255 hops. The default number of hops is 20.

mode Specifies one of three spanning tree modes:

disabled

Specifies to discard spanning tree bridge protocol data units (BPDUs) received on any interface.

mstp Specifies multiple spanning tree protocol.

passthru

Forwards spanning tree bridge protocol data units (BPDUs) received on any interface to all other interfaces. Essentially, passthru mode makes the traffic management system transparent to spanning tree BPDUs. This is the system default.

rstp Specifies rapid spanning tree protocol (RSTP) converges to a fully-connected state quickly.

stp The system supports STP mode for legacy systems. If STP is detected in the network, the traffic management system changes to STP mode even when the mode option is set to disabled, mstp, or rstp.

transmit hold

Specifies the absolute limit on the number of spanning tree protocol packets the traffic management system may transmit on a port in any hello-time interval. It is used to ensure that spanning tree packets do not unduly load the network even in unstable situations. The default value is 6 packets, and the valid range is 1 through 10 packets.

net stp

NAME

stp - Configures a Spanning Tree Protocol (STP) instance.

MODULE

net

SYNTAX

Configure the stp component within the net module using the syntax shown in the following sections.

CREATE/MODIFY

```
create stp [all | [name] ]
modify stp [all | [name] ]
options:
  app-service [[string] | none]
  description [string]
  instance-id [integer]
  interfaces [ add | delete | modify | replace-all-with ] {
    [interface name] {
      options:
        app-service [[string] | none]
        external-path-cost [integer]
        internal-path-cost [integer]
        priority [integer]
      }
    }
  interfaces none
  priority [integer]
  trunks [ add | delete | modify | replace-all-with ] {
    [interface name] {
      options:
        app-service [[string] | none]
        external-path-cost [integer]
        internal-path-cost [integer]
        priority [integer]
      }
    }
  trunks none
  vlans [ add | delete | replace-all-with ] {
    [vlan name ...]
  }
  vlans none
```

```
edit stp [ [ all | [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list stp
list stp [ [ all | [name] | [glob] | [regex] ] ... ]
show stp running-config
show stp running-config [ [ all | [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete stp [all | [name] ]
```

DESCRIPTION

You can use the stp component to configure an STP instance.

EXAMPLES

```
list stp
```

Displays all STP instances on the system.

```
show running-config stp
```

Displays the running configuration information for all STP instances.

```
delete stp myStp2
```

Removes all members from the STP instance, and then deletes the instance itself.

Note that you cannot delete spanning tree instance 0 (the Common and Internal Spanning Tree). You can

only use the command delete in Multiple Spanning Tree Protocol (MSTP) mode.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

external-path-cost

Specifies the external path cost number for either an interface or trunk. The default value is 20000.

Each network interface has an associated path cost within each spanning tree instance. The path cost represents the relative cost of sending network traffic through that interface. In calculating the spanning tree, the algorithm tries to minimize the total path cost between each point of the tree and the root bridge. By manipulating the path costs of different interfaces or trunks it is possible to steer traffic toward paths that are faster, more reliable, and/or more economical. Path costs can take values in the range 1 - 200,000,000. The default path cost for an interface or a trunk is based on the maximum, not actual speed, of the interface or trunk.

In MSTP mode there are two kinds of path cost: external and internal. The external path cost applies only to spanning tree instance 0, the Common and Internal Spanning Tree (CIST). It is used to calculate the cost to reach an adjacent spanning tree region.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

instance-id

The instance ID for this STP instance. In Multiple Spanning Tree Protocol (MSTP) mode, there will be exactly one STP instance with ID 0. The instance ID can be a value between 1 and 255.

internal-path-cost

Specifies the internal path cost number for either an interface or trunk. The default value is 20000.

Each network interface has an associated path cost within each spanning tree instance. The path cost represents the relative cost of sending network traffic through that interface. In calculating the spanning tree, the algorithm tries to minimize the total path cost between each point of the tree and the root bridge. By manipulating the path costs of different interfaces or trunks it is possible to steer traffic toward paths that are faster, more reliable, and/or more economical. Path costs can take values in the range 1 - 200,000,000. The default path cost for an interface or a trunk is based on the maximum, not actual speed, of the interface or trunk.

In MSTP mode there are two kinds of path cost: external and internal. The internal path costs can be independently set for each spanning tree instance (including instance 0) in MSTP mode. The internal path costs are used to calculate the costs of reaching adjacent bridges within the same spanning tree region.

priority

Specifies the priority number of either a bridge, interface, or trunk. The default value for a bridge is 61440. The default value for both interfaces and trunks is 128.

Each bridge, interface, and trunk in a spanning tree instance has a priority value. The relative values of the priorities control the topology of the spanning tree chosen by the protocol. The bridge with the lowest priority value (numerically) will become the root of the spanning tree. Priority values vary from 0 - 61440 in steps of 4096.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

vlan

Specifies the VLANs that you want to add to, delete from, or replace-all-with for this STP instance.

SEE ALSO

create, delete, edit, glob, list, modify, net interface, net trunk, net vlan, regex, show, tmsb

BIG-IP 2014-05-16 net stp(1)

NAME

timer-policy - Configures the timer policy.

MODULE

net

SYNTAX

Modify the timer policy component within the net module using the syntax shown in the following sections. A timer-policy is attached to a service-policy and applied either through an ACL rule or policy applied on a context. The list of supported contexts where a timer policy can be applied are: Virtual Server, SelfIP, Route Domain and Global. The precedence of the timer policy is as follows (highest precedence is 1):

1. ACL rule configured on a Virtual Server or SelfIP
2. Policy configured on a Virtual Server or SelfIP
3. ACL rule configured on a Route Domain
4. Policy configured on a Route Domain
5. ACL rule configured through Global Rules
6. Policy configured on Global Service Policy

Note that within the same context, ACL rule based service policy takes first precedence. Among the different contexts, the order of precedence is as follows: Virtual Server, SelfIP, Route Domain, Global.

CREATE/MODIFY

create timer-policy [name]

modify timer-policy [name]

options:

description [string]

rules [add | delete | modify | replace-all-with] {
[[rule name]] {

options:

description [string]

destination-ports [add | delete | replace-all-with] {
[[port] | [port1-port2]]

}

destination-ports none

ip-protocol [protocol name]

timers [add | delete | modify | replace-all-with] {
[[flow timer type]] {

value [timeout]

}

}

timers none

}

}

rules none

edit timer-policy [[name] | all]

options:

all-properties

non-default-properties

DISPLAY

list timer-policy

show running-config timer-policy

options:

all-properties

non-default-properties

one-line

DESCRIPTION

You can use the timer-policy component to configure a shareable and reusable set of network timer policies which can be associated with a service policy object.

EXAMPLES

```
create net timer-policy add idle-flow-policy { rules add { r1 { ip-protocol tcp destination-ports add { 80
8080 } timers add { flow-idle-timeout { value 120 } } } r2 { ip-protocol udp destination-ports add { 7878 }
timers add { flow-idle-timeout { value 300 } } } }
```

```
list timer-policy
```

```
net timer-policy {
```

```
  idle-flow-policy {
```

```
    rules {
```

```
      r1 {
```

```
        ip-protocol tcp
```

```
        destination-ports {
```

```
          http { }
```

```
          webcache { }
```

```
        }
```

```
      timers {
```

```
        flow-idle-timeout {
```

```
          value 120
```

```
        }
```

```
      }
```

```
    }
```

```
    r2 {
```

```
      ip-protocol udp
```

```
      destination-ports {
```

```

    7878 { }
}
timers {
    flow-idle-timeout {
        value 300
    }
}
}
}
}
}
}
}

```

Creates timer policy rules to set specific timeout configuration for tcp ports 80 & 8080 traffic and another entry for protocol udp.

Here is another example to illustrate the rule match behavior for policy with rules configured with 'all-other' for destination-ports and ip-protocol. Consider a policy as listed below.

```

list timer-policy
net timer-policy {
    flow-idle-policy {
    rules {
        r1 {
            ip-protocol tcp
            destination-ports {
                all-other { }
            }
        }
        timers {
            flow-idle-timeout {
                value 120
            }
        }
        r2 {
            ip-protocol udp
            destination-ports {
                9090 { }
            }
        }
        timers {
            flow-idle-timeout {
                value 300
            }
        }
        r3 {
            ip-protocol all-other
            destination-ports {
                all-other { }
            }
        }
        timers {
            flow-idle-timeout {
                value 40
            }
        }
    }
}
}
}
}
}
}
}
}

```

For an incoming flow:-

- a) TCP, any port: Matches rule r1
- b) UDP, port 1010: Matches no rule
- c) ICMP: Matches rule r3

For the above policy, since there is a specific UDP rule for port 9090, a UDP flow with port other than 9090 will not match any rule. If the rule r2 were to be deleted, all UDP traffic will match against the 'all-other' ip-protocol rule r3.

If the user would like to apply a specific timeout for UDP traffic with destination port being anything other than 9090, one can enter rule r4 to the above policy:

```

r4 {
ip-protocol udp
destination-ports {
    all-other { }
}
}
timers {
    flow-idle-timeout {
        value 60
    }
}
}
}
}

```

modify timer-policy idle-flow-policy delete r1

Removes the timer policy rule r1.

list timer-policy

Displays the current timer policy configuration list.

OPTIONS

description

User defined description.

rules

Adds, deletes, or replaces a named timer policy rule.

ip-protocol

Specifies the IP protocol entry for which the timer policy rule is being configured. This could be a layer-4 protocol (such as tcp, udp or sctp). Only flows matching the configured protocol will make use of this rule. Press the `?` key for a full list of valid protocols. Keyword 'all-other' as an ip-protocol entry means, if there are no specific ip-protocol rule that matches the flow, the flow then matches the 'all-other' ip-protocol rule. Please see example above for rule match behavior.

destination-ports

Specifies the destination port or port range to match against the flow. Keyword 'all-other' as a port entry means, if there are no specific port entry rules to match against the flow, the flow then matches the 'all-other' port rule. For eg. if a policy consists of just two rules r1 and r2, with the same protocol 'tcp' but destination port 80 for r1 and port 'all-other' for r2 configured, an incoming flow with port 80 will match r1 and incoming flow with port 9090 will match r2. Without the 'all-other' port rule r2, incoming flow with port 9090 will not match any rule.

timers

Specifies the flow timer configuration for the different timer types.

value

Specifies the timeout value in seconds.

DELETE

delete trunk [all | [name]]

DESCRIPTION

Link Aggregation allows multiple physical links to be treated as one logical link. It is also referred to as trunking.

The main objective of link aggregation is to provide increased bandwidth at a lower cost, without having to upgrade hardware. The bandwidth of the aggregated trunk is the sum of the capacity of individual member links. Thus, it provides an option for linearly incremental bandwidth as opposed to bandwidth options available through physical layer technology. The traffic management system supports link aggregation control protocol (LACP).

When a trunk is created, LACP is disabled by default. In this mode, no control packets are exchanged and the member links carry traffic as long as the physical layer is operational. In the event of physical link failure, an LACP member is removed from the aggregation.

Note that both endpoints of the trunk should have identical LACP configuration to work properly. A mixed configuration where one endpoint is LACP enabled and the other is LACP disabled, is not valid.

EXAMPLES

create trunk my_trunk interfaces add {1.1 1.2 1.3}

Creates a trunk named my_trunk that includes the interfaces 1.1, 1.2, and 1.3.

modify trunk my_trunk lacp enabled

Enable LACP on the trunk named my_trunk.

modify trunk my_trunk lacp-mode active

Enable active LACP mode on the trunk my_trunk.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

bandwidth

Specifies the operation bandwidth in bytes per second.

cfg-mbr-count

Displays the number of configured members that are associated with this trunk.

description

User defined description.

distribution-hash

Specifies the basis for the hash that the system uses as the frame distribution algorithm. The system uses the resulting hash to determine which interface to use for forwarding traffic.

When frames are transmitted on a trunk, they are distributed across the working member links. The distribution function ensures that the frames belonging to a particular conversation are neither mis-ordered nor duplicated at the receiving end. Distribution is done by calculating a hash value based on source and destination addresses carried in the frame and associating the hash value with a link. All frames with a particular hash value are transmitted on the same link, thereby maintaining frame order.

The options are:

dst-mac

Uses the destination MAC addresses to calculate the hash value.

`src-dst-mac`

Uses the source, destination, and MAC addresses to calculate the hash value.

`src-dst-ipport`

Uses the source and destination IP addresses and ports to calculate the hash value.

`glob` Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

`id` Displays the ID of the trunk.

`interfaces`

Specifies the interfaces by name separated by spaces that you want to add to the trunk, delete from the trunk, or with which you want to replace all existing interfaces associated with the trunk.

`lACP` Specifies, when enabled, that the system supports the link aggregation control protocol (LACP), which monitors the trunk by exchanging control packets over the member links to determine the health of the links. If LACP detects a failure in a member link, it removes the link from the link aggregation. LACP is disabled by default, for backward compatibility.

`lACP-mode`

Specifies the operation mode for LACP if the lACP option is enabled for the trunk. The options are:

`active`

Specifies that the system periodically transmits LACP packets, regardless of the control value of the peer system.

`passive`

Specifies that the system periodically transmits LACP packets, unless the control value of the peer system is active.

`lACP-timeout`

Specifies the rate at which the system sends the LACP control packets. The default value is long.

The options are:

`long` Specifies that the system exchanges LACP packets every 30 seconds.

`short`

Specifies that the system exchanges LACP packets every second.

`link-select-policy`

Sets the LACP policy that the trunk uses to determine which member link (interface) can handle new traffic.

Link aggregation is allowed only when all the interfaces are operating at the same media speed and connected to the same partner aggregation system. When there is a mismatch among configured members due to configuration errors or topology changes (auto-negotiation), link selection policy determines which links become working members and form the aggregation.

The options are:

`auto` Specifies that the system chooses the lowest numbered operational link as the reference link. All the members that have the same media speed and are connected to the same partner as that of the reference link are declared as working members, and they are aggregated. The other configured members do not carry traffic.

`maximum-bandwidth`

Specifies that the system adds to the aggregation a subset of links that gives maximum aggregate bandwidth to the trunk.

`mac-address`

Specifies the media access control (MAC) address, which is associated with the trunk, in not case-sensitive hexadecimal colon notation, for example, 00:0b:09:88:00:9a.

`media`

Displays the media settings for the trunk.

`name` Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

`stp` Enables or disables spanning tree protocols (STP). The default value is enabled.

If you disable STP, the system does not transmit or receive STP, RSTP, or MSTP packets on the trunk, and STP has no control over forwarding or learning on the trunk.

`stp-reset`

Resets STP, which forces a migration check.

`qinq-ethertype`

Specifies the ether-type value used for the packets handled on this trunk when it is a member in a QinQ vlan. The ether-type can be set to any string containing a valid hexadecimal 16 bits number, or any of the well known ether-types: 0x8100, 0x9100, 0x88a8. Default value is set to 0x8100.

working-mbr-count

Displays the number of working members associated with this trunk.

net tunnels endpoint

NAME

endpoint - Tunnel endpoint statistics

MODULE

net tunnels

SYNTAX

Show the statistics of tunnel remote endpoints within the net tunnel component using the syntax described in the following sections.

DISPLAY

show endpoint tunnel-name [name]

options:

remote-address [IP address]

MODIFY

reset-stats endpoint tunnel-name [name]

options:

remote-address [IP address]

DESCRIPTION

The command displays the statistics of tunnel remote endpoints. Currently, the command is only supported for network virtualization tunnels, e.g., VXLAN and NVGRE tunnels.

EXAMPLES

show endpoint tunnel-name t1

Display the statistics of remote endpoints of tunnel t1.

show endpoint tunnel-name t1 remote-address 10.10.0.2

Display the statistics of remote endpoint 10.10.0.2 of tunnel t1.

reset-stats endpoint tunnel-name t1

Reset the statistics of remote endpoints of tunnel t1.

reset-stats endpoint tunnel-name t1 remote-address 10.10.0.2

Reset the statistics of remote endpoint 10.10.0.2 of tunnel t1.

BIG-IP 2016-09-23 net tunnels endpoint(1)

net tunnels etherip

NAME

etherip - Configures an EtherIP tunnel profile.

MODULE

net tunnels

SYNTAX

Configure the etherip component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create etherip [name]
modify etherip [name]
options:
  app-service [[string] | none]
  defaults-from [name]
  description [string]
```

```
edit etherip [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list etherip
list etherip [ [ [name] | [glob] | [regex] ] ... ]
show running-config etherip
show running-config etherip [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

DELETE

```
delete etherip [ all | [name] ]
```

DESCRIPTION

You can use the etherip component to create an EtherIP profile that you associate with a tunnel using the tunnel component. This will cause ethernet frames to be sent over the tunnel. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create etherip my_etherip
```

Creates an EtherIP profile called my_etherip.

```
list etherip all-properties
```

Displays all of the properties of all EtherIP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is etherip.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, modify, net tunnels tunnel, regex, show, tmsh

net tunnels fec-stat

NAME

fec-stat - Displays FEC tunnels statistics.

MODULE

net tunnels

SYNTAX

Display statistics for the FEC tunnels using the syntax in the following section.

DISPLAY

show action

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the fec-stat component to display FEC tunnels statistics. The statistics details are described below:

name Specifies the FEC tunnel name.

profile

Specifies the FEC profile name used for the tunnel.

out_raw_packets

Specifies the number of FEC outgoing raw packets coming from the LAN.

out-raw-bits

Specifies the number of FEC outgoing raw bits coming from the LAN.

out_rdnd_packets

Specifies the number of FEC outgoing redundant packets sent to the WAN.

out_rdnd_bits

Specifies the number of FEC outgoing redundant bits sent to the WAN.

in_raw_packets

Specifies the number of incoming raw packets sent to the LAN.

in-raw-bits

Specifies the number of incoming raw bits sent to the LAN.

in_rdnd_packets

Specifies the number of FEC redundant packets incoming from the WAN.

in_rdnd_bits

Specifies the number of FEC redundant bits incoming from the WAN.

in_rdnd_lost

Specifies the number of FEC redundant packets lost incoming from the WAN.

in_raw_lost

Specifies the number of incoming from WAN raw packets lost.

rmt_in_rdnd_packets

Specifies the number of FEC redundant packets from a remote server when incoming from the WAN.

rmt_in_raw_packets

Specifies the number of raw packets from remote a server when incoming from the WAN.

rmt_in_rdnd_lost

Specifies the number of FEC redundant packets lost from a remote server when incoming from the WAN.

rmt_in_raw_lost

Specifies the number of raw packets lost from a remote server when incoming from the WAN.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, fec, net tunnels, net tunnels fec, net tunnels tunnel, tmsh

non-default-properties

one-line

partition

DELETE

delete fec [all | [name]]

DESCRIPTION

You can use the fec component to create a FEC profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

create fec my_fec

Creates a FEC profile called my_fec.

list fec all-properties

Displays all of the properties of all of the FEC profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default

value is fec.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

decode-idle-timeout

Specifies the maximum waiting time for packets in decoding queues. Packets waiting longer than this time are discarded. Range is from 250 to 2000 milliseconds. The default value is 1500 milliseconds.

decode-max-packets

Specifies the maximum number of waiting packets in decoding queues. Range is from 200 to 8000. The default value is 512.

decode-queues

Specifies the number of decoding queues. Valid numbers are 8,16,32,64,128,256,512,1024. The default value is 32.

encode-max-delay

Specifies the maximum waiting time for packet aggregation. Range is from 500 to 5000 microseconds. The default value is 500 microseconds.

keepalive-interval

Specifies the interval between keepalive (statistical data) packets. Range is from 0 to 100 seconds. The default value is 5 seconds.

lzo Controls the use of the LZO compression algorithm to compress data packets. The default value is enabled.

repair-adaptive

Controls the use of the adaptive FEC repair technique to modify the number of redundant packets according to actual network conditions. The default value is enabled.

repair-packets

Specifies the number of redundant packets to add. Range is from 0 to 15. The default value is 15. This value should be less than or equal to the value specified for source-packets.

source-adaptive

Controls the use of the adaptive FEC source packets technique to reduce the number of packets for better MTU usage. The default value is enabled.

source-packets

Specifies the number of packets into which the system divides the aggregated payload. Range is from 1 to 15. The default value is 15.

udp-port

Specifies the local port for receiving FEC packets. The default value is 8288.

SEE ALSO

net tunnels geneve

NAME

geneve - Configures a Geneve profile.

MODULE

net tunnels

SYNTAX

Configure the geneve component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create geneve [name]
modify geneve [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
  port [integer]
  flooding-type [none | multicast | multipoint]

edit geneve [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list geneve
list geneve [ [ [name] | [glob] | [regex] ] ... ]
show running-config geneve
show running-config geneve [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

DELETE

```
delete geneve [ all | [name] ]
```

DESCRIPTION

You can use the geneve component to create a geneve profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create geneve my_geneve
```

Creates a geneve profile called my_geneve.

```
list geneve all-properties
```

Displays all the properties of all the geneve profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is geneve.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

port Specifies the local port for receiving geneve packets. The default is 6081.

flooding-type

Specifies the flooding type to use to transmit multicast, broadcast and unknown destination frames. The default is multipoint.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, modify, net tunnels tunnel, regex, show, tmsh

net tunnels gre

NAME

gre - Configures a Generic Router Encapsulation (GRE) profile.

MODULE

net tunnels

SYNTAX

Configure the gre component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

create gre [name]

modify gre [name]

options:

app-service [[string] | none]

defaults-from [name]

description [string]

rx-csum [disabled | enabled]

tx-csum [disabled | enabled]

encapsulation [standard | nvgre]

flooding-type [none | multipoint]

edit gre [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list gre

list gre [[[name] | [glob] | [regex]] ...]

show running-config gre

show running-config gre [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE

delete gre [all | [name]]

DESCRIPTION

You can use the gre component to create a GRE profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

create gre my_gre

Creates a GRE profile called my_gre.

list gre all-properties

Displays all of the properties of all of the GRE profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is gre.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rx-csum

Specifies whether the system verifies the checksum on received packets. The default value is disabled.

tx-csum

Specifies whether the system includes a checksum on transmitted packets. The default value is disabled.

encapsulation

Specifies the flavor of GRE header to use for encapsulation. The default value is standard.

flooding-type

Specifies the flooding type to use to transmit broadcast and unknown destination frames. The default is none.

BIG-IP 2014-05-16 net tunnels gre(1)

net tunnels ipip

NAME

ipip - Configures an IP over IP (IPIP) profile.

MODULE

net tunnels

SYNTAX

Configure the ipip component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

create ipip [name]

modify ipip [name]

options:

app-service [[string] | none]

defaults-from [name]

description [string]

proto [IPv4 | IPv6]

ds-lite [bool]

edit ipip [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list ipip

list ipip [[[name] | [glob] | [regex]] ...]

show running-config ipip

show running-config ipip [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE

delete ipip [all | [name]]

DESCRIPTION

You can use the ipip component to create an IPIP profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

create ipip my_ipip

Creates an IPIP profile called my_ipip.

list ipip all-properties

Displays all of the properties of all of the IPIP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is ipip.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the partition within which this component resides.

proto

Specifies the next header protocol. The default value is IPv4.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ds-lite

Specifies whether the profile is used for a DS-lite deployment. When enabled, an augmented flow lookup is made using the IPv6 address in the outer header in addition to the inner header addresses for packets coming over this tunnel. The default value is disabled.

SEE ALSO

create, delete, edit, glob, list, modify, net tunnels gre, net tunnels tunnel, net tunnels wccp, regex, show, tmsh

BIG-IP 2014-03-18 net tunnels ipip(1)

net tunnels ipsec

NAME

ipsec - Configures an IPsec profile.

MODULE

net tunnels

SYNTAX

Configure the ipsec component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

create ipsec [name]

modify ipsec [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

traffic-selector [name]

edit ipsec [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

```
DISPLAY
list ipsec
list ipsec [ [ [name] | [glob] | [regex] ] ... ]
show running-config ipsec
show running-config ipsec [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

```
DELETE
delete ipsec [ all | [name] ]
```

DESCRIPTION

You can use the ipsec component to create an ipsec profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create ipsec my_ipsec
```

Creates an IPsec profile called my_ipsec.

```
list ipsec all-properties
```

Displays all the properties of all the IPsec profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is ipsec.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

traffic-selector

Specifies the IPsec traffic selector for the IPsec tunnel.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, modify, net tunnels tunnel, regex, show, tmsh

BIG-IP 2015-11-17 net tunnels ipsec(1)

net tunnels lw4o6

NAME

lw4o6 - Configures a LW4o6 tunnel profile.

MODULE

net tunnels

SYNTAX

Configure the lw4o6 component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

create lw4o6 [name]

modify lw4o6 [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

lwtbl-file [string]

psid-length [integer]

all-protocols-pass [enabled | disabled]

edit lw4o6 [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list lw4o6

list lw4o6 [[[name] | [glob] | [regex]] ...]

show running-config lw4o6

show running-config lw4o6 [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE

delete lw4o6 [all | [name]]

DESCRIPTION

You can use the lw4o6 component to create a LW4o6 profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

create lw4o6 my_lw4o6 lwtbl-file name

Creates a LW4o6 profile called my_lw4o6, lwtbl-file name have to be created before. For more information about creating a lwtbl-file see sys file lwtunneltbl.

list lw4o6 all-properties

Displays all the properties of all the LW4o6 profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is lw4o6.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

lwtbl-file

Specifies the existing lw4o6 configuration file.

psid-length

Specifies the length of Port Set ID (PSID). The default value is 0.

all-protocols-pass

When enabled and PSID is 0, permits passthrough for all IP sub-protocols. If PSID != 0, value have to be disabled. If it is disabled only TCP/UDP/ICMP traffic can pass lw4o6 tunnel. The default value is disabled."

net tunnels map

NAME

map - Configures a MAP tunnel profile.

MODULE

net tunnels

SYNTAX

Configure the map component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

create map [name]

modify map [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

ip6-prefix [ipv6 address/prefix length]

ip4-prefix [ipv4 address/prefix length]

ea-bits-length [integer]

port-offset [integer]

edit map [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list map

list map [[[name] | [glob] | [regex]] ...]

show running-config map

show running-config map [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE

delete map [all | [name]]

DESCRIPTION

You can use the map component to create a MAP profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

create map my_map

Creates a MAP profile called my_map.

list map all-properties

Displays all the properties of all the MAP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is map.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression

syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ip6-prefix

Specifies the IPv6 Prefix using CIDR notation, such as 2014::/48. The default prefix length is 48.

ip4-prefix

Specifies the IPv4 Prefix using CIDR notation, such as 192.0.0.0/8. The default prefix length is 8.

ea-bits-length

Specifies the length in bits of the EA (Embedded Address) of the MAP domain. The default is 32 (IPv4 prefix 24 bits + PSID 8 bits).

port-offset

Specifies the port offset bits length of the MAP domain. The default is 6.

SEE ALSO

create, delete, edit, glob, list, modify, net tunnels tunnel, regex, show, tmsh

BIG-IP 2016-03-14 net tunnels map(1)

net tunnels ppp

NAME

ppp - Configures a PPP profile.

MODULE

net tunnels

SYNTAX

Configure the ppp component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

create ppp [name]

modify ppp [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

lcp-echo-failure [integer]

lcp-echo-interval [integer]

vj [disabled | enabled]

edit ppp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list ppp

list ppp [[[name] | [glob] | [regex]] ...]

show running-config ppp

show running-config ppp [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE

delete ppp [all | [name]]

DESCRIPTION

You can use the ppp component to create a ppp profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create ppp my_ppp
```

Creates a PPP profile called my_ppp.

```
list ppp all-properties
```

Displays all the properties of all the PPP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is ppp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

lcp-echo-failure

Specifies the number of consecutive PPP LCP echo messages that must go unanswered for the server to drop PPP connection. For example, if the server sends number of consecutive PPP LCP Echo Request messages that go unanswered (by Echo Reply), it will close the PPP connection. The default value is 4.

lcp-echo-interval

Specifies the interval, in seconds, between the PPP LCP Echo Request messages that the server sends to the peer (client). The default value is 30.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

vj Specifies whether the system uses Van Jacobson Header Compression (also known as VJ compression, or just Header Compression), which is an option in most versions of PPP. VJ is a data compression protocol described in RFC 1144, specifically designed by Van Jacobson to improve TCP/IP performance over slow serial links. The default value is disabled.

BIG-IP 2014-05-16 net tunnels ppp(1)

net tunnels tcp-forward

NAME

tcp-forward - Configures a tcp-forward tunnel profile.

MODULE

net tunnels

SYNTAX

Configure the tcp-forward component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create tcp-forward [name]
```

```
modify tcp-forward [name]
```

options:
app-service [[string] | none]
defaults-from [[name] | none]
description [string]

edit [[name] ...]
options:
all-properties
non-default-properties

DISPLAY
list tcp-forward
list tcp-forward [[[name] ...]
show running-config tcp-forward
show running-config tcp-forward [[name] ...]
options:
all-properties
app-service
non-default-properties
one-line
partition

DELETE
delete tcp-forward [all | [name]]

DESCRIPTION

You can use the tcp-forward component to create a TCP-FORWARD profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

create tcp-forward my_tcp_forward

Creates a TCP_FORWARD profile called my_tcp_forward.

list tcp-forward all-properties

Displays all the properties of all the TCP-FORWARD profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is tcp-forward.

description

User defined description.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

SEE ALSO

BIG-IP 2018-10-20 net tunnels tcp-forward(1)

net tunnels tunnel

NAME

tunnel - Configures a tunnel.

MODULE

net tunnels

SYNTAX

Configure the tunnel component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY
create tunnel [name]
modify tunnel [name]
options:
 app-service [[string] | none]
 auto-lasthop [default | enabled | disabled]
 description [string]
 local-address [ip address]
 secondary-address [ip address]
 mode [bidirectional | inbound | outbound]
 mtu [integer]
 use-pmtu [enabled | disabled]
 profile [name]
 remote-address [ip address]
 traffic-group [[traffic group] | none]
 tos [integer]
 transparent [enabled | disabled]
 idle-timeout [integer]
 key [integer]

edit tunnel [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list tunnel
list tunnel [[[name] | [glob] | [regex]] ...]
show running-config tunnel
show running-config tunnel [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 app-service
 non-default-properties
 one-line
 partition

DELETE
delete tunnel [all | [name]]

DESCRIPTION
You can use the tunnel component to configure a tunnel.

EXAMPLES
create tunnel my_tunnel local-address 10.10.10.1 remote-address 11.11.11.1 profile gre

Creates a tunnel named my_tunnel between the local IP address 10.10.10.1 and the remote IP address 11.11.11.1.

list tunnel all-properties

Displays all of the properties of all of the tunnels.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auto-lasthop
When enabled, specifies that the system returns packets to the MAC address from which they were sent. The default setting is default, which specifies that the system uses the default route to send back the request.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

if-index
Displays the index assigned to this tunnel. It is a unique identifier assigned for all objects displayed in the SNMP IF-MIB.

local-address
Specifies a local IP address. This option is required.

secondary-address
Specifies a secondary non-floating IP address when the local-address is set to a floating address. Currently this setting is supported by NVGRE tunnels only.

mode Specifies how the tunnel carries traffic. The default value is bidirectional.

mtu Specifies the maximum transmission unit (MTU) of the tunnel. The default value is 0. When the MTU is set to the default value (of 0), the MTU of the tunnel is computed by the system and is set to the MTU size of the underlying interface minus the encapsulation overhead introduced by the tunneling protocol. The valid range is 0 - 65535.

use-pmtu

Enables or disables the tunnel to use the PMTU (Path MTU) information provided by ICMP NeedFrag error messages. If enabled and the tunnel MTU is set to 0, the tunnel will use the PMTU information. If enabled and the tunnel MTU is fixed to a non-zero value, the tunnel will use the minimum of PMTU and MTU. If disabled, the tunnel will use fixed MTU, or calculate its MTU using tunnel encapsulation configurations.

name Specifies a unique name for the component. This option is required for the commands create, and modify.

partition

Displays the administrative partition within which the component resides.

profile

Specifies the profile that you want to associate with the tunnel. This option is required for the create command.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

remote-address

Specifies a remote IP address. This value is required for the commands create and modify.

traffic-group

Specifies a traffic-group for use with the tunnel. Traffic group determines the ConfigSync behavior of the tunnel object.

tos Specifies a value for insertion into the Type of Service (ToS) octet within the IP header of the encapsulating header of transmitted packets. The default value is preserve. The possible values are 0 (zero) - 255.

transparent

Enables or disables the tunnel to be transparent. If enabled, the user can inspect and/or manipulate the encapsulated traffic flowing through the BIG-IP. A transparent tunnel terminates a tunnel while presenting the illusion that the tunnel transits the device unperturbed i.e. the BIG-IP appears like an intermediate router that simply routes IP traffic through the device. The default value is disabled.

idle-timeout

Specifies an idle timeout for wildcard tunnels in seconds. This setting specifies the number of seconds that a wildcard tunnel connection is idle before the connection is eligible for deletion. The default value is 300 seconds.

key The key field may represent different values depending on the type of the tunnel. For VXLAN it represents the Virtual Network Identifier (VNI). The default value is 0.

SEE ALSO

BIG-IP 2016-03-14 net tunnels tunnel(1)

net tunnels v6rd

NAME

v6rd - Configures a 6RD profile.

MODULE

net tunnels

SYNTAX

Configure the v6rd component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

create v6rd [name]

modify v6rd [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

v6rdprefix [IPv6 address]

v6rdprefixlen [integer]

ipv4prefix [IPv4 address]

ipv4prefixlen [integer]

edit v6rd [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list v6rd

list v6rd [[[name] | [glob] | [regex]] ...]

show running-config v6rd

show running-config v6rd [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE

delete v6rd [all | [name]]

DESCRIPTION

You can use the v6rd component to create a v6rd profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

create v6rd my_v6rd

Creates a 6RD profile called my_v6rd.

list v6rd all-properties

Displays all the properties of all the 6RD profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is v6rd.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

v6rdprefix

Specifies the IPv6 prefix for 6rd domain.

v6rdprefixlen

Specifies the IPv6 prefix length of the 6rd domain. The default is 56.

ipv4prefix

As an extension not mentioned in the RFC5969, it specifies the IPv4 prefix for the Customer-Edge (CE) devices of a 6RD domain at a Border-Relay (BR) in case that the subnet prefixes used by the 6RD devices do not share the same IPv4 prefix. If they do, there is no need to configure this parameter. The default value is 0.0.0.0.

ipv4prefixlen

Also noted as IPv4MaskLen in RFC5969, it specifies the number of identical high-order bits shared by all CE and BR IPv4 addresses in a given 6RD domain. The valid range is from zero to 32. It is a required value for create. It defaults to zero, i.e. the full ipv4 address must be encapsulated.

net tunnels vxlan

NAME

vxlan - Configures a VXLAN profile.

MODULE

net tunnels

SYNTAX

Configure the vxlan component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create vxlan [name]
modify vxlan [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
  port [integer]
  flooding-type [none | multicast | multipoint | replicator]
  encapsulation-type [vxlan | vxlan-gpe]
```

```
edit vxlan [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list vxlan
list vxlan [ [ [name] | [glob] | [regex] ] ... ]
show running-config vxlan
show running-config vxlan [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

DELETE

```
delete vxlan [ all | [name] ]
```

DESCRIPTION

You can use the vxlan component to create a vxlan profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create vxlan my_vxlan
```

Creates a VXLAN profile called my_vxlan.

```
list vxlan all-properties
```

Displays all the properties of all the VXLAN profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is vxlan.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

port Specifies the local port for receiving VXLAN packets. The default is 4789.

flooding-type

Specifies the flooding type to use to transmit multicast, broadcast and unknown destination frames. The default is multicast.

encapsulation-type

Specifies whether the VXLAN header is formatted according to RFC 7348 (vxlan) or with the Generic Protocol Extension (vxlan-gpe). The default is vxlan.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

BIG-IP 2016-03-14 net tunnels vxlan(1)

net tunnels wccp

NAME

wccp - Configures a Web-cache coordination protocol (WCCP) GRE profile.

MODULE

net tunnels

SYNTAX

Configure the wccp component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

create wccp [name]

modify wccp [name]

options:

app-service [[string] | none]

defaults-from [name]

description [string]

rx-csum [disabled | enabled]

tx-csum [disabled | enabled]

wccp-version [1 | 2]

edit wccp [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list wccp

list wccp [[[name] | [glob] | [regex]] ...]

show running-config wccp

show running-config wccp [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE

delete wccp [all | [name]]

DESCRIPTION

You can use the wccp component to create a WCCP GRE profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

create wccp my_wccp_gre

Creates a WCCP GRE profile called my_wccp_gre.

list wccp all-properties

Displays all of the properties of all of the WCCP GRE profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is wccpgre.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rx-csum

Specifies whether the system verifies the checksum on received packets. The default value is disabled.

tx-csum

Specifies whether the system includes a checksum on transmitted packets. The default value is disabled.

wccp-version

Specifies the version of WCCP that the system uses. The default value is 2.

SEE ALSO

net vlan-group

NAME

vlan-group - Configures a VLAN group.

MODULE

net

SYNTAX

Modify the vlan-group component within the net module using the syntax shown in the following sections.

CREATE/MODIFY

```
create vlan-group [name]
modify vlan-group [name]
options:
  app-service [[string] | none]
  auto-lasthop [default | enabled | disabled ]
  bridge-in-standby [disabled | enabled]
  bridge-multicast [disabled | enabled]
  bridge-traffic [disabled | enabled]
  description [string]
  members
    [add | delete | replace-all-with] ] {
[vlan name] ...
  }
  members [default | none]
  migration-keepalive [disabled | enabled]
  mode [opaque | translucent | transparent | virtual-wire]
  proxy-excludes
    [add | delete | replace-all-with] ] {
[ip address] ...
  }
  proxy-excludes [default | none]

edit vlan-group [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list vlan-group
list vlan-group [ [ [name] | [glob] | [regex] ] ... ]
show running-config vlan-group
show running-config vlan-group
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

show vlan-group
show vlan-group [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

DELETE

```
delete vlan-group [name]
```

DESCRIPTION

The vlan-group component defines a VLAN group, which is a grouping of two or more VLANs belonging to the same IP network for the purpose of allowing Layer 2 packet forwarding between those VLANs.

The VLANs between which the packets are to be passed must be on the same IP network, and they must be grouped using the vlan-group component. For example: modify vlan-group network11 members add { internal external }.

EXAMPLES

```
create vlan-group my_vlan-group members add { vlan1 vlan2 }
```

Creates a VLAN group named my_vlan-group that consists of VLANs named vlan1 and vlan2.

```
modify vlan-group proxy-excludes add { 10.10.10.1 }
```

Sets the global VLAN group proxy exclusion list.

delete vlan-group my_vlan-group

Deletes the VLAN group named my_vlan-group.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

bridge-traffic

When enabled, specifies that the VLAN group forwards all frames, including non-IP traffic. The default value is disabled.

bridge-in-standby

When enabled, specifies that the VLAN group forwards packets, even when the system is the standby unit in a redundant system. This option is designed for deployments in which the VLAN group exists on only one of the units. If that does not match your configuration, using this option may cause adverse effects. The default value is disabled.

bridge-multicast

When enabled, allows bridging of non-Internet Protocol (IP) Address Resolution Protocol (ARP) multicast frames across a VLAN group. An example of when you might want to use this option is when you are implementing the Spanning Tree Protocol (STP).

description

User-defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

if-index

Displays the index assigned to this VLAN group. It is a unique identifier assigned for all objects displayed in the SNMP IF-MIB.

members

The names of the VLANs that you want to add to or delete from the VLAN group.

migration-keepalive

Specifies whether the system will send keepalive frames (TCP keepalives and empty UDP packets depending on the connection type) when a node is moved from one VLAN group member to another VLAN group member for all existing connections that the system has to that node.

mode Specifies the level of exposure of remote MAC addresses within VLAN groups. The default value is translucent.

The options are:

virtual-wire

Use this option to create a Layer 2 bridge that only forwards traffic between two configured members. Traffic forwarded by such a VLAN group keeps intact the Ethernet header from ingress to egress, thus making this device transparent. A VLAN group configured to be virtual-wire is restricted to two member VLANs.

opaque

Use this option when you have a Cisco router in the network sending CDP packets to the system. Because opaque VLAN groups require a source and destination MAC address, and CDP packets do not contain a source and destination MAC address, the CDP packets are not forwarded through the VLAN group. This mode changes the MAC address to the MAC address assigned to the VLAN group, a proxy ARP with Layer 3 forwarding.

translucent

Uses the real MAC address of the requested host with the locally unique bit toggled. Specifies that the system uses Layer 2 forwarding with locally-unique bit, toggled in ARP response across VLANs.

transparent

Leaves the MAC address unchanged by the traffic management system. Specifies that the system uses Layer 2 forwarding with the original MAC address of the remote system preserved across VLANs.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

proxy-excludes

Specifies the IP addresses that you want to include in the proxy ARP exclusion list. If you use VLAN groups, you must configure a proxy ARP forwarding exclusion list. F5 Networks recommends that you configure this feature if you use VLAN groups with a redundant system. The reason is that both units need to communicate directly with their gateways and the back-end nodes. Creating a proxy ARP exclusion list prevents traffic from being proxied through the active unit due to proxy ARP. This traffic needs to be sent directly to the destination, not proxied.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

field-fmt

DELETE

delete vlan [name]

DESCRIPTION

VLANs are part of the configuration of the BIG-IP(r) network components. VLANs can be based on either ports or tags. When creating a VLAN, a tag value for the VLAN is automatically chosen unless you specify a tag value on the command line.

VLANs can have both tagged and untagged interfaces. You can add an interface to multiple VLANs as a tagged interface. You can add an interface to a single VLAN as an untagged interface. The tagged traffic can be single tagged and double tagged.

Note: To reset the statistics that display when you use the command sequence show vlan, you must reset the statistics for the trunks and interfaces associated with the VLAN.

EXAMPLES

```
create vlan my_vlan interfaces add { 1.2 1.3 1.4 }
```

Create the VLAN my_vlan that includes the interfaces 1.2, 1.3, and 1.4.

```
delete vlan my_vlan
```

Delete the VLAN named my_vlan.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User-defined description.

failsafe

Enables a fail-safe mechanism that causes the active cluster to fail over to a redundant cluster when loss of traffic is detected on a VLAN, and traffic is not restored during the failover timeout period for that VLAN. The default value is disabled.

When you set the VLAN failsafe option to enabled, the default failsafe-action value is restart-all. Therefore, when the fail-safe mechanism is triggered, all the daemons are restarted and the unit fails over.

failsafe-action

Specifies the action for the system to take when the fail-safe mechanism is triggered. The default value is failover-restart-tm.

failsafe-timeout

Specifies the number of seconds that an active unit can run without detecting network traffic on this VLAN before it starts a failover. The default value is 90 seconds.

fwd-mode

Displays the current forwarding mode which is derived from the vlan member port-fwd-mode property. This property is read-only and cannot be modified. See "net interface" for details on port-fwd-mode.

The options are:

I3 The VLAN consists of interface member(s) with port-fwd-mode set to I3.

passive

The VLAN consists of interface member(s) with port-fwd-mode set to passive.

virtual-wire

The VLAN consists of interface member(s) with port-fwd-mode set to virtual-wire.

none The VLAN has no interface member.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

if-index

Displays the index assigned to this VLAN. It is a unique identifier assigned for all objects displayed in the SNMP IF-MIB.

interfaces

Specifies a list of tagged or untagged interfaces and trunks that you want to configure for the VLAN. Use tagged interfaces or trunks when you want to assign a single interface or trunk to multiple VLANs.

A tagged interface is one that you assign to a VLAN in a way that causes the system to add a VLAN tag into the header of any frame passing through that interface or trunk.

A trunk is a combination of two or more interfaces and cables configured as one link.

tag-mode

Specifies the tag mode of the interface or trunk associated with. The default value is none.

The available values are:

customer

Specifies tag-mode setting for vlan members that are facing customer network and carry single tagged traffic.

service

Specifies tag-mode setting for vlan members that are facing the service provider networks and carry single tagged traffic.

double

Specifies tag-mode setting for vlan members that are facing the service provider networks and carry double tagged traffic.

none Specifies no tag-mode setting.

learning

Specifies whether switch ports placed in the VLAN are configured for switch learning, forwarding only, or dropped. The default value is enable-forward.

mtu Sets a specific maximum transition unit (MTU) for the VLAN. The default value is 1500. This value does not include the layer2 header.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

sflow

Specifies sFlow settings for the VLAN:

poll-interval

Specifies the maximum interval in seconds between two pollings. The default value is 0. To enable this setting, you must also set the poll-interval-global setting to no.

poll-interval-global

Specifies whether the global VLAN poll-interval setting, which is available under sys sflow global-settings module, overrides the object-level poll-interval setting. The default value is yes.

The available values are:

no Specifies to use the object-level poll-interval setting.

yes Specifies to use the global VLAN poll-interval setting.

sampling-rate

Specifies the ratio of packets observed to the samples generated. For example, a sampling rate of 2000 specifies that 1 sample will be randomly generated for every 2000 packets observed. The default value is 0. To enable this setting, you must also set the sampling-rate-global setting to no.

sampling-rate-global

Specifies whether the global VLAN sampling-rate setting, which is available under sys sflow global-settings module, overrides the object-level sampling-rate setting. The default value is yes.

The available values are:

no Specifies to use the object-level sampling-rate setting.

yes Specifies to use the global VLAN sampling-rate setting.

source-checking

Specifies that only connections that have a return route in the routing table are accepted. The default value is disabled.

tag Specifies a number that the system adds into the header of any frame passing through the VLAN. The value can be 1 through 4094, or 4096. The default is to not use this option, and the system assigns a tag number between 1 to 4094. A VLAN with the special tag 4096 is not used in the packet processing path; rather it assists with virtual-wire configuration, and such VLANs can only have interfaces with the port-fwd-mode property set to virtual-wire.

customer-tag

Specifies a number that the system adds into the header of any double tagged frame passing through the VLAN. The value can be any of the following: 1 through 4094, or none. The default is none.

cmp-hash

Specifies how the traffic on the VLAN will be disaggregated. The traffic disaggregation on the VLAN can be based on source ip, dest ip, or L4 ports. The default cmp hash uses L4 ports.

dag-tunnel

Specifies whether the ip tunnel traffic on the VLAN should be disaggregated based on the inner ip header or outer ip header. The default value is outer.

dag-round-robin

Specifies whether intended stateless traffic on the VLAN should be disaggregated in a round-robin order instead of using static hash. The stateless traffic include nonIP L2 traffic and user-specified UDP protocols. The sys db variable dag.roundrobin.redag allows HSBs to round robin stateless traffic to remote HSBs/blades.

hardware-syncookie

Enables hardware syncookie mode on a VLAN. When enabled, the hardware per-VLAN SYN cookie protection will be triggered when the certain traffic threshold is reached on supported platforms. The default value is disabled.

syncache-threshold

Specifies the number of outstanding SYN packets on the VLAN that will trigger the hardware per-VLAN SYN cookie protection. The default value is set to 6000 packets.

syn-flood-rate-limit

Specifies the max number of SYN flood packets per second received on the VLAN before the hardware per-VLAN SYN cookie protection is triggered. The default value is set at 1000 packets per second.

DELETE
delete wccp [name]

DESCRIPTION

You can use the wccp component to create and modify WCCPv2 service groups. WCCPv2 is a content-routing protocol developed by Cisco Systems, Inc., which provides a mechanism to redirect traffic flows in real time. A WCCP service in this context is a set of redirection criteria and processing instructions that the BIG-IP(r) system applies to any traffic that a router in the service group redirects to the BIG-IP system.

EXAMPLES

list wccp service-wccp all-properties

Displays the services and their attributes in the service group named service-wccp.

modify server-wccp cache-timeout 40

Changes the cache-timeout setting to 40 for the service group named server-wccp.

modify server-wccp services modify { 77 {weight 60} }

Changes the weight setting to 60 for the service identified as 77 in the service group named server-wccp.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

cache-timeout

Specifies the frequency of control messages between the system and the router. The range is from 1 to 60 seconds. The default value is 10.

description

User-defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

services

Specifies the service group identifier, a number between 51 and 255 that matches a service ID configured on the router.

Adds, deletes, or replaces a set of services. You can configure the following options for a service:

alt-hash-fields

Specifies to the router which traffic attributes to use to determine which BIG-IP system it should forward traffic to for load balancing (traffic-assign mask) : destination IP address (dest-ip) or destination port (dest-port) or source IP address (src-ip), or source port (src-port).

app-service

Specifies the name of the application service to which the service belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the service. Only the application service can modify or delete the service.

custom-mask

Specifies the hexadecimal mask used when traffic-assign mask; it should have not more than 6 bits ON.

hash-fields

Specifies to the router which traffic attributes to use to determine which BIG-IP system it should forward traffic to for load balancing (traffic-assign hash): destination IP address (dest-ip), destination port (dest-port), source IP address (src-ip), and/or source port (src-port).

object identifier

Specifies the service group identifier, a number between 51 and 255 that matches a service ID

configured on the router.

password
Specifies the password for MD5 authentication or none.

port-type
Specifies whether the WCCP interception of traffic is based on the destination port (dest) or source port (source), or is not specified (none). The default value is none.

ports
Specifies one or more ports (up to 8) on which traffic is redirected.

priority
Specifies the precedence of the service group relative to the other service groups. The range is from 1 to 255. The default value is 100.

protocol
Specifies the protocol of the traffic to be redirected: TCP (tcp) or UDP (udp). The default value is tcp.

redirection
Specifies the method the router uses to redirect traffic: GRE gre or L2 l2. The default value is gre.

return
Specifies the method used to return passthrough traffic to the router: GRE (gre) or L2 (l2). The default value is gre.

routers
Specifies the IP addresses of the WCCP-enabled routers that redirect traffic.

traffic-assign
Specifies whether load balancing is achieved by a hash algorithm or a mask. If you specify hash, specify one or more attributes using the option hash-fields. If you specify mask, specify one attribute using the option alt-hash-fields

tunnel-local-address
Specifies an IP address on the BIG-IP system to which the WCCP-enabled routers should redirect traffic. Specify a self IP address of an external VLAN on the BIG-IP system.

tunnel-remote-addresses
Specifies the Router Identifier IP address of the router that redirects traffic.

weight
Specifies the relative importance of this traffic in a load-balancing environment. The range is from 1 to 100. The default value is 50.

SEE ALSO

```

```

edit forwarding-endpoint [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

```

```

DISPLAY
list forwarding-endpoint
list forwarding-endpoint [ [ [name] | [glob] | [regex] ] ... ]
show running-config forwarding-endpoint
show running-config forwarding-endpoint [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
    partition

```

```

DELETE
delete forwarding-endpoint [name]

```

Note: All references to the forwarding-endpoint must be removed before it can be deleted.

DESCRIPTION

forwarding-endpoint is used to specify PEM policy forwarding action(s).

Note: A valid LTM pool with at least one member must be pre-configured before creating a forwarding-endpoint. Please refer to ltm pool for more info about configuring LTM pools.

EXAMPLES

```

create forwarding-endpoint my_endpoint { pool my_pool snatpool my_snatpool source-port preserved translate-
address enabled translate-service enabled }

```

Creates a Policy Enforcement Manager forwarding endpoint named my_endpoint.

```

delete forwarding-endpoint my_endpoint

```

Deletes the forwarding-endpoint named my_endpoint.

```

list forwarding-endpoint my_endpoint

```

Displays the properties of the forwarding-endpoint named my_endpoint.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, user cannot modify or delete the object. Only the application service can modify or delete the object.

description

Specifies a user-defined description.

persistence

Allows to set a specific persistence method for the pool member selection.

fallback

Specifies the fallback persistence method so that it applies when default persistence fail.

The options are:

destination-ip

Map the destination ip address to a specific pool member so that subsequent traffic sent to this address is directed to the same pool member.

source-ip

Map the source ip address to a specific pool member so that subsequent traffic from this address is directed to the same pool member.

disabled

Specifies that this feature is disabled.

hash-settings
Specifies the settings for the hash persistence method.

algorithm
Specifies the algorithm to calculate the hash value. Currently only the carp algorithm is available.

length
Specifies the length of the source string used to calculate hash value. Default value of length is 1024.

offset
Specifies the offset in bytes from start of the source string to calculate the hash value. Default value of offset is 0.

source
Specifies the source for the string value which is used to calculate hash value.

tcl-value
Specifies the tcl script snippet so that when this script is executed its result used to calculate the hash value.

type Specifies the persistence method.

The options are:

destination-ip
Map the destination ip address to a specific pool member so that subsequent traffic sent to this address is directed to the same pool member.

hash Map the hash value to a specific pool member so that subsequent traffic with the same hash value is directed to the same pool member.

source-ip
Map the source ip address to a specific pool member so that subsequent traffic from this address is directed to the same pool member.

disabled
Specifies that this feature is disabled.

pool Specifies the name of an LTM pool where the traffic is going to be directed to. Is used in the PEM policy rule forwarding actions. Note that the pool must be pre-configured before it can be referenced by a forwarding action.

snat-pool
Specifies the name of an existing LTM SNAT pool (snatpool) that is used to translate the client IP address to one of the configured IP addresses in that SNAT pool. The Self-IP addresses of the BIG-IP system must not be included in the SNAT pool. The default value is none.

source-port
Specifies whether the system preserves the source port of the connection. The default value is preserve.

The options are:

change
Specifies that the system changes the source port. This setting is useful for obfuscating internal network address.

preserve
Specifies that the system preserves the value configured for the source port, unless the source port from a particular snat is already in use, in which case the system uses a different port.

preserve-strict
Specifies that the system preserves the value configured for the source port. If the port is in use, the system does not process the connection. F5 Networks recommends restricting the use of this setting to cases that meet at least one of the following conditions:

The port is configured for UDP traffic.

The system is configured for nPath routing or is running in transparent mode (that is, there is no translation of any other Layer 3 or Layer 4 field).

There is a one-to-one relationship between virtual IP addresses and node addresses, or clustered multiprocessing (CMP) is disabled.

translate-address
Specifies, when enabled, that the system translates the original destination address of the virtual server. When disabled, specifies that the system uses the address without translation. The default value is disabled.

translate-service
Note that translate-service is really translate-port. It specifies, when enabled, that the system translates the original destination port. When disabled, it specifies that the system uses the original destination port without translation. The default value is disabled.

pem global-settings analytics

NAME

Analytics - Configures the global settings that pertain to Analytics reporting for Policy Enforcement Manager (PEM).

MODULE

pem global-settings

SYNTAX

Modify the analytics component within the pem global-settings module using the syntax shown in the following sections.

MODIFY

```
modify analytics {
  options:
    mode [disabled | enabled]
    subscriber-aware [disabled | enabled]
    logging {
      hsl {
        endpoint-id [log-publisher]
      }
    }
}
```

edit analytics [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

DISPLAY

list analytics

list analytics [[[name] | [glob] | [regex]] ...]

show running-config analytics

show running-config analytics [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties
one-line
partition

DESCRIPTION

You can use the analytics component to configure global settings for analytics reporting.

EXAMPLES

modify analytics mode disabled subscriber-aware disabled logging hsl endpoint-id hsl_endpoint

Enables the analytics reporting for PEM and configures logging endpoint as hsl_endpoint.

list analytics

Displays the configuration for analytics settings.

OPTIONS

mode Specifies the mode for analytics reporting. It can take enable or disable as value.

subscriber-aware

Specifies the subscriber awareness for analytics reporting. It can take enable or disable as value.

logging

You can configure the following option for logging.

hsl You can configure the following options for hsl endpoint.

endpoint-id

Specifies the endpoint name.

SEE ALSO

create, delete, edit, glob, list, modify, pem listener, pem policy, pem profile diameter-endpoint, pem profile spm, pem reporting format-script, pem service-chain-endpoint, pem subscriber, pem subscribers, regex, show, tmsh

pem global-settings gx

NAME

gx - Configures the global settings that pertain to gx reporting for Policy Enforcement Manager (PEM).

MODULE

pem global-settings

SYNTAX

Modify the gx component within the pem global-settings module using the syntax shown in the following sections.

MODIFY

modify gx

options:

gx-immediate-reporting [disabled | enabled]

gx-usage-record-merge [disabled | enabled]

edit gx [...]

options:

all-properties

non-default-properties

DISPLAY

list gx

list gx [...]

show running-config gx

options:

all-properties

current-module

non-default-properties

one-line

partition

DESCRIPTION

You can use the gx component to configure global settings for gx reporting.

EXAMPLES

modify gx gx-immediate-reporting disabled

Disables immediate reporting for gx.

list gx

Displays the configuration of gx reporting.

OPTIONS

gx-immediate-reporting

Displays the value of gx-immediate-reporting option.

gx-usage-record-merge

Displays the value of gx-usage-record-merge option.

SEE ALSO

create, delete, edit, glob, list, modify, pem reporting format-script, show, tmsh

pem global-settings hsl-flow

NAME

hsl-flow - Configures the global settings that pertain to hsl flow reporting for Policy Enforcement Manager (PEM).

MODULE

pem global-settings

SYNTAX

Modify the hsl-flow component within the pem global-settings module using the syntax shown in the following sections.

MODIFY

modify hsl-flow

options:

format-version

report-on-start [disabled | enabled]

report-on-interim [disabled | enabled]

edit hsl-flow [...]

options:

all-properties

non-default-properties

DISPLAY

list hsl-flow

list hsl-flow [...]

show running-config hsl-flow

options:

all-properties

non-default-properties

one-line

partition

DESCRIPTION

You can use the hsl-flow component to configure global settings for hsl flow reporting.

EXAMPLES

modify hsl-flow report-on-interim disable

Disables the generation of interim reports during the flow.

list hsl-flow

Displays the configuration for hsl-flow.

OPTIONS

format-version

DEPRECATED since version 15.1.0. Displays the value of formatting version used by hsl flow reporting.

report-on-start

Displays the value of report-on-start option.

report-on-interim

Displays the value of report-on-interim option.

SEE ALSO

create, delete, edit, glob, list, modify, pem reporting format-script, show, tmsh

DESCRIPTION

You can use the hsl-report component to configure global settings for hsl report.

EXAMPLES

modify hsl-report format-version

Modifies the format version used for HSL reporting.

list hsl-report

Displays the configuration of hsl report.

OPTIONS

format-version

Displays the value of formatting version used by hsl reporting.

SEE ALSO

pem global-settings insert-content

NAME

insert-content - Configures the global settings that pertain to insert content for Policy Enforcement Manager (PEM).

MODULE

pem global-settings

SYNTAX

Modify the insert-content component within the pem global-settings module using the syntax shown in the following sections.

MODIFY

modify insert-content {

options:

max-duration [value]

}

edit insert-content [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

DISPLAY
list insert-content
list insert-content [[[name] | [glob] | [regex]] ...]
show running-config insert-content
show running-config insert-content [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

DESCRIPTION
You can use the insert-content component to configure global settings for content insert functionality.

EXAMPLES
modify insert-content max-duration 3600

Modifies the content insertion max duration when action is throttled to apply once.

list insert-content

Displays the configuration for insert-content settings.

OPTIONS
mode Specifies the max duration for applying insert content action when frequency Once is used.

SEE ALSO
create, delete, edit, glob, list, modify, pem listener, pem policy, pem profile diameter-endpoint, pem profile

pem global-settings policy

NAME
policy - Configures the global settings that pertain to policy for Policy Enforcement Manager (PEM).

MODULE
pem global-settings

SYNTAX
Modify the policy component within the pem global-settings module using the syntax shown in the following
sections.

MODIFY
modify policy
options:
mandatory-action-list [rules [add | delete | modify | replace-all-with] {
options:
report-flow
}
single-rule-match-mode [disabled | enabled]

edit policy [...]
options:
all-properties
non-default-properties

DISPLAY
list policy
list policy [...]
show running-config policy
options:
all-properties
non-default-properties
one-line
partition

DESCRIPTION

You can use the policy component to configure global settings for PEM policy.

EXAMPLES

modify policy single-rule-match-mode disable

Disables the single rule match mode for PEM policy.

list policy

Displays the configuration for policy.

OPTIONS

single-rule-match-mode

Displays the value of single-rule-match-mode option.

mandatory-action-list

Displays the list mandatory actions applied.

SEE ALSO

create, delete, edit, glob, list, modify, show, tmsh

pem global-settings quota-mgmt

NAME

quota-mgmt - Configures the global settings that pertain to quota management over Gy for Policy Enforcement Manager (PEM).

MODULE

pem global-settings

SYNTAX

Modify the quota-mgmt component within the pem global-settings module using the syntax shown in the following sections.

MODIFY

modify quota-mgmt

options:

default-rating-group [rating-group-name]

service-context-id [string]

edit quota-mgmt [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list quota-mgmt

list quota-mgmt [[[name] | [glob] | [regex]] ...]

show running-config quota-mgmt

show running-config quota-mgmt [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DESCRIPTION

You can use the quota-mgmt component to configure global settings for quota management over Gy.

EXAMPLES

modify quota-mgmt default-rating-group rg_grp_1 service-context-id 32251@3gpp.org

Configures rg_grp_1 as default rating group and service-context-id as 32251@3gpp.org. rg_grp_1 should be defined before.

list quota-mgmt

Displays the configuration for quota-mgmt.

OPTIONS

default-rating-group

Specifies the default rating group for quota management over Gy.

service-context-id

Specifies the service-context-id to be used for CCR message over Gy.

SEE ALSO

create, delete, edit, glob, list, modify, pem quota-mgmt rating-group, pem listener, pem policy, pem profile

pem global-settings session-mgmt-attributes

NAME

session-mgmt-attributes - Configures the global settings that pertain to session management attributes for Policy Enforcement Manager (PEM).

MODULE

pem global-settings

SYNTAX

Modify the session-mgmt-attributes component within the pem global-settings module using the syntax shown in the following sections.

MODIFY

modify session-mgmt-attributes

options:

clear-on-nas-reboot [enabled | disabled]

flow-term-on-sess-delete [enabled | disabled]

create-event

mode [enabled | disabled]

update-event

mode [enabled | disabled]

delete-event

mode [enabled | disabled]

edit session-mgmt-attributes

options:

clear-on-nas-reboot [enabled | disabled]

flow-term-on-sess-delete [enabled | disabled]

create-event

mode [enabled | disabled]

update-event

mode [enabled | disabled]

delete-event

mode [enabled | disabled]

DISPLAY

list session-mgmt-attributes

list session-mgmt-attributes [name]

show running-config session-mgmt-attributes

show running-config session-mgmt-attributes [name]

options:

clear-on-nas-reboot

flow-term-on-sess-delete

create-event

mode

update-event

mode

delete-event

mode

DESCRIPTION

You can use the session-mgmt-attributes component to configure global settings for session management attributes.

EXAMPLES

modify session-mgmt-attributes clear-on-nas-reboot enabled

Enable clear-on-nas-reboot so that when accounting-on or accounting-off Radius message is received for a particular NAS address, which indicates NAS reboot, will trigger clearing all PEM sessions associated with the NAS address.

modify session-mgmt-attributes flow-term-on-sess-delete enabled

Enable flow-term-on-sess-delete so that flow will be terminated shortly after session is marked for deletion.

modify session-mgmt-attributes create-event mode enabled

Enables event generation for subscriber session creation.

modify session-mgmt-attributes update-event mode disabled

Disables event generation for subscriber session update.

modify session-mgmt-attributes delete-event mode enabled

Enables event generation for subscriber session deletion.

list session-mgmt-attributes

Displays the configuration for session-mgmt-attributes.

OPTIONS

clear-on-nas-reboot

Specifies clear on nas reboot config for session-mgmt-attributes. The default value is disabled.

flow-term-on-sess-delete

Specifies flow termination on session delete config for session-mgmt-attributes. The default value is disabled.

create-event

You can configure the following options for create-event.

mode Specifies whether to generate event for subscriber session creation. The default value is disabled.

update-event

You can configure the following options for update-event.

mode Specifies whether to generate event for subscriber session update. The default value is disabled.

delete-event

You can configure the following options for delete-event.

mode Specifies whether to generate event for subscriber session deletion. The default value is disabled.

SEE ALSO

pem global-settings subscriber-activity-log

NAME

subscriber-activity-log - Configures the global settings that pertain to subscriber activity log messages for Policy Enforcement Manager (PEM).

MODULE

pem global-settings

SYNTAX

Modify the subscriber-activity-log component within the pem global-settings module using the syntax shown in the following sections.

MODIFY

modify subscriber-activity-log

options:

dynamic-subscriber-ids [add | delete | modify | replace-all-with] {
[id_name ...]

```

}
dynamic-subscriber-ids [none]
publisher [name]
static-subscriber-ids [add | delete | replace-all-with] {
    [id_name ...]
}
static-subscriber-ids [default | none]
subscriber-ip-addresses [add | delete | modify | replace-all-with] {
    [ip address/prefixlen ...]
}
subscriber-ip-addresses [none]

```

edit subscriber-activity-log [[[name] | [glob] | [regex]] ...]

```

options:
    all-properties
    non-default-properties

```

reset-stats subscriber-activity-log

```

DISPLAY
list subscriber-activity-log
list subscriber-activity-log [ [ [name] | [glob] | [regex] ] ... ]
show running-config subscriber-activity-log
show running-config subscriber-activity-log [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
    partition

```

```

show subscriber-activity-log
options:
    all-properties
    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
    default
    field-fmt

```

DESCRIPTION

You can use the subscriber-activity-log component to monitor behavior of the subscribers in the troubleshooting mode by sending activity log messages to one or more destinations. You can add static and dynamic subscribers by IDs, or by subscriber IP addresses. The activity log messages contain the internal information exposing the subscribers behavior.

EXAMPLES

```
modify subscriber-activity-log publisher pub1 dynamic-subscriber-ids add { 4081112222 }
```

Adds dynamic subscriber 4081112222 to troubleshooting mode by sending activity log messages to all destinations defined in pub1.

```
list subscriber-activity-log
```

Displays the list of the subscribers in troubleshooting mode.

```
show subscriber-activity-log
```

Displays the logging statistics of the subscribers in troubleshooting mode.

```
reset-stats subscriber-activity-log
```

Resets the logging statistics of the subscribers in troubleshooting mode.

OPTIONS

```
dynamic-subscriber-ids
Specifies a list of dynamic subscriber IDs to be in troubleshooting mode.
```

```
publisher
Specifies the external logging publisher used to send activity log messages to one or more destinations.
```

```
static-subscriber-ids
Specifies a list of static subscriber IDs to be in troubleshooting mode.
```

```
subscriber-ip-addresses
Specifies a list of subscriber IP addresses to be in troubleshooting mode.
```

pem interception-endpoint

NAME

interception-endpoint - Configures interception endpoints for the Policy Enforcement Manager (PEM).

MODULE

pem

SYNTAX

Modify the interception-endpoint component within the pem module using the syntax shown in the following sections.

CREATE/MODIFY

create interception-endpoint [name]

modify interception-endpoint [name]

options:

app-service [[string] | none]

persistence [destination-ip | disabled | source-ip]

pool [name]

edit interception-endpoint [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list interception-endpoint

list interception-endpoint [[[name] | [glob] | [regex]] ...]

show running-config interception-endpoint

show running-config interception-endpoint [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete interception-endpoint [name]

Note: You must remove all references to an interception-endpoint before you can delete the interception-endpoint.

DESCRIPTION

You can use the interception-endpoint component to configure interception-endpoint definitions for the Policy Enforcement Manager. The interception-endpoint is used to clone all traffic. Note: Before you create a cloning-endpoint you have to create a valid pool. Please refer to Itm pool for more information about how to create a pool.

EXAMPLES

```
create interception-endpoint my_endpoint { pool pool1 }
```

Creates a Policy Enforcement Manager interception-endpoint named my_endpoint.

```
delete interception-endpoint my_endpoint
```

Deletes the interception-endpoint named my_endpoint.

```
list interception-endpoint my_endpoint
```

Displays the properties of the interception-endpoint named my_endpoint.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

persistence

Specifies the persistence that is based on either the source or destination IP addresses only.

pool Specifies the pool. It is mandatory to specify a pool when creating any interception-endpoint. Before you create an interception-endpoint you have to create a valid pool.

SEE ALSO

create, delete, edit, glob, list, modify, pem forwarding-endpoint, pem listener, pem policy, pem profile diameter-endpoint, pem profile spm, pem reporting format-script, pem service-chain-endpoint, pem subscriber, pem subscribers, regex, show, tmsh

BIG-IP 2013-03-21 pem interception-endpoint(1)

pem irule

NAME

irule - Configures an PEM iRule for traffic management system configuration.

MODULE

pem

SYNTAX

Configure the irule component within the pem module using the syntax shown in the following sections.

CREATE/MODIFY

create irule [name]

edit irule [name]

modify irule [[[name] | [glob] | [regex]] ...]

Note: When using tmsh, you can only create pem iRule using the editor, which starts when you use the create or edit commands. You cannot create an pem iRule directly on the command line. The vim editor applies the autoindent and smartindent options. You can toggle on/off paste mode using the F12 key.

Note: You can also edit user metadata associated with a pem iRule. See the example section for more information.

DISPLAY

list irule

list irule [[[name] | [glob] | [regex]] ...]

show running-config irule

show running-config irule [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

show irule

show irule [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

DELETE

delete irule [name]

DESCRIPTION

You can apply pem iRules as an action when the traffic matches the filter criteria defined in pem policy rule.

The syntax that you use to write pem iRules is based on the Tools Command Language (Tcl) programming standard.

Thus, you can use many of the standard Tcl commands, plus a robust set of extensions that the BIG-IP(r) policy enforcement management system provides to help you customize the actions you want to apply to the traffic.

You cannot edit the system iRules that come with the BIG-IP system. However, you can open a system iRule in the editor and use it as a template to create a new rule.

To create a new pem iRule using a system rule as a template:

1. Enter the command sequence edit irule [system rule name].

tmsh opens the system rule in an editor.

2. Change the name of the rule in the editor.

3. Edit the rule and exit the editor.

tmsh checks for syntax errors, and if there are none, it saves the new rule.

For more information about iRules(r), see <http://devcentral.f5.com/>.

EXAMPLES

list irule

Displays all iRules.

delete irule my_irule

Deletes the pem iRule named my_irule.

create irule my_irule {

```

priority 1
when PEM_POLICY {
}
}

```

Creates a pem iRule named my_irule with priority 1.

```

modify rule my_irule {
  when RULE_INIT {}
  metadata replace-all-with {
my_meta {
  persist false
  value "hello"
}
my_meta2 {
  persist false
  value "hello 2"
}
}
}
}

```

Modifies an existing pem iRule named my_irule by adding a new metadata and modifying an existing metadata.

The metadata attribute is the user defined key/value pair. Metadata has the following format:

```

metadata
[add | delete | modify] {
[metadata_name] {
  value [ "value content" ]
  persist [ true | false ]
}
}

modify irule my_irule {
  when RULE_INIT {}
  metadata delete { my_meta }
}

```

Deletes a metadata from a pem iRule.

OPTIONS

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the create, delete, and modify commands.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

metadata
Specifies the user-defined key/value pair associated with the rule. See the example section for usage format.

SEE ALSO

pem listener

NAME

listener - Configures listeners for the Policy Enforcement Manager (PEM).

MODULE

pem

SYNTAX

Modify the listener component within the pem module using the syntax shown in the following sections.

```

CREATE/MODIFY
create listener [name]
modify listener [name]
options:
  app-service [[string] | none]
  description [string]
  profile-spm [name]
  profile-subscriber-mgmt [name]
  virtual-servers [name] [add | delete | replace-all-with] {
    [virtual_server_name ... ]
  }

edit listener [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list listener
list listener [ [ [name] | [glob] | [regex] ] ... ]
show running-config listener
show running-config listener [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete listener [name]

```

Note: You must remove all references to a listener before you can delete the listener.

DESCRIPTION

You can use the listener component to configure listener definitions for the Policy Enforcement Manager.

EXAMPLES

```
create listener lis1 { profile-spm spm1 virtual-servers add {vs_tcp vs_udp} }
```

Creates a Policy Enforcement Manager listener named lis1.

```
delete listener lis1
```

Deletes the listener named lis1.

```
list listener lis1
```

Displays the properties of the listener named lis1.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

profile-spm

Specifies the spm profile name.

profile-subscriber-mgmt

Specifies the subscriber-mgmt profile name.

virtual-servers

Adds, deletes, or replaces a set of virtual servers, by specifying a virtual server name.

SEE ALSO

create, delete, edit, glob, list, modify, pem forwarding-endpoint, pem interception-endpoint, pem policy, pem profile diameter-endpoint, pem profile spm, pem profile subscriber-mgmt, pem reporting format-script, pem service-chain-endpoint, pem subscriber, pem subscribers, regex, show, tmsh

COPYRIGHT

DELETE
delete policy [name]

```

Note: You must remove all references to a policy before you can delete the policy.

DESCRIPTION

You can use this policy component to configure the policy definitions on the Policy Enforcement Manager. A policy is a set of rules which are used to match traffic flow and apply actions. A rule has configuration for filters and actions. All configured filters must match before the actions can be applied to the traffic flow. There are four filters: classification-filter, url-category-filter, flow-info-filter, and tcl-filter. Classification-filter allows for matching the traffic based on the flow L7 features, such as a specific application (for example, Google Mail) or application category (for example, Web). URL-category-filter allows for matching the type of URL, such as adult content. Flow-info-filter allows for matching the traffic using L2-L4 flow parameters. Tcl-filter provides a customized method to match traffic flows using iRule commands. The actions can be steering or/and reporting. Steering allows the user to manipulate the traffic when all configured filters match the flow. The steering options can be forwarded (option forwarding), drop/pass(option gate-status), redirect(option http-redirect), or intercept(option intercept). Reporting allows the user to report the usage to different endpoints by different output formats. The reporting options can be gx or hsl. Policy attribute transactional allow policy enforcement for HTTP traffic for each transaction. Quota allows users to do quota management over Gy by specifying the rating group, which has all the parameters associated.

EXAMPLES

```

create policy my_policy rules add {
    rule_1 {
        flow-info-filters {
            flow_1 {
                dscp-code 8
            }
            flow_2 {
                dst-port 80
            }
        }
        forwarding {

```

```

        endpoint server1
        fallback-action continue
    }
}
precedence 1
}
rule_2 {
    reporting {
        dest {
            hsl {
                endpoint-id pem_hsl
                format-script fm1
            }
        }
    }
    granularity flow
    volume {
        total 5000
    }
}
precedence 2
}
}
}

```

Creates a Policy Enforcement Manager policy named my_policy with two rules, rule_1 and rule_2. rule_1 defines the flow-info-filters so that when the flow with DSCP is 8 or destination port is 80, the traffic will be forwarded to server1. rule_2 defines a flow-based reporting rule which will send flow usage record to pem_hsl endpoint using format script defined in fm1 whenever total increases by 5000 bytes.

delete policy my_policy

Deletes the policy named my_policy.

list policy my_policy

Displays properties of the policy named my_policy.

OPTIONS

app-service

Specifies the name of the application service to which the policy belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the policy. Only the application service can modify or delete the policy.

description

User defined description.

transactional

Indicate the policy enable or disable policy enforcement for each HTTP transaction.

partition

Displays the administrative partition within which the policy resides.

rules

Adds, deletes, or replaces a set of rules, by specifying a rule name. If a rule by the specified name does not exist, it will be created. You can configure the following options for a rule:

app-service

Specifies the name of the application service to which the rule belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the rule. Only the application service can modify or delete the rule.

classification-filters

Adds, deletes, or replaces a set of classification-filters. You can configure the following options for a classification-filter.

app-service

Specifies the name of the application service to which the classification-filter belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the rule. Only the application service can modify or delete the classification-filter.

application

Specifies the name of the application where the rule applies to the traffic. The default value is none.

category

Specifies the name of the category of applications where the rule applies to the traffic. The default value is none.

operation

The options match and nomatch indicate the traffic flow must match or not match the condition specified in the classification filter. The default value is match.

dscp-marking-downlink

Specifies the action to modify the DSCP code in the downlink packet when the traffic flow matches the rule matching criteria. The range is 0 to 63, or pass-through. The default value is pass-through, indicating the DSCP code of the downlink packet will not be changed when the traffic flow matches the rule.

dscp-marking-uplink

Specifies the action to modify the DSCP code in the uplink packet when the traffic flow matches the rule matching criteria. The range is 0 to 63, or pass-through. The default value is pass-through, indicating the DSCP code of the uplink packet will not be changed when the traffic flow matches the rule.

dtos-tethering

Defines the device type & OS and tethering detection action and its options.

dtos-detect

Specifies the device type & OS detection to be enabled or disabled. Default is disabled

tethering-detect

Specifies the tethering detection to be enabled or disabled. Default is disabled

report

You can configure the following options for dtos and tethering reporting.

dest You can configure the following options for destination.

hsl You can configure the following options for hsl publisher.

publisher

Specifies the publisher name.

format-script

Specifies the format script name to format the HSL output string format.

ran-congestion

Detect congestion in the Radio Access Network.

detect

Enable or disable the ran congestion detection. Default is disabled.

lowerthreshold-bw

Configured lowerthreshold bandwidth for a session in kbps. Session bandwidth below this value will be marked as congested. Default is 1000kbps.

report

You can configure the following options for ran congestion reporting.

dest You can configure the following options for destination.

hsl You can configure the following options for hsl publisher.

publisher

Specifies the publisher name.

format-script

Specifies the format script name to format the HSL output string format.

flow-info-filters

Adds, deletes, or replaces a set of the flow-info-filters. The flow info filter defines the flow conditions (Layer 4) that the traffic should meet (or not meet) for this enforcement policy rule to apply. You can configure the following options for a flow-info-filter.

app-service

Specifies the name of the application service to which the flow-info-filter belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the rule. Only the application service can modify or delete the flow-info-filter.

dscp-code

Specifies the value of DSCP code which matches incoming traffic based on a value in the DSCP field in the IP header. The range is 0 to 63, or disabled. The default value is disabled, indicating that the DSCP code will not be used to filter the packet in the flow-info-filter.

dst-ip-addr

Specifies the destination IP address and prefix length that the rule applies to. The format is [ip address/prefixlen]. The default value is 0.0.0.0/0.

dst-port

Specifies the destination port against which the packet will be compared. The default value is any.

from-vlan

Specifies the name of the source vlan to match the ingress flow arriving from that vlan.

l2-endpoint

Specifies an L2 endpoint type to be used when matching the traffic flows. The default value is disabled, indicating that L2 endpoint is not used for matching the flows. You can configure the following options:

disabled

Flows are not matched based on the L2 endpoint specification.

vlan The vlan name specified in from-vlan is used to match the traffic flows.

operation

Specifies whether the rule applies to traffic that matches (match) or does not match (nomatch) the traffic flow defined here. The options are match and nomatch. The default value is match.

proto

Specifies the protocol that this rule applies to. The options are any, tcp, and udp. The default value is any.

ip-add-type

Specifies the ip address type (IPv4 or IPv6) that this rule applies to. The options are any, IPv4, and IPv6. The default value is any.

src-ip-addr

Species the source IP address and prefix length that the rule applies to. The format is [ip address/prefixlen]. The default value is 0.0.0.0/0.

src-port

Specifies the source port of the network you want the rule to affect. The default value is any.

forwarding

Manages the forwarding action and its attributes.

endpoint

Specifies the forwarding endpoint. The endpoint can be icap, pool or route-to-network. Depending on the type chosen flow can be steered to icap server, pool or to the network.

fallback-action

Specifies whether the connection should continue unchanged or should be dropped in the event the forwarding action fails for any reason. The options are: drop or continue, and the default is drop.

internal-virtual

Specifies the internal virtual server name if the type selected is icap.

icap-type

Defines the ICAP adaptation type: request only adaptation, request and response adaptation or both types of adaptations combined.

type Specifies the type of forwarding action.

gate-status

Specifies, when set to enabled, that the traffic can pass through the system without being changed. Set disabled to drop traffic that this rule applies to. The options are disabled and enabled. The default is enabled.

http-redirect

Manages the HTTP redirect action and its attributes.

redirect-url

Specifies the HTTP redirection URL.

fallback-action

Specifies whether the connection should continue unchanged or should be dropped in the event the forwarding action fails for any reason. The options are: drop or continue, and the default is drop.

intercept

Specifies the name of the intercept endpoint.

l2-marking-downlink

Set Layer-2 Quality of Service Marking in downlink traffic that matches a rule. Setting a L2 QoS Marking affects the packet delivery priority. The range is 0 to 7, or pass-through. The default value is pass-through, indicating the L2 QoS Marking of the packet will not be changed when the packet matches the rule.

l2-marking-uplink

Set Layer-2 Quality of Service Marking in uplink traffic that matches a rule. Setting a L2 QoS marking affects the packet delivery priority. The range is 0 to 7, or pass-through. The default value is pass-through, indicating the L2 QoS Marking of the packet will not be changed when the packet matches the rule.

tcp-optimization-uplink

Set tcp optimization profile to be applied to the uplink traffic that matches a rule. The profile name should be one from the common tcp profile list.

tcp-optimization-downlink

Set tcp optimization profile to be applied to the downlink traffic that matches a rule. The profile name should be one from the common tcp profile list.

tcp-analytics-enable

Specifies the action to enable tcp analytics when the traffic flow matches the rule matching criteria. The options are disabled and enabled. The default is disabled.

modify-http-hdr

Specifies the action to modify the HTTP header when the traffic flow matches the rule matching

criteria. You can configure the following options for modifying the HTTP header.

name Specifies the HTTP header name used by the operation option to modify the HTTP header.

operation

Specifies the operation used to modify the HTTP header. The options are insert, none, and remove. The default value is none which indicates that no HTTP header modifications will be made.

value-content

Specifies the HTTP header value content used by the operation option to modify the HTTP header. Based on the selected value-type option, the content format will be interpreted either as a string or a tcl snippet. Note: This field is applicable only when the operation option is set to insert.

value-type

Specifies the type of content format used in the value-content field. The options are string and tcl-snippet. The default value is string which indicates that the value-content field will be interpreted as a string.

insert-content

Specifies the action to insert content into the webpage.

duration

Specifies the periodicity of the insert action. Note: This value is useful only when the frequency is set to once-every.

frequency

Specifies the frequency of the insert content action. It can take values once, once-every, always.

The options are:

always

Specifies if the action need to be applied always on the matched flow.

once Specifies if the action need to be applied once per subscriber.

once-every

Specifies if the action need to be applied once-every time interval configured in duration per subscriber.

position

Specifies the position with respect to the tag name configured. It can take values append, prepend.

value-content

Specifies the value content to be inserted into the webpage. Based on the selected value-type option, the content format will be interpreted either as a string or a tcl-snippet.

value-type

Specifies the type of content format used in the value-content field. The options are string and tcl-snippet. The default value is string which indicates that the value-content field will be interpreted as a string.

tag_name

Specifies the tag name to which the content is either appended or prepended.

precedence

Specifies the precedence for the rule in relation to the other rules. The range is 1 to 4294967295 where 1 has the highest precedence. A rule with higher precedence is evaluated at a high priority. It is mandatory to specify precedence when creating a rule in a policy.

qoe-reporting

Deprecated since 15.0.0. You can configure the following options for Quality-of-Experience (QoE) reporting.

dest You can configure the following options for destination.

hsl You can configure the following options for hsl publisher.

publisher

Specifies the publisher name.

format-script

Specifies the format script name to format the HSL output string format.

reporting

You can configure the following options for reporting.

dest You can configure the following options for destination.

gx You can configure the following options for gx endpoint.

application-reporting

Specifies whether the application reporting is enabled. When it is enabled, the APPLICATION_START and APPLICATION_STOP Event-Triggers will be reported when the

application start/stop is detected. The default value is disabled.

monitoring-key

Specifies the monitoring-key.

hsl You can configure the following options for hsl endpoint.

publisher

Specifies the publisher.

format-script

Specifies the format script name to format the HSL output string format.

session-reporting-fields

Specifies the session fields and their order based on which messages should be published.

3gpp-parameters

Reports the 3gpp-parameters of the session subscriber.

application-id

Reports the application/category ID that is classified for this session.

called-station-id

Reports the called station ID of the session subscriber.

calling-station-id

Reports the calling station ID of the session subscriber.

concurrent-flows

Reports the number of concurrent flows of this session.

downlink-volume

Reports the aggregate incoming bytes for the traffic associated with this session.

duration-seconds

Reports the total duration of all the flows belonging to the traffic associated with this session.

last-record-sent

Reports the time (seconds) when sending the last record.

new-flows

Reports the number of new flows associated with this session since last record.

observation-time-seconds

Reports the timestamp of the record.

record-reason

Reports the reason for sending the record.

record-type

Reports the reporting record type as 3 : session based record.

report-id

Reports the reporting module ID.

report-version

Reports the format version of this record.

subscriber-id

Reports the subscriber ID that of this session.

subscriber-id-type

Reports the ID type of the subscriber of this session.

successful-transactions

Reports the total number of successful transactions associated with this session.

terminated-flows

Reports the total number of terminated flows during this session.

timestamp-msec

Reports the time stamp on this record in milli-seconds.

total-transactions

Reports the total number of transactions of this session.

uplink-volume

Reports the aggregate outgoing bytes for the traffic associated with this session.

flow-reporting-fields

Specifies the flow fields and their order based on which messages should be

published.

application-id

Reports the application/category ID that is classified for this flow.

destination-ip

Reports the destination IP address of the traffic.

destination-transport-port

Reports the destination port of the traffic.

downlink-volume

Reports the total number of bytes received for this flow by the subscriber.

flow-end-milli-seconds

Reports the timestamp (milli-seconds) in UNIX time format when the flow ends.

flow-end-seconds

Reports the timestamp (seconds) in UNIX time format when the flow ends.

flow-start-milli-seconds

Reports the timestamp (milli-seconds) in UNIX time format when the flow starts.

flow-start-seconds

Reports the timestamp (seconds) in UNIX time format when the flow starts.

observation-time-seconds

Reports the timestamp (seconds) of the record.

protocol-identifier

Reports the transport layer protocol of the flow (TCP or UDP).

record-type

Reports the reporting record type of the flow: 0 - flow start, 1 - flow end, 2 - flow interim.

report-id

Reports the reporting module ID.

report-version

Reports the format version of this record.

route-domain

Reports the route domain ID of the flow.

source-ip

Reports the source IP address of the subscriber that initiates the flow.

source-transport-port

Reports the source port of the subscriber.

subscriber-id

Reports the subscriber ID that initiates this flow.

subscriber-id-type

Reports the ID type of the subscriber that initiates this flow.

timestamp-msec

Reports the timestamp (milli-seconds) of the record.

total-transactions

Reports the total number of transactions of this flow.

uplink-volume

Reports the number of bytes sent from the subscriber in this flow.

url-category-id

Reports the ID of the first URL category that is classified for the flow.

vlan-id

Reports the Vlan ID of the flow.

transaction-reporting-fields

Specifies the transaction fields and their order based on which messages should be published.

application-id

Reports the application/category ID that is classified for this transaction.

destination-ip

Reports the destination IP address of the traffic.

destination-transport-port

Reports the destination port of the traffic.

downlink-volume

Reports the number of HTTP response bytes for this transaction.

http-hostname

Reports the HTTP host name of this traffic.

http-hostname-truncated

Reports the truncated HTTP host name due to excessive length.

http-response-code

Reports the HTTP response code of the transaction.

http-url

Reports the HTTP URL of the transaction.

http-url-truncated

Reports the truncated HTTP URL of the transaction due to excessive length.

http-user-agent

Reports the user agent of the HTTP request in this transaction.

http-user-agent-truncated

Reports the truncated user agent of the HTTP request in this transaction due to excessive length.

protocol-identifier

Reports the transport layer protocol of the traffic (TCP or UDP).

record-type

Reports the reporting record type as 10-transactional.

report-id

Reports the reporting module ID.

report-version

Reports the format version of the transaction record.

route-domain

Reports the route domain ID of the traffic.

skipped-transactions

Reports the number of transactional reports skipped within the flow since the last successfully transmission in the transaction.

source-ip

Reports the source IP address of the subscriber.

source-transport-port

Reports the source port of the subscriber.

subscriber-id

Reports the subscriber ID that initiates this transaction.

subscriber-id-type

Reports the subscriber ID type of the subscriber that initiates this transaction.

transaction-classification-result

Reports all the classification tokens from the classification engine.

transaction-end-milli-seconds

Reports the transaction timestamp (milli-seconds) in UNIX time format when the corresponding HTTP response is received.

transaction-end-seconds

Reports the transaction timestamp (seconds) in UNIX time format when the corresponding HTTP response is received.

transaction-number

Reports the sequential number of transaction in this flow (starting from 1).

transaction-start-milli-seconds

Reports the transaction timestamp (milli-seconds) in UNIX time format when an HTTP request is received.

transaction-start-seconds

Reports the transaction timestamp (seconds) in UNIX time format when an HTTP request is received.

uplink-volume

Reports the number of HTTP request bytes for this transaction.

url-category-id

Reports the ID of the first URL category that is classified for the transaction.

vlan-id

Reports the Vlan ID of traffic.

radius-accounting

You can configure the following options for radius-accounting endpoint.

radius-aaa-virtual

Specifies the internal virtual server for radius-accounting endpoint.

sd You can configure the following options for sd endpoint.

application-reporting

Specifies whether the application reporting is enabled. When it is enabled, the APPLICATION_START and APPLICATION_STOP Event-Triggers will be reported when the application start/stop is detected. The default value is disabled.

monitoring-key

Specifies the monitoring-key.

granularity

Specifies the type of reporting will be generated when the policy applies. The options are flow, session and transaction. The default value is session which indicates the session report will be generated if this policy applies.

interval

Specifies the time interval in seconds the report will be generated. The default value is 0 which indicates this feature is disabled.

transaction

You can configure the following options when the transaction report granularity is selected.

http Specifies the HTTP transaction report options for the following HTTP attributes.

hostname-len

Specifies the maximum HTTP hostname string length to include in the HTTP transaction report. The range is 0 to 65535. The default value is 0.

uri-len

Specifies the maximum HTTP URI string length to include in the HTTP transaction report. The range is 0 to 65535. The default value is 256.

user-agent-max

Specifies the maximum HTTP user agent string length to include in the HTTP transaction report. The range is 0 to 65535. The default value is 0.

volume

You can configure the following options for volume threshold. The report will be generated when any of the following conditions happened. If reporting dest is set, either interval must be set to non-0 or one of volume properties must be set to non-0.

downlink

The report will be generated if the downlink traffic exceeds the threshold. The default value is 0 which indicates this feature is disabled.

total

The report will be generated if the uplink and downlink traffic exceeds the threshold. The default value is 0 which indicates this feature is disabled.

uplink

The report will be generated if the uplink traffic exceeds the threshold. The default value is 0 which indicates this feature is disabled.

quota

You can configure the following options for quota management.

rating-group

Specifies the rating-group name.

reporting-level

Specifies the quota reporting level whether per rating group or per service-id.

qos-rate-pir-downlink

Specifies the configured bandwidth control policy for Peak Information Rate (PIR) to apply to downlink traffic that matches this rule. Use none to reset bwc policy name or category name.

qos-rate-pir-uplink

Specifies the configured bandwidth control policy for Peak Information Rate (PIR) to apply to uplink traffic that matches this rule. Use none to reset bwc policy name or category name.

service-chain

Specifies where to forward the traffic affected by this rule.

sfc-action The following options can be configured for sfc-action.

path-name

Specifies the path name used by Service Function Chain (SFC) to program the path-id.

metadata-template
Specifies the SFC (Service-Function-Chain) metadata template.

tcl-filter
Specifies the tcl expression which uses iRule commands to filter the packet. It is a match if tcl-filter returns TRUE/1 or nomatch if FALSE/0. All configured filters (flow-info-filters, classification-filters, and tcl-filter) must match before rule actions are applied.

url-categorization-filters
Adds, deletes, or replaces a set of url-categorization-filters. You can configure the following options for a url-categorization-filter.

app-service
Specifies the name of the application service to which the url-categorization-filter belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the rule. Only the application service can modify or delete the url-categorization-filter.

url-category
Specifies the name of the url-category of the traffic where the rule applies. The default value is none.

operation
The options match and nomatch indicate the traffic flow must match or not match the condition specified in the classification filter. The default value is match.

status
Specifies the current status of the policy. The options are disabled and enabled. The default value is enabled.

pem profile diameter-endpoint

NAME
diameter-endpoint - Configures a Diameter endpoint profile.

MODULE
pem profile

SYNTAX
Configures the diameter-endpoint profile within the pem profile module using the syntax shown in the following sections.

MODIFY
create diameter-endpoint [name]
modify diameter-endpoint [name]
options:
 defaults-from [[name] | none]
 destination-host [string]
 destination-realm [string]
 fatal-grace-time {
 options:
enabled [yes | no]
time [integer]
 }
 msg-max-retransmits [integer]
 msg-retransmit-delay [integer]
 origin-host [string]
 origin-realm [string]
 pem-protocol-profile-gx [[profile_name] | none]
 pem-protocol-profile-gy [[profile_name] | none]
 product-name [string]
 supported-apps [Gx | Gy | Sd]
 gx-session-id-prefix [string]

```
    gy-session-id-prefix [string]
    sd-session-id-prefix [string]
}
```

edit diameter-endpoint [[[name] | [glob] | [regex]] ...]

options:

- all-properties
- non-default-properties

reset-stats diameter-endpoint

reset-stats diameter-endpoint [[[name] | [glob] | [regex]] ...]

DISPLAY

list diameter-endpoint

list diameter-endpoint [[[name] | [glob] | [regex]] ...]

show running-config diameter-endpoint

show running-config diameter-endpoint [[[name] | [glob] | [regex]] ...]

options:

- all-properties
- non-default-properties
- one-line
- partition

show diameter-endpoint

show diameter-endpoint [[[name] | [glob] | [regex]] ...]

options:

- (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
- field-fmt
- global

DESCRIPTION

You can use the diameter-endpoint component to modify or display a diameter-endpoint profile.

EXAMPLES

create my_diam_endpt defaults-from diameter-endpoint add { Gx }

Creates a custom diameter-endpoint profile name my_diam_endpt that inherits its settings from the system default diameter-endpoint profile with Gx capability.

modify my_diam_endpt origin-host example-host.example-realm.org origin-realm example-realm destination-host example-peer.peer-realm.org destination-realm peer-realm.org

Modifies the origin-host and destination-host of a diameter-endpoint profile named my_diam_endpt.

modify my_diam_endpt msg-max-retransmits 8 msg-retransmit-delay 10000

Modifies the maximum times a message will be retransmitted to 8 and the retransmission delay to 10 seconds of a diameter-endpoint profile named my_diam_endpt.

OPTIONS

defaults-from

Specifies the name of the object to inherit the settings from.

destination-host

Specifies the destination host for diameter messages. This should be a FQDN.

destination-realm

Specifies the destination realm for diameter messages. This should be a FQDN.

fatal-grace-time

You can configure following options for fatal-grace-time. It defines the period that a diameter connection can be down before all sessions associated with that diameter endpoint are terminated. If the connection is re-established before fatal-grace-time seconds then the sessions will not be terminated automatically.

enabled

Specifies whether fatal-grace-time option is enabled or no.

time

Specifies the fatal-grace-time period in seconds.

msg-max-retransmits

Specifies the number of times an outgoing request message will be retransmitted before being dropped.

msg-retransmit-delay

Specifies the delay in milliseconds after which an unanswered request will be retransmitted.

origin-host

Specifies the origin host for diameter messages. This should be a FQDN.

origin-realm

Specifies the origin realm for diameter messages. This should be a FQDN.

pem-protocol-profile-gx

Specifies PEM protocol profile to be used when subscriber discovery is enabled. This protocol profile defines mapping of Diameter AVPs to subscriber ID and other PEM subscriber session attributes for

Diameter application.

pem-protocol-profile-gy

Specifies PEM protocol profile to be used when subscriber discovery is enabled. This protocol profile defines mapping of Diameter AVPs to subscriber ID and other PEM subscriber session attributes for Diameter application.

product-name

Specifies the string used in the product-name AVP in the capabilities exchange messages.

supported-apps

Adds, deletes, or replaces a set of the supported applications. Gx and Sd are mutually exclusive and cannot be added at the same time. When Gx or Sd is added, pem-protocol-profile-gx can be specified for the protocol profile. When Gy is added, pem-protocol-profile-gy can be specified for the protocol profile.

gx-session-id-prefix

Specifies the string used as Gx session id prefix in Gx protocol messages exchanged between PEM and PCRF.

gy-session-id-prefix

Specifies the string used as Gy session id prefix in Gy protocol messages exchanged between PEM and OCS.

sd-session-id-prefix

Specifies the string used as Sd session id prefix in Sd protocol messages exchanged between PEM and PCRF.

SEE ALSO

pem profile radius-aaa

NAME

radius-aaa - Configures a PEM radius AAA profile.

MODULE

pem profile

SYNTAX

Configures the radius-aaa profile within the pem profile module using the syntax shown in the following sections.

CREATE/MODIFY

create radius-aaa [name]

modify radius-aaa [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

retransmission-timeout [integer]

shared-secret [string]

password [string]

transaction-timeout [integer]

edit radius-aaa [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list radius-aaa

list radius-aaa [[[name] | [glob] | [regex]] ...]

show running-config radius-aaa

show running-config radius-aaa [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

```
show radius-aaa
show radius-aaa [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

```
DELETE
delete radius-aaa [name]
```

DESCRIPTION

You can use the radius-aaa component to create, modify, display, or delete a radius-aaa profile.

EXAMPLES

```
create radius-aaa my_radius_aaa_profile
```

Creates a custom radius-aaa profile named my_radius_aaa_profile.

```
list radius-aaa my_radius_aaa_profile
```

Displays the properties of the radius-aaa profile named my_radius_aaa_profile.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is radiusaaa.

description

User defined description.

retransmission-timeout

Specifies the retransmission timeout value of the Radius-AAA profile in seconds.

shared-secret

Specifies the shared secret of the Radius-AAA profile when connecting to the RADIUS server.

password

Specifies the password of the Radius-AAA profile for authenticating to the RADIUS server.

transaction-timeout

Specifies the transaction timeout value of the Radius-AAA profile in seconds.

partition

Specifies the administrative partition within which the profile resides.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, tmsh

COPYRIGHT

pem profile spm

NAME

spm - Configures a Subscriber Policy Manager profile.

MODULE

pem profile

SYNTAX

Configures the spm profile within the pem profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create spm [name]
```

```
modify spm [name]
```

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

global-policies-high-precedence [add | delete | replace-all-with] {
 [policy_name ...]

```

}
global-policies-high-precedence [ default | none ]
global-policies-low-precedence [add | delete | replace-all-with] {
    [policy_name ...]
}
global-policies-low-precedence [ default | none ]
unknown-subscriber-policies [add | delete | replace-all-with] {
    [policy_name ...]
}
unknown-subscriber-policies [ default | none ]
fast-pem [enable | disable]
fast-vs-name [name]

```

```

edit spm [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

```

```

reset-stats spm
reset-stats spm [ [ [name] | [glob] | [regex] ] ... ]

```

```

DISPLAY
list spm
list spm [ [ [name] | [glob] | [regex] ] ... ]
show running-config spm
show running-config spm [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
    partition

```

```

DELETE
delete spm [name]

```

DESCRIPTION

You can use the spm component to create, modify, display, or delete a spm profile.

EXAMPLES

```
create spm my_spm_profile
```

Creates a custom spm profile named my_spm_profile.

```
list spm my_spm_profile
```

Displays the properties of the spm profile named my_spm_profile.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is spm.

description

User defined description.

global-policies-high-precedence

Adds, deletes, or replaces a set of the policies.

global-policies-low-precedence

Adds, deletes, or replaces a set of the policies.

unknown-subscriber-policies

Adds, deletes, or replaces a set of the policies.

fast-pem

Specifies whether fast PEM optimization is enabled or not. The default is enabled.

Specifies whether fast PEM optimization is enabled or not. PEM optimization will use the fast-vs-name virtual server for a portion of the traffic. The default is enabled.

fast-vs-name

Specifies the virtual server which will be used in fast PEM optimization when fast-pem is enabled. The virtual server should have fastL4 profile attached.

partition

Specifies the administrative partition within which the profile resides.

SEE ALSO

edit, glob, list, ltm virtual, modify, pem forwarding-endpoint, pem interception-endpoint, pem listener, pem policy, pem profile diameter-endpoint, pem reporting format-script, pem service-chain-endpoint, pem subscriber, regex, reset-stats, tmsh

pem profile subscriber-mgmt

NAME

subscriber-mgmt - Configures a Subscriber Management profile.

MODULE

pem profile

SYNTAX

Configures the subscriber-mgmt profile within the pem profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create subscriber-mgmt [name]
modify subscriber-mgmt [name]
options:
  app-service [[string] | none]
  defaults-from [[name] | none]
  description [string]
  dhcp-lease-query {
    options:
  }
enabled [false | true]
vs-name [name]
}
drop-unknown-traffic-from-server-side [enabled | disabled]
sess-creation-from-server-side [enabled | disabled]

edit subscriber-mgmt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list subscriber-mgmt
list subscriber-mgmt [ [ [name] | [glob] | [regex] ] ... ]
show running-config subscriber-mgmt
show running-config subscriber-mgmt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  app-service
  description
  dhcp-lease-query {
    options:
  }
enabled
vs-name
}
drop-unknown-traffic-from-server-side
sess-creation-from-server-side

DELETE
delete subscriber-mgmt [name]
```

DESCRIPTION

You can use the subscriber-mgmt component to create, modify, display, or delete a subscriber management profile.

EXAMPLES

```
create subscriber-mgmt my_subscriber_mgmt_profile
```

Creates a custom subscriber management profile named my_subscriber_mgmt_profile.

```
list subscriber-mgmt my_subscriber_mgmt_profile
```

Displays the properties of the subscriber management profile named my_subscriber_mgmt_profile.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings

and values from the parent profile. The default value is subscriber-mgmt.

description
User defined description.

dhcp-lease-query
Specifies the DHCP lease query attributes to be used for traffic triggered subscribers.

The options are:

enabled
The default is disabled.

vs-name
Specifies the name of the DHCP virtual server that is used to handle lease query and reply.

sess-creation-from-server-side
Specifies whether session creation from server side is enabled or not. The default is enabled.

drop-unknown-traffic-from-server-side
Specifies whether drop unknown traffic from server side is enabled or not. The default is disabled.

partition
Specifies the administrative partition within which the profile resides.

SEE ALSO

edit, glob, list, ltm virtual, modify, pem forwarding-endpoint, pem interception-endpoint, pem listener, pem policy, pem profile diameter-endpoint, pem profile spm, pem reporting format-script, pem service-chain-endpoint, pem subscriber, regex, tmsh

pem protocol diameter-avp

NAME
diameter-avp - Configures diameter AVPs in Policy Enforcement Manager (PEM).

MODULE
pem protocol

SYNTAX
Configure the diameter-avp component within the pem protocol module using the syntax shown in the following sections.

CREATE/EDIT/MODIFY
create diameter-avp [name]
modify diameter-avp [name]
options:
 app-service [[string] | none]
 avp-code [integer]
 data-type [address | enumerated | float32 | float64 | grouped | integer32 | integer64 | octetstring | rat-type | time | unsigned32 | unsigned64]
 description [string]
 length [integer]
 parent-avp [[diameter_avp_name | none]
 vendor-id [integer]

edit diameter-avp [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list diameter-avp
list diameter-avp [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line
 partition

DELETE
delete diameter-avp [name]

Note: You must remove all references to a diameter-avp before you can delete the diameter-avp.

DESCRIPTION

You can use the diameter-avp component to configure Diameter AVP definitions in Policy Enforcement Manager.

EXAMPLES

```
create diameter-avp user_equipment_value { data-type octetstring avp-code 460 }
```

Creates a PEM diameter-avp user_equipment_value with avp-code 460 and data-type octetstring.

```
delete diameter-avp user_equipment_value
```

Deletes the diameter-avp named user_equipment_value.

```
list diameter-avp user_equipment_value
```

Displays the properties of the diameter-avp named user_equipment_value.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

avp-code

Specifies the avp-code of the Diameter AVP.

data-type

Specifies the data type of the Diameter AVP. The default value is octetstring.

Note: The 'V' bit, known as the Vendor-Specific bit, indicates whether the optional vendor-id field is present in the AVP header. When set, the AVP code belongs to the specific vendor code address space. The 'V' bit is defined as flag-vendor-specific property in pem protocol profile gx.

The options are:

address

The address format is derived from the octetstring AVP base format. It is a discriminated union, representing, for example a 32-bit (IPv4) or 128-bit (IPv6) address, most significant octet first. The first two octets of the address AVP represents the AddressType, which contains in address family. The AddressType is used to discriminate the content and format the remaining octets.

enumerated

Enumerated is derived from the integer32 AVP Base Format. The definition contains a list of valid values and their interpretation and is described in the Diameter application introducing the AVP.

float32

This represents floating point values of single precision. The 32-bit value is transmitted in network byte order. The AVP length field MUST be set to 12 (16 if the 'V' bit is enabled).

float64

This represents floating point values of double precision. The 64-bit value is transmitted in network byte order. The AVP length field MUST be set to 16 (20 if the 'V' bit is enabled).

grouped

The data field is specified as a sequence of AVPs. Each of these AVPs follows - in the order in which they are specified - including their headers and padding. The AVP length field is set to 8 (12 if the 'V' bit is enabled) plus the total length of all included AVPs, including their headers and padding. Thus the AVP length field of an AVP of type grouped is always a multiple of 4.

integer32

32 bit signed value, in network byte order. The AVP length field MUST be set to 12 (16 if the 'V' bit is enabled).

integer64

64 bit signed value, in network byte order. The AVP length field MUST be set to 16 (20 if the 'V' bit is enabled).

octetstring

The data contains arbitrary data of variable length. Unless otherwise noted, the AVP length field MUST be set to at least 8 (12 if the 'V' bit is enabled). AVP Values of this type that are not a multiple of four-octets in length is followed by the necessary padding so that the next AVP (if any) will start on 32-bit boundary.

rat-type

specifies the value format to be encoded or decoded as the RAT-Type defined in 3GPP TS 29.212.

time The time format is derived from the octetstring AVP base format. The string MUST contain four octets, in the same format as the first four bytes are in the NTP timestamp format.

unsigned32

32 bit unsigned value, in network byte order. The AVP length field MUST be set to 12 (16 if the 'V' bit is enabled).

unsigned64

64 bit signed value, in network byte order. The AVP length field MUST be set to 16 (20 if the 'V' bit is enabled).

bit is enabled).

utf8string
The utf8string format is derived from the octetstring AVP base format. This is a human readable string represented using the ISO/IEC IS 10646-1 character set, encoded as an octetstring using the UTF-8 transformation format described in RFC 2279.

description
User defined description.

length
Specifies the data length of the Diameter AVP.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

parent-avp
Specifies the name of the parent AVP if it is in a grouped AVP.

vendor-id
Specifies the vendor-id of the Diameter VSA.

SEE ALSO

EXAMPLES

```
create cust_diam messages add {my_ccr direction out message-type ccr { avps add {avp1 { subscriber-attr
3gpp_location diameter-avp user_equipment_value flag-mandatory enabled} } } }
```

Creates a custom PEM Diameter protocol profile `cust_diam` and adds a message. The message is defined as CCR on the egress direction. PEM will insert the Diameter AVP as specified in `user_equipment_value` with the value stored subscriber attribute `3gpp_location` with mandatory flag enabled.

```
delete diameter cust_diam
```

Deletes the PEM diameter protocol profile named `cust_diam`.

```
list diameter cust_diam
```

Displays the properties of the PEM diameter protocol profile named `cust_diam`.

OPTIONS

`app-service`

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`description`

User defined description.

`messages`

Adds, deletes, or replaces a set of messages which specify mapping of Diameter AVPs to subscriber session attribute for specific Diameter message. If a message by the specified name does not exist, it will be created. You can configure the following options for a message:

`app-service`

Specifies the name of the application service to which the message belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the message. Only the application service can modify or delete the message.

`direction`

Specifies the direction of the message.

The options are:

`any` PEM will process the message in both ingress and egress directions.

`in` PEM will process the message in ingress direction.

`out` PEM will process the message in egress direction.

`message-type`

Specifies the type of the message.

The options are:

`ccr-i`

The message is Diameter Credit-Control-Request (CCR) Initial.

`cca-i`

The message is Diameter Credit-Control-Answer (CCA) Initial.

`ccr-u`

The message is Diameter Credit-Control-Request (CCR) Update.

cca-u

The message is Diameter Credit-Control-Answer (CCA) Update.

ccr-t

The message is Diameter Credit-Control-Request (CCR) Terminate.

rar The message is Diameter Re-Authorization-Request (RAR).

raa The message is Diameter Re-Authorization-Answer (RAA).

avps Adds, deletes, or replaces a set of mapping between Diameter AVPs and PEM subscriber attributes. You can configure the following options.

app-service

Specifies the name of the application service to which the AVP belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the avp. Only the application service can modify or delete the avp.

default

Specifies the Diameter AVP default value. When inserting the AVP, the default value is used if the corresponding subscriber attribute is not defined or is not present.

diameter-avp

Specifies the name of the Diameter AVP. The default value is none.

flag-mandatory

Specifies the value of the mandatory flag in the Diameter AVP when inserting into the message. This flag only applies to Diameter AVP in outgoing message.

flag-protected

Specifies the value of the protected flag in the Diameter AVP when inserting into the message. This flag only applies to Diameter AVP in outgoing message.

flag-vendor-specific

Specifies the value of the vendor-specific flag in the Diameter AVP when inserting into the message. This flag only applies to Diameter AVP in outgoing message.

interim-message-include

Specifies whether this AVP needs to be included in the interim-message (ccr-u only) updates which are generated if there is any change related to session parameters. This flag only applies to Diameter AVP in outgoing message.

parent-label

Specifies how grouped AVPs can be combined. The AVPs with the same parent-label will be combined in the same grouped AVP.

reporting-message-include

Specifies whether this AVP needs to be included in the reporting-message (ccr-u only) updates which are generated for reporting usage information. This flag only applies to Diameter AVP in outgoing message.

subscriber-attr

Specifies the name of the subscriber session attribute to be mapped to Diameter AVP. The default value is none.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

subscriber-id

Specifies how subscriber ID specified by PCRF should be read by PEM.

avp Subscription ID comes with type and data in diameter. This field specifies the avp in the message that should be matched to get subscriber ID data in raw format.

type Specifies the subscriber ID type (imsi, e164, private) that PEM will use for the session for the ID read by avp.

The options are:

e164 A numbering plan that defines the format of an MSISDN international phone number (up to 15 digits). The number typically consists of three fields: country code, national destination code, and subscriber number.

imsi International Mobile Subscriber Identity. A globally unique code number that identifies a GSM, UMTS, or LTE mobile phone user.

nai Network Access Identifier. A fully qualified network name in the form @; identifies a subscriber and the home network to which the subscriber belongs.

private

The subscriber id type is private for the given deployment.

type-avp

Subscription ID comes with type and data in diameter. type-avp specifies avp in message that should be matched.

BIG-IP 2017-07-19 pem protocol profile gx(1)

pem protocol profile radius

NAME

radius - Configures a RADIUS protocol profile in Policy Enforcement Manager (PEM).

MODULE

pem protocol profile

SYNTAX

Configure the radius component within the pem protocol profile module using the syntax shown in the following sections.

CP/CREATE/EDIT/MODIFY

```
cp radius [source_name] [destination_name]
create radius [name]
modify radius [name]
options:
  app-service [[string] | none]
  description [string]
  messages [add | delete | modify | replace-all-with] {
    [ [message-name] ] {
options:
  direction [any | in | out]
  message-type [acct-req-start | acct-req-stop | acct-req-interim-update]
  avps [add | delete | modify | replace-all-with] {
    [ [avp-name] ] {
      options:
  default [string]
  ingress-op [ import | none]
  radius-avp [ [radius_avp_name] | none]
  subscriber-attr [ [subscriber_attribute_name] | none]
    }
  }
  }
  subscriber-id [add | delete | modify | replace-all-with] {
    [ [id-name] ] {
options:
  order [integer]
  prefix [[string] | none]
  radius-avp [[radius_avp_name] | none]
  suffix [[string] | none]
    }
  }
  subscriber-id-type [e164 | imsi | nai | private]
```

```
edit radius [ [ [name] | [glob] | [regex] ] ... ]
```

options:

all-properties
non-default-properties

DISPLAY

```
list radius
```

```
list radius [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config radius
```

```
show running-config radius [ [ [name] | [glob] | [regex] ] ... ]
```

options:

all-properties
non-default-properties
one-line
partition

DELETE

```
delete radius [name]
```

Note: You must remove all references to a pem protocol profile radius before you can delete it.

DESCRIPTION

You can use the radius component to configure pem protocol profile radius definitions in Policy Enforcement Manager.

EXAMPLES

```
create cust_acct_start messages add { my_acct_start { direction in message-type acct-req-start avps add { avp1 { subscriber-attr _sys_attr_3gpp_imeisv radius-avp _sys_radius_3gpp_imeisv ingress-op import } } } }
```

Creates a custom PEM RADIUS protocol profile cust_acct_start and add a message to define how the RADIUS message can be processed. The message is defined as RADIUS accounting on the ingress direction. The mapping action ingress-op is to extract RADIUS AVP defined in _sys_radius_3gpp_imeisv and store the value into subscriber attribute _sys_attr_3gpp_imeisv.

```
delete radius cust_acct_start
```

Deletes the PEM RADIUS protocol profile named cust_acct_start.

```
list radius cust_acct_start
```

Displays the properties of the PEM RADIUS protocol profile named cust_acct_start.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

messages

Adds, deletes, or replaces a set of messages which specify mapping of RADIUS AVPs to subscriber session attributes for specific Gx message. If a message by the specified name does not exist, it will be created. You can configure the following options for a message:

app-service

Specifies the name of the application service to which the message belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the message. Only the application service can modify or delete the message.

direction

Specifies the direction of the message.

The options are:

any PEM will process the message in both ingress and egress directions.

in PEM will process the message in ingress direction.

out PEM will process the message in egress direction.

message-type

Specifies the type of the message.

The options are:

acct-req-start

The message is RADIUS accounting with the value of Acct-Status-Type AVP set to 1 (Start).

acct-req-stop

The message is RADIUS accounting with the value of Acct-Status-Type AVP set to 2 (Stop).

acct-req-interim-update

The message is RADIUS accounting with the value of Acct-Status-Type AVP set to 3 (Interim-Update).

avps Adds, deletes, or replaces a set of mapping between RADIUS AVPs and PEM subscriber attributes. You can configure the following options.

app-service

Specifies the name of the application service to which the avp belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the message. Only the application service can modify or delete the avp.

default

Specifies the RADIUS AVP default value. When inserting the AVP, the default value is used if the corresponding subscriber session attribute is not defined or is not present.

ingress-op

Specifies the ingress operation applied when processing the RADIUS AVP. The default value is none.

The options are:

import
Specifies that the RADIUS AVP will be parsed and the value will be stored in the subscriber attribute.

none Specifies that there is no ingress operation applied to the RADIUS AVP.

radius-avp
Specifies the name of the RADIUS AVP. The default value is none.

subscriber-attr
Specifies the name of the subscriber session attribute to be mapped to RADIUS AVP. The default value is none.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

subscriber-id
Adds, deletes, or replaces a set of RADIUS AVPs to form PEM subscriber ID. You can configure the following options:

order
Specifies the order of RADIUS AVPs when constructing the subscriber ID.

prefix
Specifies the prefix string when constructing subscriber ID with the value of the RADIUS AVP.

radius-avp
Specifies the value of RADIUS AVP which will be used to construct the subscriber ID.

suffix
Specifies the suffix string when constructing subscriber ID with the value of the RADIUS AVP.

subscriber-id-type
Specifies the subscriber ID type session attribute value for the session created.

The options are:

e164 A numbering plan that defines the format of an MSISDN international phone number (up to 15 digits). The number typically consists of three fields: country code, national destination code, and subscriber number.

imsi International Mobile Subscriber Identity. A globally unique code number that identifies a GSM, UMTS, or LTE mobile phone user.

nai Network Access Identifier. A fully qualified network name in the form @; identifies a subscriber and the home network to which the subscriber belongs.

private
The subscriber id type is private for the given deployment.

pem protocol radius-avp

NAME
radius-avp - Configures RADIUS AVPs in Policy Enforcement Manager (PEM).

MODULE
pem protocol

SYNTAX
Configure the radius-avp component within the pem protocol module using the syntax shown in the following sections.

CREATE/EDIT/MODIFY
create radius-avp [name]
modify radius-avp [name]

options:
app-service [[string] | none]
data-type [3gpp-rat-type | 3gpp-user-location-info | integer | ipaddr | ipv6addr | ipv6prefix | octet | string | time]
description [string]
max-length [integer]
min-length [integer]
type [integer]
vendor-id [integer]
vendor-type [integer]

edit radius-avp [[[name] | [glob] | [regex]] ...]

options:
all-properties
non-default-properties

DISPLAY

list radius-avp

list radius-avp [[[name] | [glob] | [regex]] ...]

options:
all-properties
non-default-properties
one-line
partition

DELETE

delete radius-avp [name]

Note: You must remove all references to a radius-avp before you can delete the radius-avp.

DESCRIPTION

You can use the radius-avp component to configure RADIUS AVP definitions in Policy Enforcement Manager.

EXAMPLES

```
create radius-avp imeisv { data-type string type 26 vendor-id 10415 vendor-type 20 }
```

Creates a PEM radius-avp imeisv which is an Vendor Specific Attribute of 3GPP with type value 26.

```
delete radius-avp imeisv
```

Deletes the radius-avp named imeisv.

```
list radius-avp imeisv
```

Displays the properties of the radius-avp named imeisv.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

data-type

Specifies the data type of the RADIUS AVP. The default value is string.

The options are:

3gpp-rat-type

specifies the value format to be encoded or decoded as the 3GPP-RAT-Type defined in 3GPP TS 29.061.

3gpp-user-location-info

specifies the value format to be encoded or decoded as the 3GPP-User-Location-Info defined in 3GPP TS 29.061.

integer

32-bit unsigned integer in network byte order.

ipaddr

IPv4 address in network byte order.

ipv6addr

IPv6 address in network byte order.

ipv6prefix

IPv6 prefix data format is defined in RFC 3162.

octet

UTF-8 text [RFC3629], totaling 253 octets or less in length.

string

string (i.e., binary data), totaling 253 octets or less in length. This includes the opaque encapsulation of data structures defined outside of RADIUS.

time time as a 32-bit unsigned value in network byte order and in seconds since 00:00:00 UTC, January 1, 1970.

description

User defined description.

max-length

Specifies the maximum data length of the RADIUS AVP/VSA. It doesn't include the AVP/VSP header. The default value is 253.

min-length

Specifies the minimum data length of the RADIUS AVP/VSA. It doesn't include the AVP/VSP header. The default value is 1.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

type Specifies the type of the RADIUS AVP. 26 is for vendor specific attribute (VSA).

vendor-id

Specifies the vendor-id of the RADIUS VSA. This property is mandatory if type is 26.

vendor-type

Specifies the vendor-type of the RADIUS VSA. This property is mandatory if type is 26.

SEE ALSO

pem quota-mgmt rating-group

NAME

rating-group - Configures a rating-group for quota management in Policy Enforcement Manager (PEM).

MODULE

pem quota management

SYNTAX

Modify the rating-group component within the pem quota-mgmt module using the syntax shown in the following sections.

CREATE/MODIFY

create rating-group [name]

modify rating-group [name]

options:

app-service [[string] | none]

rating-group-id [integer]

description [string]

request-on-install [yes | no]

default-threshold [integer]

default-validity-time [integer]

default-quota-holding-time [integer]

initial-quota-request {

interval [integer]

volume {

input-octets

output-octets

total-octets

}

default-quota {

interval [integer]

volume {

input-octets

output-octets

total-octets

}

time {

usage-time

consumption-time

}

default-breach-action [terminate | allow | redirect]

default-forwarding-endpoint [name]

edit rating-group [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

DISPLAY

list rating-group
list rating-group [[[name] | [glob] | [regex]] ...]
show running-config rating-group
show running-config rating-group [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

DELETE

delete rating-group [name]

Note: You must remove all references to a rating-group object before you can delete it.

EXAMPLES

```
create rating-group rg1 {  
  rating-group-id 1  
  initial-quota-request {  
    volume {  
      input-octets 1000  output-octets 1000  total-octets 2000  
    }  
  }  
  default-quota {  
    volume {  
      input-octets 1000  output-octets 1000  total-octets 2000  
    }  
  }  
  request-on-install yes }
```

Creates a PEM rating-group named rg1.

delete rating-group rg1

Deletes the rating-group named rg1.

list rating-group rg1

Displays the properties of the rating-group named rg1.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

rating-group-id

Specifies the rating-group-id that will be used by quota managing endpoint. For instance, this could be the rating group in case of Gy endpoint.

request-on-install

Specifies whether quota has to be requested from the quota managing endpoint (Eg : Gy) when policy referring to this rating-group is installed for a subscriber or later when flow is initiated.

default-threshold

Specifies the default threshold if the quota managing endpoint does not specify threshold.

default-validity-time

Specifies the default validity time for the quota in seconds if OCS did not specify it.

default-quota-holding-time

Specifies the default quota holding time in seconds for which quota is valid without any usage if not specified by OCS.

initial-quota-request

Specifies the initial quota, that will be requested from the quota managing endpoint. Could be either time or volume.

time Specifies the time in seconds.

volume

You can configure the following options for volume initial quota.

output-octets

Specifies the initial quota for downlink traffic.

total-octets

Specifies the initial quota for total uplink and downlink traffic.

input-octets

Specifies the initial quota for uplink traffic.

default-quota

Specifies the default quota, that will be used if quota managing endpoint does not respond. Could be either time or volume.

time Specifies the quota in time.

usage-time

Specifies the usage time in seconds.

consumption-time

Specifies the quota consumption time in seconds.

volume

You can configure the following options for volume default quota.

output-octets

Specifies the default quota for downlink traffic.

total-octets

Specifies the default quota for total uplink and downlink traffic.

input-octets

Specifies the default quota for uplink traffic.

SEE ALSO

BIG-IP 2016-01-07 pem quota-mgmt rating-group(1)

pem reporting format-script

NAME

format-script - Configures format scripts for the Policy Enforcement Manager (PEM).

MODULE

pem reporting

SYNTAX

Modify the format-script component within the pem reporting module using the syntax shown in the following sections.

CREATE/MODIFY

create format-script [name]

modify format-script [name]

options:

app-service [[string] | none]

definition [string]

description [string]

edit format-script [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list format-script

list format-script [[[name] | [glob] | [regex]] ...]

show running-config format-script

show running-config format-script [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete format-script [name]

Note: You must remove all references to a format script object before you can delete it.

DESCRIPTION

You can use the format-script component to create scripts for HSL reporting. The scripts use TCL syntax and define a custom format that is applied in an enforcement policy rule. The format and fields available differ

depending on whether the rule specifies session-based or flow-based reporting.

EXAMPLES

```
create format-script fm1 { definition { return "(flow app_id[PEM::flow stats reported app-id],
bytes-in:[PEM::flow stats reported bytes-in])" } }
```

Creates a PEM reporting format script named fm1.

```
delete format-script fm1
```

Deletes the format script named fm1.

```
list format-script fm1
```

Displays the properties of the format script named fm1.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

definition

Specifies a script using TCL syntax that defines a custom format for HSL reporting applied in an enforcement policy rule. The format and fields available differ depending on whether you are using session-based or flow-based reporting in the rule.

Session-based formats:

The options are:

app-id

Specifies the application id of the session record.

bytes-in

Specifies the aggregate incoming bytes of the session.

bytes-out

Specifies the aggregate outgoing bytes of the session.

calling-station-id

Specifies the calling station Id.

called-station-id

Specifies the called station Id.

flows-concurrent

Specifies the number of concurrent flows in the session.

flows-duration

Specifies the duration of the flow in the session.

flows-ended

Specifies the number of flows ended in the session.

flows-new

Specifies the number of new flows in the session.

last-sent-sec

Specifies the value of seconds of the timestamp since the previous record was sent.

param-3gpp

Specifies the comma-separated string of the value of imsi, imeisv, tower-id, and user-name.

record-reason

Specifies the reason for sending report. The values are 1: period time, 2: volume threshold, 3: subscriber logout, 4: inactivity.

record-type

Specifies the type of the session-based record (always 3).

report-id

Specifies the report Id.

report-version

Specifies the report version.

subscriber-id

Specifies the subscriber id.

subscriber-id-type

Specifies the subscriber id type (e164, imsi, nai, or private).

timestamp

Specifies the seconds value of the timestamp when the record was generated. The Unix epoch is 1970-01-01T00:00:00Z.

timestamp-milliseconds

Specifies the milliseconds value of the timestamp when the record was generated.

Note: Recommend not to use the following options. They are available for backward compatibility.

last-send-usec

Specifies the value of microseconds of the timestamp since the previous record was sent.

rec-reason

Specifies the reason for sending report. The values are 1: period time, 2: volume threshold, 3: subscriber logout, 4: inactivity.

rec-type

Specifies the type of the session-based record (always 3).

subs-id

Specifies the subscriber id.

subs-id-type

Specifies the subscriber id type (e164, imsi, nai, or private).

timestamp-sec

Specifies the seconds value of the timestamp when the record was generated. The Unix epoch is 1970-01-01T00:00:00Z.

timestamp-usec

Specifies the microseconds value of the timestamp when the record was generated.

Flow-based formats:
The options are:

app-id

Specifies the application id of the flow record.

bytes-in

Specifies the aggregate incoming bytes of the flow.

bytes-out

Specifies the aggregate outgoing bytes of the flow.

dst-ip

Specifies the destination ip address of the flow.

dst-port

Specifies the destination port of the flow.

flow-start-milli-seconds

Specifies the milliseconds value of the timestamp when the flow starts.

flow-start-time-sec

Specifies the seconds value of the timestamp when the flow starts. The Unix epoch is 1970-01-01T00:00:00Z.

flow-end-milli-seconds

Specifies milliseconds value of the timestamp when the flow ends.

flow-end-time-sec

Specifies the seconds value of the timestamp when the flow ends. The Unix epoch is 1970-01-01T00:00:00Z.

proto

Specifies the protocol of the flow.

record-type

Specifies the type of the flow-based record. The value is 0: flow init, 1: flow interim, and 2: flow end.

report-id

Specifies the report Id.

route-domain

Specifies the route domain Id of the traffic.

report-version

Specifies the report version.

src-ip

Specifies the source ip address of the flow.

src-port

Specifies the destination port of the flow.

subscriber-id

Specifies the subscriber id.

subscriber-id-type

Specifies the subscriber id type (e164, imsi, nai, or private).

timestamp
Specifies the of seconds value of the timestamp when the record was generated. The Unix epoch is 1970-01-01T00:00:00Z.

timestamp-milliseconds
Specifies the milliseconds value of the timestamp when the record was generated.

transactions
Specifies the number of transactions in the flow.

urlcat-id
Specifies the unique number that represents the first (most relevant) URL category that is classified for the flow.

vlan-id
Specifies the vlan Id of the traffic.

Note:Recommend not to use the following options. They are available for backward compatibility.

flow-start-time-usec
Specifies microseconds value of the timestamp when the flow starts.

flow-end-time-usec
Specifies microseconds value of the timestamp when the flow ends.

rec-type
Specifies the type of the flow-based record. The value is 0: flow init, 1: flow interim, and 2: flow end.

subs-id
Specifies the subscriber id.

subs-id-type
Specifies the subscriber id type (e164, imsi, nai, or private).

timestamp-sec
Specifies the of seconds value of the timestamp when the record was generated. The Unix epoch is 1970-01-01T00:00:00Z.

timestamp-usec
Specifies the microseconds value of the timestamp when the record was generated.

description
Specifies a user-defined description.

pem service-chain-endpoint

NAME
service-chain-endpoint - Configures service chain endpoints for the Policy Enforcement Manager (PEM).

MODULE
pem

SYNTAX
Modify the service-chain-endpoint component within the pem module using the syntax shown in the following sections.

CREATE/MODIFY
create service-chain-endpoint [name]
modify service-chain-endpoint [name]
options:
 app-service [[string] | none]
 service-endpoints [add | delete | modify | replace-all-with] {
[service endpoint name ...] {
 options:

```

app-service [[string] | none]
forwarding-endpoint
  to-endpoint [forwarding endpoint name]
from-vlan [vlan name]
http-adapt-service
  internal-virtual [internal virtual server | none]
  icap-type [request | response | both | none]
order [integer]
service-option [optional | mandatory]
steering-policy [policy name | none]
}
}

```

```

edit service-chain-endpoint [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

```

```

DISPLAY
list service-chain-endpoint
list service-chain-endpoint [ [ [name] | [glob] | [regex] ] ... ]
show running-config service-chain-endpoint
show running-config service-chain-endpoint [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

```

```

DELETE
delete service-chain-endpoint [name]

```

Note: You must remove all references to a service-chain-endpoint before you can delete the service-chain-endpoint.

DESCRIPTION

You can use the service-chain-endpoint component to configure service-chain-endpoint definitions for the Policy Enforcement Manager (PEM). Each service-chain-endpoint consists of one or more service-endpoints, where a service-endpoint consists of a non-zero integer order, existing from-vlan a valid fwd-endpoint or a http-adaptation-service endpoint. When you configure a BIG-IP that has a service-chain-endpoint with multiple service-endpoints, traffic will pass through different endpoints chosen dynamically.

Note: You must create a valid forwarding-endpoint and a valid vlan before you can create a service-endpoint. If you are enabling http-adapt-service, you must create Request Adapt and Response Adapt profiles and attach to the traffic virtual. Also create an internal-virtual and enable icap profile. You must also give each service-endpoint an order from 1 up to $2^{32}-1$. The lower the service-endpoint order is, the higher its precedence is (i.e., traffic will pass through it before other higher order service-endpoints). Each service-endpoint has a boolean (true/false) service-option that defines what would happen if the service-endpoint is down. If service-option is mandatory, the traffic flow is dropped if the service-endpoint is down. If service-option is optional, the traffic flow will be bypassed to the next available service-endpoint.

For more information about how to create a vlan, please refer to net vlan. Also please refer to pem forwarding-endpoint for more information about how to create a pem forwarding-endpoint.

EXAMPLES

```

create service-chain-endpoint chain1 service-endpoints add { ser_ep1 { order 10 from-vlan vlan1 forwarding-
endpoint { to-endpoint fw_ep1 } service-option optional } ser_ep2 { order 5 from-vlan vlan2 http-adapt-service
{internal-virtual iv1} service-option mandatory } }

```

Creates a PEM service-chain-endpoint named chain1 that has two service-endpoints: ser_ep1 and ser_ep2. The first ser_ep1 has an order of 10 and is optional and has forwarding-endpoint with to-endpoint fw_ep1, type transparent and vlan1 as a from-vlan. The second ser_ep2 has an order of 5 is mandatory and has http-adapt-service enabled with ivs1 as internal-server and vlan2 as a from-vlan. Note that ser_ep2 will precede ser_ep1 because the lower the service-endpoint order is, the higher its precedence is.

```

delete service-chain-endpoint chain1

```

Deletes the service-chain-endpoint named chain1.

```

list service-chain-endpoint chain1

```

Displays the properties of the service-chain-endpoint named chain1.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

service-endpoints

Adds, deletes, or replaces a set of the service endpoints by specifying a series of service-endpoint names. If any of these names did not exist before, then new names will be created. Each service-endpoint is identified by a vlan and a forwarding-endpoint.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object,

you cannot modify or delete the object. Only the application service can modify or delete the object.

forwarding-endpoint
Specifies the forwarding endpoint attributes to be set. The below attributes can be set:

to-endpoint
This is a default endpoint that will be chosen if steering policy is not configured. You have to create a valid PEM forwarding-endpoint before you can add to-endpoint to a service-endpoint.

from-vlan
Specifies the vlan that the traffic will come from toward the service-endpoint. Note: The vlan has to exist before you can create a from-vlan field.

http-adapt-service
Specifies the option to set attributes for http adapt services. Below are the attributes that can be set.

internal-virtual
This is the internal virtual on which icap is enabled. You have to create the internal-virtual and assign icap profile before adding here.

icap-type
Defines the ICAP adaptation type: request only adaptation, request and response adaptation or both types of adaptations combined.

order
Specifies the order of the service-endpoint among other service-endpoints. The lower the service-endpoint's order is, the more precedence it has (i.e., the traffic will go through the lowest-ordered service-endpoint first, then through higher order service-endpoint, ... etc.).

service-option
Specifies the behavior when a service-endpoint is not available (i.e., is down). This option is limited when ICAP is defined as the service-endpoint and will not apply if the ICAP service is unavailable. You can configure the following options:

mandatory
If the service-endpoint is down, the traffic flow is dropped.

optional
If the service-endpoint is down, the traffic flow will be bypassed to the next available service-endpoint.

steering-policy
If the steering policy is configured, the policy is evaluated and if steering is enabled the flow will be steered to the corresponding endpoint.

BIG-IP 2016-01-07 pem service-chain-endpoint(1)

pem sessiondb

NAME
sessiondb - Displays, deletes, modifies, and reset-stats a PEM subscriber session record on the BIG-IP(r) system.

MODULE
pem

DESCRIPTION
You can use the sessiondb component to display session record on the BIG-IP system. Additionally, you can delete, reset-stats and modify a specified session record. The subscriber-id or session-ip or all and/or the filtering arguments can be specified as the query key. session-state must be specified in modify command.

When specifying an IP address in show/delete/modify/reset-stats sessiondb session-ip commands, the route domain ID may be optionally included. The route domain ID follows the IP address and is separated by '%'. For example, 10.10.10.100%5 is an IP address in route domain 5.

Note: show and reset-stats commands apply to both static and dynamic subscribers. Delete and modify commands only apply to dynamic subscribers. The session of static subscribers cannot be deleted. The session-state of static subscribers cannot be changed. To delete a static subscriber session you have to delete the static subscriber configuration in pem subscriber.

SHOW command SYNTAX

show sessiondb subscriber-id []

show sessiondb session-ip [/[] []]

show all

options:
all-properties
field-fmt

DESCRIPTION

Used to display the session information.

subscriber-id can either be the complete subscriber-id or a wildcard.

session-ip be either the complete IP address, or a subnet, by specifying the prefix.

all is used to display all the sessions. Due to existing limitations, some of the arguments cannot be used with the 'all' option. In this case, 'subscriber-id *' can be used.

all-properties options enables the per-IP traffic statistics in case of sessions with multiple IP addresses.

field-fmt option provides a structured output. This option is used for REST API compatibility.

args is an optional list of arguments, which can contain the following-

- filtering arguments: These specify the criteria for selecting sessions to display. The filtering arguments can be one or more of the following

- . imsi
- . imeisv
- . calling-station-id
- . called-station-id
- . user-name
- . session-origin
- . session-state
- . device-name
- . device-os
- . user-location-info

This can either be the user location as a hex string, or the location info broken down into individual fields as name value pairs. The values can be combined using '&' or '|' and can have only one of the operators, not both. The key value pairs allowed are as follows ('D' stands for a decimal value and 'H' for hex digit) -

- type=[CGI | SAI | RAI | TAI | TAI+ECGI] - mcc=DD[D] - mnc=DD[D] - lac=[0x]HHHH - ci=[0x]HHHH
- sac=[0x]HHHH - rac=[0x]HHHH - tac=[0x]HHHH - eci=[0x]HHHHHHH

For e.g.

user-location-info 0x1234567 user-location-info type=CGI&mcc=123 user-location-info
type=TAI+ECGI|mcc=123|lac=0x3f5d

This is not allowed -

user-location-info type=CGI&mcc=123|mcc=456

. attr

This is the list of custom attribute key-value pairs. Multiple attributes can be combined with either '&' or '|'. (cannot have a mix of '&' and '|' operators). There can be a maximum of 30 custom attributes.

. policy

List of policy names. This can again be combined using the '&' or '|' operators. There can be maximum of 30 policies.

. blade

. tmm

- include-deleted: This specifies whether to include sessions marked for deletion in the output.
- view-mode: This specifies the format of the output and can be one of extended, table or count. The extended view mode is the default and gives a formatted output of all the session attributes and flow statistics. In the table mode, the user can select the information to be displayed by selecting the list of columns. In this mode, the 'columns' argument HAS to be specified containing the list of columns to display. Column names should be separated by ':' and should be from the following list -

. subscriber_id

. tmm_number

. blade_number

- . session_state_str
- . session_origin_str
- . ppe_session_id
- . qpe_session_id
- . imsi
- . imeisv
- . called_station_id
- . calling_station_id
- . user_name
- . device_name
- . device_os
- . tower_id
- . ip_info.ip_address
- . policy_info.policy_name
- . any custom attribute e.g. _sys_attr_3gpp_rat_type.

Any unknown column name is considered to be a custom attribute name.

If the view-mode is set to count, then only a count of the number of sessions matching the specified criteria is displayed.

- max-count: This is used to specify an upper limit on the number of matching sessions to be considered for the command.
- resume-from: This argument is used to get a page-by-page listing of the sessions, and can be used only with the field-fmt option.

DELETE command

SYNTAX

```
delete sessiondb subscriber-id []
```

```
delete session-ip [ip address>/[] []
```

```
delete all
```

DESCRIPTION

Used to delete sessions.

The optional arguments here can specify the filtering arguments, as explained in the show command above.

All the sessions matching the criteria are deleted.

MODIFY command

SYNTAX

```
modify sessiondb subscriber-id [] session-state [marked-for-deletion | not-provisioned |  
provisioned | provisioning-pending ]
```

```
modify session-ip [ip address>/[] [] session-state [marked-for-deletion | not-provisioned |  
provisioned | provisioning-pending ]
```

DESCRIPTION

Used to modify the session state.

The optional arguments here can specify the filtering arguments, as explained in the show command above.

The state of all the matching sessions are modified to the value specified.

session-state

Specifies the new subscriber session state.

The options are:

marked-for-deletion

Specifies that the subscriber session should be scheduled for deletion.

provisioned

Specifies that the subscriber session state should be marked as provisioned, regardless of whether the policies have been assigned or not. The unknown subscriber policies are not applied to the subscriber flows, even if no subscriber policies are provisioned.

not-provisioned

Specifies that the subscriber session state should be marked as not-provisioned. No further attempts to provision the session are made. The unknown subscriber policies are applied to the subscriber flows.

provisioning-pending

Specifies that the subscriber session state should be marked as being in the process of provisioning. This will trigger a session provisioning request (e.g. Gy CCR request) immediately. If no response is received, or the provisioning process fails for any reason, another request will be sent after the retry timeout, until the session is provisioned successfully, or the number of retries is reached.

RESET-STATS command

SYNTAX

```
reset-stats sessiondb subscriber-id []
```

```
reset-stats session-ip [ip address>/[] []]
```

```
reset-stats all
```

DESCRIPTION

Used to reset the session statistics.

The optional arguments here can specify the filtering arguments, as explained in the show command above.

The statistics for all the sessions matching the criteria are reset.

EXAMPLES

```
show sessiondb subscriber-id 4085551212
```

Displays the session record of subscriber id 4085551212.

```
show sessiondb subscriber-id 408*
```

Displays the session record of all subscribers with id beginning with '408'.

```
show sessiondb subscriber-id *
```

Displays the session records of all subscribers.

```
show sessiondb session-ip 10.10.10.100
```

Displays the session record of session ip address 10.10.10.100.

```
show sessiondb session-ip 10.10.10.100%5
```

Displays the session record of session ip address 10.10.10.100 in route domain 5.

```
show sessiondb session-ip 10.10.10.10/24
```

Displays the session records of session ip addresses in the 10.10.10.0 subnet.

```
show sessiondb subscriber-id 4085551212 all-properties
```

Displays the session record of subscriber id 4085551212, and statistics for each IP.

```
show sessiondb session-ip 10.10.10.100 all-properties
```

Displays the session record of session ip address 10.10.10.100, and statistics for each IP.

```
show sessiondb session-ip 10.10.10.10/24 view-mode count
```

Displays the count of the number of session records with session ip address in the 10.10.10.0 subnet.

```
show sessiondb subscriber-id 408* session-state provisioned
```

Displays the count of the number of sessions whose id begins with '408' and are in the provisioned state.

```
delete sessiondb subscriber-id 4085551212
```

Deletes the session record of subscriber id 4085551212.

```
delete sessiondb session-ip 10.10.10.100
```

Deletes the session record of IP address 10.10.10.100.

```
delete sessiondb session-ip 10.10.10.100%5
```

Deletes the session record of IP address 10.10.10.100 in route domain 5.

```
delete sessiondb session-ip session-state provisioning-pending
```

Deletes all sessions that are in the provision pending state.

```
reset-stats sessiondb subscriber-id 4085551212
```

Reset the session statistics of subscriber id 4085551212. Flows Current specifies the active flows and it cannot be reset.

modify sessiondb subscriber-id 4085551212 session-state provisioned

Modifies the session state of subscriber id 4085551212 to provisioned.

modify sessiondb subscriber-id 408* session-state provisioned

Modifies the session state of sessions with subscriber id starting with 408 to state provisioned.

pem stats action

NAME

action - Displays and resets PEM policy action statistics.

MODULE

pem stats

SYNTAX

Display statistics for the action component within the pem stats module using the syntax in the following section.

DISPLAY

show action

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the action component to display PEM policy action statistics. The statistics details are described below:

Pass Specifies the number of flows that are passed (gate enabled).

Drop Specifies the number of flows that are dropped (gate disabled).

Clone

Specifies the number of flows to which clone actions apply.

HTTP Redirect

Specifies the number of flows to which redirection actions apply.

ICAP Request

Specifies the number of flows to which ICAP actions apply on the request direction.

ICAP Response

Specifies the number of flows to which ICAP actions apply on the response direction.

Steering

Specifies the number of flows to which steering actions apply.

Service Chain

Specifies the number of flows to which steering endpoint actions apply.

Steering on Response

Specifies the number of flows to which steering actions apply on the response direction.

QoS Uplink

Specifies the number of uplink flows to which QoS actions apply. Uplink means to network.

QoS Downlink

Specifies the number of downlink flows to which QoS actions apply. Downlink means to subscriber.

DSCP Marking Uplink

Specifies the number of uplink flows with DSCP action applies.

DSCP Marking Downlink

Specifies the number of downlink flows with DSCP action applies.

HTTP Headers Modify

Specifies the number of HTTP Headers Modify actions.

Insert Content

Specifies the number of Insert Content actions.

iRule

Specifies the number of iRule actions.

L2 Marking Uplink

Specifies the number of uplink flows to which L2 Marking actions apply.

L2 Marking Downlink

Specifies the number of downlink flows to which L2 Marking actions apply.

Flow Reporting

Specifies the number of actions of flow reporting record generation applied.

Session Reporting

Specifies the number of actions of session record generation applied.

Transaction Reporting

Specifies the number of actions of transaction record generation applied.

Policy Re-evaluation Rate (count/min)

Specifies the number of successful policy reevaluations per minute.

Policy Re-evaluation Rate Maximum

Specifies the maximum number of policy reevaluations overall for all subscribers and flows.

You can reset the PEM policy action statistics using reset-stats command.

EXAMPLES

show action

Displays the PEM policy action statistics.

reset-stats action

Resets the PEM policy action statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, pem stats gx, pem stats gy, pem stats hsl, pem stats radius, pem stats subscriber, tmsh

pem stats dtos

NAME

dtos - Displays and resets PEM dtos statistics.

MODULE

pem stats

SYNTAX

Display statistics for the dtos component within the pem stats module using the syntax in the following section.

DISPLAY

show dtos

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the dtos component to display PEM dtos statistics. The statistics details are described below:

TAC Database

Specifies the number of TAC database queries and successful lookups since the last reset of the counter.

Customdb

Specifies the number of custom TAC database queries and successful lookups since the last reset of the counter.

Default/Licensed

Specifies the number of default/licensed TAC database queries and successful lookups since the last reset of the counter.

TCP Fingerprint

Specifies the number of TCP fingerprint queries and successful OS identification since the last reset of the counter.

User-agent

Specifies the number of user-agent queries and successful OS identification since the last reset of the counter.

You can reset the PEM dtos statistics using reset-stats command.

EXAMPLES

```
show dtos
```

Displays the PEM dtos statistics.

```
reset-stats dtos
```

Resets the PEM dtos statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

pem stats gx

NAME

gx - Displays and resets PEM gx statistics.

MODULE

pem stats

SYNTAX

Display statistics for the gx component within the pem stats module using the syntax in the following section.

DISPLAY

```
show gx
```

```
option:
```

```
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
```

DESCRIPTION

You can use the gx component to display PEM gx statistics. The Current column represents count of Gx sessions that exist at the moment. The Max column represents maximal count of Gx sessions that ever existed at the same time. The Total column represents total count of Gx sessions that existed or messages that were sent or received since the start or the last statistics reset. The Retries column represents total count of retransmitted Gx messages. The Errors column represents total count of received Gx messages that were invalid or outgoing Gx messages that could not be sent. The statistics details are described below:

Gx sessions

Specifies the number of all Gx sessions established.

Provisioned Gx sessions

Specifies the number of provisioned Gx sessions.

Provisioning pending Gx sessions

Specifies the number sessions for which provisioning or creation over Gx has been initiated.

Not provisioned Gx sessions

Specifies the number of not provisioned Gx sessions, i.e. all existing Gx sessions that have not been provisioned.

Provisioning failed Gx sessions

Specifies the number of inactive Gx sessions for which provisioning or creation error happened.

Termination pending Gx sessions

Specifies the number of Gx sessions for which close is initiated.

Terminated Gx sessions

Specifies the total number of Gx sessions terminated since the last reset of the counter.

CCR Sent

Specifies the number of Credit-Control-Request (CCR) requests of all types sent.

CCR Initial Sent

Specifies the number of Credit-Control-Request (CCR) Initial requests sent since the last reset of the counter.

CCR Update Sent

Specifies the number of Credit-Control-Request (CCR) Update requests sent since the last reset of the counter.

CCR Usage Monitoring Sent

Specifies the number of Credit-Control-Request (CCR) requests with usage monitoring report sent.

CCR Application Start Sent

Specifies the number of Credit-Control-Request (CCR) requests with application start report sent.

CCR Application Stop Sent

Specifies the number of Credit-Control-Request (CCR) requests with application stop report sent.

CCR Termination Sent

Specifies the number of Credit-Control-Request (CCR) Termination requests sent since the last reset of the counter.

CCA Received

Specifies the number of Credit-Control-Answer (CCA) responses of all types received.

CCA Initial Received

Specifies the number of Credit-Control-Answer (CCA) Initial responses received since the last reset of the counter.

CCA Update Received

Specifies the number of Credit-Control-Answer (CCA) Update responses received since the last reset of the counter.

CCA Usage Monitoring Received

Specifies the number of Credit-Control-Answer (CCA) responses with usage monitoring report ack received.

CCA Termination Received

Specifies the number of Credit-Control-Answer (CCA) Termination responses received since the last reset of the counter.

RAR Received

Specifies the number of Re-Auth-Request (RAR) requests received.

RAA Sent

Specifies the number of Re-Auth-Answer (RAA) responses sent.

You can reset the PEM gx statistics using reset-stats command.

EXAMPLES

show gx

Displays the PEM gx statistics.

reset-stats gx

Resets the PEM gx statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, pem stats action, pem stats gy, pem stats hsl, pem stats radius, pem stats subscriber, tmsh

pem stats gy

NAME

gy - Displays and resets PEM gy statistics.

MODULE

pem stats

SYNTAX

Display statistics for the gy component within the pem stats module using the syntax in the following section.

DISPLAY

show gy

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the gy component to display PEM gy statistics. The Current column represents count of Gy sessions that exist at the moment. The Max column represents maximal count of Gy sessions that ever existed at the same time. The Total column represents total count of Gy that existed or messages that were sent or received since the start or the last statistics reset. The Retries column represents total count of retransmitted Gy messages. The Errors column represents total count of received Gy messages that were invalid or outgoing Gy messages that could not be sent. The statistics details are described below:

Gy sessions

Specifies the number of all Gy sessions established.

Late binding Gy sessions

Specifies the number of all late binding Gy sessions.

Provisioned Gy sessions

Specifies the number of provisioned Gy sessions.

Provisioning pending Gy sessions

Specifies the number sessions for which provisioning or creation over Gy has been initiated.

Not provisioned Gy sessions

Specifies the number of not provisioned Gy sessions, i.e. provisioning pending and provisioning failed Gy sessions.

Provisioning failed Gy sessions

Specifies the number of inactive Gy sessions for which provisioning or creation error happened.

Termination pending Gy sessions

Specifies the number of Gy sessions for which close is initiated.

Terminated Gy sessions

Specifies the total number of Gy sessions terminated since the last reset of the counter.

CCR Sent

Specifies the number of Credit-Control-Request (CCR) requests of all types sent.

CCR Initial Sent

Specifies the number of Credit-Control-Request (CCR) Initial requests sent since the last reset of the counter.

CCR Update Sent

Specifies the number of Credit-Control-Request (CCR) Update requests sent since the last reset of the counter.

CCR Termination Sent

Specifies the number of Credit-Control-Request (CCR) Termination requests sent since the last reset of the counter.

CCA Received

Specifies the number of Credit-Control-Answer (CCA) responses of all types received.

CCA Initial Received

Specifies the number of Credit-Control-Answer (CCA) Initial responses received since the last reset of the counter.

CCA Update Received

Specifies the number of Credit-Control-Answer (CCA) Update responses received since the last reset of the counter.

CCA Termination Received

Specifies the number of Credit-Control-Answer (CCA) Termination responses received since the last reset of the counter.

RAR Received

Specifies the number of Re-Auth-Request (RAR) requests received.

RAA Sent

Specifies the number of Re-Auth-Answer (RAA) responses sent.

You can reset the PEM gy statistics using `reset-stats` command.

EXAMPLES

`show gy`

Displays the PEM gy statistics.

`reset-stats gy`

Resets the PEM gy statistics.

OPTIONS

For information about the options that you can use with the command `show`, see `help show`.

SEE ALSO

`show`, `pem stats action`, `pem stats gx`, `pem stats hsl`, `pem stats radius`, `pem stats subscriber`, `tmsh`

BIG-IP 2017-05-15 `pem stats gy(1)`

pem stats hsl

NAME

`hsl` - Displays and resets PEM hsl statistics.

MODULE

`pem stats`

SYNTAX

Display statistics for the hsl component within the `pem stats` module using the syntax in the following section.

DISPLAY

`show hsl`

`option:`

(`default` | `exa` | `gig` | `kil` | `meg` | `peta` | `raw` | `tera` | `yotta` | `zetta`)

DESCRIPTION

You can use the `hsl` component to display PEM hsl statistics. The statistics details are described below:

Session Records

Specifies the number of Session-based records sent to each HSL endpoint since the last reset of the counter.

Flow Start Records

Specifies the number of Flow Start records sent to each HSL endpoint since the last reset of the counter.

Flow Interim Records

Specifies the number of Flow Interim records sent to each HSL endpoint since the last reset of the counter.

Flow Stop Records

Specifies the number of Flow Stop records sent to each HSL endpoint since the last reset of the counter.

Transaction Records

Specifies the number of HTTP Transaction records sent to each HSL endpoint since the last reset of the counter.

Records Skipped

Specifies the number of reporting records skipped from being sent the HSL endpoint since the last reset of the counter.

You can reset the PEM hsl statistics using `reset-stats` command.

EXAMPLES

`show hsl`

Displays the PEM hsl statistics.

reset-stats hsl

Resets the PEM hsl statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

pem stats hudnode-opt

NAME

hudnode-opt - Resets PEM hudnode-opt statistics.

MODULE

pem stats

SYNTAX

Reset statistics for the hudnode-opt component within the pem stats module using the syntax in the following section.

DESCRIPTION

You can use the hudnode-opt component to reset PEM hudnode-opt statistics.

EXAMPLES

reset-stats hudnode-opt

Resets the PEM hudnode-opt statistics.

OPTIONS

For information about the options that you can use with the command reset-stats, see help reset-stats.

SEE ALSO

reset-stats, pem stats action, tmsh, pem stats gx

COPYRIGHT

pem stats multiple-ip

NAME

multiple-ip - Displays and resets PEM multiple IP statistics.

MODULE

pem stats

SYNTAX

Display statistics for the multiple-ip component within the pem stats module using the syntax in the following section.

DISPLAY

show multiple-ip

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the multiple-ip component to display PEM multiple IP statistics. The Total column represents total count of packets received. The Processed column represents total count of packets processed, i.e. packets that were successfully parsed, validated and initiated session creation, deletion or update. The Processed column is incremented regardless of success or failure of session creation, deletion or update and is incremented for retransmitted packets. The Retransmitted column represents total count of packets that were discarded, because they were retransmissions of already processed packets. The Error column represents total count of packets that could not be parsed or validated. The statistics details are described below:

Forwarded Flows

Specifies the number of flows that have been forwarded.

Sessions Merged

Specifies the number of sessions have been merged due to multiple IP.

You can reset the PEM multiple IP statistics using reset-stats command.

EXAMPLES

show multiple-ip

Displays the PEM multiple IP statistics.

reset-stats multiple-ip

Resets the PEM multiple IP statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, pem stats action, pem stats gx, pem stats gy, pem stats hsl, pem stats subscriber, tmsh

pem stats persistence

NAME

persistence - Displays and resets PEM persistence statistics.

MODULE

pem stats

SYNTAX

Display statistics for the persistence component within the pem stats module using the syntax in the following section.

DISPLAY

show persistence

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the persistence component to display PEM persistence statistics. The statistics details are described below:

Source IP

Number of times CARP persistence is based on source IP address.

Destination IP

Number of times CARP persistence is based on destination IP address.

HASH URI

Number of times CARP persistence is based on URI of the HTTP transaction.

HASH TCL

Number of times CARP persistence is based on TCL script.

Fallback Source IP

Number of times CARP persistence is based on fallback source IP address.

Fallback Destination IP

Number of times CARP persistence is based on fallback destination IP address.

You can reset the PEM persistence statistics using reset-stats command.

EXAMPLES

show persistence

Displays the PEM persistence statistics.

reset-stats persistence

Resets the PEM persistence statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, pem stats action, pem stats gx, pem stats gy, pem stats radius, pem stats subscriber, pem stats hsl, pem stats dtos, pem stats tethering, tmsb

pem stats radius

NAME

radius - Displays and resets PEM radius statistics.

MODULE

pem stats

SYNTAX

Display statistics for the radius component within the pem stats module using the syntax in the following section.

DISPLAY

show radius

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the radius component to display PEM radius statistics. The Total column represents total count of packets received. The Processed column represents total count of packets processed, i.e. packets that were successfully parsed, validated and initiated session creation, deletion or update. The Processed column is incremented regardless of success or failure of session creation, deletion or update and is incremented for retransmitted packets. The Retransmitted column represents total count of packets that were discarded, because they were retransmissions of already processed packets. The Error column represents total count of packets that could not be parsed or validated. The statistics details are described below:

Accounting-Request START

Specifies the number of Accounting-Start packets.

Accounting-Request STOP

Specifies the number of Accounting-Stop packets.

Accounting-Request INTERIM_UPDATE

Specifies the number of Accounting-Interim packets.

Accounting-Request ACCOUNTING_ON

Specifies the number of Accounting-On packets.

Accounting-Request ACCOUNTING_OFF

Specifies the number of Accounting-Off packets.

You can reset the PEM radius statistics using reset-stats command.

EXAMPLES

show radius

Displays the PEM radius statistics.

reset-stats radius

Resets the PEM radius statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

pem stats sd

NAME

sd - Displays and resets PEM sd statistics.

MODULE

pem stats

SYNTAX

Display statistics for the sd component within the pem stats module using the syntax in the following section.

DISPLAY

show sd

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the sd component to display PEM sd statistics. The Current column represents count of Sd sessions that exist at the moment. The Max column represents maximal count of Sd sessions that ever existed at the same time. The Total column represents total count of Sd sessions that existed or messages that were sent or received since the start or the last statistics reset. The Retries column represents total count of retransmitted Sd messages. The Errors column represents total count of received Sd messages that were invalid or outgoing Sd messages that could not be sent. The statistics details are described below:

Sd sessions

Specifies the number of all Sd sessions established.

Provisioned Sd sessions

Specifies the number of provisioned Sd sessions.

Provisioning pending Sd sessions

Specifies the number sessions for which provisioning or creation over Sd has been initiated.

Not provisioned Sd sessions

Specifies the number of not provisioned Sd sessions, i.e. all existing Sd sessions that have not been provisioned.

Provisioning failed Sd sessions

Specifies the number of inactive Sd sessions for which provisioning or creation error happened.

Termination pending Sd sessions

Specifies the number of Sd sessions for which close is initiated.

Terminated Sd sessions

Specifies the total number of Sd sessions terminated since the last reset of the counter.

CCR Sent

Specifies the number of Credit-Control-Request (CCR) requests of all types sent.

CCR Initial Sent

Specifies the number of Credit-Control-Request (CCR) Initial requests sent since the last reset of the counter.

CCR Update Sent

Specifies the number of Credit-Control-Request (CCR) Update requests sent since the last reset of the counter.

CCR Usage Monitoring Sent

Specifies the number of Credit-Control-Request (CCR) requests with usage monitoring report sent.

CCR Application Start Sent

Specifies the number of Credit-Control-Request (CCR) requests with application start report sent.

CCR Application Stop Sent

Specifies the number of Credit-Control-Request (CCR) requests with application stop report sent.

CCR Termination Sent

Specifies the number of Credit-Control-Request (CCR) Termination requests sent since the last reset of the counter.

CCA Received

Specifies the number of Credit-Control-Answer (CCA) responses of all types received.

CCA Initial Received

Specifies the number of Credit-Control-Answer (CCA) Initial responses received since the last reset of the counter.

CCA Update Received

Specifies the number of Credit-Control-Answer (CCA) Update responses received since the last reset of the counter.

CCA Usage Monitoring Received

Specifies the number of Credit-Control-Answer (CCA) responses with usage monitoring report ack received.

CCA Termination Received

Specifies the number of Credit-Control-Answer (CCA) Termination responses received since the last reset of the counter.

RAR Received

Specifies the number of Re-Auth-Request (RAR) requests received.

RAA Sent

Specifies the number of Re-Auth-Answer (RAA) responses sent.

You can reset the PEM sd statistics using reset-stats command.

EXAMPLES

show sd

Displays the PEM sd statistics.

reset-stats sd

Resets the PEM sd statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, pem stats action, pem stats gy, pem stats hsl, pem stats radius, pem stats subscriber, tmsh

BIG-IP 2016-03-14 pem stats sd(1)

pem stats subscriber

NAME

subscriber - Displays and resets PEM subscriber statistics.

MODULE

pem stats

SYNTAX

Display statistics for the subscriber component within the pem stats module using the syntax in the following section.

DISPLAY

show subscriber

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the subscriber component to display PEM subscriber statistics. The Current column represents count of sessions or other objects that exist at the moment. The Max column represents maximal count of sessions or other objects that ever existed at the same time. The Total column represents total count of sessions or other

objects that existed since the start or the last statistics reset. Some entries support only the Total column. The statistics details are described below:

Active subscriber sessions

Specifies the number of all subscriber sessions. Note that you can use the db component in the sys module to configure tmm.pem.spm.maxsessionlimit to set the number of subscribers supported per processing unit (TMM). Then, the max number of the subscribers per device is set accordingly.

Subscriber sessions marked for deletion

Specifies the number of sessions that were marked for deletion, but not yet deleted.

Dynamic subscriber sessions without data from RADIUS

Specifies the number of sessions related to non-static subscribers that were neither created by RADIUS accounting start message nor updated by RADIUS accounting interim message. This counter is not incremented for a session related to static subscriber, even if this session is created dynamically.

Subscriber sessions by state/Waiting for provisioning

Specifies the number of sessions that are pending for provision.

Subscriber sessions by state/Waiting for provisioning Hold Timeout

Specifies the number of sessions that are within the provisioning hold time period.

Subscriber sessions by state/Provisioned

Specifies the number of provisioned sessions.

Subscriber sessions by state/Failed provisioning

Specifies the number of sessions, which provisioning failed. Usually this state is temporary and these sessions will try to be reprovisioned.

Subscriber sessions by origin/Sessions discovered via RADIUS

Specifies the number of sessions, which were created by RADIUS accounting start message.

Subscriber sessions by origin/Sessions discovered via DHCP

Specifies the number of sessions, which were created by DHCP message.

Subscriber sessions by origin/Sessions discovered from traffic

Specifies the number of sessions, which were created by client traffic that doesn't correspond to any existing session.

Subscriber sessions by origin/Sessions discovered via iRules

Specifies the number of sessions, which were created by iRules using PEM::session create or other command.

Subscriber sessions by origin/Pre-configured Static Subscriber Sessions

Specifies the number of sessions, which were created for static subscriber with pre-configured IP-addresses.

Subscriber sessions provisioning source/Sessions provisioned via Gx

Specifies the number of sessions, which were provisioned from PCRF via Gx interface.

Subscriber sessions provisioning source/Sessions provisioned via Sd

Specifies the number of sessions, which were provisioned from PCRF via Sd interface.

Subscriber sessions provisioning source/Sessions provisioned via iRules

Specifies the number of sessions, which were provisioned by iRule command.

Subscriber sessions provisioning source/Sessions provisioned from static subscriber database

Specifies the number of sessions which policies were defined on creation of the corresponding static subscriber.

Subscriber sessions provisioning source/Sessions not provisioned (pending and failed)

Specifies the number of not provisioned sessions.

Subscriber session update statistics/Session updates received

Specifies total count of session update attempts, e.g. by RADIUS accounting interim message, Gx Credit-Control-Request (CCR) Update request or iRule command.

Subscriber session update statistics/Session updates applied successfully

Specifies total count of session update attempts that were successful.

Subscriber session update statistics/Session updates received via RADIUS

Specifies total count of session update attempts by RADIUS accounting interim message.

Subscriber session update statistics/Session updates received via Gx

Specifies total count of session update attempts by Gx Credit-Control-Request updates (CCR-U) or Re-Auth-Requests updates (RAR).

Subscriber session update statistics/Session updates received via Sd

Specifies total count of session update attempts by Sd Credit-Control-Request updates (CCR-U) or Re-Auth-Requests updates (RAR).

Subscriber session update statistics/Session updates received via iRules

Specifies total count of session update attempts by iRule command.

Subscriber session deletion statistics/Total sessions fully deleted

Specifies total count of completely deleted sessions.

Subscriber session deletion statistics/Sessions replaced

Specifies total count of sessions that were deleted because they were replaced by other sessions.

Subscriber session deletion statistics/Provisioned sessions deleted

Specifies total count of deleted sessions that had been provisioned at the moment of deletion.

Subscriber session deletion statistics/Waiting for provisioning sessions deleted

Specifies total count of deleted sessions that were pending for provisioning at the moment of deletion.

Subscriber session deletion statistics/Failed provisioning sessions deleted

Specifies total count of deleted sessions that were in provisioning failed state at the moment of deletion.

Subscriber session deletion statistics/Sessions deleted via RADIUS

Specifies total count of sessions deleted by RADIUS accounting stop message.

Subscriber session deletion statistics/Sessions deleted via Gx

Specifies total count of sessions deleted by Gx RAR-t message.

Subscriber session deletion statistics/Sessions deleted due to Gx connectivity problems

Specifies total count of sessions deleted by the Fatal Grace Time timer associated with a diameter endpoint.

Subscriber session deletion statistics/Sessions deleted via Sd

Specifies total count of sessions deleted by Sd RAR-t message.

Subscriber session deletion statistics/Sessions deleted due to Sd connectivity problems

Specifies total count of sessions deleted by the Fatal Grace Time timer associated with a diameter endpoint.

Subscriber session deletion statistics/Sessions deleted via DHCP

Specifies total count of sessions deleted by DHCP release message.

Subscriber session deletion statistics/Sessions deleted due to Inactivity

Specifies total count of sessions deleted due to inactivity for time configured in the `tmm.pem.session.inactivitytimeout` variable.

Subscriber session deletion statistics/Sessions deleted via iRules

Specifies total count of sessions deleted by iRule command.

Subscriber session deletion statistics/Sessions deleted administratively

Specifies total count of sessions deleted interactively by operator.

Subscriber session deletion statistics/Sessions deleted due to static subscriber removal

Specifies total count of sessions deleted due to deletion of the corresponding static subscriber. This includes sessions that were created by RADIUS accounting start message, but deleted by deletion of static subscriber.

Subscriber session deletion statistics/Pre-configured static subscriber sessions deleted

Specifies total count of deleted sessions, which policies were defined on creation of the corresponding static subscriber. This includes sessions that were configured in static subscriber, but created and deleted by RADIUS accounting messages.

Multiple IP address subscriber sessions/Active sessions with single IP address

Specifies the number of sessions, which are associated with one IP address.

Multiple IP address subscriber sessions/Active sessions with multiple IP addresses

Specifies the number of sessions, which are associated with more than one IP address.

Multiple IP address subscriber sessions/Active sessions with both IPv4 and IPv6 addresses

Specifies the number of sessions, which are associated with one or multiple IPv4 addresses and one or multiple IPv6 addresses

Multiple IP address subscriber sessions/Active sessions with more than one IPv4 address

Specifies the number of sessions, which are associated with more than one IPv4 address.

Multiple IP address subscriber sessions/Active sessions with more than one IPv6 address

Specifies the number of sessions, which are associated with more than one IPv6 address.

Multiple IP address subscriber sessions/Total session IPv4 addresses

Specifies the number of IPv4 addresses associated with existing sessions. IP address uniqueness is not checked, so if the same IP address is added and removed several times, the total counter is incremented the each time address is added.

Multiple IP address subscriber sessions/Total session IPv6 addresses

Specifies the number of IPv6 addresses associated with existing sessions. IP address uniqueness is not checked, so if the same IP address is added and removed several times, the total counter is incremented the each time address is added.

Multiple IP address subscriber sessions/Sessions provisioned after hold timeout

Specifies the number of sessions, which were put on provision hold and were provisioned after the provision hold period finished.

Multiple IP address subscriber sessions/Session IP addresses added after session is provisioned

Specifies the total number of IP addresses that were added to already provisioned sessions. IP address uniqueness is not checked, so if the same IP address is added and removed several times, this counter is incremented the each time address is added.

Multiple IP address subscriber sessions/Session IP addresses removed without session delete
Specifies the total number of IP addresses that were removed from existing sessions without session deletion. This is possible for sessions associated with multiple IP addresses.

Exceptions, Errors, Other Statistics/Failed provisioning attempts
Specifies the aggregated number of failed provisioning attempts for all subscribers in the system since the last reset of the counter. For example, a provisioning attempt fails if a policy server (PCRF) returns an error, or does not respond for any reason.

Exceptions, Errors, Other Statistics/Subscriber Limit Exceeded
Specifies the count of the session creation failures, which are caused by exceeding the max number of subscribers supported by one processing unit (TMM).

Exceptions, Errors, Other Statistics/Session IP address limit exceeded
Specifies the count of the session creation or update failures, which are caused by exceeding the max number of IP addresses per session.

Exceptions, Errors, Other Statistics/Attempts to remove non-existent session via RADIUS
Specifies the count of attempts to remove session by RADIUS accounting stop message, which failed because the session was not found.

Exceptions, Errors, Other Statistics/Attempts to remove non-existent session via DHCP
Specifies the count of attempts to remove session by DHCP release message, which failed because the session was not found.

Exceptions, Errors, Other Statistics/Attempts to remove non-existent session via Gx
Specifies the count of attempts to remove session by Gx RAR-t message, which failed because the session was not found.

Exceptions, Errors, Other Statistics/Attempts to remove non-existent session via Sd
Specifies the count of attempts to remove session by Sd RAR-t message, which failed because the session was not found.

Exceptions, Errors, Other Statistics/Attempts to remove non-existent session via iRules
Specifies the count of attempts to remove session by iRule command, which failed because the session was not found.

Exceptions, Errors, Other Statistics/Subscriber sessions with activity log enabled Specifies the number of sessions for which the activity log was enabled.

You can reset the PEM subscriber statistics using reset-stats command.

EXAMPLES

show subscriber

Displays the PEM subscriber statistics.

reset-stats subscriber

Resets the PEM subscriber statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

pem stats tethering

NAME

tethering - Displays and resets PEM tethering statistics.

MODULE

pem stats

SYNTAX

Display statistics for the tethering component within the pem stats module using the syntax in the following section.

DISPLAY
show tethering
option:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the tethering component to display PEM tethering statistics. The statistics details are described below:

Subscribers Monitored

Specifies the number of subscribers being monitored for tethering since the last reset of the counter.

Subscribers Tethering

Specifies the number of subscribers tethering since the last reset of the counter.

Subscribers Tethering Maximum

Specifies the maximum number of subscribers that were found to be tethering at any point since the last reset of the counter.

You can reset the PEM tethering statistics using reset-stats command.

EXAMPLES

show tethering

Displays the PEM tethering statistics.

reset-stats tethering

Resets the PEM tethering statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, pem stats action, pem stats gx, pem stats gy, pem stats radius, pem stats subscriber, pem stats hsl, tmsh

BIG-IP 2014-10-27 pem stats tethering(1)

pem subscriber-attribute

NAME

subscriber-attribute - Configures subscriber attributes in Policy Enforcement Manager (PEM).

MODULE

pem

SYNTAX

Configure the subscriber-attribute component within the pem module using the syntax shown in the following sections.

CREATE/EDIT/MODIFY

create subscriber-attribute [name]

modify subscriber-attribute [name]

options:

app-service [[string] | none]

description [string]

export [disabled | enabled]

import [disabled | enabled]

well-known-attr-id [called-station-id | calling-station-id | imeisv | imsi | ipaddr | not-defined | subs-id | user-location-info | username]

edit subscriber-attribute [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list subscriber-attribute

list subscriber-attribute [[[name] | [glob] | [regex]] ...]

show running-config subscriber-attribute

show running-config subscriber-attribute [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties
one-line
partition

DELETE

delete subscriber-attribute [name]

Note: You must remove all references to a subscriber-attribute before you can delete the subscriber-attribute.

DESCRIPTION

You can use the subscriber-attribute component to configure subscriber attribute definitions in Policy Enforcement Manager.

EXAMPLES

```
create subscriber-attribute 3gpp_imsi { import enabled export enabled well-known-attr-id imsi}
```

Creates a PEM subscriber attribute 3gpp_imsi with import enabled, export enabled, and well-known attribute id 'imsi'.

```
delete subscriber-attribute 3gpp_imsi
```

Deletes the PEM subscriber attribute named 3gpp_imsi.

```
list subscriber-attribute 3gpp_imsi
```

Displays the properties of the PEM subscriber attribute named 3gpp_imsi.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

export

Specifies whether the subscriber attribute can be exported (inserted) to the outgoing messages defined in pem protocol profile. This configuration is not applicable when referenced in pem protocol profile radius. It is applicable when referenced in pem protocol profile gx. The default value is enabled.

import

Specifies whether the subscriber attribute can be imported (parsed) from the incoming messages defined pem protocol profile. The default value is enabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the name of the administrative partition within which the subscriber attribute resides.

well-known-attr-id

Specifies an identifier of a well-known (build-in) subscriber attribute. The system provides a special handling for well-known subscriber attributes. For instance, most of the well-known attributes are included into session reporting records by default.

The options are:

called-station-id

The well-known subscriber attribute ID is called-station-id.

calling-station-id

The well-known subscriber attribute ID is calling-station-id.

imeisv

The well-known subscriber attribute ID is imeisv.

imsi The well-known subscriber attribute ID is imsi.

ipaddr

The well-known subscriber attribute ID is ipaddr. It can be ipv4 or ipv6 address.

not-defined

The well-known subscriber attribute ID is not defined. This is the default value.

subs-id

The well-known subscriber attribute ID is subs-id.

user-location-info

The well-known subscriber attribute ID is user-location-info.

username

The well-known subscriber attribute ID is username.

SEE ALSO

create, delete, edit, glob, list, modify, pem protocol profile gx, pem protocol profile radius, pem protocol

diameter-avp, pem protocol radius-avp, regex, show, tmsh

BIG-IP 2016-03-14 pem subscriber-attribute(1)

pem subscriber

NAME

subscriber - Configures subscribers for the Policy Enforcement Manager (PEM).

MODULE

pem

SYNTAX

Modify static subscriber component within PEM module using the syntax shown in the following sections.

CREATE/MODIFY

create subscriber [name]

modify subscriber [name]

options:

app-service [[string] | none]

ip-address-list [add | delete | replace-all-with] {
[ip address ...]

}

policies [add | delete | replace-all-with] {
[policy_name ...]

}

policies [default | none]

subscriber-id-type [dhcp | dhcp-custom | e164 | imsi | mac-address | mac-dhcp | nai | private]

edit subscriber [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list subscriber

list subscriber [[[name] | [glob] | [regex]] ...]

show running-config subscriber

show running-config subscriber [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete subscriber [name]

Note: You must remove all references to a subscriber before you can delete the subscriber.

DESCRIPTION

You can use the subscriber component to configure subscriber definitions for the Policy Enforcement Manager.

Subscriber session IP addresses may optionally include a route domain ID. When specified, the route domain ID follows the IP address, after '%' separator. For example, 10.10.10.100%5 is an IP address in route domain 5.

A subscriber session may have multiple IP addresses in different route domains.

EXAMPLES

```
create subscriber 4085551212 { ip-address-list add { 10.10.10.2 10.10.10.3 } policies add { policy1 }  
subscriber-id-type imsi }
```

Creates a PEM subscriber 4085551212 with IP addresses 10.10.10.2 and 10.10.10.3, subscriber id type imsi, and a policy policy1.

```
create subscriber 4085551212 { ip-address-list add { 10.10.10.2%5 10.10.10.3%77 } policies add { policy1 }  
subscriber-id-type imsi }
```

Creates a PEM subscriber 4085551212 with IP addresses 10.10.10.2 and 10.10.10.3 in route domains 5 and 77 respectively, subscriber id type imsi, and a policy policy1.

```
create subscriber 4085551212 { ip-address-list add { 10.10.10.2%5 10.10.10.2%77 } policies add { policy1 }  
subscriber-id-type imsi }
```

Creates a PEM subscriber 4085551212 with two IP address entries that consist of the same IP address 10.10.10.2 and different route domain IDs: 5 and 77, subscriber id type imsi, and a policy policy1.

delete subscriber sub1

Deletes the subscriber named sub1.

list subscriber sub1

Displays the properties of the subscriber named sub1.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies a unique subscriber identifier (up to 64 characters). This option is required for the commands create, delete, and modify.

ip-address-list

Adds, deletes, or replaces a list of the ip address to associate with the subscriber.

policies

Adds, deletes, or replaces a set of the policies to associate with the subscriber.

subscriber-id-type

Specifies the format to use for the subscriber id. The default value is imsi.

The options are:

dhcp For subscribers discovered via DHCP: an identifier comprises either Relay Option (option 82) for DHCPv4 based subscriber IDs or REMOTE-ID and SUBSCRIBER-ID Options (options 37 and 38) for DHCPv6, as configured in the corresponding DHCP profile.

dhcp-custom

For subscribers discovered via DHCP: an identifier created using a custom TCL snippet.

e164 A numbering plan that defines the format of an MSISDN international phone number (up to 15 digits). The number typically consists of three fields: country code, national destination code, and subscriber number.

imsi International Mobile Subscriber Identity. A globally unique code number that identifies a GSM, UMTS, or LTE mobile phone user.

mac-address

For subscribers discovered via DHCP: subscriber MAC address in a standard IEEE 802 format for MAC-48 (six groups of two hexadecimal digits, separated by colons ':').

mac-dhcp

For subscribers discovered via DHCP: a concatenation of mac-address and dhcp identifier as configured in the corresponding DHCP profile.

nai Network Access Identifier. A fully qualified network name in the form @; identifies a subscriber and the home network to which the subscriber belongs.

private

The subscriber id type is private for the given deployment.

pem subscribers

NAME

subscribers - Loads static subscribers for the Policy Enforcement Manager (PEM) from a file.

MODULE

pem

SYNTAX

Loads static subscribers from a file within the pem module using the syntax shown in the following sections.

LOAD

load subscribers file [filename]

DESCRIPTION

You can use the command load pem subscribers to load static subscribers definitions for the Policy Enforcement Manager (PEM). The maximum number of static subscribers allowed is (2 * sys db variable tmm.pem.spm.maxsessionlimit) or 100000, whichever is the lesser.

The static subscribers file is a csv file with the following fields: „[,]*[,]+“. Each record can have zero IP address but must have at least one policy.

The maximum number of IP addresses per subscriber is set by sys db variable tmm.pem.session.ip.addr.max.

The maximum number of IPv4 addresses per subscriber is set by sys db variable tmm.pem.session.ipv4.addr.max.

The maximum number of IPv6 addresses per subscriber is set by sys db variable tmm.pem.session.ipv6.addr.max.

For example, these are the examples from such file:

subscriber1,e164,2,11.1.1.1,11.1.1.2,bronze,gold,silver

subscriber2,imsi,0,gold

The filename either absolute file name or just the base file name under folder: /var/local/pem/subscribers/

For more information about static subscriber, please refer to pem subscriber module.

EXAMPLES

load subscribers file my_ss_file

Loads static subscribers from file "my_ss_file" under the folder: /var/local/pem/subscribers/.

load subscribers file /shared/tmp/new_ss_file

Loads static subscribers from file "new_ss_file" under the folder: /shared/tmp/.

security

security analytics settings

NAME

settings - Configure global settings for security (AFM) analytics.

MODULE

security analytics

SYNTAX

Configure the settings component within the security analytics module using the syntax shown in the following sections.

MODIFY

modify settings

options:

```
acl-rules {
  collect-client-ip [enabled | disabled]
  collect-client-port [enabled | disabled]
  collect-dest-ip [enabled | disabled]
  collect-dest-port [enabled | disabled]
  collect-server-side-stats [enabled | disabled]
}
```

```

collected-stats-internal-logging [enabled | disabled]
collected-stats-external-logging [enabled | disabled]
dns {
  collect-client-ip [enabled | disabled]
}
dos-l2-l4 {
  collect-client-ip [enabled | disabled]
}
l3-l4-errors {
  collect-client-ip [enabled | disabled]
  collect-dest-ip [enabled | disabled]
}
publisher [name]
smtp-config [name]
stale-rules {
  collect [enabled | disabled]
}

```

DISPLAY
list settings

DESCRIPTION

Use the settings component to modify the settings for analytics entity collection for the AFM (advanced firewall) module.

EXAMPLES

```
modify settings acl-rules { collect-client-ip disabled }
```

Disables source/client IP analytics collection for ACL rules.

```
list settings
```

Displays analytics settings for AFM.

OPTIONS

acl-rules
Firewall (ACL) security statistics collection options.

collect-client-ip
Specifies whether source/client IP address should be collected for ACL rule matching.

collect-client-port
Specifies whether source/client port should be collected for ACL rule matching.

collect-dest-ip
Specifies whether the destination IP address should be collected for ACL rule matching.

collect-dest-port
Specifies whether the destination port should be collected for ACL rule matching.

collect-server-side-stats
Specifies whether server side statistics (source address translation information, self IP address and pool member address) should be collected for ACL rule matching.

collected-stats-internal-logging
Enables or disables the internal logging of the collected statistics.

collected-stats-external-logging
Enables or disables the external logging of the collected statistics.

dns DNS security statistics collection options.

collect-client-ip
Specifies whether source/client IP address should be collected for DNS security.

dos-l2-l4
Network DoS security statistics collection options.

collect-client-ip
Specifies whether source/client IP address should be collected for network layer's DoS security.

l3-l4-errors
Firewall errors statistics collection options.

collect-client-ip
Specifies whether source/client IP address should be collected for firewall errors.

collect-dest-ip
Specifies whether the destination IP address should be collected for firewall errors.

publisher
Specifies the external logging publisher used to send statistical data to one or more destinations.

smtp-config
Specifies the default SMTP configuration used for exporting CSV or PDF security analytics reports.

stale-rules

collect
Specifies whether statistics about all firewall rules should be collected in order to present information regarding rule staleness.

security anti-fraud engine-update

NAME
engine-update - Runs or loads an Anti-fraud engine update.

MODULE
security anti-fraud

SYNTAX
Run or load the engine-update component within the security anti-fraud module using the syntax in the following sections:

LOAD
load engine-update
options:
file [filename]

If optional parameter file filename is specified in the load command, the command loads and installs engine update from local file instead of the cloud.

RUN
run engine-update

DISPLAY
list engine-update
options:
all-properties
current-version-create-datetime
download-available
install-datetime
install-user
message
non-default-properties
one-line
partition
progress-status
progress-status-datetime
last-update-check-datetime
readme

DESCRIPTION
You can use the engine-update component to run, load or display status of engine update.

EXAMPLES
list security anti-fraud engine-update

Displays the status of engine update.

OPTIONS
current-version-create-datetime
Displays the creation time of currently installed engine update version.

download-available
Displays whether new engine version is available for download from the cloud.

file Specifies the file name from which the engine update is going to be installed when using the load command. A full path should be specified.

install-datetime
Displays the time when engine update was installed.

install-user
Displays the name of the user who installed the last engine update.

message

Displays the message describing the failure status of engine update.

partition

Displays the administrative partition within which this object resides.

progress-status

Displays the engine update progress status.

progress-status-datetime

Displays the time when engine update progress status was last changed.

last-engine-check-datetime

Displays the time when last checked for engine update.

readme

Displays the Readme content for the current engine update.

SEE ALSO

DESCRIPTION
 You can use the profile component to create, modify, display, or delete an Anti-Fraud profile.

Note: The users property may be specified only for the commands modify, edit, and list and only when no other properties are specified. By default, users are not displayed.

Note: The first-login-time property of user modes may be specified only for the list command.

EXAMPLES
 create profile my_antifraud_profile

Creates a custom Anti-Fraud profile named my_antifraud_profile with default parameters.

list profile

Displays the properties of all Anti-Fraud profiles.

OPTIONS
 alert-client-side-caching
 Specifies whether or not to cache the sent alerts in order to prevent multiple alerts from being sent to the dashboard.

alert-identifier
 Specifies the ID of the customer in the dashboard.

alert-path
 Specifies the BIG-IP URL path where the alert is sent. This path cannot be none and must start with '/'.

alert-pool
 Specifies the name of the pool used when the system sends alerts.

alert-publisher
 Specifies the name of the log publisher used for sending alerts originating from the BIG-IP. If only DPS is licensed, this publisher is used for reporting encryption failures.

alert-token-header
 Specifies the name of the custom HTTP header in alerts for exchanging a random token between the client side and the BIG-IP.

app-layer-encryption
 Specifies how the system performs Application layer encryption. With Application layer encryption, the system detects an attempt to steal and tamper with end-user passwords (or other protected information), and also prevents it by encrypting the protected information. You can configure the following options for Application layer encryption:

fail-open
 Specifies, when enabled, that upon encryption error the system disables encryption in consecutive requests in the current session.

app-service
 Specifies the name of the application service to which the profile belongs. The default value is none.
 Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

auto-transactions

Specifies how the system differentiates between human and automatic (bot) transactions. You can configure the following options for automatic transactions:

bot-score

Deprecated since v13.0.0. Please use bot-score in auto-transactions under urls instead. Specifies the score added to an alert that is triggered if the system determines that the client is a bot and not a human. The default is a score of 50.

click-score

Deprecated since v13.0.0. Please use click-score in auto-transactions under urls instead. Specifies the score added to an alert that is triggered if the min-mouse-over-count and min-mouse-move-count conditions are not met. The default is a score of 40.

integrity-fail-score

Deprecated since v13.0.0. Please use integrity-fail-score in auto-transactions under urls instead. Specifies the score added to an alert that is triggered if the system detects a difference between the actual parameter value and the expected value of a protected parameter sent after a user clicks a web form's Submit button. The default is a score of 40.

min-mouse-move-count

Deprecated since v13.0.0. Please use min-mouse-move-count in auto-transactions under urls instead. Specifies the minimum number of mouse movements necessary per page load in order for the system to consider the transaction to be of human origin. The default is 5 movements.

min-mouse-over-count

Deprecated since v13.0.0. Please use min-mouse-over-count in auto-transactions under urls instead. Specifies the minimum number of times the client's mouse is positioned over the Submit button in a web form in order for the system to consider the transaction to be of human origin. The default is 2 button interactions.

min-report-score

Deprecated since v13.0.0. Please use min-report-score in auto-transactions under urls instead. Specifies the lowest score necessary for the system to send an alert. The default value is 50.

min-time-to-request

Deprecated since v13.0.0. Please use min-time-to-request in auto-transactions under urls instead. Specifies the minimum amount of time (in seconds) permitted between when a web form is opened and the Submit button is clicked. The default is 2 seconds.

not-human-score

Deprecated since v13.0.0. Please use not-human-score in auto-transactions under urls instead. Specifies the score added to an alert that is triggered if the system only suspects that the client is a bot and not a human. The default is a score of 25.

strong-integrity

Specifies how the system performs strong integrity. You can configure the following options for strong integrity:

hide-encrypted-parameters

Deprecated since v14.1.0. Please use attach-to-vtoken-report under parameters instead. Specifies, when enabled, that JavaScript does not add the expected value of encrypted parameters to strong integrity parameter.

parameter

Deprecated since v14.1.0. Specifies the name of the HTTP parameter in POST requests added by JavaScript with the expected user-input data verified with physical input events.

tampered-cookie-score

Deprecated since v13.0.0. Please use tampered-cookie-score in auto-transactions under urls instead. Specifies the score added to an alert that is triggered if the system detects that the transaction-data cookie was tampered with. The default is a score of 50.

time-fail-score

Deprecated since v13.0.0. Please use time-fail-score in auto-transactions under urls instead. Specifies the score added to an alert that is triggered if the min-time-to-request condition is not met. The default is a score of 20.

before-load-function

Specifies the implementation of additional function to be run before JavaScript load, in the following format: function(configs){...}. Note: For certain advanced configurations, F5 support may provide relevant code to be entered here, please do not use it on your own.

blocking-page

Specifies information to display when the profile blocks a user account. You can configure the following options for blocking page:

response-body

Specifies the HTML code the system sends to the user whose account is blocked.

response-headers

Specifies the set of response headers that the system sends to the user whose account is blocked. Separate each header with a new line (Ctrl-V followed by Ctrl-J).

[case-sensitive | case-insensitive]

Specifies whether the profile treats protected URL paths as case sensitive, or not. The default value is case-insensitive. Note: If you create a profile, you can use either property, thereafter it becomes read

only. If the profile is case insensitive, the system stores protected URL paths in lowercase in the profile configuration.

cloud-service-pool

Specifies the name of the pool used by the system for various internal purposes, like signing Forensics tool.

config-location

Specifies the BIG-IP URL directory where the configuration for the injected JavaScript is located. The path here does not include the actual filename of the configuration for the injected JavaScript. This path cannot be none and must start with '/'.

cookies

Specifies names and lifetimes for the cookies that the system uses to optimize its detection of malware, data transactions, and phishing attacks on the web application. If you do not assign a name to a cookie, a random name is assigned. You can configure the following cookies:

application

Adds, deletes, or replaces a set of application cookies that will be removed if at least one of the protected cookies is missing.

base-domain

Specifies base domain settings for the cookies. You can configure the following options for base domain:

apply

Specifies, when enabled, that the system applies the cookies to the base domain.

exceptions

Adds, deletes, or replaces a set of exceptional base domains that take precedence when the system resolves the base domain from a host header.

client-side

Specifies the name of the cookie in which the system inserts plain text with a record about client side alerts already sent. This is done in order to prevent flooding the system with additional alerts if the page reloads.

client-side-lifetime

Specifies whether the client-side cookie is persistent, and if so, after how many minutes it expires.

components-state

Specifies the name of the cookie that verifies that the system's expected JavaScript can run successfully, and whether the system successfully decrypted configuration data arriving from server.

components-state-lifetime

Specifies whether the components-state cookie is persistent, and if so, after how many minutes it expires.

components-state-removal-protection

Enables or disables removal detection for the secure-alert cookie.

encryption-disabled

Specifies the name of the cookie that the system adds if the system fails to decrypt a password (to restore the original password as the user typed it), and the system forwards a request to the server and waits for a login failure response. In this case, the cookie does not encrypt the password on the next login attempt. This is used in situations where Application layer encryption is not possible (for example, if the user is using an old browser that cannot encrypt passwords).

encryption-disabled-lifetime

Specifies whether the encryption-disabled cookie is persistent, and if so, after how many minutes it expires.

encryption-disabled-removal-protection

Enables or disables removal detection for the encryption-disabled cookie.

fingerprint

Specifies the name of the cookie that contains fingerprint data.

fingerprint-lifetime

Specifies whether the fingerprint cookie is persistent, and if so, after how many minutes it expires.

fingerprint-removal-protection

Enables or disables removal detection for the fingerprint cookie.

html-field-obfuscation

Specifies the name of the cookie that the system sets to identify the fields that were created by HTML field obfuscation, in order to remove them from the request before sending it back to the web application, and to know which field names to decrypt.

html-field-obfuscation-lifetime

Specifies whether the html-field-obfuscation cookie is persistent, and if so, after how many minutes it expires.

malware-forensic

Specifies the name of the cookie that stores the essential response header values from the web

application to be sent to the user after he finishes or skips downloading and running Forensics tool on his host.

malware-forensic-lifetime

Specifies whether the malware-forensic cookie is persistent, and if so, after how many minutes it expires.

malware-guid

Specifies the name of the cookie set by JavaScript to a random string (12 chars long, not encrypted). The system sends this cookie value in a special alert to the dashboard in order to associate it with the logged in user.

malware-guid-lifetime

Specifies whether the malware-guid cookie is persistent, and if so, after how many minutes it expires.

malware-guid-removal-protection

Enables or disables removal detection for the malware-guid cookie.

rules

Specifies the name of the cookie that the system sets in order to perform the actions block-user, forensic, inspection, remediation, or redirect.

rules-lifetime

Specifies whether the rules cookie is persistent, and if so, after how many minutes it expires.

rules-removal-protection

Enables or disables removal detection for the rules cookie.

secure-alert

Specifies the name of the cookie that secures arrival of alerts originating from JavaScript to the dashboard.

secure-alert-lifetime

Specifies whether the secure-alert cookie is persistent, and if so, after how many minutes it expires.

secure-alert-removal-protection

Enables or disables removal detection for the secure-alert cookie.

secure-channel

Specifies the name of the cookie that the system sets when the system provides JavaScript with a public key for encryption operations. This cookie is used for the system to correlate incoming encrypted data with the private key when a request comes from the client.

secure-channel-lifetime

Specifies whether the secure-channel cookie is persistent, and if so, after how many minutes it expires.

secure-channel-removal-protection

Enables or disables removal detection for the secure-channel cookie.

secure-mode

Specifies the status of secure mode, to set 'Secure' flag or not for all FPS cookies.

auto Specifies that secure mode for FPS cookies will be set automatically depending on connection type. enabled for HTTPS (SSL) connections and disabled for HTTP connections. This is the default value.

disabled

Specifies that secure mode for FPS cookies will be disabled and FPS cookies will not have 'Secure' flag.

enabled

Specifies that secure mode for FPS cookies will be enabled and all FPS cookies will have 'Secure' flag.

transaction-data

Specifies the name of the cookie that contains information (such as mouse movement, clicks, and events) in encrypted format and sends that information to the system.

transaction-data-lifetime

Specifies whether the transaction-data cookie is persistent, and if so, after how many minutes it expires.

user-inspection

Specifies the name of cookie that is set once a user is identified in a web form submitted by the client and this user is enforced in inspection mode.

user-name

Specifies the name of the cookie with the username value after a username is identified in a request. This ensures that further transactions from the client are still associated with that user even if they do not include the username field.

user-name-lifetime

Specifies whether the user-name cookie is persistent, and if so, after how many minutes it expires.

user-name-removal-protection
Enables or disables removal detection for the user-name cookie.

debug
Specifies troubleshooting settings to add and filter debug logs of the system. Note: Only F5 support should configure this section, please do not use it on your own. F5 support can configure the following debug options:

console-log
Specifies when the system add prints to browser console. TMM logs are also enabled in such cases. F5 support can configure the following options for console log:

client-ips
Adds, deletes, or replaces a set of client IP addresses for which the system adds prints to browser console.

user-agents
Adds, deletes, or replaces a set of strings contained in user-agent header for which the system adds prints to browser console.

fingerprints
Adds, deletes, or replaces a set of strings contained in fingerprint data for which the system adds prints to browser console.

send-alert
Specifies when the system sends debug alerts to the dashboard. TMM logs are also enabled in such cases. F5 support can configure the following options for sending alerts:

client-ips
Adds, deletes, or replaces a set of client IP addresses for which the system sends debug alerts to the dashboard.

user-agents
Adds, deletes, or replaces a set of strings contained in user-agent header for which the system sends debug alerts to the dashboard.

fingerprints
Adds, deletes, or replaces a set of strings contained in fingerprint data for which the system sends debug alerts to the dashboard.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified.

description
User defined description.

dummy-alert-html-maximum-length
Specifies the maximum length of HTML attached to dummy alert.

encryption-staging-mode
Specifies, when enabled, that the system activates Anti-fraud encryption staging mode. If decrypted data differs from original data, an alert will be sent and original data will be used.

fingerprint
Specifies how the system collects fingerprint data. You can configure the following fingerprint options:

collect
Specifies, when enabled, that the system collects fingerprint data.

location
Specifies the BIG-IP URL location of the fingerprint JavaScript. This path cannot be none and must start with '/'.

forensic
Specifies how the system enforces scanning client host for malware (Forensics) and its removal (remediation). You can configure the following options for Forensics and remediation:

alert-path
Specifies the BIG-IP URL path for alerts from Forensics tool. This path cannot be none and must start with '/'.

client-domains
Adds, deletes, or replaces a set of client domains to be resolved by Forensics tool.

cloud-config-path
Specifies the BIG-IP URL path for requests from Forensics tool to cloud-service-pool. This path cannot be none and must start with '/'.

cloud-forensics-mode
Specifies the numeric value sent to cloud-service-pool to download Forensics tool.

cloud-remediation-mode
Specifies the numeric value sent to cloud-service-pool to download Forensics tool in remediation mode.

continue-element

Specifies the HTML element with continue option that replaces %SKIP_PART% in the entire html, when enforce-policy is enforce. Note: This property may be modified only when the DB variable antifraud.forensic.showgui has value enable.

exe-location

Specifies the BIG-IP URL path to download Forensics tool that also replaces %EXE_LOCATION% in the entire html. This path cannot be none and must start with '/'.

html Specifies the HTML code the system sends to the user after successful login with option to download Forensics tool. Note: This property may be modified only when the DB variable antifraud.forensic.showgui has value enable.

self-post-location

Specifies the BIG-IP URL path for self POST page opened by Forensics tool during scanning. This path cannot be none and must start with '/'.

skip-element

Specifies the HTML element with skip option that replaces %SKIP_PART% in the entire html, when enforce-policy is not enforce. Note: This property may be modified only when the DB variable antifraud.forensic.showgui has value enable.

skip-path

Specifies the BIG-IP URL path for skip / continue option that also replaces %SKIP_PATH% in both continue-element and skip-element (before their replacement in the entire html). This path cannot be none and must start with '/'.

geolocation

Specifies, when enabled, that the client collects geolocation data which will be sent as part of the alert data.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

inject-main-javascript

Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies where the system injects the main JavaScript. You can configure the following options for main JavaScript injection position:

[after | before]

Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies whether the system injects the main JavaScript after an opening tag or before a closing tag.

tag Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies the HTML tag for injection of the main JavaScript. This tag cannot be none.

javascript-grace-threshold

Specifies the maximum amount of time (in seconds) permitted between when a protected web page is loaded and its injected JavaScript activates.

javascript-location

Specifies the BIG-IP URL directory where the injected JavaScript is located. The path here does not include the actual filename of the injected JavaScript. This path cannot be none and must start with '/'.

javascript-removal-location

Specifies the BIG-IP URL location of the JavaScript removal detection location. This path cannot be none and must start with '/'.

local-syslog-publisher

DPS mode only. Specifies the name of the log publisher used for reporting encryption failures.

malware

Specifies how the system detects a malware attack on the web application. You can configure the following options for Malware protection:

allowed-domains

Adds, deletes, or replaces a set of whitelisted domains. The system does not send alerts on requests for URLs from these domains, even if the system detects malware injection on these domains.

bait-check-generic

Specifies, when enabled, that the system checks predefined baits. Note: The configured baits are checked anyway.

bait-location

Specifies the BIG-IP URL location of a file that acts as bait for attackers. This path cannot be none and must start with '/'.

blacklist-words

Deprecated since v13.0.0. Please use blacklist-js-words and blacklist-words in detected-malware instead. Adds, deletes, or replaces a set of words that are blacklisted if they appear in the web application's HTML or JavaScript code. If the system detects these words, the system generates a malware alert.

detected-malware

Adds, deletes, or replaces a set of malware detected by the system. You can configure the following options for each malware:

baits

Adds, deletes, or replaces a set of baits for this malware. You can configure the following options for each bait:

data-before

Specifies the HTML code that the malware searches and injects data-inject after it.

data-inject

Specifies the malicious code that the malware injects after data-before.

trigger-url

Specifies trigger URL settings for this bait. You can configure the following options for trigger URL:

name Specifies the URL pattern that triggers the malware to inject malicious code.

position

Specifies the position of this URL pattern in the query string of a bait request.

alone

Specifies that this trigger URL must be alone in the query string of a bait request.

any Specifies that the this trigger URL can be anywhere in the query string of a bait request. This is the default value.

last Specifies that the this trigger URL must be last in the query string of a bait request.

blacklist-functions

Adds, deletes, or replaces a set of regular expression patterns to detect functions that this malware can use when executing AJAX requests.

blacklist-js-words

Adds, deletes, or replaces a set of words that are blacklisted if they appear in the JavaScript code. If the system detects these words, the system generates a malware alert.

blacklist-urls

Adds, deletes, or replaces a set of regular expression patterns to detect URLs that this malware can use for AJAX requests and external scripts.

blacklist-words

Adds, deletes, or replaces a set of words that are blacklisted if they appear in the web application's HTML code. If the system detects these words, the system generates a malware alert.

browser-cache

Specifies how the system checks client network connection as targeted method. You can configure the following options for Browser cache:

blacklist-urls

Adds, deletes, or replaces a set of resources that are loaded by the malware.

whitelist-urls

Adds, deletes, or replaces a set of non-existent resources.

domain-availability

Specifies how the system checks client network connection as generic method. You can configure the following options for Domain availability:

blacklist-urls

Adds, deletes, or replaces a set of URLs that are not blocked by the malware.

whitelist-urls

Adds, deletes, or replaces a set of URLs that are blocked by the malware.

dom-signatures

Adds, deletes, or replaces a set of DOM signatures for this malware. You can configure the following options for each DOM signature:

attribute-name

Specifies the name of the attribute in which the pattern should be search for. Used only if search-in is attribute.

hash-id

Specifies unique ID that identifies this DOM signature in profile.

html-tag

Specifies the name of the HTML tag in which the pattern should be search for.

match-type

Specifies the type of DOM signature pattern matching.

contains

Specifies that this DOM signature pattern should be matched as partial match (not applicable when search-in is js-global-variable).

is Specifies that this DOM signature pattern should be matched as exact match.

search-for
Specifies the DOM signature pattern to search for.

search-in
Specifies search location for DOM signature.

all Specifies that this DOM signature should be searched in all locations.

attribute
Specifies that this DOM signature pattern should be searched only in an attribute with name attribute-name.

html Specifies that this DOM signature pattern should be searched only in HTML.

js-global-variable
Specifies that this DOM signature pattern should be searched only in JavaScript global variables (match-type contains not applicable in such case).

text Specifies that this DOM signature pattern should be searched only in text.

generic-whitelist-words
Deprecated since v15.0.0. Please use whitelist-dom-signatures in urls instead. Adds, deletes, or replaces a set of generic blacklisted words that are ignored.

domain-availability-urls
Deprecated since v13.0.0. Please use blacklist-urls and whitelist-urls in domain-availability under detected-malware instead. Specifies a JSON object containing URLs for which client network connectivity should be checked.

external-sources-targets
Adds, deletes, or replaces a set of HTML element types and their attributes for which external injections should be checked.

flash-cookie-content
Specifies the flash file (in hexadecimal format) used to allow JavaScript to access the Flash object on the client side. The default content is none. The length is limited to 64k.

flash-cookie-location
Specifies the BIG-IP URL location of the SWF file that JavaScript requests to get the Flash file. This path cannot be none and must start with '/'.

flash-cookies
Specifies, when enabled, that the system may use a Flash shared object (FSO) as a place to store an alternative malware cookie. This cookie tells the system, after a login attempt, that this user has malware, and the system sends an alert.

generic-whitelist-words
Deprecated since v13.0.0. Please use generic-whitelist-words in detected-malware instead. Adds, deletes, or replaces a set of generic blacklisted words that are ignored.

inline-scripts-whitelist-signatures
Adds, deletes, or replaces a set of signatures for allowed inline scripts. In case a signature appears as part of JavaScript inline script, the system does not count this script in the source integrity feature.

removed-scripts
Specifies how the system detects self-removed malicious scripts. You can configure the following options for removed scripts detection:

blacklist-functions
Adds, deletes, or replaces a set of functions that are used for detecting self-removed malicious scripts.

whitelist-functions
Adds, deletes, or replaces a set of functions that are NOT used for detecting self-removed malicious scripts.

same-domain-scripts-validation-header
Specifies the name of the custom HTTP header used to identify PING-PONG requests between JavaScript and BIG-IP for same-domain scripts validations. This name cannot be none.

self-bait-header
Specifies the name of the custom HTTP header used to identify self-bait requests from JavaScript to BIG-IP for malicious injections scan. This name cannot be none.

source-integrity-location
Specifies the BIG-IP URL path where the system collects information about the HTML source from multiple users. This path cannot be none and must start with '/'.

web-rootkit
Specifies how the system detects Web-RootKit malware. You can configure the following options for Web-RootKit detection:

blacklist-functions
Adds, deletes, or replaces a set of additional functions to be checked.

whitelist-functions

Adds, deletes, or replaces a set of native functions that are allowed to be overwritten.

mobilesafe

Specifies how the system detects and prevents phishing, Trojan, and pharming attacks on mobile devices in real time. You can configure the following options for mobile security:

alert-custom-config

Specifies alert custom configuration for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

alert-threshold

Specifies the minimal score for sending alerts from mobile devices.

app-integrity

Specifies how the system checks if the application on the mobile device has been tampered with. You can configure the following options for Application integrity:

custom-config

Specifies custom configuration of Application integrity for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

[enabled | disabled]

Enables or disables Application integrity.

android

Specifies Application integrity settings for Android platform. You can configure the following options for Android Application integrity:

score

Specifies Application integrity score for Android platform.

signature

Specifies signature of Android application (in hexadecimal format).

ios Specifies Application integrity settings for iOS platform. You can configure the following options for iOS Application integrity:

hashes

Adds, deletes, or replaces a set of iOS Application hashes (in base64-encoded format). You can configure the following options for iOS Application hash:

version

Specifies iOS Application version for this hash.

score

Specifies Application integrity score for iOS platform.

general-custom-config

Specifies general custom configuration for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

malware

Specifies how the system checks for malicious applications on the customer's mobile devices. You can configure the following options for Malware detection:

android

Specifies Malware detection settings for Android platform. You can configure the following options for Android Malware detection:

custom-malware

Adds, deletes, or replaces a custom set of checked malware for Android platform. You can configure the following options for each Android malware:

package

Specifies package of checked Android malware.

score

Specifies score for checked Android malware.

custom-whitelist

Adds, deletes, or replaces a custom set of whitelist applications for Android platform. You can configure the following options for each whitelist Android application:

package

Specifies package of whitelist Android application.

check-custom

Enables or disables custom malware check.

check-generic

Enables or disables generic malware check.

custom-config

Specifies custom configuration of Malware detection for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

[enabled | disabled]

Enables or disables Malware detection.

ios Specifies Malware detection settings for iOS platform. You can configure the following options for iOS Malware detection:

custom-malware

Adds, deletes, or replaces a custom set of checked malware for iOS platform. You can configure the following options for each iOS malware:

path Specifies path of checked iOS malware.

score

Specifies score for checked iOS malware.

custom-whitelist

Adds, deletes, or replaces a custom set of whitelist applications for iOS platform. You can configure the following options for each whitelist iOS application:

path Specifies path of whitelist iOS application.

behaviour-analysis

Specifies how the system checks for suspicious behavior and characteristics on all applications on the customer's mobile devices. You can configure the following options for behavior analysis:

run Enables or disables behaviour analysis run.

score

Specifies score for behavior analysis.

mitm Specifies how the system checks the defined domains for DNS Spoofing and Certificate Forging on customer devices. You can configure the following options for Man-in-the-middle detection:

certificate-custom-config

Specifies custom configuration of Certificate forging detection for SDK forward compatibility.

Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

dns-custom-config

Specifies custom configuration of DNS spoofing detection for SDK forward compatibility. Note:

For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

domains

Adds, deletes, or replaces a set of domains for Man-in-the-middle detection. You can configure the following options for a MITM domain:

dns Specifies DNS spoofing detection settings for this domain. You can configure the following options for DNS spoofing detection:

ip-ranges

Adds, deletes, or replaces a set of IP address ranges for DNS spoofing detection.

spoofing-score

Specifies score for DNS spoofing detection.

certificate

Specifies Certificate forging detection settings for this domain. You can configure the following options for Certificate forging detection:

forging-score

Specifies score for Certificate forging detection.

hash Specifies certificate hash.

[enabled | disabled]

Enables or disables Man-in-the-middle detection.

os-security

Specifies how the system checks the customer's mobile devices for old, unsupported, and unpatched operation system (OS) versions. You can configure the following options for OS security:

android

Specifies OS security settings for Android platform. You can configure the following options for Android OS security:

versions

Adds, deletes, or replaces an ordered set of version ranges for Android platform. You can configure the following options for Android version range:

from Specifies Android version number from which OS is unpatched.

priority

Specifies a unique ordinal number for Android version range in the set. This option is required for the operations add, delete, modify, and replace-all-with.

score

Specifies score for Android version range.

to Specifies Android version number to which OS is unpatched.

custom-config

Specifies custom configuration of OS security for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

[enabled | disabled]

Enables or disables OS security.

ios Specifies OS security settings for iOS platform. You can configure the following options for iOS OS security:

versions

Adds, deletes, or replaces an ordered set of version ranges for iOS platform. You can configure the following options for iOS version range:

from Specifies iOS version number from which OS is unpatched.

priority

Specifies a unique ordinal number for iOS version range in the set. This option is required for the operations add, delete, modify, and replace-all-with.

score

Specifies score for iOS version range.

to Specifies iOS version number to which OS is unpatched.

untrusted-apps-score

Specifies score for untrusted applications.

rooting-jailbreak

Specifies how the system checks customer's mobile devices to determine if they are rooted / jailbroken. You can configure the following options for Rooting / Jailbreak detection:

custom-config

Specifies custom configuration of Rooting / Jailbreak detection for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

[enabled | disabled]

Enables or disables Rooting / Jailbreak detection.

jailbreak-score

Specifies score for jailbreak on iOS platform.

rooting-score

Specifies score for rooting on Android platform.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

phishing

Specifies how the system detects a phishing attempt. You can configure the following options for phishing site detection:

alert-path

Specifies the BIG-IP URL path for alerts from the phishing inline script. This path cannot be none and must start with '/'.

allowed-elements

Adds, deletes, or replaces a set of URLs in requests for which the system does not verify (check) the referrer header value.

allowed-referrers

Adds, deletes, or replaces a set of domain names that are allowed to appear in the referrer header when requesting protected resources.

application-css

Specifies, when enabled, that the system injects the CSS content to the existing application CSS files.

application-css-locations

Adds, deletes, or replaces a set of server URL locations of the application CSS files, used when application-css is enabled.

css-attribute-name
Specifies the attribute name as part of the CSS content. This name cannot be none.

css-location
Specifies the BIG-IP URL location of the CSS file, used when application-css is disabled. Injecting JavaScript protects the web application against phishing attempts because even if an attacker removes the injected JavaScript from the copied web page, the CSS element is not modified, and this triggers an alert. This path cannot be none and must start with '/'.

expiration-checks
Specifies, when enabled, that the system sends an alert if expired JavaScript engine files are used, as this is an indication of a phishing attack.

image-location
Specifies the BIG-IP URL location of the 1x1 pixel image file. If an attacker copies a web page with this image, it most likely lacks the JavaScript, and this triggers an alert. This path cannot be none and must start with '/'.

inject-css-element
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies where the system injects the CSS element. You can configure the following options for CSS element injection position:

[after | before]
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies whether the system injects the CSS element after an opening tag or before a closing tag.

tag Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies the HTML tag for injection of the CSS element. This tag cannot be none.

inject-css-link
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies where the system injects the CSS link, when application-css is disabled. You can configure the following options for CSS link injection position:

[after | before]
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies whether the system injects the CSS link after an opening tag or before a closing tag.

tag Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies the HTML tag for injection of the CSS link. This tag cannot be none.

inject-inline-javascript
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies where the system injects the phishing inline script and image. You can configure the following options for phishing inline script and image injection position:

[after | before]
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies whether the system injects the phishing inline script and image after an opening tag or before a closing tag.

tag Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies the HTML tag for injection of the phishing inline script and image. This tag cannot be none.

protected-elements
Adds, deletes, or replaces a set of URLs in requests for which the system verifies (checks) the referrer header value. You can use wildcards, for example *.gif.

referrer-checks
Specifies, when enabled, that the system verifies (checks) requests coming to the web application for resources from different domains.

referrer-info-header
Specifies the name of the custom HTTP header used by client side to communicate referrer and view identifier to BIG-IP.

risk-engine-path
Specifies the BIG-IP URL path to where a risk-engine report is sent by client. This path cannot be none and must start with '/'.

risk-engine-publisher
Specifies the name of the log publisher used for reports to a Risk engine.

rules
Adds, deletes, or replaces a set of rules used by the system to perform actions upon detected events. You can configure the following options for each rule:

action
Specifies the type of the action that the system performs when this event is detected. The options are:

block-user
Specifies that the system adds the user with block mode to be enforced from the next login.

forensic

Specifies that the system adds the user with forensic mode to be enforced from the next login.

inspection

Specifies that the system adds the user with inspection mode to be enforced from the next login.

redirect

Specifies that the system redirects the next request to a specific web page.

remediation

Specifies that the system adds the user with remediation mode to be enforced from the next login.

route

Deprecated in v13.1.0. Specifies that the system routes to a specific pool all subsequent requests for a specific time.

web-service

Specifies that the system sends a POST request to a specific Web service.

duration

Specifies number of minutes during which the system performs the action block-user, forensic, inspection, remediation or route.

enforce-policy

Specifies enforcement policy for the action block-user, forensic, inspection or remediation. The options are:

enforce

Specifies that the system adds the user mode with the enforce policy.

time-limited

Specifies that the system adds the user mode with the time-limited policy.

unlimited

Specifies that the system adds the user mode with the unlimited policy.

event

Specifies a unique event for the rule. This option is required for the operations create, delete, modify, and replace-all-with. The options are:

auto-transaction

Specifies that the action is performed when the system detects automatic (bot) transaction.

client-network-connection

Specifies that the action is performed when the system detects that client network connectivity is blocked.

client-side-missing-components

Specifies that the action is performed when the system detects missing components on the client side.

encryption-failure

Specifies that the action is performed when the system fails to decrypt a password.

generic-malware

Specifies that the action is performed when the system detects generic malware.

mandatory-words

Specifies that the action is performed when the system detects that mandatory words are changed in the page.

phishing

Specifies that the action is performed when the system detects a phishing attempt.

phishing-user

Specifies that the action is performed when the system detects a user attacked by a phishing attempt.

rat-detection

Specifies that the action is performed when the system detects a Remote Access Trojan (RAT) on a client web browser.

referrer-checks

Specifies that the action is performed when the system detects a request from a different domain by the referrer header.

server-side-missing-components

Specifies that the action is performed when the system detects missing components on the BIG-IP.

source-integrity

Specifies that the action is performed when the system detects a mismatch of the URL's HTML source code.

web-injection

Specifies that the action is performed when the system detects an attempt to inject malware.

min-score

Specifies the lowest score of this event necessary for the system to perform the action.

payload

Specifies the payload for the web-service action.

pool Specifies the name of the pool for the route action.

publisher

Specifies the name of the log publisher for the web-service action.

url Specifies the URL for the action redirect or web-service.

suggested-username-header

Specifies the name of the custom HTTP header in AJAX requests added by JavaScript with a username value identified on the client side.

trigger-irule

Specifies, when enabled, that the system activates Anti-fraud iRule events. The default value is disabled.

urls Adds, deletes, or replaces a set of URLs in the web application that are protected by the system. You can configure the following options for a protected URL:

app-layer-encryption

Specifies how the system performs Application layer encryption for this URL. With Application layer encryption, the system detects an attempt to steal and tamper with end-user passwords (or other protected information), and also prevents it by encrypting the protected information. You can configure the following options for Application layer encryption:

add-decoy-inputs

Specifies, when enabled, that the system randomly and continuously generates and removes decoy fields that are added to the web page, thus making it harder for an attacker to identify sensitive information with either JavaScript or a proxy. In order to enable it, you must first enable html-field-obfuscation.

auto-complete-block

Specifies, when enabled, that the system prevents auto-complete functionality in browser.

auto-complete-whitelist-functions

Specifies a list of customer-specific global functions that require access to the value of a parameter with substitute-value enabled.

custom-encryption-function

Specifies the name or implementation of custom encryption function to be run instead of built-in encryption.

[enabled | disabled]

Specifies whether the system protects this URL with Application layer encryption, and sends an alert if an attacker attempts to breach Application layer encryption for this URL, or not.

fake-strokes

Specifies, when enabled, that the system protects against in-browser key loggers by generating fake keyboard events.

full-ajax-encryption

Specifies, when enabled, that the system encrypts the full AJAX payload.

hide-password-revealer

Specifies, when enabled, that the system hides the password revealer icon found in web pages.

html-field-obfuscation

Specifies, when enabled, that the system encrypts the names of defined fields on the client, and then decrypts them back to the original names on the BIG-IP.

real-time-encryption

Specifies, when enabled, that the system encrypts passwords as they are typed (even before the user clicks the Submit button in a web form).

remove-element-ids

Specifies, when enabled, that the system removes the ID attribute from the fields in a web form. In order to enable it, you must first enable html-field-obfuscation.

remove-event-listeners

Specifies, when enabled, that the system removes event listeners from the encrypted fields in a web form.

stolen-creds

Specifies, when enabled, that the system examines whether the user was trying to use a fabricated password.

substitute-value-function

Specifies a JavaScript function that receives the real password as an argument and returns a

fake value.

auto-transactions

Specifies how the system protects this URL from automatic (bot) transactions. You can configure the following options for Automated transactions detection:

attach-ajax-payload-to-alerts

Specifies whether to attach the actual AJAX payload to alerts. Use the DB variable `antifraud.antifraud.maxalertrequestsize` to limit the attached payload size.

bot-score

Specifies the score added to an alert that is triggered if the system determines that the client is a bot and not a human. The default is a score of 50.

browser

Specifies, when enabled, that the system looks for bot automation performed within the browser.

click-score

Specifies the score added to an alert that is triggered if the min-mouse-over-count and min-mouse-move-count conditions are not met. The default is a score of 40.

[enabled | disabled]

Specifies whether the system protects this URL against non-human transactions, and sends an alert if the system detects a non-human transaction attempt for this URL, or not.

full-ajax-integrity

Specifies, when enabled, that the system verifies whether the full AJAX payload was changed by malware when it left the browser for the server.

integrity-fail-score

Specifies the score added to an alert that is triggered if the system detects a difference between the actual parameter value and the expected value of a protected parameter sent after a user clicks a web form's Submit button. The default is a score of 40.

integrity-fail-max-score

Specifies the maximal score added to an alert that is triggered if the system detects a difference between the actual parameter value and the expected value of a protected parameter sent after a user clicks a web form's Submit button. The default is a score of 100

min-mouse-move-count

Specifies the minimum number of mouse movements necessary per page load in order for the system to consider the transaction to be of human origin. The default is 5 movements.

min-mouse-over-count

Specifies the minimum number of times the client's mouse is positioned over the Submit button in a web form in order for the system to consider the transaction to be of human origin. The default is 2 button interactions.

min-report-score

Specifies the lowest score necessary for the system to send an alert. The default value is 50.

min-time-to-request

Specifies the minimum amount of time (in seconds) permitted between when a web form is opened and the Submit button is clicked. The default is 2 seconds.

non-browser

Specifies, when enabled, that the system looks for bot automation performed not within the browser.

not-human-score

Specifies the score added to an alert that is triggered if the system only suspects that the client is a bot and not a human. The default is a score of 25.

strong-integrity

Specifies, when enabled, that Enhanced Data Integrity is active. When Enhanced Data Integrity is active, the system detects a difference between the actual parameter value and the expected value of a protected parameter verified with physical input events.

strong-integrity-user-functions

Adds, deletes, or replaces a set of configures a list of customer functions that change a parameter value protected by Enhanced Data Integrity.

submit-buttons

Adds, deletes, or replaces a set of non-standard Submit buttons found in forms of the web application. You can specify the name, or the CSS syntax (ID, class, or tagname) for each button.

tampered-cookie-score

Specifies the score added to an alert that is triggered if the system detects that the transaction-data cookie was tampered with. The default is a score of 50.

time-fail-score

Specifies the score added to an alert that is triggered if the min-time-to-request condition is not met. The default is a score of 20.

custom-alerts

Adds, deletes, or replaces a set of user-defined alerts sent by the system upon searches in

different parts of the request. You can configure the following options for each user-defined alert:

attach-request-part

Specifies whether to attach the original client-side request to this alert.

component

Specifies the alert component that the system sends in this alert. Select either: malware (the default value), phishing, auto-transactions, or mobilesafes.

header-name

Specifies a header name in which the system searches for the value when search-in is header.

malware-name

Specifies the malware detected by this alert when component is malware.

message

Specifies the user-defined message that the system sends in this alert.

search-in

Specifies the part of the request where the system must find the value to send this alert.

Note: If you create a user-defined alert, you can use either request part, thereafter it becomes read only.

client-ip

Specifies that the systems sends this alert if the client IP address equals to the value.

header

Specifies that the systems sends this alert if the header-name header contains the value.

payload

Specifies that the systems sends this alert if the request payload contains the value.

query-string

Specifies that the systems sends this alert if the URL query string contains the value.

value

Specifies a value that the system searches for in the search-in part of the request. The default value is none, which means that the system searches for any value.

before-load-function

Specifies the implementation of additional function to be run before JavaScript load, in the following format: function(configs){...}. Note: For certain advanced configurations, F5 support may provide relevant code to be entered here, please do not use it on your own.

description

Specifies an optional description of this URL.

destination-urls

Specifies a list of destination URLs for requests from SPA URLs/Views.

fallback-to-base-url

Specifies if a request to a non-configured view should use same configuration as the base URL or disable FPS for that request.

include-query-string

Specifies, when enabled, that the system includes query string of URLs to match this wildcard expression. The default value is disabled.

inject-javascript

Enables or disables JavaScript injection into responses to this URL. The default value is enabled.

inject-main-javascript

Specifies where the system injects the main JavaScript. You can configure the following options for main JavaScript injection position:

[after | before]

Specifies whether the system injects the main JavaScript after an opening tag or before a closing tag.

tag Specifies the HTML tag for injection of the main JavaScript. This tag cannot be none.

inject-javascript-removal

Specifies where the system injects the JavaScript removal detection image. You can configure the following options for JavaScript removal detection image injection position:

[after | before]

Specifies whether the system injects the JavaScript removal detection image after an opening tag or before a closing tag.

tag Specifies the HTML tag for injection of the JavaScript removal detection image. This tag cannot be none.

login-response

Specifies validation criteria on the response of this URL when it is Login page. You must configure at least one of them. If you configure more than one validation criteria, then all the criteria must be fulfilled for successful login. You can configure the following Login page properties:

status-code

Specifies an HTTP response status code that the server must return to the user upon successful login.

domain-cookie

Specifies a defined domain cookie that the successful response to the login URL must include.

exclude-string

Specifies a string that should NOT appear in the successful response to the login URL.

header

Specifies a header name and value that the successful response to the login URL must match.

include-string

Specifies a string that should appear in the successful response to the login URL.

validation

Enables or disables successful login validation.

malware

Specifies when the system detects attempts of attackers to inject malware in the URL. You can configure the following options for Malware detection:

attach-html-to-alerts

Specifies, when enabled, that the system attaches forensics information along with the alerts.

auto-learn-form-tags

Specifies, when enabled, that the system learns the number of HTML form tags that appear in the URL. In order to enable it, you must first enable source-integrity.

auto-learn-input-tags

Specifies, when enabled, that the system learns the number of HTML input tags that appear in the URL. In order to enable it, you must first enable source-integrity.

auto-learn-script-tags

Specifies, when enabled, that the system learns the number of HTML script tags that appear in the URL. In order to enable it, you must first enable source-integrity.

blocked-enter-key-detection

Specifies, when enabled, that the system detects blocked "Enter" key.

deferred-execution

Specifies, when enabled, that the system detects deferred execution attack.

domain-availability

Specifies, when enabled, that the system checks that client network connectivity is not blocked by malware.

enable-symbols

Specifies, when enabled, that the system looks for malware strings (signatures) within JavaScript.

[enabled | disabled]

Specifies whether the system protects this URL against injected malware, and sends an alert if this URL is detected to have malware, or not.

external-injection

Specifies, when enabled, that the system detects malicious scripts injected from domains not in the profile's allowed-domains.

generic-malware

Specifies, when enabled, that the system applies the detection of generic malware, using honeypots.

manual-count-form-tags

Specifies the number of HTML forms that appear in the URL.

manual-count-input-tags

Specifies the number of HTML inputs that appear in the URL.

manual-count-script-tags

Specifies the number of HTML scripts that appear in the URL.

password-exfiltration-detection

When enabled, the system detects attempts to steal the user's password in the web browser. An alert is triggered if such an attempt is detected.

rat-detection

Specifies, when enabled, that the system checks for Remote Access Trojans (RATs) on clients' web browsers.

removed-scripts-detection

Specifies, when enabled, that the system detects malicious scripts that removed their own injection from the DOM.

same-domain-scripts-validation

Specifies, when enabled, that the system detects malicious responds to same-domain scripts.

self-bait

Specifies, when enabled, that the system scans the original source code of the page for malicious injections.

source-integrity

Specifies, when enabled, that the system verifies that the URL's HTML source code matches the HTML code sent from the server. The source integrity feature counts script tags that are external (with src) and inline (without src).

vbkclip-detection

Specifies, when enabled, that the system checks for VBKlip malware.

visibility-check

Specifies, when enabled, that the system searches HTML pages for words from visibility-check-items.

visibility-check-items

Adds, deletes, or replaces a set of words that must appear in the web site's HTML pages and may not be changed. If these words are changed, the system sends an alert.

web-rootkit-detection

Specifies, when enabled, that the system detects malware that overwrites native browser functions.

whitelist-dom-signatures

Adds, deletes, or replaces a set of hash-IDs of DOM signatures that are permitted to appear in requests for this URL, even though they are otherwise blacklisted by the system for other URLs.

whitelist-words

Deprecated since v15.0.0. Please use 'whitelist-dom-signatures' configuration instead. Adds, deletes, or replaces a set of words that are permitted to appear in requests for this URL, even though they are otherwise blacklisted by the system for other URLs.

mobilesafe-encryption

Specifies, when enabled, that the system protects requests for this URL from mobile devices with Application layer encryption.

parameters

Adds, deletes, or replaces a set of sensitive parameters protected by the system. You can configure the following options for each parameter:

ajax-mapping

Specifies the mapping between the parameter name and its location in AJAX payload.

attach-to-vtoken-report

Specifies, when enabled, that the system adds the parameter value data to the alerts.

check-integrity

Specifies, when enabled, that the system verifies whether the user-input data was changed by malware when it left the browser for the server.

encrypt

Specifies, when enabled, that the system encrypts the parameter's value attribute.

identify-as-username

Specifies, when enabled, that the system considers this parameter a username. Note: There may be only one such parameter per URL, and its value is used only when login is successful (according to the URL's login-response).

method

Deprecated since v14.1.0. Please use parameter 'search-in' configuration instead. Specifies the method of the request from which the system gets the parameter data. Select either: POST (the default value) or GET.

mobilesafe-encrypt

Specifies that this parameter contains the encrypted fields from mobile devices. Note: There may be only one such parameter per URL (usually called auth), it cannot have other settings enabled and its method must be POST.

mobilesafe-entangle

Specifies that this parameter must be encrypted by mobile devices. The system replaces its value in the request payload and sends an alert if the mobilesafe-encrypt parameter does not contain this field.

obfuscate

Specifies, when enabled, that the system encrypts the parameter's name attribute.

priority

Specifies a unique ordinal number for this parameter in the set of wildcard parameters.

protect-by-selector

Specifies, when enabled, that the client considers this parameter's name to be a CSS selector. Note: To enable it, the parameter name must be defined as explicit and you must enable full-ajax-encryption.

search-in

Specifies the request part from which the system gets the parameter data. Select either: payload or query-string or any (the default value). If any is selected, then the query string will be searched first and only if the parameter is not found there, the payload will be also searched in.

substitute-value

Specifies, when enabled, that the system substitutes the parameter's value with asterisks [*] in the web application while the form is being filled. In order to enable it, you must first enable encrypt.

type Specifies a type of the parameter. Note: If you create a parameter, you can use either type, thereafter it becomes read only. The options are:

explicit

Specifies that the parameter has an exact path. This is the default value.

wildcard

Specifies that any parameter that matches this wildcard expression is considered protected.

phishing

Specifies when the system detects phishing attempts by attackers who set up a fake URL that imitates the real URL. You can configure the following options for Phishing detection:

capture-users

Specifies, when enabled, that the system logs the usernames and text fields (not passwords) of users attacked by a phishing attempt.

copy-detection

Specifies, when enabled, that the system detects copied web pages.

css-protection

Specifies, when enabled, that the system activates the CSS module, which is part of the system's phishing detection backup mechanism.

[enabled | disabled]

Specifies whether the system protects this URL against phishing, and sends an alert if the system detects this URL to be under a phishing attempt, or not.

field-types-to-send

Adds, deletes, or replaces a set of HTML input types whose values should be included in phishing alerts.

inject-css-element

Specifies where the system injects the CSS element. You can configure the following options for CSS element injection position:

[after | before]

Specifies whether the system injects the CSS element after an opening tag or before a closing tag.

tag Specifies the HTML tag for injection of the CSS element. This tag cannot be none.

inject-css-link

Specifies where the system injects the CSS link, when application-css is disabled. You can configure the following options for CSS link injection position:

[after | before]

Specifies whether the system injects the CSS link after an opening tag or before a closing tag.

tag Specifies the HTML tag for injection of the CSS link. This tag cannot be none.

inject-inline-javascript

Specifies where the system injects the phishing inline script and image. You can configure the following options for phishing inline script and image injection position:

[after | before]

Specifies whether the system injects the phishing inline script and image after an opening tag or before a closing tag.

tag Specifies the HTML tag for injection of the phishing inline script and image. This tag cannot be none.

priority

Specifies a unique ordinal number for this URL in the set of wildcard URLs.

type Specifies a type of the URL. Note: If you create a URL, you can use either type, thereafter it becomes read only. The options are:

explicit

Specifies that the URL has an exact path. This is the default value.

wildcard

Specifies that any URL that matches this wildcard expression is considered protected.

users

Adds, deletes, or replaces a set of users enforced by the system upon successful login. You can configure the following options for an enforced user:

modes

Adds or deletes a single mode in the set of existing user modes.

mode Specifies a unique mode for the user. This option is required for the operations add and delete. The options are:

block

Specifies that the system blocks the user account by displaying blocking-page.

forensic

Specifies that the system enforces the user to run Forensics tool on his host by displaying forensic.html.

inspection

Specifies that the system turns on verbose activity logging for this user, i.e. collects all HTML and JS sources from sessions and sends this data to the dashboard.

remediation

Specifies that the system enforces the user to run Forensics tool in remediation mode that deploys Anti-malware client on his host by displaying forensic.html.

duration

Specifies number of minutes during which the user is enforced in this mode since its first login, when enforce-policy is time-limited. After their expiration the user mode will be removed automatically.

enforce-policy

Specifies enforcement policy for this user mode. The options are:

enforce

Specifies that the user must download and run Forensics tool in order to continue online actions. Note: This policy may be specified only for the modes forensic and remediation.

time-limited

Specifies that the user is enforced in this mode for a limited time, namely until first-login-time + duration minutes. When this policy is specified for the modes forensic and remediation, the user may skip downloading and running Forensics tool every time.

unlimited

Specifies that the user is enforced in this mode for unlimited time. When this policy is specified for the modes forensic and remediation, the user may skip downloading and running Forensics tool every time.

first-login-time

Displays time when the user firstly logged in being in this mode. A new user mode is added with value none and it is updated automatically during traffic, when enforce-policy is time-limited.

whitelist-custom-alerts

Specifies a list of predefined alerts that are ignored.

security anti-fraud signatures-update

NAME

signatures-update - Runs or loads an Anti-fraud signatures update.

MODULE

security anti-fraud

SYNTAX

Configure, run or load the signatures-update component within the security anti-fraud module using the syntax in the following sections:

MODIFY

modify security anti-fraud signatures-update

options:
update-automatically [enabled | disabled]

edit security anti-fraud signatures-update

options:
all-properties
non-default-properties

LOAD

load signatures-update

options:
file [filename]

RUN

run signatures-update

DISPLAY

list signatures-update

options:
all-properties
current-version-create-datetime
download-available
install-datetime
install-user
message
non-default-properties
one-line
partition
progress-status
progress-status-datetime
last-update-check-datetime
readme
update-automatically

DESCRIPTION

You can use the signatures-update component to run, load, configure or display status of signatures update.

EXAMPLES

list security anti-fraud signatures-update

Displays the status of signatures update.

OPTIONS

current-version-create-datetime

Displays the creation time of currently installed signatures update version.

download-available

Displays whether new signatures version is available for download from the cloud.

file Specifies the file name from which the signatures update is going to be installed when using the load command. A full path should be specified.

install-datetime

Displays the time when signatures update was installed.

install-user

Displays the name of the user who installed the last signatures update.

message

Displays the message describing the failure status of signatures update.

partition

Displays the administrative partition within which this object resides.

progress-status

Displays the signatures update progress status.

progress-status-datetime

Displays the time when signatures update progress status was last changed.

last-update-check-datetime

Displays the time when last checked for signatures update.

readme

Displays the Readme content for the current signatures update.

update-automatically

Enables or disables automatic nightly update.

SEE ALSO

security blacklist-publisher all-blacklist-publisher

NAME

all-blacklist-publisher - Show command for blacklist publisher for use by firewall. An all-blacklist-publisher shows all the category records and their associated profiles.

MODULE

security blacklist-publisher

SYNTAX

Shows the category component within the security blacklist-publisher module using the syntax in the following sections.

show all-blacklist-publisher

EXAMPLES

show all-blacklist-publisher

Displays all the blacklist publisher records. Each record displays its category, profile association, route domain, traffic group, next hop, advertised count, and deadadvertised count.

FIELDS

category name
Specifies the category which is associated with the profile.

profile name
Specifies the profile which is associated with the category.

route domain
Specifies the route domain in the route advertisement.

traffic group
Specifies the traffic group which will be utilized in route injection fault tolerance.

next hop
Specifies the next-hop address which will be utilized in route advertisement in blackhole routes.

advertised count
Specifies the number of times this route has been advertised.

deadadvertised count
Specifies the number of times this route has been dropped.

SEE ALSO

show, profile category, security, security blacklist-publisher, tmsh

security blacklist-publisher blacklist-publisher-stats

NAME

blacklist-publisher-stats - Show/reset-stats command for blacklist publisher for use by firewall. A blacklist-publisher-stats shows all the category records and their associated profiles.

MODULE

security blacklist-publisher

SYNTAX

Shows the category component within the security blacklist-publisher module using the syntax in the following sections.

```
show blacklist-publisher-stats
