show blacklist-publisher-stats category-name [name]
show blacklist-publisher-stats profile-name [name]
show blacklist-publisher-stats category-name [name] profile-name [name]
```

Reset-Stats the category component within the security blacklist-publisher module using the syntax in the following sections.

```
reset-stats blacklist-publisher-stats
reset-stats blacklist-publisher-stats category-name [name]
reset-stats blacklist-publisher-stats profile-name [name]
reset-stats blacklist-publisher-stats category-name [name] profile-name [name]
```

SHOW EXAMPLES

```
show blacklist-publisher-stats
```

Displays all the blacklist publisher records. Each record displays its category, profile association, advertised count, and deadadvertised count.

FIELDS

`category_name`
Specifies the category which is associated with the profile.

`profile_name`
Specifies the profile which is associated with the category.

`advertise_it`
Specifies the number of times this route has been advertised.

`deadvertise_it`
Specifies the number of times this route has been dropped.

RESET_STATS EXAMPLES

```
reset-stats blacklist-publisher-stats
```

Reset stats for all the blacklist publisher records.

```
reset-stats blacklist-publisher-stats category_name <\Common\botnets
```

Reset stats of all blacklist publisher records that are associated with "\Common\botnets" category.

```
reset-stats blacklist-publisher-stats profile_name <\Common\botnets-profile
```

Reset stats of all blacklist publisher records that are associated with "\Common\botnets-profile" profile.

```
reset-stats blacklist-publisher-stats category_name <\Common\botnets profile_name <\Common\botnets-profile>
```

Reset stat of all the blacklist publisher records that are associated with "\Common\botnets" category and "\Common\botnets-profile" profile.

security blacklist-publisher by-addr

NAME

by-addr - Show command for blacklist publisher for use by firewall. A by-addr shows all the category records and their associated profiles for the specified shun address.

MODULE

security blacklist-publisher

SYNTAX

Shows the shun-ip component within the security blacklist-publisher module using the syntax in the following sections.

```
show by-addr [enter IP address, IP address/prefix, or IP address range (two addresses separated by a hyphen).]
```

EXAMPLES

```
show by-addr 8.8.8.8
```

show by-addr 8.8.8.8/24

show by-addr 8.8.8.8-8.8.8.10

Displays all the blacklist publisher records for the specified shun address.

FIELDS

IP Address

Specifies the shun ip to be advertised.

category name

Specifies the category which is associated with the profile.

profile name

Specifies the profile which is associated with the category.

route domain

Specifies the route domain in the route advertisement.

traffic group

Specifies the traffic group which will be utilized in route injection fault tolerance.

next hop

Specifies the next-hop address which will be utilized in route advertisement in blackhole routes.

time-to-live

Specifies the amount of time left until this route will be dropped.

SEE ALSO

show, profile category, security, security blacklist-publisher, tmsb

security blacklist-publisher by-category

NAME

by-category - Show command for blacklist publisher for use by firewall. A by-category shows all the category records and their associated profiles for the specified category name.

MODULE

security blacklist-publisher

SYNTAX

Shows the category component within the security blacklist-publisher module using the syntax in the following sections.

show by-category category-name [[name] | all]

EXAMPLES

show by-category category-name /Common/botnets show by-category category-name all

Displays all the blacklist publisher records for the specified category.

FIELDS

category name

Specifies the category which is associated with the profile.

profile name

Specifies the profile which is associated with the category.

route domain

Specifies the route domain in the route advertisement.

traffic group

Specifies the traffic group which will be utilized in route injection fault tolerance.

next hop

Specifies the next-hop address which will be utilized in route advertisement in blackhole routes.

shun-ip

Specifies the shun ip to be advertised.

time-to-live
Specifies the amount of time left until this route will be dropped.

advertised
Specifies whether this record is currently being advertised.

BIG-IP 2015-08-28 security blacklist-publisher by-category(1)

security blacklist-publisher category

NAME
category - Configures a blacklist publisher category for use by firewall. A category enables a user to advertise shuns based on the route-advertisement-nextthop value(s) in the category's associated profile(s).

MODULE
security blacklist-publisher

SYNTAX
Configure the category component within the security blacklist-publisher module using the syntax in the following sections.

CREATE/MODIFY
create category [name]
modify category [name]
options:
 profile-names [add | default | delete | none | replace-all-with] {
 [name]
 }
}

edit category [[name] | all]
options:
 all-properties
 non-default-properties

list category [[name] | all | [property]]
show running-config profile [[name] | all | [property]]
options:
 all-properties
 non-default-properties
 one-line

DELETE
delete category [[name] | all | recursive]

Note: If the category is referencing any profile the delete will fail.

DESCRIPTION
You can use the category component to create, modify, display, or delete a blacklist-publisher category.

EXAMPLES
create category botnets profile-names add { botnets-profile }

Creates the above category and adds the profile (botnets-profile).

modify category botnets profile-names delete { botnets-profile }

Modifies the above category by deleting the profile (botnets-profile).

delete category botnets

Deletes the above category.

list category botnets

Displays the properties of the above category.

OPTIONS
profile-names

Specifies the profiles referenced in the category.

SEE ALSO

create, delete, edit, modify, list, profile, security, security blacklist-publisher, tmsh

COPYRIGHT

BIG-IP 2015-08-28 security blacklist-publisher category(1)

security blacklist-publisher profile

NAME

profile - Configures a publisher profile for use by firewall. A profile specifies the network path and method (how and where) the IP-Intelligence Blacklist data will be advertised.

MODULE

security blacklist-publisher

SYNTAX

Configure the profile component within the security blacklist-publisher module using the syntax in the following sections.

CREATE/MODIFY

```
create profile [name]
modify profile [name | all]
options:
  bgp-flowspec-advertisement-action [drop | rate-limit | qos]
  bgp-flowspec-dscp-value [integer]
  bgp-flowspec-rate-limit [integer]
  description [string]
  route-domain [name]
  traffic-group [name]
  route-advertisement-nexthop [IP address]
  route-advertisement-nexthop-v6 [IP address]
```

```
edit profile [[name] | all]
```

```
options:
  all-properties
  non-default-properties
```

```
list profile [[name] | all | [property]]
show running-config profile [[name] | all | [property]]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete profile [[name] | all | recursive]
```

Note: If the profile is referenced in a category the delete will fail.

DESCRIPTION

You can use the profile component to create, modify, display, or delete a blacklist-publisher profile.

EXAMPLES

```
create profile botnets-profile { route-domain 0 route-advertisement-nexthop 10.10.10.1 }
```

Creates the above profile with the specified route-domain, and route-advertisement-nexthop.

```
modify profile botnets-profile description "this profile is used for botnets category"
```

Modifies the above profile with a description.

```
delete profile botnets-profile
```

Deletes the above profile.

```
list profile botnets-profile
```

Displays the properties of the above profile.

OPTIONS

bgp-flowspec-advertisement-action

Specifies the BGP FlowSpec Advertisement Action to be used for Blackholing. The default is drop.

bgp-flowspec-dscp-value
Specifies the BGP FlowSpec DSCP value for advertisement qos action.

bgp-flowspec-rate-limit
Specifies the BGP FlowSpec rate limit (bytes/sec) for advertisement rate limiting action.

description
User defined description.

route-advertisement-nexthop
Specifies the next-hop v4 address which will be utilized in route advertisement in blackhole routes.

route-advertisement-nexthop-v6
Specifies the next-hop v6 address which will be utilized in route advertisement in blackhole routes.

route-domain
Specifies the route-domain in the route advertisement.

traffic-group
Deprecated since v13.1.0. Specifies the traffic group which will be utilized in route injection fault tolerance.

security bot-defense anomaly

NAME

anomaly - Shows the Bot Defense anomalies.

MODULE

security bot-defense

SYNTAX

Shows the anomaly component within the security bot-defense module using the syntax shown in the following sections.

DISPLAY

list anomaly

DESCRIPTION

You can use the anomaly component to display a Bot Defense Anomaly

EXAMPLES

list anomaly

Displays the properties of all Bot Defense Anomalies.

OPTIONS

type Specifies the anomaly type. The possible values are general, js-free, js-verification, cshui, micro-service.

category

The category of the anomaly.

description

A description of the anomaly.

security bot-defense class

NAME

class - Shows the bot defense classes

MODULE

security bot-defense

SYNTAX

Shows the class component within the security bot-defense module using the syntax shown in the following sections.

DISPLAY

list class

DESCRIPTION

You can use the class component to display a Bot Defense Class

EXAMPLES

list class

Displays the properties of all Bot Defense Classes.

OPTIONS

description

A description of the anomaly.

micro-services

The default mitigation or verification action for this class in each micro service.

templates

The default mitigation or verification action for this class in each template.

type The type of the class. The options are: none, browser, mobile, trusted-bot, untrusted-bot, malicious-bot, suspicious-browser, unknown.

NAME

micro-service - Shows the Bot Defense Microservices Types

MODULE

security bot-defense

SYNTAX

Shows the micro-service component within the security bot-defense module using the syntax shown in the following sections.

DISPLAY

list bot-defense-class

DESCRIPTION

You can use the micro-service component to display a Bot Defense Microservices Types.

EXAMPLES

list micro-service

Displays the properties of all Bot Defense Microservices Types.

OPTIONS

detection-threshold

The default number of times the microservice was accessed by a client after which the microservice anomaly is declared, for this type.

detection-time

The default period in seconds for this type during which the microservice anomaly threshold is tested.

intent

The corresponding OWASP threat.

mitigation-time

The time in seconds for the microservice anomaly mitigation duration, for this type.

DELETE
delete profile [name]

```

DESCRIPTION

You can use the profile component to create, modify, display, or delete a Bot Defense profile for use with Bot Defense Protection functionality.

EXAMPLES

```
create profile my_bot_profile
```

Creates a custom Bot Defense profile named my_bot_profile with initial settings.

```
list profile
```

Displays the properties of all Bot Defense profiles.

OPTIONS

api-access-strict-mitigation

Determines, when enabled, whether to apply the strict mitigation settings on API access requests.

anomaly-category-overrides

List or define anomaly categories that have mitigation settings overriding the defaults determined by the template.

action

The overriding mitigation action for the anomaly category. The options are:

alarm

Mark the request log entry with the alarm flag. Request passes through.

block

Block the request and send the blocking page in response.

captcha

Send a CAPTCHA challenge in response. If the user solves the challenge successfully the requests from this user are passed to the server for a limited period of time.

none The category will not be detected. This may affect the classification of the client and hence the action based on that classification.

tcp-reset

Discard the request by resetting the TCP connection it was sent on.

redirect-to-pool

Send the request to the configured pool.

honeypot-page

Block the request and send the Honeypot response page in response.

anomaly-overrides

List or define anomalies that have mitigation settings overriding the defaults determined by the template.

action

The overriding mitigation action for the anomaly. The options are:

alarm

Mark the request log entry with the alarm flag. Request passes through.

block

Block the request and send the blocking page in response.

captcha

Send a CAPTCHA challenge in response. If the user solves the challenge successfully the requests from this user are passed to the server for a limited period of time.

none The anomaly will not be detected. This may affect the classification of the client and hence the action based on that classification.

tcp-reset

Discard the request by resetting the TCP connection it was sent on.

redirect-to-pool

Send the request to the configured pool.

honeypot-page

Block the request and send the Honeypot response page in response.

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

blocking-page

body Configures the body of the blocking page response.

headers

Configures the HTTP headers of the blocking page response.

status-code

Configures the HTTP status code of the blocking page response.

type Configures a type of the blocking page response.

captcha-response

Specifies properties of the CAPTCHA response in Application Security. You can configure the following options for CAPTCHA Response Settings:

failure

Specifies properties of a failed CAPTCHA response. You can configure the following options for a failed CAPTCHA response:

body Configures a failed CAPTCHA response body.

type Configures a type of a failed CAPTCHA response body. You can configure the following options for a failed CAPTCHA response type:

custom

Configures a custom failed CAPTCHA response type.

default

Configures a default failed CAPTCHA response type.

first

Specifies properties of the first CAPTCHA response. You can configure the following options for the first CAPTCHA response:

body Configures the first CAPTCHA response body.

type Configures a type of the first CAPTCHA response body. You can configure the following options for the first CAPTCHA response type:

custom

Configures a custom first CAPTCHA response type.

default

Configures a default first CAPTCHA response type.

class-overrides

List or define classes that have settings overriding the defaults determined by the template.

mitigation

These set which type of mitigation to take for each type of bot.

action

The overriding mitigation action for the class. The options are:

alarm

Mark the request log entry with the alarm flag. Request passes through.

block

Block the request and send the blocking page in response.

captcha

Send a CAPTCHA challenge in response. If the user solves the challenge successfully the requests from this user are passed to the server for a limited period of time.

none The class will not be detected. This may affect the classification of the client and hence the action based on that classification.

rate-limit

Traffic from this source will be limited to a given transaction rate. Relevant only to classes and signature categories.

tcp-reset

Discard the request by resetting the TCP connection it was sent on.

redirect-to-pool

Send the request to the configured pool.

honeypot-page

Block the request and send the Honeypot response page in response.

rate-limit-tps

The TPS limit for the signature Relevant only if the action is rate limit.

verification

action

The overridden verification action for the class. Relevant only to Browser and Mobile Application classes. The options are:

browser-challenge-free-verification

Verify the browser authenticity by examining the request header without sending any JavaScript challenge to the client.

browser-verify-after-access-detection

Verify the browser authenticity by examining the request header and by a JavaScript challenge injected to the server response after letting the request to the server. The request is not mitigated even if the JavaScript challenge failed, rather, it is only reported, classifying the client as a Bot.

browser-verify-after-access-blocking

Verify the browser authenticity by examining the request header and by a JavaScript challenge injected to the server response after letting the request to the server. Upon challenge failure, the request is mitigated according to the respective mitigation settings.

browser-verify-before-access

Verify the browser authenticity by examining the request header and by responding with a JavaScript challenge before letting the request to the server. Request is sent to the server only upon successful completion of the challenge.

mobile-verify-integrity

Enable verification of mobile applications with Anti-Bot mobile SDK.

none No verification action taken. This may affect the classification of the client and hence the action based on that classification.

cross-domain-requests

Specifies a cross-domain requests handling mode. The options are:

allow-all

Allows all cross-domain requests. This is the default value.

validate-bulk

System validates domains in bulk: the cookies for the related domains are created together with the cookie for the current domain, by generating challenges in iframes - one per each domain.

validate-upon-request

System validates domains upon request: the cookie for the related domain is generated when a request arrives to an unqualified URL without a cookie.

defaults-from

Specifies the profile that you want to use as the parent profile.

description

User textual description of the profile.

deviceid-mode

Specifies how the Device ID will be collected.

The options are:

generate-after-access

Device ID is collected by injecting a JavaScript in the response. This is less intrusive and has less of a latency impact. Use when sensitive to response time or time-to-first-byte. Note that some requests at the beginning of the session will have no Device ID until the handshake is complete and the Device ID is generated.

generate-before-access

Device ID is collected by generating a JavaScript challenge before forwarding the HTTP request to the application. This guarantees that every request that reaches the application has a Device ID. This has more of a latency impact than Generate After Access. Bots that present as browsers and are unable to execute JavaScript will be blocked.

none Device ID will not be collected.

dos-attack-strict-mitigation

Determines, when enabled, whether to apply strict mitigation settings during DoS attacks.

enforcement-mode

Specifies whether to execute the mitigation actions or just report the detection results.

blocking

The system will replace responses with client side JavaScript and if the client cannot run JavaScript, it will not be able to receive the server responses.

transparent

The system logs all mitigation and verification actions but no action is taken on the traffic.

enforcement-readiness-period

How many days, since the bot defense profile was last changed, that the profile remains in staging mode before the system suggests you enforce. The system does not enforce profile entities and attack signatures in staging. Staging allows you to test the bot defense profile entities and the attack signatures for false positives without enforcing them. The default is 604800 seconds (7 days).

external-domains

List of external domain names that may refer to resources on the application. Used for handling cross-domain requests.

grace-period

The period in seconds during which requests for resources are not required to have browser verification cookies.

micro-services

List of microservices for which there exists specialized detection and mitigation behavior.

action

The mitigation action for the anomaly of the microservice. The options are:

alarm

Mark the request log entry with the alarm flag. Request passes through.

block

Block the request and send the blocking page in response.

captcha

Send a CAPTCHA challenge in response. If the user solves the challenge successfully the requests from this user are passed to the server for a limited period of time.

none Microservice anomaly will not be detected. This may affect the classification of the client and its mitigation action.

tcp-reset

Discard the request by resetting the TCP connection it was sent on.

redirect-to-pool

Send the request to the configured pool.

honeypot-page

Block the request and send the Honeypot response page in response.

class-overrides

The list of classes for which the settings override the ones determined by the microservice type.

mitigation

These set which type of mitigation to take for each type of bot.

action

The name of the overriding mitigation action for the class in the scope of the microservice. The options are:

alarm

Mark the request log entry with the alarm flag. Request passes through.

block

Block the request and send the blocking page in response.

captcha

Send a CAPTCHA challenge in response. If the user solves the challenge successfully the requests from this user are passed to the server for a limited period of time.

none The class will not be detected. This may affect the classification of the client and hence the action based on that classification.

rate-limit

Traffic from this source will be limited to a given transaction rate. Relevant only to classes and signature categories.

tcp-reset

Discard the request by resetting the TCP connection it was sent on.

redirect-to-pool

Send the request to the configured pool.

honeypot-page

Block the request and send the Honeypot response page in response.

verification

action

The name of the overriding verification action for the class in the scope of the microservice. Relevant only to Browser class. The options are:

browser-captcha

Send a CAPTCHA challenge response on each request with Browser User-Agent. The request is passed to the server only if the CAPTCHA was successfully solved.

browser-challenge-free-verification

Verify the browser authenticity by examining the request header without sending any JavaScript challenge to the client.

browser-verify-after-access-detection

Verify the browser authenticity by examining the request header and by a JavaScript challenge injected to the server response after letting the request to the server. The request is not mitigated even if the JavaScript challenge failed, rather, it is only reported, classifying the client as a Bot.

browser-verify-after-access-blocking

Verify the browser authenticity by examining the request header and by a JavaScript challenge injected to the server response after letting the request to the server. Upon challenge failure, the request is mitigated according to the respective mitigation settings.

browser-verify-before-access

Verify the browser authenticity by examining the request header and by responding with a JavaScript challenge before letting the request to the server. Request is sent to the server only upon successful completion of the challenge.

none No verification action taken. This may affect the classification of the client and hence the action based on that classification.

description

User textual description of the microservice.

detection-threshold

The number of times the microservice was accessed by a client after which the microservice anomaly is declared.

detection-time

The period in seconds during which the microservice anomaly threshold is tested.

enforcement-mode

Determines the enforcement mode for the microservice, or use the default one from the profile settings.

blocking

The system will replace responses with client side JavaScript and if the client cannot run JavaScript, it will not be able to receive the server responses.

profile-default

The enforcement mode (transparent or blocking) for the microservice is determined by the profile setting.

transparent

The system logs all mitigation and verification actions but no action is taken on the traffic.

hostname

The host domain name used to access the microservice. Wildcards are supported.

match-order

Ordinal number (1,2,3...) specifying the order that the microservice entries are checked for matches.

mitigation-time

The time in seconds for the microservice anomaly mitigation duration.

type The type of the microservice.

urls

match-order

Ordinal number (1,2,3...) specifying the order that the URL entries in the microservice are checked for matches.

url The URL entry in the microservice. Wildcards are supported.

mobile-detection

This feature detects mobile applications built with the Anti-Bot Mobile SDK and defines how requests from these mobile application clients are handled. This feature requires an Anti-Bot Mobile SK license to be operational.

allow-android-rooted-device

Specifies, when enabled, whether to allow mobile applications from Android rooted devices.

allow-any-android-package

Specifies, when enabled, whether to allow any mobile applications from Android devices.

allow-any-ios-package

Specifies, when enabled, whether to allow any mobile applications from iOS devices.

allow-emulators

Specifies, when enabled, whether to allow mobile applications running on emulators.

allow-jailbroken-devices

Specifies, when enabled, whether to allow mobile applications from iOS jailbroken devices.

android-publishers

List of allowed publisher certificates for Android mobile applications.

block-debugger-enabled-device

Specifies, when enabled, whether to allow mobile applications from devices with debugger enabled.

client-side-challenge-mode

Determines the substitute action for CAPTCHA or client-side integrity check for mobile applications. In those cases, the options for the mobile applications are:

cshui

The SDK checks for human interactions with the screen in the last few seconds. If none are detected, the traffic is blocked.

pass The traffic is passed without incident.

ios-allowed-packages

List of fully qualified iOS mobile application package names that will be allowed.

signatures

List of signature names for detecting mobile applications without Anti-Bot Mobile SDK.

perform-challenge-in-transparent

Determines, when enabled, whether browser challenges are still executed in transparent enforcement mode.

signature-category-overrides

List of signature categories that have mitigation settings overriding the defaults determined by the template.

action

The overriding mitigation action for the Bot signature category. The options are:

alarm

Mark the request log entry with the alarm flag. Request passes through.

block

Block the request and send the blocking page in response.

captcha

Send a CAPTCHA challenge in response. If the user solves the challenge successfully the requests from this user are passed to the server for a limited period of time.

none The category will not be detected. This may affect the classification of the client and hence the action based on that classification.

tcp-reset

Discard the request by resetting the TCP connection it was sent on.

redirect-to-pool

Send the request to the configured pool.

honeypot-page

Block the request and send the Honeypot response page in response.

signature-overrides

List of signatures that have mitigation settings overriding the defaults determined by the template.

action

The overriding mitigation action for the Bot signature. The options are:

alarm

Mark the request log entry with the alarm flag. Request passes through.

block

Block the request and send the blocking page in response.

captcha

Send a CAPTCHA challenge in response. If the user solves the challenge successfully the requests from this user are passed to the server for a limited period of time.

none The signature will not be detected. This may affect the classification of the client and hence the action based on that classification.

rate-limit

Traffic from this source will be limited to a given transaction rate. Relevant only to classes and signature categories.

tcp-reset

Discard the request by resetting the TCP connection it was sent on.

redirect-to-pool

Send the request to the configured pool.

honeypot-page

Block the request and send the Honeypot response page in response.

rate-limit-tps

The TPS limit for the signature Relevant only if the action is rate limit.

signature-staging-upon-update

In staging, the system does not block the request, but logs the request. When not in staging, the system enforces the mitigation action configured for the signature in Mitigation Settings.

single-page-application

Enable if your website is a Single Page Application, meaning a web application that loads new content without triggering a full page-reload. The system will inject JavaScript code to every HTML response. This will allow handling browser challenges and CAPTCHA without requiring page reloading. The default is Disabled.

site-domains

Configures a list of domains that are part of the website.

staged-signatures

List of signatures that are put in staging.

template

Specifies the template for the profile. The template determines default values for the mitigation settings and some other settings. The options are:

balanced

Allow limited access to non-malicious bots and verify browsers without affecting the user experience.

relaxed

Allow full access to non-malicious bots and perform non-intrusive browser verification.

strict

Allow only fully verified browsers, mobile applications and trusted bots and block the rest. User experience may be affected.

whitelist

These are the whitelisted sources. A source can be an IP address or a geolocation.

disable-mitigation

Specifies whether to exempt the whitelist entry from mitigation actions.

disable-verification
Specifies whether to exempt the whitelist entry from browser verification actions.

geolocation
The name of the source geolocation that is whitelisted.

match-order
Ordinal number (1,2,3...) specifying the order that the whitelist entries are checked for matches.

source-address
The name of the source IP address that is whitelisted.

url The name of the URL (wildcard supported) that is whitelisted.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

security bot-defense signature-category

NAME
signature-category - Configures the Bot Defense Signature Categories.

MODULE
security dos

SYNTAX
Configure the signature-category component within the security bot-defense module using the syntax shown in the following sections.

CREATE/MODIFY
create signature-category [string]
modify signature-category [name]
options:
 class [class-name]

DISPLAY
list signature-category

DELETE
delete signature-category [name]

DESCRIPTION
You can use the signature-category component to create, modify, display, or delete a Bot Defense Signature Category.

EXAMPLES
create signature-category my_signature_category

Creates a custom Bot Defense Signature Category named my_signature_category with initial settings.

list signature-category

Displays the properties of all Bot Defense Signature Categories.

OPTIONS

class

Specifies the class to which the category belongs.

SEE ALSO

edit, list, modify, security, security dos, tmsh

COPYRIGHT

BIG-IP 2018-10-20 security bot-defense signature-category(1)

security bot-defense signature

NAME

signature - Configures the Bot Defense Signatures.

MODULE

security dos

SYNTAX

Configure the signature component within the security bot-defense module using the syntax shown in the following sections.

CREATE/MODIFY

create signature [string]

modify signature [name]

options:

category [name]

domains [none | add | delete | replace-all-with] { [string] ... }

risk [high | low | medium]

rule [string]

signature-references [string]

url {

match-type [contains | regexp]

search-string [string]

}

user-agent {

match-type [contains | regexp]

search-string [string]

}

DISPLAY

list signature

DELETE

delete signature [name]

DESCRIPTION

You can use the signature component to create, modify, display, or delete a Bot Defense Signature.

EXAMPLES

create signature my_signature

Creates a custom Bot Defense Signature named my_signature with initial settings.

list signature

Displays the properties of all Bot Defense Signatures.

OPTIONS

category

Specifies the Bot category to which the Bot signature belongs.

domains

Specifies the domain names from which the client has to come for the respective signature. Required for signatures of the Trusted Bot class, optional for others

risk Specifies the risk from Bot detected by the signature. The possible values are high, low and medium.

rule Specifies the signature matching rule in Snort-like format. Advanced alternative to the User-Agent/URL search strings.

signature-references

Specifies references to resources on the signature.

url Specifies the bot signature's URL matching rule. The following options are available:

match-type

Specifies how the URL search string is matched: simple substring or regexp match. The possible values are contains or regexp.

search-string

Specifies the string to be matched to the URL string in order for the singature to be detected.

user-agent

Specifies the bot signature's User-Agent matching rule. The following options are available:

match-type

Specifies how the User-Agent search string is matched: simple substring or regexp match. The possible values are contains or regexp.

search-string

Specifies the string to be matched to the User-Agent string in order for the singature to be detected.

BIG-IP 2018-10-20 security bot-defense signature(1)

security bot-defense template

NAME

template - Shows the template for the profile. The template determines default values for the mitigation settings and some other settings

MODULE

security bot-defense

SYNTAX

Shows the template component within the security bot-defense module using the syntax shown in the following sections.

DISPLAY

list template

DESCRIPTION

You can use the template component to display a Bot Defense Template

EXAMPLES

list template

Displays the properties of all Bot Defense Templates

OPTIONS

api-access-strict-mitigation

Determines, when enabled, whether to apply the strict mitigation settings on API access requests in this template.

deviceid-mode

Specifies how the Device ID will be collected in this template.

The options are:

generate-after-access

Device ID is collected by injecting a JavaScript in the response. This is less intrusive and has less of a latency impact. Use when sensitive to response time or time-to-first-byte. Note that some requests at the beginning of the session will have no Device ID until the handshake is complete and the Device ID is generated.

generate-before-access

Device ID is collected by generating a JavaScript challenge before forwarding the HTTP request to the application. This guarantees that every request that reaches the application has a Device ID. This has more of a latency impact that Generate After Access. Bots that present as browsers and are unable to execute JavaScript will be blocked.

none
dos-attack-strict-mitigation
Determines, when enabled, whether to apply strict mitigation settings during DoS attacks in this template.

SEE ALSO

security cloud-services cmd

NAME

cmd - Commands to the Security Cloud Services

MODULE

security cloud-services

SYNTAX

Send commands to the Security Cloud Services using the syntax shown in the following sections.

RUN

run cmd activate start
run cmd activate finalize
run cmd reactivate start
run cmd reactivate finalize
run cmd reload connector
run cmd portal open

DESCRIPTION

You can use cmd to send various commands to the Security Cloud Services component.

OPTIONS

activate

Activate the Cloud Services for the first time. The command will fail if activation is complete. First call start and a login link will be returned. Open the link in a browser, and follow the instructions within. Then, call finalize to complete the process.

start

Start the activation process. A login link will be returned. Open the link in a browser, and follow the instructions within.

finalize

Finalize the activation process.

reactivate

Re-activate the Cloud Services. The command will fail if activation was not previously done. First call start and a login link will be returned. Open the link in a browser, and follow the instructions within. Then, call finalize to complete the process.

start

Start the re-activation process. A login link will be returned. Open the link in a browser, and follow the instructions within.

finalize

Finalize the re-activation process.

reload connector

Reload the connector details from the Cloud Services.

portal open

Open the Cloud Services Portal. A temporary login link will be returned which must be opened in a browser.

SEE ALSO

run, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

security cloud-services connector

NAME

connector - Configure the Cloud Services Connector

MODULE

security cloud-services

SYNTAX

Manage the connector component within the security cloud-services module using the syntax shown in the following sections.

CREATE/MODIFY

```
create connector [string]
modify connector [name]
options:
  activation-time [time]
  activation-note [string]
  expiration-time [time]
  deployment-id [string]
  description [string]
  params [string]
  control-url [string]
  control-token [string]
  control-key [string]
  clientside-url [string]
  clientside-token [string]
  clientside-key [string]
  services {
    centralized-device-id {
      [enabled | disabled]
    }
  }
}
```

```
edit connector [name]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list connector
list connector [name]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete connector [name]
```

DESCRIPTION

You can use the connector component to create, modify, display, or delete a Cloud Services connector.

OPTIONS

description
User defined description.

activation-time
Specifies the activation time of the connector.

activation-note
Specifies the activation note of the connector.

expiration-time
Specifies the expiration time of the connector.

deployment-id
Specifies the deployment id of the connector.

params
Specifies the custom parameters of the connector.

control-url
Specifies the control url of the connector.

control-token
Specifies the control token of the connector.

control-key
Specifies the control key of the connector.

clientside-url
Specifies the clientside url of the connector.

clientside-token
Specifies the clientside token of the connector.

clientside-key
Specifies the clientside key of the connector.

services
You can configure the following services:

centralized-device-id
You can configure the following options for Centralized Device ID:

enabled
Enables the Centralized Device ID service.

disabled
Disables the Centralized Device ID service.

SEE ALSO

security datasync background-tasks

NAME
background-tasks - Configure the Schedule of the Datasync Background Tasks

MODULE
security datasync

SYNTAX
Manage the background-tasks component within the security datasync module using the syntax shown in the following sections.

MODIFY
modify background-tasks [task_name]
options:
daily-start-time [time]

edit background-tasks [task_name]
options:
all-properties
non-default-properties

DISPLAY
list background-tasks
list background-tasks [task_name]
show running-config background-tasks
show running-config background-tasks [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line

show background-tasks
show background-tasks [[[name] | [glob] | [regex]] ...]
options:
field-fmt

DESCRIPTION
You can use the background-tasks component to modify or display the Schedule of the Datasync Background Tasks. This controls the Daily Start Time of each task.

The objects cannot be created or deleted, but only modified and displayed. All of the times displayed and configured are in local time. However, they are stored as UTC, so changing the timezone of the BIG-IP will change the display of the configured time.

There is a limitation on the time which can be configured: the new configuration cannot be within 2 hours of the active time. The configured daily-start-time must be before the value of daily-start-time-must-be-before, OR after the value of daily-start-time-must-be-after, inclusive.

These objects are synchronized via the datasync-global-dg device-group.

Use the show command to display the current task schedule. This shows the start time of each task.

OPTIONS

daily-start-time

Specifies the time of day in which the generation will start.

daily-start-time-must-be-before

Displays the upper limitation: daily-start-time must be before this displayed time.

daily-start-time-must-be-after

Displays the lower limitation: daily-start-time must be after this displayed time.

error-msg

Displays the configuration error message which causes daily-start-time to be non-configurable, or "none" if there is no error.

SEE ALSO

edit, list, modify, show, tmsh

COPYRIGHT

BIG-IP 2017-08-30 security datasync background-tasks(1)

security datasync device-stats

NAME

device-stats - Display the Datasync Framework device stats.

MODULE

security datasync

SYNTAX

Display the device-stats component within the security datasync module using the syntax shown in the following sections.

DISPLAY

list device-stats

list device-stats [[[name] | [glob] | [regex]] ...]

show running-config device-stats

show running-config device-stats [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

recursive

DESCRIPTION

You can use the device-stats component to display the datasync device-stats for that are updated by the Datasync Framework.

OPTIONS

device

Displays the device name reflected by the stats.

table

Displays the table type reflected by the stats.

profile-chksum

Displays the checksum of the current active profile.

activation-epoch

Displays the activation epoch of the current active generation.

rows-available

Displays the number of available rows in the current active buffer.

rows-in-use

Displays the number of rows that are in use in the current active buffer.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh, trust-domain

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

security datasync global-profile

NAME

global-profile - Manage the Datasync Framework settings that are globally synced across devices.

MODULE

security datasync

SYNTAX

Manage the global-profile component within the security datasync module using the syntax shown in the following sections.

CREATE/MODIFY

create global-profile [name]

modify global-profile [name]

options:

table [name]

activation-epoch [auto | [integer]]

deactivation-epoch [deactivated | always-active | [integer]]

min-rows [default | [integer]]

max-rows [default | [integer]]

regen-time-offset [default | [integer]]

regen-interval [default | none | [integer]]

grace-time [default | [integer]]

master-key [string]

scramble-alg [string]

hash-alg [string]

mac-alg [string]

mode-of-op [string]

rsa-exp [none | rsa-3 | rsa-f4 | default]

rsa-bits [default | none | [integer]]

params [string]

edit global-profile [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list global-profile

list global-profile [[[name] | [glob] | [regex]] ...]

show running-config global-profile

show running-config global-profile [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

recursive

DELETE

delete global-profile [name]

DESCRIPTION

You can use the global-profile component to create, modify, display, or delete a datasync global-profile for use with the Datasync Framework. All global-profiles must reside in the automatically created /Common/datasync-global folder. These profiles are synced across all of the devices in the trust domain using the manually-synced device-group datasync-global-dg.

Warning: Creating, modifying or deleting global-profiles may result in the system being offline, in the case

of a bad configuration.

EXAMPLES

create global-profile /Common/datasync-global/my_global_profile table table_name

Creates a custom datasync global-profile named my_global_profile for table table_name with initial settings, a random master-key, and an activation-epoch 30 minutes in the future.

list global-profile /Common/datasync-global/*

Displays the properties of all datasync global-profiles.

OPTIONS

table

Specifies the table to which the profile belongs.

activation-epoch

Specifies the epoch at which the profile becomes active, in UNIX-time.

deactivation-epoch

Specifies the epoch at which the profile becomes inactive, in UNIX-time.

create-timestamp

Displays the timestamp at which the profile was created, in UNIX-time.

min-rows

Specifies the minimum number of rows to generate before going online.

max-rows

Specifies the maximum number of rows to generate.

regen-time-offset

Specifies the time offset at which regeneration will be done, in seconds.

regen-interval

Specifies the time interval at which regeneration will be done, in seconds.

grace-time

Specifies the grace time during which new buffers are supported, but not yet activated, in seconds.

master-key

Specifies the secured master key upon which all cryptography is based. Use \"auto\" to generate a random key.

scramble-alg

Specifies the scrambling algorithm to use.

hash-alg

Specifies the hashing algorithm to use.

mac-alg

Specifies the MAC algorithm to use.

mode-of-op

Specifies the scrambling mode-of-operation to use.

rsa-exp

Specifies the RSA exponent.

rsa-bits

Specifies the number of bits to use for RSA keys.

params

Specifies additional internal parameters.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh, trust-domain

COPYRIGHT

BIG-IP 2014-07-10 security datasync global-profile(1)

NAME

local-profile - Manage the Datasync Framework settings that are local, and not synced across devices.

MODULE

security datasync

SYNTAX

Manage the local-profile component within the security datasync module using the syntax shown in the following sections.

MODIFY

modify local-profile [table_name]

options:

buf-size [integer]
ds-area [none | asm | fps]
rows-bulk [integer]
gen-timeout-sec [integer]
min-mem-mb [integer]
min-cpu-percent [integer]
max-gen-rows [infinite | [integer]]
keep-conf-files [integer]
gen-pause-sec [integer]
offline-until-gen [enable | disable]
max-iowait-percent [integer]

edit local-profile [table_name]

options:

all-properties
non-default-properties

DISPLAY

list local-profile

list local-profile [table_name]

show running-config local-profile

show running-config local-profile [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties
one-line
partition
recursive

DESCRIPTION

You can use the local-profile component to modify or display a datasync local-profile for use with the Datasync Framework. Each profile is for a single table. The profiles cannot be created or deleted, only modified. These profiles are local; they are not synced across devices.

OPTIONS

buf-size

Specifies the size of each buffer in the table, in bytes.

ds-area

Specifies the memory area on which the table will be allocated.

rows-bulk

Specifies the number of rows to generate in each bulk.

gen-timeout-sec

Specifies the timeout of running the external generator per single bulk.

min-mem-mb

Specifies the minimum available memory in MB to start generator in non-urgent mode.

min-cpu-percent

Specifies the minimum available CPU percent to start generator in non-urgent mode.

max-gen-rows

Specifies the maximum rows to generate.

keep-conf-files

Specifies the number of configuration files to keep when rolling old ones.

gen-pause-sec

Specifies the time in seconds to pause between each bulk generation when in non-urgent mode.

offline-until-gen

Specifies if the system should be offline until the table is generated.

min-cpu-percent

Specifies the maximum iowait percent to start generator in non-urgent mode.

SEE ALSO

edit, list, modify, show, tmsh

security debug matcher

NAME

debug - Configures Debuggability drop redirect mode.

MODULE

security firewall

SYNTAX

Configure drop redirect feature or display stats using the following syntax.

MODIFY

```
modify debug
matcher {
  drop-redirect {
    drop-redirect-mode {
  disable
  redirect-all
  redirect-hw-only
  redirect-sw-only
    }
  }
}
```

DISPLAY

```
show debug
drop-redirect-stats
```

DESCRIPTION

Debuggability drop redirection feature redirects HW dropped packets to a specified interface. This interface may be set using sys db variable debug.hwdropredirect.interface. The feature can also redirect only certain types of drops. This can be done by using sys db variable debug.doshwdropredirect.disable.

Full List of HW Redirect Modes # Disable GlobalDoSVector drop redirects bit-0 # Disable sPVADoSVector

drop redirects bit-1 # Disable sPVAIPBlacklist drop redirects bit-2 # Disable sPVAIPRateLimit drop
redirects bit-3 # Disable NeuronBlacklist drop redirects bit-4 # Disable DuplicateSYN drop redirects
bit-5

Once an interface is set-up, redirect-hw-only mode can be enabled as the following example.

EXAMPLES

modify security debug matcher drop-redirect drop-redirect-mode redirect-hw-only

Configures dropped packets to be redirected to a specified interface.

BIG-IP 2018-01-10 security debug matcher(1)

security debug register

NAME

register - Configures a debug register.

MODULE

security debug

SYNTAX

Configure the register component within the security debug module using the syntax in the following sections.

MODIFY

```
modify register [name]
options:
  all
  description [string]
  destination {
    address [ip_address/prefixlen]
    port [port]
  }
  [disabled | enabled]
  match-ip-version [false | true]
  protocol [any | [protocol] ]
  source {
    address [ip_address/prefixlen]
    port [port]
    vlan [vlan name]
  }
```

```
edit register [ [name] ... ]
```

```
options:
  all-properties
  non-default-properties
```

```
reset-stats register [ [name] ... ]
```

DISPLAY

```
list register
list register [ [name] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

```
show register [ [name] ... ]
```

```
options:
  all-properties (default | exa | gig | kil | meg | peta | raw | tera |
  yotta | zetta)
  field-fmt
```

RUN

```
run register [name]
options:
  filename [filename | stdout]
  max-file-mb [integer]
  max-packets [integer]
  unidirectional [true | false]
  capture-start
  capture-stop
```

DESCRIPTION

This component configures the traffic flow for hardware debug functionality based on the incoming packets' IP header 6-tuple values.

The run command performs the hardware debug functionality by capturing the network traffic which matches the register configuration.

EXAMPLES

modify register r1 enabled source { address 1.1.1.0/24 port any vlan vlan-168 }

Configure register r1 to match the traffic from address 1.1.1.0/24 on any port and vlan defined in vlan-168.

reset-stats register r1

Reset the statistics of register named r1.

show register r1

Displays statistics and status of register named r1.

run register r1 filename /shared/f1.cap max-file-mb 100 max-packets 5000 capture-start

Start capturing the network traffic based on r1 configuration and save the tcpdump file to /shared/f1.cap, up to 100 mb or 5000 packets whichever comes first.

run register r1 capture-stop

Stop capturing the network traffic on r1 manually.

OPTIONS

description

User-defined description.

destination

Matches against each packet's destination IP and/or destination port.

address

Specifies an IP address and network to compare against the packet's destination address.

The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:ca90:ff00:0042:8329" to "2001:db7:3f4a:9dd:ca90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:23ff:678" to "2001::c34a:0:23ff:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

port Specifies a port to compare against the packet's destination port.

match-ip-version

Specifies whether any/any6 in source/destination address is to match 'any IPv4', 'any IPv6', or 'any IPv4 and any IPv6' addresses.

If match-ip-version is true, both source and destination addresses must have the same IP address family. If match-ip-version is false and both source and destination addresses are any or any6, both addresses represent 'any IPv4 and IPv6 addresses'.

If match-ip-version is false and only one address is set to any or any6, the address is interpreted based on the other IP address' family (IPv4 or IPv6). The default is false.

protocol

Specifies the IP protocol to compare against the packet. The default value is any.

source

Matches against each packet's source IP, source port, and/or source VLAN.

address

Specifies an IP address and network to compare against the packet's source address.

The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]

port Specifies a port to compare against the packet's source port.

vlan Specifies a vlan name.

filename

Specifies the full path of the file in which to capture the packets from the run command.

The option is only for the run command with option capture-start. The default value is stdout if it's not specified. The tcpdump will be displayed on the console if the value is stdout.

max-file-mb

Specifies the maximum file size in the run command.

The option is only for the run command with option capture-start. The default value is 1 if it's not specified. The unit is in 1,000,000 bytes.

max-packets

Specifies the maximum number of packets that can be captured in the run command.

The option is only for the run command with option capture-start. The default value is 1000 if it's not specified.

unidirectional

Specifies that only the unidirectional traffic can be captured in the run command.

The option is only for the run command with option capture-start. The default value is false which means bidirectional traffic will be captured. If the value is true, the command will only capture unidirectional traffic.

capture-start

Specifies the action to start capturing the network traffic.

The option is only for the run command. Either capture-start or capture-stop must be specified as the last option on the run command.

capture-stop

Specifies the action to stop capturing the network traffic.

The option is only for the run command. Either capture-start or capture-stop must be specified as the last option on the run command.

security device-id attribute

NAME

device-id - Configures Device-ID collected attributes.

MODULE

security

SYNTAX

Configure the device-id component within the security module using the syntax shown in the following sections.

MODIFY

modify attribute [name]

options:

collect {

[enabled | disabled]

}

DISPLAY

list device-id

DESCRIPTION

You can use the device-id component to modify or display a Device-ID attribute collection.

EXAMPLES

modify device-id attribute att05 {collect disabled}

Disables collection of att05 by Device-ID JavaScript.

list device-id

Displays the properties of all device-id attributes.

OPTIONS

attribute

Specifies the Device-ID category to be configured.

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2017-05-24 security device-id attribute(1)

security device device-context

NAME

device-context - Configures the security device context policies.

MODULE

security device

SYNTAX

MODIFY

```
modify device-context
options:
  description [string]
  nat-policy [ [policy_name] | none ]
```

```
edit device-context
```

options:

```
  all-properties
  non-default-properties
```

```
reset-stats device-context
```

```
  nat-rules { [rule name] }
```

DISPLAY

```
list device-context
```

```
show running-config device-context nat-rules
```

```
show device-context nat-rules
```

DESCRIPTION

You can use the device-context component to configure device level (a.k.a global) policies.

EXAMPLES

```
modify device-context nat-policy policy1
```

Configures nat policy named policy1 to be used as the device level nat policy.

```
list device-context
```

```
security device device-context {
  nat-policy /Common/policy1
}
```

Displays the current list of policies at device context level.

OPTIONS

description

Specifies nat policies on device context level.

nat-policy

Specifies a NAT policy. This is the policy used to match incoming traffic to a virtual server and perform source/destination translations (as per the matched NAT rule) if and only if: virtual server does not have a NAT policy configured (see ltm virtual)

AND virtual server has nat-policy.use-route-domain-policy disabled

OR virtual server has nat-policy.use-route-domain-policy enabled but the route domain does not have a NAT policy configured

AND virtual server has nat-policy.use-device-policy enabled.

nat-rules

Specifies security nat rules enforced on device context level via referenced nat-policy.

SEE ALSO

edit, list, modify, security firewall address-list, security firewall port-list, security nat policy, security log profile, security nat source-translation, security nat destination-translation, ltm virtual, show, tmsh

security dos auto-thresholds heavy-urls

NAME

heavy-urls - Displays the heavy URL auto-calculated thresholds.

MODULE

security dos auto-thresholds

SYNTAX

Display information about the heavy-urls component within the security dos auto-thresholds module using the following syntax.

DISPLAY

show heavy-urls

options:

all

field-fmt

recursive

DESCRIPTION

You can use the heavy-urls component to display the heavy URL auto-calculated thresholds.

EXAMPLES

show heavy-urls my_dos_profile

Display the heavy URL auto-calculated thresholds for a DoS profile named my_dos_profile.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

security dos auto-thresholds stress-based

NAME

stress-based - Displays the Stress-based auto-calculated thresholds.

MODULE

security dos auto-thresholds

SYNTAX

Display information about the stress-based component within the security dos auto-thresholds module using the following syntax.

DISPLAY

show stress-based

options:

all

field-fmt

recursive

DESCRIPTION

You can use the stress-based component to display the Stress-based auto-calculated thresholds.

EXAMPLES

show stress-based my_dos_profile

Display the Stress-based auto-calculated thresholds for a DoS profile named my_dos_profile.

OPTIONS

For information about the options that you can use with the command show, see help show.

security dos auto-thresholds top-device-ids

NAME

top-device-ids - Displays the top device ID auto-calculated thresholds.

MODULE

security dos auto-thresholds

SYNTAX

Display information about the top-device-ids component within the security dos auto-thresholds module using the following syntax.

DISPLAY

show top-device-ids

options:

all

field-fmt

recursive

DESCRIPTION

You can use the top-device-ids component to display the top device ID auto-calculated thresholds.

EXAMPLES

show top-device-ids my_dos_profile

Display the top device ID auto-calculated thresholds for a DoS profile named my_dos_profile.

OPTIONS

For information about the options that you can use with the command show, see help show.

security dos auto-thresholds top-geolocations

NAME

top-geolocations - Displays the top geolocation auto-calculated thresholds.

MODULE

security dos auto-thresholds

SYNTAX

Display information about the top-geolocations component within the security dos auto-thresholds module using the following syntax.

DISPLAY

show top-geolocations

options:

all

field-fmt

recursive

DESCRIPTION

You can use the top-geolocations component to display the top geolocation auto-calculated thresholds.

EXAMPLES

show top-geolocations my_dos_profile

Display the top geolocation auto-calculated thresholds for a DoS profile named my_dos_profile.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

security dos auto-thresholds top-source-ips

NAME

top-source-ips - Displays the top source IP auto-calculated thresholds.

MODULE

security dos auto-thresholds

SYNTAX

Display information about the top-source-ips component within the security dos auto-thresholds module using the following syntax.

DISPLAY

show top-source-ips

options:

all

field-fmt

recursive

DESCRIPTION

You can use the top-source-ips component to display the top source IP auto-calculated thresholds.

EXAMPLES

show top-source-ips my_dos_profile

Display the top source IP auto-calculated thresholds for a DoS profile named my_dos_profile.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

security dos auto-thresholds tps-based

NAME

tps-based - Displays the TPS-based auto-calculated thresholds.

MODULE

security dos auto-thresholds

SYNTAX

Display information about the tps-based component within the security dos auto-thresholds module using the following syntax.

DISPLAY

show tps-based
options:
all
field-fmt
recursive

DESCRIPTION

You can use the tps-based component to display the TPS-based auto-calculated thresholds.

EXAMPLES

show tps-based my_dos_profile

Display the TPS-based auto-calculated thresholds for a DoS profile named my_dos_profile.

OPTIONS

For information about the options that you can use with the command show, see help show.

security dos autodos-file-object

NAME

autodos-file-object - autodos internal file object.

MODULE
security

SYNTAX
Configure autodos-file-object within security dos module using the syntax shown in the following sections.

CREATE/MODIFY
create autodos-file-object [name]
modify autodos-file-object [name]
options:
 app-service [[string] | none]
 source-path [file name]

DELETE
delete autodos-file-object [name]

DESCRIPTION
autodos file object is used internally for synchronization of dos module data across HA (high availability) or Cluster setup.

EXAMPLES
create name source-path /var/dos/file.json

Creates a file object named name, that gets its contents from source file /var/dos/file.json.

delete filename

Deletes the file object named filename.

OPTIONS
 app-service
Specifies the name of the application service to which the file object belongs. The default value is none.

 source-path
The name of the source file from which the contents are copied to create the file object.

SEE ALSO
create, delete, edit, modify, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2017-07-07 security dos autodos-file-object(1)

security dos behavioral-signature

NAME
behavioral-signature - Configures a Behavioral Bot Signature.

This component has been deprecated and replaced by dos-signature in 13.1.0.

MODULE
security dos

SYNTAX
Configure the behavioral-signature component within the security dos module using the syntax shown in the following sections.

MODIFY
modify behavioral-signature [name]
options:
 alias [name]
 status [approved | new | revoked }

DISPLAY
list behavioral-signature

DELETE
delete behavioral-signature [name]

DESCRIPTION
You can use the behavioral-signature component to modify, display, or delete a Behavioral Signature.

EXAMPLES

list behavioral-signature

Displays the properties of all Behavioral Signatures.

OPTIONS

alias

Specifies the behavioral signature user defined alias.

status

Specifies the behavioral signature status.

SEE ALSO

edit, list, modify, security, security dos, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2017. All rights reserved.

BIG-IP 2017-03-09 security dos behavioral-signature(1)

security dos bot-signature-category

NAME

bot-signature-category - Configures the Bot Signature Categories.

MODULE

security dos

SYNTAX

Configure the bot-signature-category component within the security dos module using the syntax shown in the following sections.

CREATE/MODIFY

create bot-signature-category [string]

modify bot-signature-category [name]

options:

type [benign | malicious]

DISPLAY

list bot-signature-category

DELETE

delete bot-signature-category [name]

DESCRIPTION

You can use the bot-signature-category component to create, modify, display, or delete a Bot Signature Category.

EXAMPLES

create bot-signature my_signature_category

Creates a custom Bot Signature Category named my_signature_category with initial settings.

list bot-signature-category

Displays the properties of all Bot Signature Categories.

OPTIONS

type Specifies the bot signature type. The possible values are benign or malicious.

SEE ALSO

edit, list, modify, security, security dos, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

security dos bot-signature

NAME
bot-signature - Configures the Bot Signatures.

MODULE
security dos

SYNTAX
Configure the bot-signature component within the security dos module using the syntax shown in the following sections.

CREATE/MODIFY
create bot-signature [string]
modify bot-signature [name]
options:
 category [name]
 domains [none | add | delete | replace-all-with] { [string] ... }
 risk [high | low | medium]
 rule [string]
 signature-references [string]
 url {
 match-type [contains | regexp]
 }
 search-string [string]
 }
 user-agent {
 match-type [contains | regexp]
 search-string [string]
 }
 }

DISPLAY
list bot-signature

DELETE
delete bot-signature [name]

DESCRIPTION
You can use the bot-signature component to create, modify, display, or delete a Bot Signature.

EXAMPLES
create bot-signature my_signature

Creates a custom Bot Signature named my_signature with initial settings.

list bot-signature

Displays the properties of all Bot Signatures.

OPTIONS
category
Specifies the bot signature category.

domains
Specifies the bot signature domain names.

risk Specifies the bot signature risk. The possible values are high, low and medium.

rule Specifies the bot signature rule.

signature-references
Specifies the bot signature references.

url Specifies the bot signature's url matching rule. The following options are available:

 match-type
 Specifies the bot signature's url rule match type. The possible values are contains or regexp.

 search-string
 Specifies the bot signature's url string that should be matched.

 user-agent
 Specifies the bot signature's user-agent matching rule. The following options are available:

 match-type
 Specifies the bot signature's user-agent rule match type. The possible values are contains or regexp.

 search-string
 Specifies the bot signature's user-agent string that should be matched.

DESCRIPTION
 This component is used to modify or display the global device DoS profile and statistics for use with network DoS Protection functionality.

EXAMPLES
 modify device-config ...
 Modifies the global DoS profile settings.

list device-config
 Displays all the properties of the device DoS profile.

run device-config dos-device-config auto-threshold-relearn
 Clears the auto-threshold history for all the device auto-threshold vectors.

run device-config dos-device-config dns-nxdomain-relearn
 Clears the dns-nxdomain history for all the device dns-nxdomain vectors.

run device-config dos-device-config dynamic-signatures-history-relearn

Clears the dynamic-signatures history for all the device dynamic-signatures vectors.

show device-config dos-device-config dns-nxdomain-stat

Displays the dns-nxdomain statistics for the device.

reset-stats device-config dos-device-config dns-nxdomain-stat

Resets the dns-nxdomain statistics for the device.

OPTIONS

auto-threshold-sensitivity

This option is deprecated in version 13.0.0.

dos-device-vector

Configures attack detection thresholds and rate limit parameters for network DoS vectors.

log-publisher

Specifies the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system.

ip-uncommon-protolist

Specifies the name of an IP uncommon protocol list component. The default is /Common/ip-uncommon-protolist. This is read-only field.

threshold-sensitivity

Specifies the guidance on how aggressively (how much to pad) to adjust the "Detection/Rate-limit Threshold". Available settings are low, medium and high. This setting is used for Autodos and Behavioral DoS features. Default is set to medium.

network-dos-mitigation-percentage

Specifies the mitigation multiplier value of all the device network dos vector in percentage in the manual-multiplier-mitigation mode.

dns-dos-mitigation-percentage

Specifies the mitigation multiplier value of all the device dns dos vector in percentage in the manual-multiplier-mitigation mode.

sip-dos-mitigation-percentage

Specifies the mitigation multiplier value of all the device sip dos vector in percentage in the manual-multiplier-mitigation mode.

syn-cookie-dsr-flow-reset-by

Specifies how TCP SYN Flood is handled when syn-cookie-whitelist is enabled and the attack is detected in Direct Server Return(DSR) mode. The default value is none.

syn-cookie-whitelist

Specifies whether or not to use a SYN Cookie WhiteList when doing software SYN Cookies. This means not doing a SYN Cookie for the same src IP address if it has been done already in the previous tm.flowstate.timeout (30) seconds. The default value is disabled.

dynamic-signatures

Specifies options related to L4-L7 Behavioral DoS (Dynamic Signatures) feature that is applicable at the global/device level. These settings are used to learn the characteristic of the traffic at the device level (across all domains and virtual servers) and generate dynamic signatures as applicable to detect and mitigate anomalous traffic.

Following options are configurable for this feature at global/device level:

network
detection

Specifies the mode for detection of anomalies in traffic for the purpose of dynamic signature generation. Following modes are supported: disabled, enabled and learn-only.

Mode learn-only is same as enabled except that the system does not generate any logs (or alerts the user). It is used mainly to learn the baseline thresholds for the traffic.

Default is disabled.

mitigation

Specifies the mode for mitigation of anomalous traffic (specified in form of dynamic signatures). Following modes are supported: none, low, medium and high.

Each mode represents the severity (or aggressiveness) at which the system should try to mitigate the anomalous traffic.

Default is none.

multiplier-mitigation-percentage

Specifies the mitigation multiplier value of this specific dos signature in percentage when using manual-multiplier-mitigation mode. The default value is inherited from the corresponding device level/profile mitigation multiplier value of the same dos family.

scrubber-enable

Specifies the configuration mode for enabling or disabling the feature to scrub the attack traffic upon dynamic signature match. Default is no.

scrubber-category

Specifies the IP Intelligence category used for scrubbing the attack traffic upon dynamic signature match that constitutes destination IP address component. Default category is attacked_ips.

scrubber-advertisement-period

Specifies the advertisement period for which the attack traffic is scrubbed. Default is 300 seconds.

dns detection

Specifies the mode for detection of anomalies in traffic for the purpose of dynamic signature generation. Following modes are supported: disabled, enabled and learn-only.

Mode learn-only is same as enabled except that the system does not generate any logs (or alerts the user). It is used mainly to learn the baseline thresholds for the traffic.

Default is disabled.

mitigation

Specifies the mode for mitigation of anomalous traffic (specified in form of dynamic signatures). Following modes are supported: none, low, medium and high.

Each mode represents the severity (or aggressiveness) at which the system should try to mitigate the anomalous traffic.

Default is none.

custom-signatures

Specifies options related to L4 Behavioral DoS Signatures feature that is applicable at the global/device level. Signatures can be added to a dos-profile and the signature criteria will be used for detection and mitigation of anomalous traffic.

Following options are configurable for each signature added:

threshold-mode

Specifies the mode for setting the rate limit thresholds to be used for the matching traffic. Following modes are supported: manual, fully-automatic, manual-multiplier-mitigation and stress-based-mitigation. Default is manual.

state

Specifies the operational state of the attached signature. The states supported are: disabled, learn-only, detect-only and mitigate. Default is disabled.

manual-detection-threshold

Specifies manual detection threshold for a custom signature. It is applicable only if threshold-mode is set to either manual or stress-based-mitigation

Default is infinite.

manual-mitigation-threshold

Specifies manual mitigation threshold for a custom signature. It is applicable only if threshold-mode is set to either manual or stress-based-mitigation

Default is infinite.

tscookie-vlans

Specifies the VLANs on which we will do TCP timestamp cookie based validation of TCP ACK packets and use the TCP BAD ACK DoS vector to mitigate a TCP ACK flood attack.

VECTOR TYPES

arp-flood

ARP Flood.

bad-ext-hdr-order

IPv6 extension headers in packet are out of order.

bad-icmp-chksum

Bad ICMP checksum.

bad-icmp-frame

Bad ICMP frames. To see the various reasons why ICMP frames are classified as bad, please refer to the written documentation.

bad-igmp-frame

Bad IGMP frames. To see the various reasons why IGMP frames are classified as bad, please refer to the written documentation.

bad-ip-opt

IPv4 option with illegal length.

bad-ipv6-hop-cnt

Bad IPv6 hop count. Terminated packet (cnt==0). Dropped when the rate hits rate limit.

bad-ipv6-ver

Bad IPv6 version. IP Version in the IPV6 packet is not 6.

bad-sctp-chksum
Bad SCTP Checksum type.

bad-tcp-chksum
Bad TCP checksum.

bad-tcp-flags-all-clr
Bad TCP flags (all TCP header flags cleared).

bad-tcp-flags-all-set
Bad TCP flags (all flags set).

bad-ttl-val
Bad IP TTL value (TTL == 0 for IPv4).

bad-udp-chksum
Bad UDP checksum.

bad-udp-hdr
Bad UDP header. To see the various reasons why UDP headers are classified as bad, please refer to the written documentation.

bad-ver
Bad IP version 4. IPv4 version in IP header is not 4.

dns-a-query
DNS A query packet.

dns-aaaa-query
DNS AAAA query packet.

dns-any-query
DNS any query packet.

dns-axfr-query
DNS AXFR query packet.

dns-cname-query
DNS CNAME query packet.

dns-ixfr-query
DNS IXFR query packet.

dns-malformed
DNS Malformed packet.

dns-mx-query
DNS MX query packet.

dns-ns-query
DNS NS query packet.

dns-nxdomain-query
DNS NXDOMAIN query packet.

dns-other-query
DNS OTHER query packet.

dns-oversize
DNS packet with size > . This sys db tunable is configurable with Dos.MaxDNSframeSize.

dns-ptr-query
DNS PTR query packet.

dns-qdcount-limit
DNS QDCOUNT LIMIT query packet.

dns-response-flood
DNS RESPONSE FLOOD query packet.

dns-soa-query
DNS SOA query packet.

dns-txt-query
DNS TXT query packet.

dns-srv-query
DNS SRV query packet.

dup-ext-hdr
Duplicate IPv6 extension headers.

ether-brdcst-pkt
Ethernet broadcast packet.

ether-mac-sa-eq-da
Ethernet MAC SA == DA.

ether-multicast-pkt
Ethernet multicast packet.

ext-hdr-too-large
IPv6 extension header size too large. The max IPv6 extension header size is configurable via the sys db variable dos.maxipv6extsize.

fin-only-set
TCP header with only the FIN flag set.

flood
A Flood is an attack where multiple (typically many) endpoints initiate network traffic to a single subnet or receiving endpoint.

hdr-len-gt-l2-len
Header length > L2 length. No room in L2 packet for IPv4 header (including options).

hdr-len-too-short
Header length too short. IPv4 header length in IP header is less than 20 bytes.

hop-cnt-leq-one
IPv6 hop count <= and the packet needs to be forwarded. This sys db tunable is configurable by the sys db variable tm.minipv6hopcnt.

host-unreachable
ICMP packets of type "Host Unreachable".

icmp-frag-flood
ICMP fragments flood.

icmp-frame-too-large
Packets larger than the maximum ICMP frame size. The max ICMP frame size is configurable via the sys db variable dos.maxicmpframesize.

icmpv4-flood
ICMPv4 Flood.

icmpv6-flood
ICMPv6 Flood.

igmp-flood
IGMP Flood.

igmp-frag-flood
IGMP Fragment Flood.

ip-bad-src
IP addr is a broadcast or multicast address.

ip-err-chksum
IP error checksum. IPv4 header checksum error.

ip-frag-flood
IPv4 fragment flood.

ip-len-gt-l2-len
IP length > L2 length. Total length in IPv4 header is greater than the L3 part length in L2 packet.

ip-overlap-frag
IPv4 overlapping fragments.

ip-short-frag
IPv4 fragments whose payload size is less than the minimum IPv4 Fragment size. The minimum size is configurable via the db variable tm.minipfragsize.

ip-unk-prot
IP Unknown Protocol type.

ip-opt-frames
IP option frames. IPv4 packets with options. db variable tm.acceptipoptions must be enabled to receive IP options.

ip-other-frag
The total IPv4 fragments' size has exceeded the reassembly queue or the maximum IP packet size.

ipv6-atomic-frag
IPv6 frame with frag extension hdr, but the MF and offset fields are both 0.

ipv6-bad-src
IPv6 src address is a multicast address or IPv6 src or destination address is a IPv4 mapped IPv6 address.

ipv6-ext-hdr-frames
IPv6 extended header frames.

ipv6-frag-flood
IPv6 fragment flood.

ipv6-len-gt-l2-len

IPv6 length > L2 length.

ipv6-other-frag

The total IPv6 fragments' size has exceeded the reassembly queue or the maximum IP packet size.

ipv6-overlap-frag

IPv6 overlapping fragments.

ipv6-short-frag

IPv6 fragments whose payload size is less than the minimum IPv6 Fragment size. The minimum size is configurable via the db variable tm.minipv6fragsize.

ipv4-mapped-ipv6

IPv4 mapped IPv6 addresses.

land-attack

Land Attack. IP Src Address equals IP Dst Address. Both V4 and V6 are counted.

l2-len-ggt-ip-len

L2 length >> IP length. L2 packet length is much greater than payload length in IPv4 (L2 length > IP length and L2 length > minimum packet size).

l4-ext-hdrs-go-end

No L4 (extended headers go to or past the end of frame).

no-l4

No L4. No L4 payload for IPv4.

opt-present-with-illegal-len

TCP Option present with illegal length.

payload-len-ls-l2-len

Payload length < L2 length. Payload length in IPv6 header is less than L3 part length in L2 packet.

routing-header-type-0

Routing header type 0 present.

sip-malformed

SIP malformed packet

sip-invite-method

SIP INVITE method packet.

sip-ack-method

SIP ACK method packet.

sip-options-method

SIP OPTIONS method packet.

sip-bye-method

SIP BYE method packet.

sip-cancel-method

SIP CANCEL method packet.

sip-register-method

SIP REGISTER method packet.

sip-publish-method

SIP PUBLISH method packet.

sip-notify-method

SIP NOTIFY method packet.

sip-subscribe-method

SIP SUBSCRIBE method packet.

sip-message-method

SIP MESSAGE method packet.

sip-prack-method

SIP PRACK method packet.

sip-uri-limit

Limit SIP URI length.

sip-other-method

SIP OTHER method packet.

sweep

A Sweep is an attack where a single endpoint initiates network traffic to a large number of receiving endpoints or subnets.

syn-and-fin-set

SYN && FIN set.

tcp-ack-flood

TCP packets with the ACK flag set (for non-existing flows).

tcp-bad-urg

TCP packets with the URG flag set but URG pointer is 0.

tcp-hdr-len-gt-l2-len

TCP header length > L2 length. No room in packet for TCP header (including options).

tcp-hdr-len-too-short

TCP header length too short (length < 5). The offset field in TCP header is less than 20 bytes.

tcp-opt-overflow-tcp-hdr

TCP option overruns TCP header.

tcp-syn-flood

TCP header with only the SYN flag set.

tcp-synack-flood

TCP header with only the SYN and ACK flags set.

tcp-rst-flood

TCP header with only the RST flag set.

tcp-psh-flood

TCP header with PUSH flag set.

tcp-window-size

TCP non-RST pkt with window size < . This sys db tunable is configurable with Dos.TcpLowWindowSize.

tidcmp

ICMP source quench packets.

too-many-ext-hdrs

Too many extended headers. The IPv6 extended headers are more than 4. This number can be set through db variable dos.maxip6exthdrs.

tcp-syn-oversize

TCP data-SYN with pktlength > dos.maxsynsize which is 128 bytes by default.

ttl-leq-one

TTL <= . For IPv4 forwarding. This sys db tunable is configurable by tm.minipttl.

unk-tcp-opt-type

Unknown TCP option type.

udp-flood

UDP Flood.UDP flood vector counts any UDP packets that either match the UDP Port InclusionList or do not match the UDP Port ExclusionList. "tmsh modify security dos udp-portlist" can be used to configure the udp port list.For more info about udp portlist and how to configure it use "help security dos udp-portlist"

unk-ipopt-type

Unknown IP option type.

ip-uncommon-proto

ip-uncommon-proto vectors counts packets whose protocol is specified in configured ip-uncommon-protolist.

PARAMETERS

allow-advertisement

Enables allow advertisement. The default is disabled.

allow-upstream-scrubbing

Enables allow upstream scrubbing. The default value is disabled.

attacked-dst

Enables attacked-destination. The default value is disabled.

auto-blacklisting

Enables automatic blacklisting of offending source IPs. The default value is disabled.

auto-scrubbing

Enables specifying destination IP scrubbing. The default value is disabled.

auto-threshold

This option is deprecated in version 13.1.0 and is replaced by threshold-mode. Enables the auto threshold mode for dos detection and dos mitigation. The default value is disabled.

bad-actor

Enables per-source IP based bad actor detection. The default value is disabled.

blacklist-category

Blacklist category (of IP intelligence) to which this IP should be added. The default value is none.

blacklist-detection-seconds

Duration in seconds for which the IP has been offending. The default value is 60.

blacklist-duration

Duration in seconds for which this IP should be blocked. The default value is 14400.

ceiling

Option to set a maximum value ("ceiling") for the default-internal-rate-limit for this vector. The range is from 0 to infinity.

default-internal-rate-limit

This parameter is programmed in hardware to limit the traffic to BIG-IP software. If the hardware DoS support does not exist software uses default-internal-rate-limit to limit the good traffic (most of them are flood) to external servers. Bad packets are always dropped.

If the rate limit value is infinite the rate limit is disabled. The default value is 100000.

detection-threshold-percent

This parameter specifies relative threshold that uses dynamically learned 1-hour average rate to detect attacks. If the current rate (1-minute average) increases the specified percent over the 1-hour average rate, attack is detected.

If the threshold value is infinite the detection is disabled. The default value is 500.

detection-threshold-pps

This parameter specifies absolute threshold value. If the current rate (1-minute average) is equal or above the threshold value, attack is detected.

If the threshold value is infinite the detection is disabled. The default value is 100000.

enforce

This option is deprecated in version 13.1.0 and is replaced by state. Enable or disable the packet drop action of DOS detection for this attack type.

floor

Option to set a minimum value ("floor") for the detection-threshold-pps for this vector. The range is from 0 (no-floor) to infinity (no-detection). The default value is 5000.

multiplier-mitigation-percentage

Specifies the mitigation multiplier value of this specific vector in percentage when using manual-multiplier-mitigation mode. The default value used is inherited from the network dos profile.

packet-types

This parameter is used to specify type of packets that will be classified as Sweep/Flood attacks. There are various types of packet types that can be specified. The default value is none.

per-dst-ip-detection-pps

Specifies the attack detection threshold (pps) per destination IP. The default value is infinite.

per-dst-ip-limit-pps.

Specifies the attack mitigation threshold (pps) per destination IP. The default value is infinite.

per-source-ip-detection-pps

Specifies the attack detection threshold (pps) per source IP. The default value is infinite.

per-source-ip-limit-pps

Specifies the attack mitigation threshold (pps) per source IP. The default value is infinite.

scrubbing-category

Specifies per-DstIP scrubbing category. The default value is none.

scrubbing-detection-seconds

Specifies duration in seconds for which the destination IP has been offended/attacked. The default value is 10.

scrubbing-duration

Specifies duration in seconds for which this IP should be scrubbed. The default value is 900.

simulate-auto-threshold

Option to enable/disable auto-threshold simulation by generating logs if auto-threshold based detection/mitigation would have kicked in. Only valid in manual mode. The default value is disabled.

state

Specifies the run time state of this signature. The default value is mitigate.

The options are:

disabled

Do not learn, do not collect stats.

learn-only

Learn/Collect stats, but do not "detect" ("alarm" in ASM-speak) any attacks,

detect-only

Learn/Collect stats/detect, but do not mitigate (rate-limit/drop, challenge, etc.) any attacks.

mitigate

Learn/Collect stats/detect/mitigate (using whichever mitigations are configured).

suspicious

Specifies if the vector considers all packets or only unsolicited packets. The default value is false.

threshold-mode

Enables the threshold mode for DoS detection and DoS mitigation. The default value is manual.

The options are:

manual

Specifies the manual thresholds.

stress-based-mitigation

Specifies the manual detection ("alarm") threshold, but mitigation threshold is stress-based.

fully-automatic

Specifies both the detection ("alarm") and mitigation thresholds are automatically computed.

manual-multiplier-mitigation

Specifies the detection ("alarm") threshold is automatically computed. The mitigation threshold is calculated by the detection threshold multiplies the multiplier-mitigation-percentage.

valid-domains

Adds, deletes, modifies, or replaces a set of valid fully qualified domain names (FQDNs).

security dos dns-nxdomain-stat

NAME

dns-nxdomain-stat - Displays and resets dos dns-nxdomain statistics of the specified context on the BIG-IP(r) system.

MODULE

security dos

SYNTAX

Manage the virtual component within the security dos module using the syntax in the following sections.

DISPLAY

show dns-nxdomain-stat

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

MODIFY

reset-stats dns-nxdomain-stat

DESCRIPTION

You can use the dns-nxdomain-stat component to display or reset dos dns-nxdomain statistics.

EXAMPLES

show dns-nxdomain-stat

Displays the dns-nxdomain's statistics in the system default units.

show dns-nxdomain-stat raw

Displays the raw dns-nxdomain's statistics.

reset-stats dns-nxdomain-stat

Resets the dns-nxdomain statistics.

SEE ALSO

reset-stats, show, tmsh

security dos dos-signature

NAME

dos-signature - Configures DoS Behavioral Signature(s).

MODULE

security dos

SYNTAX

Configure the dos-signature component within the security dos module using the syntax shown in the following sections.

CREATE/MODIFY

create dos-signature [name]

modify dos-signature [name]

options:

alias [string]

app-service [string | none]

approval-state [unapproved | manually-approved]

parent-context-type [device | virtual-server | device-netflow]

parent-context [string]

parent-profile [string]

description [string]

family [dns| network | http | tls]

hardware-offload [disabled | enabled]

manual-detection-threshold [integer]

manual-mitigation-threshold [integer]

multiplier-mitigation-percentage [integer]

origin [dynamic-bdos | user-defined]

predicates [list of struct(string, string, string)]

shareability-state [not-shareable | fully-shareable]

state [disabled | learn-only | detect-only | mitigate]

tags [list of string]

threshold-mode [manual | manual-multiplier-mitigation | stress-based-mitigation | fully-automatic]

type [dynamic | persistent]

DISPLAY

list dos-signature [name]

DELETE

delete dos-signature [name]

DESCRIPTION

You can use the dos-signature component to modify or display a DoS signature.

EXAMPLES

create security dos dos-signature Sig_Device_ToS type persistent family http origin user-defined state disabled

This example shows how to create a DoS signature named Sig_Device_ToS

list security dos dos-signature Sig_Device_ToS

This example shows how to display a DoS signature named Sig_Device_ToS

modify dos-signature Sig_Device_TTL manual-detection-threshold 10000 manual-mitigation-threshold 4294967295

This examples show how to modify the manual detection and mitigation threshold of a DoS signature named Sig_Device_TTL

delete security dos dos-signature Sig_Device_ToS

This example shows how to delete a DoS signature named Sig_Device_ToS

OPTIONS

alias

Specifies the alias name of a signature. The default is empty string.

app-service

Specifies the application service that the object belongs to.

approval-state

Specifies whether or not the signature has been reviewed for quality/correctness. For a persistent signature with dns or network family, the default is manually-approved. Otherwise, the default is unapproved.

User can't modify approval-state for a dynamic signature with dns or network family.

The options are:

unapproved

Specifies the signature is not approved.

manually-approved

Specifies the signature has been reviewed for quality/correctness.

parent-context-type

Specifies the type of the context for which this signature has been generated.

The available options:

device

Specifies the context type is a DoS device.

virtual-server

Specifies the type of the context is a Virtual Server.

device-netflow

Specifies the context type is Netflow device.

For a dynamic type signature, it is required field and it is not allowed to be modified once specified.

For persistent type signature, it can't be reset once it is set. The default is unspecified.

For persistent type signature with dns or network family, this field is not applicable.

parent-context

Specifies the context for which this signature has been generated. The default is empty string.

This field is based on parent-context-type. If parent-context-type is device, it must be constant "Device". If parent-context-type is device-netflow, it must be constant "NetFlow".

For a dynamic type signature, it can't be empty and it is not allowed to be modified once specified.

For persistent type signature, it can't be reset once it is set.

For persistent type signature with dns or network family, this field is not applicable.

parent-profile

Specifies the profile for which this signature has been generated. The default is empty string.

This field is based on parent-context-type. If parent-context-type is device or device-netflow, it must be constant "/Common/dos-device-config".

For a dynamic type signature, it can't be empty and it is not allowed to be modified once specified.

For a persistent type signature, it can't be reset once it is set.

This field is required for a persistent type signature with dns or network family and non-shareable shareability-state.

description

Specifies user defined description for this signature.

family

Specifies the family this signature belongs to. This is a required field for creation. The options are dns, network, http

It is not allowed to be modified once it is created.

hardware-offload

Enables or disables hardware offloading on the dynamic and persistent network family signature. The default value is enabled.

manual-detection-threshold

Specifies the manual threshold (Events Per Second) above which the traffic is declared as an attack. The default is infinite(4294967295).

This field is taken effective only when threshold-mode attribute is set to manual. For a signature with http family, it should be always 0.

For a persistent signature with dns or network family, this field is not applicable and it should be always default value.

For a dynamic signature with dns or network family, this field can't be changed if threshold-mode is fully-automatic.

manual-mitigation-threshold

Specifies the manual threshold (Events Per Second) above which the system rate limits (drops) the traffic

that matches this signature. The default is infinite(4294967295).

This field is taken effective only when threshold-mode attribute is set to manual. For a signature with http family, it should be always 0.

For a persistent signature with dns or network family, this field is not applicable and it should be always default value.

For a dynamic signature with dns or network family, this field can't be changed if threshold-mode is fully-automatic.

For a signature with parent-context-type is device-netflow, this field must be infinite(4294967295).

multiplier-mitigation-percentage

Specifies the mitigation multiplier value of this specific dos signature in percentage when using manual-multiplier-mitigation mode. The default value is inherited from the corresponding device level/profile mitigation multiplier value of the same dos family.

origin

Specifies the origin where this signature is generated from. The options are dynamic-bdos and user-defined. The default is user-defined.

It is not allowed to be modified once it is created.

predicates

Specifies list of predicates that constitutes this signature. Each predicate contains 3 string fields: metric, operator, and arguments. It is required field.

User can't add/modify predicates for a dynamic signature with dns or network family.

shareability-state

Specifies whether or not the signature can be used by Contexts (Virtual Servers) other than the one that created the signature. For a persistent signature with dns or network, the default is fully-shareable. Otherwise, the default is not-shareable.

User can't modify shareability-state for a dynamic signature with dns or network family.

This field can't be changed from fully-shareable to not-shareable if the signature is referred.

The options are:

not-shareable

Specifies the signature can only be used by context which created it.

fully-shareable

Specifies the signature can be used by contexts other than the one that created it.

state

Specifies the deployment state of this signature. The default is disabled.

The options are:

disabled

Do not learn, do not collect stats.

learn-only

Learn/Collect stats, but do not "detect" ("alarm" in ASM-speak) any attacks,

detect-only

Learn/Collect stats/detect, but do not mitigate (rate-limit/drop, challenge, etc.) any attacks.

mitigate

Learn/Collect stats/detect/mitigate (using whichever mitigation(s) are configured).

For a persistent signature with dns or network family, this field is not applicable and it should be always default value.

For a dynamic signature with dns or network family, learn-only is not allowed.

For a signature with http family, only learn-only or mitigate is allowed.

tags Specifies list of tags of this signature. The default is empty.

threshold-mode

Specifies the threshold mode for DoS detection and mitigation. The default is manual.

The options are:

manual

Specifies the manual thresholds.

stress-based-mitigation

Specifies the manual detection ("alarm") threshold, but mitigation threshold is stress-based. This option is not available for a signature with http family or for a signature with parent-context-type being device-netflow.

fully-automatic

Specifies both the detection ("alarm") and mitigation thresholds are automatically computed. This option is not available for a signature with http family.

manual-multiplier-mitigation
Specifies the detection ("alarm") threshold is automatically computed. The mitigation threshold is calculated by the detection threshold multiplies the multiplier-mitigation-percentage.

For a persistent signature with dns or network family, this field is not applicable and it should be always default value.

For a signature with parent-context-type is device-netflow, this field can't be stress-based-mitigation.

For a signature with http family, this field can't be stress-based-mitigation or fully-automatic.

type Specifies the type of this signature. The options are dynamic and persistent. The default is persistent.

It is not allowed to be changed from persistent to dynamic. User can't create dynamic signature but can modify and delete it.

security dos dynamic-signatures

NAME
dynamic-signatures - Configures the dynamic signature(s) generated by L4 BDoS (or Dynamic Signature) AFM feature based on traffic characterization and anomaly detection.

This component has been deprecated and replaced by dos-signature in 13.1.0.

MODULE
security dos

SYNTAX
Configure the dynamic-signatures component within the security dos module using the syntax shown in the following sections.

CREATE
Currently this option is not supported for dynamic signatures.

MODIFY
modify dynamic-signatures [name]
options:
context-name [name]
detection-threshold [integer]
dynamic-vectors
enforce [disabled | enabled]
mitigation-threshold [integer]
partition [name]
status [disabled | enabled]

DISPLAY
list dynamic-signatures

DELETE
Currently this option is not supported for dynamic signatures.

DESCRIPTION
You can use the dynamic-signatures component to modify or display a dynamic signature.

EXAMPLES
modify dynamic-signatures Sig_Device_ToS status disabled

This example shows how to disable a dynamic signature named Sig_Device_ToS

modify dynamic-signatures Sig_Device_TTL detection-threshold 10000 mitigation-threshold 4294967295

This examples show how to modify the detection and mitigation threshold of a dynamic signature named Sig_Device_TTL

OPTIONS

context-name

Specifies the context for which the dynamic signature has been generated. This is a read-only field and possible values are 'Device' or 'Virtual server Name'.

detection-threshold

Specifies the threshold value above which the traffic is declared as 'anomalous' (or an attack). When the system generates a dynamic signature (based on traffic anomaly characterization), it assigns a value for detection threshold (based on various factors such as sensitivity, anomaly percent, confidence level etc.)

User can override this value by modifying the signature and specify a new value to be used for detection mechanism.

dynamic-vectors

Specifies the list of metrics and the corresponding values/ranges that constitutes a dynamic signature. This is a read-only field.

enforce

Specifies the run time behavior of the dynamic signature in the datapath with respect to enforcement. Possible values are: disabled or enabled.

If set to disabled, the system does not enforce the signature to rate limit traffic but only collect statistics. If set to enabled, in addition to collecting stats, system also enforces the signature to detect an attack and limit traffic as per the mitigation threshold.

mitigation-threshold

Specifies the threshold above which the system rate limits (drops) the traffic that matches this generated dynamic signature. When the system generates a dynamic signature, it assigns a value for mitigation threshold based on certain factors such as mitigation configuration, detection threshold etc.

User can override this value by modifying the signature and specify a new value to be used for mitigating traffic that matches this dynamic signature.

status

Specifies the run time status of the generated signature. Possible values are: disabled or enabled.

By default, the status is set to enabled when the system generates a dynamic signature. User can disable detection and mitigation for this dynamic signature by setting this field to disabled.

security dos ip-uncommon-protolist

NAME

ip-uncommon-protolist - Configures the DoS IP uncommon protocol list component within the security dos module using the syntax shown in the following sections.

MODULE

security dos

SYNTAX

CREATE/MODIFY

modify ip-uncommon-protolist [name]

options:

description [string]

entries [add | delete | none | replace-all-with]

DISPLAY

list ip-uncommon-protolist

list ip-uncommon-protolist [name]

DESCRIPTION

You can use the ip-uncommon-protolist component to configure a DoS IP uncommon protocol list. These DoS IP uncommon protocol entries are used to rate limit the PPS (Packet per second) rate for IP protocols (identified by the IP protocol number) that are not expected to be common in the customer deployment.

EXAMPLES

create ip-uncommon-protolist plistA entries add { 20 tcp } Creates a plistA IP uncommon protocol list with

entries protocol 20 and tcp.

modify ip-uncommon-protolist plistA entries add { udp } Modifies the plistA to add udp protocol to the list.

modify ip-uncommon-protolist plistA entries delete { 20 } Modifies the plistA to add protocol 20 from the list.

list ip-uncommon-protolist plistA Displays the current list of plistA entries.

OPTIONS

description

Specified user defined description for a DoS ip-uncommon--protolist.

entries

Specified contexts of a DoS ip-uncommon--protolist. The default is none.

The options are:

add Add a protocol entry to the specified IP uncommon protocol list.

delete

Remove a protocol entry from the specified IP uncommon protocol list.

none Remove all protocols from the specified IP uncommon protocol list.

replace-all-with

Replace all protocols in the specified IP uncommon protocol list.

name Specified name of a DoS ip-uncommon--protolist. This is required during creation.

"ip-uncommon-protolist" is the system ip-uncommon--protolist. It can't be deleted.

security dos l4bdos-file-object

NAME

l4bdos-file-object - L4 BDoS internal file object.

MODULE

security

SYNTAX

Configure l4bdos-file-object within security dos module using the syntax shown in the following sections.

CREATE/MODIFY

create l4bdos-file-object [name]

modify l4bdos-file-object [name]

options:

app-service [[string] | none]

context-name [string]

source-path [file name]

DELETE

delete l4bdos-file-object [name]

DESCRIPTION

l4bdos file object is used internally for synchronization of bdos module data across HA (high availability) or Cluster setup.

EXAMPLES

create name source-path /var/bdos/file.json context-name /Common/VS1

Creates a file object named name, that gets its contents from file object /var/bdos/file.json and is created for ltm virtual /Common/VS1.

delete filename

Deletes the file object named filename.

OPTIONS

- app-service
Specifies the name of the application service to which the file object belongs. The default value is none.
- source-path
The name of the source file from which the contents are copied to create the file object.
- context-name
The name of the virtual server to which this file object belongs.

SEE ALSO

- create, delete, edit, modify, tmsh

COPYRIGHT

 match-ip-version [false | true]
 source {
 address [ip_address/prefixlen]]
 vlans [vlan name | vlanid/mask]
 }
 }
 }
 extended-entries none

DISPLAY

- list network-whitelist

DESCRIPTION

You can use the network-whitelist component to configure two types of DoS network whitelists: 1) standard whitelist, up to eight entries; 2) extended whitelist, up to the the number of entries specified by DB variable dos.maxewlsize (range from 0 to 1024). Whitelists configured this way can be applied to all traffic except those from the management interface. Along with that you can use address-list to configure the srcIP Global whitelist. To this address-list you need to attach the address list objects. This address-list can be a nested list of fully qualified address. Subnets and IP address ranges and geo-locations are not allowed. The HSB hardware compares all incoming traffic to the network-whitelist entries. If a match is found then it does not do DoS vector checks for those packets. If a match is not found then DoS vector checks are done on those packets. The network software does its regular DoS vector checks on the incoming packets as usual. If a DoS vector is hit then it compares that packet with the DoS network-whitelist entries. If the packet matches an entry, then the system does not increment the DoS vector that matched. If the packets does not match a DoS network-whitelist entry then the matched DoS vector is incremented and appropriate action is taken.

If an entry specifies more than one of the above items, a packet must pass all of the items to successfully match. For example, if an entry specifies a source subnet and a destination port, a packet must originate from the given subnet and must also have the specified destination port.

Either destination ip_address/prefixlen or source ip_address/prefixlen can be specified in a network-whitelist entry. An ip_address/prefixlen for both source and destination cannot be specified for an entry.

EXAMPLES

```
modify network-whitelist dos-network-whitelist description "bad interfaces" entries add { re_telnet { ip-protocol tcp destination { port telnet } } }
```

Creates a new entry called re_telnet. It matches any TCP packet whose destination port is telnet.

```
modify network-whitelist dos-network-whitelist entries add { internal-net { source { address 172.27.0.0/16 } } }
```

Creates an entry that matches traffic from the 172.27.0.0 network.

```
list network-whitelist
security dos network-whitelist dos-network-whitelist {
  entries {
    re_telnet {
      ip-protocol tcp
      destination {
        port telnet
      }
    }
    internal-net {
      source {
        address 172.27.0.0/16
      }
    }
  }
}
```

Displays the current list of DoS whitelist entries.

```
modify network-whitelist dos-network-whitelist entries delete { internal-net }
```

Removes the "internal-net" entry from the list of network-whitelist entries.

```
modify security dos network-whitelist dos-network-whitelist extended-entries add { netwl { source { address 10.0.0.0/8 } destination { address 20.20.20.0/24 } ip-protocol udp } }
```

Creates a new extended entry called netwl. It matches any UDP packet matches source network address 10.x.x.x and destination network address 20.20.20.x.

```
list security dos network-whitelist dos-network-whitelist extended-entries { netwl }
security dos network-whitelist dos-network-whitelist {
  extended-entries {
    netwl {
      description none
      ip-protocol udp
      destination {
        address 20.20.20.0/24
      }
      port any
    }
    source {
      address 10.0.0.0/8
    }
    vlans any
  }
}
```

Displays the extended whitelist entry just configured.

OPTIONS

address-list
Specifies the object in security firewall address-list as the srcIP Global whitelist.

description
Your description for the DoS network-whitelist entries.

entries

Adds, deletes, or replaces a standard network-whitelist entry, by specifying an entry name. If an entry by the specified name does not exist, it will be created.

add Creates a new entry, which you specify next with a unique string in curly braces ({}).

delete

Deletes the entry that you specify next, in curly braces ({}). You can use delete {all} to empty the list of network-whitelist entries, which has the same effect as using none (see below).

modify

Modifies the existing entry that you specify next, in curly braces ({}). After the entry name, enter the new configuration settings for the entry inside a nested set of curly braces.

replace-all-with

Replaces the current set of network-whitelist entries with the entry(s) that you specify next, in curly braces ({}).

none Empties the list of network-whitelist entries.

Enter the name of a entry to be added or modified, then enter an open curly brace {}, one or more of the following options, and a closed curly brace {}.

description

Your description for the current entry.

destination

Matches against each packet's destination IP and/or destination port.

address

Specifies an IP address and network to compare against the packet's destination address.

The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:ca90:ff00:0042:8329" to "2001:db7:3f4a:9dd:ca90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:23ff:678" to "2001::c34a:0:23ff:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

port Specifies a port to compare against the packet's destination port.

ip-protocol

Specifies the IP protocol to compare against the packet. This could be any, icmp, igmp, tcp or udp. If you specify this option, a packet only matches if it uses the chosen protocol.

match-ip-version

Specifies whether any/any6 in source/destination address is to match 'any IPv4', 'any IPv6', or 'any IPv4 and any IPv6' addresses. If match-ip-version is true, both source and destination addresses must have the same IP address family. If match-ip-version is false and both source and destination addresses are any or any6, both addresses represent 'any IPv4 and IPv6 addresses'. If match-ip-version is false and only one address is set to any or any6, the address is interpreted based on the other IP address' family (IPv4 or IPv6). The default is false.

source

Matches against each packet's source IP, and/or source VLANs.

address

Specifies an IP address and network to compare against the packet's source address.

The format for an IPv4 address is a.b.c.d. The general format for an IPv6 address is a:b:c:d:e:f:g:h.

vlan

Specifies either a vlan name or a range of vlanids to compare against the packet. The range is specified as vlanid/mask. For example if you specify "3200/8" then the vlanid range will be 3200-3327.

extended-entries

Adds, deletes, or replaces an extended network-whitelist entry, by specifying an entry name. If an entry by the specified name does not exist, it will be created.

add Creates a new entry, which you specify next with a unique string in curly braces ({}).

delete

Deletes the entry that you specify next, in curly braces ({}). You can use delete {all} to empty the list of network-whitelist entries, which has the same effect as using none (see below).

modify

Modifies the existing entry that you specify next, in curly braces ({}). After the entry name, enter the new configuration settings for the entry inside a nested set of curly braces.

replace-all-with

Replaces the current set of network-whitelist entries with the entry(s) that you specify next, in curly braces ({}).

none Empties the list of network-whitelist extended-entries.

Enter the name of a entry to be added or modified, then enter an open curly brace ({), one or more of the following options, and a closed curly brace (}).

description

Your description for the current entry.

destination

Matches against each packet's destination IP and/or destination port.

address

Specifies an IP address and network to compare against the packet's destination address.

The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:ca90:ff00:0042:8329" to "2001:db7:3f4a:9dd:ca90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:23ff:678" to "2001::c34a:0:23ff:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

port Specifies a port to compare against the packet's destination port.

ip-protocol

Specifies the IP protocol to compare against the packet. This could be any, icmp, igmp, tcp or udp. If you specify this option, a packet only matches if it uses the chosen protocol.

match-ip-version

Specifies whether any/any6 in source/destination address is to match 'any IPv4', 'any IPv6', or 'any IPv4 and any IPv6' addresses. If match-ip-version is true, both source and destination addresses must have the same IP address family. If match-ip-version is false and both source and destination addresses are any or any6, both addresses represent 'any IPv4 and IPv6 addresses'. If match-ip-version is false and only one address is set to any or any6, the address is interpreted based on the other IP address' family (IPv4 or IPv6). The default is false.

source

Matches against each packet's source IP, and/or source VLANs.

address

Specifies an IP address and network to compare against the packet's source address.

The format for an IPv4 address is a.b.c.d. The general format for an IPv6 address is a:b:c:d:e:f:g:h.

vlan

Specifies either a vlan name or a range of vlanids to compare against the packet. The range is specified as vlanid/mask. For example if you specify "3200/8" then the vlanid range will be 3200-3327.

EXAMPLES

```
modify security dos network-whitelist dos-network-whitelist address-list [name]
```

It adds list1 objects to the global address-list. For configuring the address list objects (list1) you can use the following examples:

```
create security firewall address-list list1 addresses [add | delete] { 30.30.30.30 45:56:567:234:456::0 }
```

```
list security firewall address-list list1
```

```
security firewall address-list list1 {  
  addresses {  
    30.30.30.30 { }  
    45:56:567:234:456:: { }  
  } }
```

This is how you can list the address-list objects that you configured for global whitelists

```
list security dos  
network-whitelist address-list security dos network-whitelist dos-network-whitelist {  
  address-list list1 }
```

DELETE
delete profile [name]

DESCRIPTION
You can use the profile component to create, modify, display, or delete a DoS profile for use with DoS Protection functionality.

EXAMPLES
create profile my_dos_profile

Creates a custom DoS profile named my_dos_profile with initial settings.

list profile

Displays the properties of all DoS profiles.

OPTIONS
app-service
Specifies the name of the application service to which the profile belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

application
Adds, deletes, or replaces a single Application Security sub-profile. You can configure the following options for Application Security:

bot-defense
Specifies properties of proactive bot defense in Application Security. You can configure the following options for Proactive Bot Defense:

collect-stats
Enables or disables domain statistics collection.

cross-domain-requests
Specifies a cross-domain requests handling mode. The options are:

allow-all
Allows all cross-domain requests. This is the default value.

validate-bulk
System validates domains in bulk: the cookies for the related domains are created together with the cookie for the current domain, by generating challenges in iframes - one per each domain.

validate-upon-request
System validates domains upon request: the cookie for the related domain is generated when a request arrives to an unqualified URL without a cookie.

external-domains
Configures a list of external domains that are allowed to link to resources of this website.

grace-period
Specifies the length of grace period (in seconds) in which only the Simple Bot Prevention is enforced.

mode Specifies a mode of proactive bot defense. The options are:

always
Specifies that the proactive bot defense is always enabled.

disabled
Specifies that the proactive bot defense is disabled. This is the default value.

during-attacks
Specifies that the proactive bot defense is enabled only during attacks.

site-domains
Configures a list of domains that are part of the website.

url-whitelist
Configures a list of URLs to exclude from the proactive bot defense.

browser-legit-enabled

Enables or disables the proactive bot defense validation of browser legitimacy and blocking of requests from suspicious clients.

browser-legit-captcha

Enables or disables the browser legitimacy detection improvement using CAPTCHA. In order to enable it, you must first enable browser-legit-enabled.

bot-signatures

Specifies settings of Bot Signatures in Application Security. You can configure the following options for Bot Signatures:

categories

Specifies the action for each Bot Signature Category. You can configure the following options for each Bot Signature Category:

action

Specifies the action for the Bot Signature Category. The possible actions are none, block and report.

check

Enables or disables the checking of Bot Signature, allowing bots to be detected.

disabled-categories

Configures a list of disabled Bot Signatures.

captcha-response

Specifies properties of the CAPTCHA response in Application Security. You can configure the following options for CAPTCHA Response Settings:

failure

Specifies properties of a failed CAPTCHA response. You can configure the following options for a failed CAPTCHA response:

body Configures a failed CAPTCHA response body.

type Configures a type of a failed CAPTCHA response body. You can configure the following options for a failed CAPTCHA response type:

custom

Configures a custom failed CAPTCHA response type.

default

Configures a default failed CAPTCHA response type.

first

Specifies properties of the first CAPTCHA response. You can configure the following options for the first CAPTCHA response:

body Configures the first CAPTCHA response body.

type Configures a type of the first CAPTCHA response body. You can configure the following options for the first CAPTCHA response type:

custom

Configures a custom first CAPTCHA response type.

default

Configures a default first CAPTCHA response type.

geolocations

Configures a list of blacklisted/whitelisted Geolocations. You can configure the following options for each Geolocation:

[black-listed | white-listed]

Specifies a type of Geolocation.

heavy-urls

Specifies heavy URL protection in Application Security. You can configure the following options for heavy URL protection:

automatic-detection

Enables or disables automatic heavy URL detection. In order to enable it, you must first enable protection.

exclude

Configures a list of URLs (or wildcards) to exclude from the heavy URLs.

include

(Deprecated, use include-list) Configures a list of URLs to include in the heavy URLs.

include-list

Configures a list of URLs to include in the heavy URLs.

latency-threshold

Specifies the latency threshold for automatic heavy URL detection (in milliseconds).

protection

(Deprecated, use stress/tps.url-enable-heavy) Enables or disables heavy URL protection. To enable it, you must additionally enable one of the following DoS URL-based prevention policy methods: url-client-side-defense or url-rate-limiting. This can be done for either tps-based or stress-based anomaly protection.

ip-whitelist

Attribute ip-whitelist is deprecated in version 13.0.0; consider using http-whitelist instead. Adds, deletes, or replaces a set of IP addresses and subnets in the whitelist of Application Security.

name Specifies a dummy name for enabled Application Security. This option is required for the operations create, delete, modify, and replace-all-with.

stress-based

Specifies Stress-based anomaly in Application Security. You can configure the following options for Stress-based anomaly:

de-escalation-period

Specifies the de-escalation period (in seconds) in Stress-based anomaly.

escalation-period

Specifies the escalation period (in seconds) in Stress-based anomaly.

geo-captcha-challenge

Enables or disables Geolocation-based CAPTCHA challenge in Stress-based anomaly.

geo-client-side-defense

Enables or disables Geolocation-based client side integrity defense in Stress-based anomaly.

geo-minimum-share

Specifies the minimum traffic share for detection in Geolocation detection criteria of Stress-based anomaly.

geo-rate-limiting

Enables or disables Geolocation-based rate limiting in Stress-based anomaly.

geo-request-blocking-mode

Specifies a Geolocation-based request blocking mode of Stress-based anomaly. The options are:

block-all

Specifies that the system blocks all requests from the respective Geolocation.

rate-limit

Specifies that the system blocks requests from the respective Geolocation based on the traffic share ratio. This is the default value.

geo-share-increase-rate

Specifies the percentage by which TPS increased in Geolocation detection criteria of Stress-based anomaly.

ip-captcha-challenge

Enables or disables Source IP-based CAPTCHA challenge in Stress-based anomaly.

ip-client-side-defense

Enables or disables Source IP-based client side integrity defense in Stress-based anomaly.

ip-maximum-tps

Specifies the amount which TPS reached in IP detection criteria of Stress-based anomaly.

ip-minimum-tps

Specifies the minimum TPS threshold for detection in IP detection criteria of Stress-based anomaly.

ip-rate-limiting

Enables or disables Source IP-based rate limiting in Stress-based anomaly.

ip-request-blocking-mode

Specifies a Source IP-based request blocking mode of Stress-based anomaly. The options are:

block-all

Specifies that the system blocks all requests from the respective Source IP address.

rate-limit

Specifies that the system blocks requests from the respective Source IP address based on the traffic share ratio. This is the default value.

ip-tps-increase-rate

Specifies the percentage by which TPS increased in IP detection criteria of Stress-based anomaly.

mode Specifies an operation mode of Stress-based anomaly. The options are:

off Specifies that the system does not check for DoS attacks. This is the default value.

transparent

Specifies that when the system detects an attack, it displays the attack data on the Reporting DoS Attacks screen. In transparent mode the system does not drop requests either

from the attacking IP address, or to attacked URLs.

blocking

Specifies that when the system detects an attack, in addition to displaying the attack data on the Reporting DoS Attacks screen, the system also drops either connections from the attacking IP address, or requests to attacked URLs.

site-captcha-challenge

Enables or disables Site-wide CAPTCHA challenge in Stress-based anomaly.

site-client-side-defense

Enables or disables Site-wide client side integrity defense in Stress-based anomaly.

site-maximum-tps

Specifies the amount which TPS reached in Site-wide detection criteria of Stress-based anomaly.

site-minimum-tps

Specifies the minimum TPS threshold for detection in Site-wide detection criteria of Stress-based anomaly.

site-rate-limiting

Enables or disables Site-wide rate limiting in Stress-based anomaly.

site-tps-increase-rate

Specifies the percentage by which TPS increased in Site-wide detection criteria of Stress-based anomaly.

static-url-mitigation

Enables or disables Static URL mitigation in Stress-based anomaly.

url-captcha-challenge

Enables or disables URL-based CAPTCHA challenge in Stress-based anomaly.

url-client-side-defense

Enables or disables URL-based client side integrity defense in Stress-based anomaly.

url-maximum-tps

Specifies the amount which TPS reached in URL detection criteria of Stress-based anomaly.

url-minimum-tps

Specifies the minimum TPS threshold for detection in URL detection criteria of Stress-based anomaly.

url-rate-limiting

Enables or disables URL-based rate limiting in Stress-based anomaly.

url-tps-increase-rate

Specifies the percentage by which TPS increased in URL detection criteria of Stress-based anomaly.

behavioral

Specifies properties of Behavioral Detection in Stress-based anomaly. You can configure the following options for Behavioral Detection:

dos-detection

Enables or disables the Behavior Based Detection.

mitigation-mode

Specifies mitigation impact on suspicious bad actors/requests. None: Learns and monitors traffic behavior, but no action is taken. Conservative protection:If enabled, slows down and rate limits requests from anomalous IP addresses based on its anomaly detection confidence and the server's health. If enabled, blocks requests that match the attack signatures. Standard protection:If enabled, slows down requests from anomalous IP addresses based on its anomaly detection confidence and the server's health. Rate limits requests from anomalous IP addresses and, if necessary, rate limits all requests based on the server's health. Limits the number of concurrent connections from anomalous IP addresses and, if necessary, limits the number of all concurrent connections based on the server's health. If enabled, blocks requests that match the attack signatures. Aggressive protection:If enabled, slows down requests from anomalous IP addresses based on its anomaly detection confidence and the server's health. Rate limits requests from anomalous IP addresses and, if necessary, rate limits all requests based on the server's health. Limits the number of concurrent connections from anomalous IP addresses and, if necessary, limits the number of all concurrent connections based on the server's health. Proactively performs all protection actions (even before an attack). Increases the impact of the protection techniques. If enabled, blocks requests that match the attack signatures. Increases the impact of blocked requests.

signatures

Enables or disables signature usage and mitigation.

signatures-approved-only

Allows to use only manually approved signatures.

accelerated-signatures

Enables or disables signatures detection before the connection establishment. Automatically enables syn-cookie mechanism during attack.

tls-signatures

Enables or disables TLS signatures detection before the connection establishment.

tls-fp

Enables or disables TLS patterns as an extension of bad actors detection.

tcp-dump

Specifies properties of traffic recording during attacks in Application Security. You can configure the following options for Record Traffic During Attacks:

maximum-duration

Specifies the TCP dump maximum duration (in seconds).

maximum-size

Specifies the TCP dump maximum size (in megabytes).

record-traffic

Enables or disables traffic recording during attacks.

repetition-interval

Specifies the TCP dump repetition interval (in seconds).

tps-based

Specifies TPS-based anomaly in Application Security. You can configure the following options for TPS-based anomaly:

de-escalation-period

Specifies the de-escalation period (in seconds) in TPS-based anomaly.

escalation-period

Specifies the escalation period (in seconds) in TPS-based anomaly.

geo-captcha-challenge

Enables or disables Geolocation-based CAPTCHA challenge in TPS-based anomaly.

geo-client-side-defense

Enables or disables Geolocation-based client side integrity defense in TPS-based anomaly.

geo-minimum-share

Specifies the minimum traffic share for detection in Geolocation detection criteria of TPS-based anomaly.

geo-rate-limiting

Enables or disables Geolocation-based rate limiting in TPS-based anomaly.

geo-request-blocking-mode

Specifies a Geolocation-based request blocking mode of TPS-based anomaly. The options are:

block-all

Specifies that the system blocks all requests from the respective Geolocation.

rate-limit

Specifies that the system blocks requests from the respective Geolocation based on the traffic share ratio. This is the default value.

geo-share-increase-rate

Specifies the percentage by which TPS increased in Geolocation detection criteria of TPS-based anomaly.

ip-captcha-challenge

Enables or disables Source IP-based CAPTCHA challenge in TPS-based anomaly.

ip-client-side-defense

Enables or disables Source IP-based client side integrity defense in TPS-based anomaly.

ip-maximum-tps

Specifies the amount which TPS reached in IP detection criteria of TPS-based anomaly.

ip-minimum-tps

Specifies the minimum TPS threshold for detection in IP detection criteria of TPS-based anomaly.

ip-rate-limiting

Enables or disables Source IP-based rate limiting in TPS-based anomaly.

ip-request-blocking-mode

Specifies a Source IP-based request blocking mode of TPS-based anomaly. The options are:

block-all

Specifies that the system blocks all requests from the respective Source IP address.

rate-limit

Specifies that the system blocks requests from the respective Source IP address based on the traffic share ratio. This is the default value.

ip-tps-increase-rate

Specifies the percentage by which TPS increased in IP detection criteria of TPS-based anomaly.

mode Specifies an operation mode of TPS-based anomaly. The options are:

- off Specifies that the system does not check for DoS attacks. This is the default value.

- transparent

Specifies that when the system detects an attack, it displays the attack data on the Reporting DoS Attacks screen. In transparent mode the system does not drop requests either from the attacking IP address, or to attacked URLs.

- blocking

Specifies that when the system detects an attack, in addition to displaying the attack data on the Reporting DoS Attacks screen, the system also drops either connections from the attacking IP address, or requests to attacked URLs.

site-captcha-challenge

Enables or disables Site-wide CAPTCHA challenge in TPS-based anomaly.

site-client-side-defense

Enables or disables Site-wide client side integrity defense in TPS-based anomaly.

site-maximum-tps

Specifies the amount which TPS reached in Site-wide detection criteria of TPS-based anomaly.

site-minimum-tps

Specifies the minimum TPS threshold for detection in Site-wide detection criteria of TPS-based anomaly.

site-rate-limiting

Enables or disables Site-wide rate limiting in TPS-based anomaly.

site-tps-increase-rate

Specifies the percentage by which TPS increased in Site-wide detection criteria of TPS-based anomaly.

static-url-mitigation

Enables or disables Static URL mitigation in TPS-based anomaly.

url-captcha-challenge

Enables or disables URL-based CAPTCHA challenge in TPS-based anomaly.

url-client-side-defense

Enables or disables URL-based client side integrity defense in TPS-based anomaly.

url-maximum-tps

Specifies the amount which TPS reached in URL detection criteria of TPS-based anomaly.

url-minimum-tps

Specifies the minimum TPS threshold for detection in URL detection criteria of TPS-based anomaly.

url-rate-limiting

Enables or disables URL-based rate limiting in TPS-based anomaly.

url-tps-increase-rate

Specifies the percentage by which TPS increased in URL detection criteria of TPS-based anomaly.

trigger-irule

Specifies, when enabled, that the system activates an Application DoS iRule event. The default value is disabled.

- single-page-application

Specifies, when enabled, that the system supports a Single Page Applications. The default value is disabled.

- fastl4-acceleration-profile

Specifies a fastL4 profile that used for DOS acceleration. None - if disable acceleration.

- scrubbing-enable

Specifies whether to enable Traffic Scrubbing during attacks by advertising BGP routes. This requires configuration of security scrubber profile, and will function even when the mode is set to transparent.

- scrubbing-duration-sec

Specifies the duration of the Traffic Scrubbing BGP route advertisement, in seconds. This is used when scrubbing-enable is enabled.

- rtbh-enable

Specifies whether to enable Remote Triggered Black Hole (RTBH) of attacking IPs by advertising BGP routes. This requires configuration of security blacklist-publisher, and will function even when the Operation Mode is set to transparent.

- rtbh-duration-sec

Specifies the duration of the RTBH BGP route advertisement, in seconds. This is used when rtbh-enable is enabled.

- description

User defined description.

protocol-dns

Adds, deletes, or replaces a single Protocol DNS Security sub-profile. You can configure the following options for Protocol DNS Security:

name Specifies a dummy name for enabled Protocol DNS Security. This option is required for the operations create, delete, modify, and replace-all-with.

dynamic-signatures

Specifies options related to DNS Behavioral DoS (Dynamic Signatures) feature per virtual server by virtue of attaching a dos profile to a virtual server. Following options are configurable for this feature:

detection

Specifies the mode for detection of anomalies in traffic for the purpose of dynamic signature generation. Following modes are supported: disabled, enabled and learn-only.

Mode learn-only is same as enabled except that the system does not generate any logs (or alerts the user). It is used mainly to learn the baseline thresholds for the traffic.

Default is disabled.

mitigation

Specifies the mode for mitigation of anomalous traffic (specified in form of dynamic signatures). Following modes are supported: none, low, medium and high.

Each mode represents the severity (or aggressiveness) at which the system should try to mitigate the anomalous traffic.

Default is none.

multiplier-mitigation-percentage

Specifies the mitigation multiplier value of all the vectors in the dns dos profile in percentage when using manual-multiplier-mitigation mode.

dns-query-vector

Adds, deletes, or replaces Protocol DNS DoS vectors. You can configure the following options for DNS query vectors:

query-type

Specifies the vector (DNS query) type for DoS attack detection.

enforce

This option is deprecated in version 13.1.0 and is replaced by state. Enable or disable the packet drop action of DOS detection for this attack type.

auto-threshold

This option is deprecated in version 13.1.0 and is replaced by threshold-mode. Enables the auto threshold mode for dos detection and dos mitigation. The default value is disabled.

allow-upstream-scrubbing

Enables allow upstream scrubbing. The default value is disabled.

attacked-dst

Enables attacked-destination. The default value is disabled.

auto-scrubbing

Enables specifying destination IP scrubbing. The default value is disabled.

bad-actor

Enables per-source IP based bad actor detection

multiplier-mitigation-percentage

Specifies the mitigation multiplier value of this specific vector in percentage when using manual-multiplier-mitigation mode, The default value used is inherited from the dns dos profile.

per-source-ip-detection-pps

Bad actor detection rate (for single IP address) of this vector

per-source-ip-limit-pps

Bad actor allowed rate (for single IP address) of this vector

per-dst-ip-detection-pps

Specifies the attack detection threshold (pps) per destination IP. The default value is infinite.

per-dst-ip-limit-pps

Specifies the attack mitigation threshold (pps) per destination IP. The default value is infinite.

scrubbing-category

Specifies per-DstIP scrubbing category. The default value is none.

scrubbing-detection-seconds

Specifies duration in seconds for which the destination IP has been offended/attacked. The default value is 10.

scrubbing-duration

Specifies duration in seconds for which this IP should be scrubbed. The default value is 900.

`rate-increase`
Specifies the rate increase for DoS attack detection.

`rate-limit`
Specifies the rate limit for DoS attack detection. If the value is infinite the detection is disabled.

`rate-threshold`
Specifies the rate threshold for DoS attack detection. If the value is infinite the detection is disabled.

`state`
Specifies the run time state of this signature. The options are the same as those in `network-attack-vector`.

`suspicious`
Specifies if the vector considers all packets or only unsolicited packets. The default value is `false`.

`threshold-mode`
Enables the threshold mode for dos detection and dos mitigation. The default value is `manual`. The options are the same as those in `network-attack-vector`.

`prot-err-attack-detection`
Specifies if protocol errors attack detection is enabled or not. Eg: Malformed, Malicious DoS attacks.

`prot-err-atck-rate-incr`
Specifies the protocol errors rate increase for DoS attack detection.

`protocol-sip`
Adds, deletes, or replaces a single Protocol SIP Security sub-profile. You can configure the following options for Protocol SIP Security:

`name` Specifies a dummy name for enabled Protocol SIP Security. This option is required for the operations `create`, `delete`, `modify`, and `replace-all-with`.

`prot-err-atck-rate-increase`
Specifies the protocol errors rate increase for DoS attack detection.

`prot-err-atck-rate-threshold`
Specifies the protocol errors rate threshold for DoS attack detection.

`prot-err-attack-detection`
Specifies if protocol errors attack detection is enabled or not. Eg: Malformed packets DoS attacks.

`multiplier-mitigation-percentage`
Specifies the mitigation multiplier value of all the vectors in the sip dos profile in percentage when using `manual-multiplier-mitigation` mode.

`sip-attack-vector`
Adds, deletes, or replaces Protocol SIP DoS vectors. You can configure the following options for SIP method vectors:

`type` Specifies the vector type (SIP method) for DoS attack detection.

`enforce`
This option is deprecated in version 13.1.0 and is replaced by `state`. Enable or disable the packet drop action of DOS detection for this attack type.

`auto-threshold`
This option is deprecated in version 13.1.0 and is replaced by `threshold-mode`. Enables the `auto threshold` mode for dos detection and dos mitigation. The default value is disabled.

`allow-upstream-scrubbing`
Enables allow upstream scrubbing. The default value is disabled.

`attacked-dst`
Enables attacked-destination. The default value is disabled.

`auto-scrubbing`
Enables specifying destination IP scrubbing. The default value is disabled.

`bad-actor`
Enables per-source IP based bad actor detection

`multiplier-mitigation-percentage`
Specifies the mitigation multiplier value of this specific vector in percentage when using `manual-multiplier-mitigation` mode, The default value used is inherited from the sip dos profile.

`per-source-ip-detection-pps`
Bad actor detection rate (for single IP address) of this vector

`per-source-ip-limit-pps`
Bad actor allowed rate (for single IP address) of this vector

`per-dst-ip-detection-pps`
Specifies the attack detection threshold (pps) per destination IP. The default value is infinite.

`per-dst-ip-limit-pps`.
Specifies the attack mitigation threshold (pps) per destination IP. The default value is infinite.

`scrubbing-category`
Specifies per-DstIP scrubbing category. The default value is none.

`scrubbing-detection-seconds`
Specifies duration in seconds for which the destination IP has been offended/attacked. The default value is 10.

`scrubbing-duration`
Specifies duration in seconds for which this IP should be scrubbed. The default value is 900.

`rate-increase`
Specifies the rate increase for DoS attack detection.

`rate-limit`
Specifies the rate limit for DoS attack detection. If the value is infinite the detection is disabled.

`rate-threshold`
Specifies the rate threshold for DoS attack detection. If the value is infinite the detection is disabled.

`state`
Specifies the run time state of this signature. The options are the same as those in `network-attack-vector`.

`suspicious`
Specifies if the vector considers all packets or only unsolicited packets. The default value is false.

`threshold-mode`
Enables the threshold mode for dos detection and dos mitigation. The default value is manual. The options are the same as that in `network-attack-vector`.

`dos-network`
Adds, deletes, or replaces a single Network DoS Security sub-profile. You can configure the following options for Network DoS Security:

`name` Specifies a dummy name for enabled Network DoS Security. This option is required for the operations create, delete, modify, and replace-all-with.

`dynamic-signatures`
Specifies options related to L4 Behavioral DoS (Dynamic Signatures) feature per virtual server by virtue of attaching a dos profile to a virtual server. Following options are configurable for this feature:

`detection`
Specifies the mode for detection of anomalies in traffic for the purpose of dynamic signature generation. Following modes are supported: disabled, enabled and learn-only.

Mode learn-only is same as enabled except that the system does not generate any logs (or alerts the user). It is used mainly to learn the baseline thresholds for the traffic.

Default is disabled.

`mitigation`
Specifies the mode for mitigation of anomalous traffic (specified in form of dynamic signatures). Following modes are supported: none, low, medium and high.

Each mode represents the severity (or aggressiveness) at which the system should try to mitigate the anomalous traffic.

Default is none.

`scrubber-enable`
Specifies the configuration mode for enabling or disabling the feature to scrub the attack traffic upon dynamic signature match. Default is no.

`scrubber-category`
Specifies the IP Intelligence category used for scrubbing the attack traffic upon dynamic signature match that constitutes destination IP address component. Default category is `attacked_ips`.

`scrubber-advertisement-period`
Specifies the advertisement period for which the attack traffic is scrubbed. Default is 300 seconds.

`multiplier-mitigation-percentage`
Specifies the mitigation multiplier value of all the vectors in the network dos profile in percentage when using manual-multiplier-mitigation mode.

`network-attack-vector`
Adds, deletes, or replaces Network Attack DoS vectors. You can configure the following options for Network Attack vectors:

attack-type
Specifies the vector type (Network Attack) for DoS attack detection.

enforce
This option is deprecated in version 13.1.0 and is replaced by state. Enable or disable the packet drop action of DOS detection for this attack type.

auto-threshold
This option is deprecated in version 13.1.0 and is replaced by threshold-mode. Enables the auto threshold mode for dos detection and dos mitigation. The default value is disabled.

rate-increase
Specifies the rate increase for DoS attack detection.

rate-limit
Specifies the rate limit for DoS attack detection. If the value is infinite the detection is disabled.

rate-threshold
Specifies the rate threshold for DoS attack detection. If the value is infinite the detection is disabled.

packet-types
Specifies the packet types for Sweep attack vector.

allow-upstream-scrubbing
Enables allow upstream scrubbing. The default value is disabled.

attacked-dst
Enables attacked-destination. The default value is disabled.

auto-scrubbing
Enables specifying destination IP scrubbing. The default value is disabled.

bad-actor
Enables per-source IP based bad actor detection

multiplier-mitigation-percentage
Specifies the mitigation multiplier value of this specific vector in percentage when using manual-multiplier-mitigation mode, The default value used is inherited from the network dos profile.

per-source-ip-detection-pps
Bad actor detection rate (for single IP address) of this vector

per-source-ip-limit-pps
Bad actor allowed rate (for single IP address) of this vector

per-dst-ip-detection-pps
Specifies the attack detection threshold (pps) per destination IP. The default value is infinite.

per-dst-ip-limit-pps
Specifies the attack mitigation threshold (pps) per destination IP. The default value is infinite.

scrubbing-category
Specifies per-DstIP scrubbing category. The default value is none.

scrubbing-detection-seconds
Specifies duration in seconds for which the destination IP has been offended/attacked. The default value is 10.

scrubbing-duration
Specifies duration in seconds for which this IP should be scrubbed. The default value is 900.

state
Specifies the run time state of this signature.

The options are:

disabled
Do not learn, do not collect stats.

learn-only
Learn/Collect stats, but do not "detect" ("alarm" in ASM-speak) any attacks,

detect-only
Learn/Collect stats/detect, but do not mitigate (rate-limit/drop, challenge, etc.) any attacks.

mitigate
Learn/Collect stats/detect/mitigate (using whichever mitigations are configured).

threshold-mode
Enables the threshold mode for dos detection and dos mitigation. The default value is manual.

The options are:

manual

Specifies the manual thresholds.

stress-based-mitigation

Specifies the manual detection ("alarm") threshold, but mitigation threshold is stress-based.

fully-automatic

Specifies both the detection ("alarm") and mitigation thresholds are automatically computed.

manual-multiplier-mitigation

Specifies the detection ("alarm") threshold is automatically computed. The mitigation threshold is calculated by the detection threshold multiplies the multiplier-mitigation-percentage.

whitelist

Specifies the Dos srcIP whitelist configuration.

http-whitelist

Specifies the IP addresses and subnets whitelist configuration for Application Security (Overrides the global whitelist).

custom-signatures

Specifies options related to L4 Behavioral DoS Signatures feature per virtual server by virtue of attaching one or more signatures objects. Following options are configurable for this feature:

threshold-mode

Specifies the mode for setting the rate limit thresholds to be used for the matching traffic. Following modes are supported: manual, fully-automatic and stress-based-mitigation. Default is manual.

state

Specifies the operational state of the attached signature. The states supported are: disabled, learn-only, detect-only and mitigate. Default is disabled.

suspicious

Specifies if the vector considers all packets or only unsolicited packets. The default value is false.

manual-detection-threshold

Specifies the attack detection threshold of the attached signature.

Default is infinite.

manual-mitigation-threshold

Specifies the attack mitigation threshold of the attached signature.

Default is infinite.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

NAME

spva-stats - Shows the Configuration and Data path stats for sPVA.

MODULE

security dos

SYNTAX

Displays the sPVA stats

DISPLAY

show security dos spva-stats

DESCRIPTION

This module shows the sPVA related configuration and data path stats. sPVA stats are relevant only in case the Hardware is sPVA capable.

EXAMPLES

show security dos spva-stats

Displays the below sPVA reslated stats

Total SW entry

Total sPVA entry count present in SW

Total HSB entry

Max number of sPVA entries in HSB

Used HSB entry

Total number of sPVA entries present in HSB

Global white list SW entry

Global whitelist entries present in SW

Global white list HSB entry

Global Whitelist entries present in HSB.

Global white list total entry

Total number of Global white list entries present in SW and HSB

Global black list SW entry

Total number of global back list sPVA entries present in SW

Global black list HSB entry

Total number of global black list sPVA entries present in HSB

Global black list total entry

Total number of global black list entry count present in SW and HSB

VS white list SW entry

Total whitelist SW entry count for virtual server with port as wildcard.

VS white list HSB entry

Total whitelist HSB entry count for virtual server with port as wildcard.

VS white list total entry

Total count of white list entries present in SW and HSB for virtual server with port as wildcard.

VS black list SW entry

Total black list SW entry count for virtual server with port as wildcard.

VS black list HSB entry

Total black list HSB entry count for virtual server with port as wildcard.

VS black list total entry

Total count of black list entries present in SW and HSB for virtual server with port as wildcard.

App white list SW entry

Total whitelist SW entry count for application virtual server.

App white list HSB entry

Total whitelist HSB entry count for application virtual server.

App white list total entry

Total count of white list entries present in SW and HSB for application virtual server

App black list SW entry

Total black list SW entry count for application virtual server

App black list HSB entry

Total black list HSB entry count for application virtual server.

App black list total entry

Total count of black list entries present in SW and HSB for application virtual server

Global white list SW hit

Total packets hits for global white list in SW

Global white list HSB hit
Total packets hits for global white list in HSB

Global white list total hit
Total packets hits for global white list in SW and HSB.

Global black list SW hit
Total packets hits for global black list in SW

Global black list HSB hit
Total packets hits for global black list in HSB

Global black list total hit
Total packets hits for global black list in SW and HSB.

VS white list SW hit
Total packet hits for white list in SW for virtual server with port as wildcard.

VS white list HSB hit
Total packet hits for white list in HSB for virtual server with port as wildcard.

VS white list total hit
Total packet hits for white list in SW and HSB for virtual server with port as wildcard.

VS black list SW hit
Total packet hits for black list in SW for virtual server with port as wildcard.

VS black list HSB hit
Total packet hits for black list in HSB for virtual server with port as wildcard.

VS black list total hit
Total packet hits for black list in SW and HSB for virtual server with port as wildcard.

App white list SW hit
Total packet hits for white list in SW for application virtual server.

App white list HSB hit
Total packet hits for white list in HSB for application virtual server.

App white list total hit
Total packet hits for white list in SW and HSB for application virtual server.

App black list SW hit
Total packet hits for black list in SW for application virtual server.

App black list HSB hit
Total packet hits for black list in HSB for application virtual server.

App black list total hit
Total packet hits for black list in SW and HSB for application virtual server.

White list SW hit
Total packet hits for white list in SW

White list HSB hit
Total packet hits for white list in HSB

White list total hit
Total packet hits for white list in SW and HSB

Black list SW hit
Total packet hits for black list in SW

Black list HSB hit
Total packet hits for black list in HSB

Black list total hit
Total packet hits for black list in SW and HSB

BIG-IP 2016-01-07 security dos spva-stats(1)

NAME

stress-stats - Displays DoS stress statistics, or runs DoS stress statistics to set stress calculation mode on the BIG-IP(r) system.

MODULE

security dos

SYNTAX

Display and run DoS stress statistics using the following syntax.

MODIFY

run stress-stats

options:

context-name [string]

stress [0-100 | auto]

DISPLAY

show stress-stats

options:

field-fmt

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the stress-stats component to display DoS stress-stats statistics, or run dos stress-stats command to set auto or manual mode on stress calculation.

EXAMPLES

run stress-stats context-name vs1 stress auto

Makes the stress level calculation to be in auto-mode on virtual server/context vs1 that have DoS Profile attached.

run stress-stats context-name vs1 stress 10

Makes the stress level calculation to be in manual-mode with value 10% on virtual server/context vs1 that have DoS Profile attached.

show stress-stats

Shows the stress-stats statistics on all virtual servers.

show stress-stats field-fmt

Shows the stress-stats statistics on all virtual servers in field format.

OPTIONS

Use these options to control stress-stats of the security dos:

context-name

Specifies the unique name for the context in run command. This option is required.

stress

Specifies the stress value for the context in run command. This option is required. The range is from 0 to 100 (0% to 100%) for manual-mode or auto for auto-mode.

SEE ALSO

show, run, security dos stress-stats

BIG-IP 2019-06-20 security dos stress-stats(1)

security dos udp-portlist

NAME

udp-portlist - Configures the DoS udp portlist component within the security dos module using the syntax shown in the following sections. These DoS udp portlist entries are applied to all udp packets except those going through the management interface.

MODULE

security dos

SYNTAX

MODIFY

```

modify udp-portlist dos-udp-portlist
options:
  description [string]
  list-type [exclude-listed-ports | include-listed-ports]
  entries [modify | replace-all-with] {
    [entry] {
      options:
        description [string]
        match-direction [both | dst | none | src]
        port-number [number]
      }
    }
  }
}

```

```

DISPLAY
list udp-portlist

```

DESCRIPTION

You can use the udp-portlist component to configure a DoS UDP portlist of upto eight entries for all UDP traffic except the management interface. The HSB hardware compares all incoming UDP traffic to the udp-portlist entries. There are 2 types of behavior, depending upon whether the udp port list is configured as a white list or as a black list. White list and black list are mutually exclusive properties of a UDP port list.

If the udp port list is configured as a list-type of exclude-listed-ports, and if a match is found on an incoming packet, then we do not increment the UDP Flood DoS vector. If a match is not found, then the UDP Flood DoS vector checks are done on those packets.

If the udp port list is configured as a list-type of include-listed-ports, and if a match is found on an incoming packet, then we increment the UDP Flood DoS vector. If a match is not found, then the UDP Flood DoS vector checks are not done on the packets.

Either destination port or source port or both can be specified in a udp-portlist entry.

EXAMPLES

modify udp-portlist dos-udp-portlist description "bad ports" list-type include-listed-ports Modifies the udp-portlist dos-udp-portlist to a blacklist.

modify udp-portlist dos-udp-portlist list-type exclude-listed-ports Modifies the udp-portlist dos-udp-portlist to a white-list.

modify udp-portlist dos-udp-portlist description "bad ports" entries modify { entry1 { match-direction src port-number 161 } } Modifies an entry. The new entry is for source UDP port 161. It matches any UDP packet whose source port is 161.

modify udp-portlist dos-udp-portlist entries modify { 161 { match-direction both } }

Modifies the entry for destination UDP port 161 to source and destination port 161. It matches any UDP packet whose destination or source port is 161.

```

security dos udp-portlist dos-udp-portlist {
  entries {
    entry1 {
      match-direction both
      port-number snmp
    }
    entry2 { }
    entry3 { }
    entry4 { }
  }
  white-list
}

```

Displays the current list of DoS UDP portlist entries.

OPTIONS

description
Your description for the DoS udp-portlist.

list-type
Sets the list type to be either exclude-listed-ports or include-listed-ports

include-listed-ports
Sets the property of the dos-udp-portlist list to include-listed-ports (Blacklist).

exclude-listed-ports
Sets the property of the dos-udp-portlist list to exclude-listed-ports (Whitelist).

entries
Modifies a udp-portlist entry.

modify
Modifies the existing entry that you specify next, in curly braces ({}). After the entry name, enter the new configuration (port mode and port number) settings for the entry inside a nested set of curly braces.

replace-all-with
Replaces the current set of udp-portlist entries with the entry(s) that you specify next, in curly braces ({}).

Enter the name of a entry to be modified, then enter an open curly brace ({), one or more of the following options, and a closed curly brace (}).

description

Your description for the current entry.

match-direction

Set the mode of matching (source, destination or both).

port-number

Set the port number for matching.

SEE ALSO

edit, list, modify, security, security dos, tmsh

security dos virtual

NAME

virtual - Displays and resets dos per-virtual statistics, or run dos per-virtual command on the BIG-IP(r) system.

MODULE

security dos

SYNTAX

Manage the virtual component within the security dos module using the syntax in the following sections.

DISPLAY

show virtual name [vs_name]

options:

dns-nxdomain-stat

field-fmt

query-valid-domain [fqdn]

MODIFY

reset-stats virtual name [vs_name]

options:

dns-nxdomain-stat

RUN

run virtual name [vs_name]

options:

auto-threshold-relearn

dns-nxdomain-relearn

dynamic-signatures-history-relearn

DESCRIPTION

You can use the virtual component to display and reset dos per-virtual statistics, or run dos per-virtual commands.

EXAMPLES

show virtual name my_virtual query-valid-domain www.f5.com

Displays if a FQDN(Fully Qualified Domain Name) is present in the per-virtual learned valid domains.

show virtual name my_virtual dns-nxdomain-stat

Displays the dns-nxdomain statistics on the specified virtual server.

reset-stats virtual name my_virtual dns-nxdomain-stat

Resets the dns-nxdomain-stat statistics on the specified virtual server.

run virtual name my_virtual auto-threshold-relearn

Clears the auto-threshold history on the specified virtual server auto-threshold vector.

run virtual name my_virtual dns-nxdomain-relearn

Clears the dns-nxdomain history on the specified virtual server.

run virtual dns-nxdomain-relearn

Clears the dns-nxdomain history on all virtual servers.

run virtual name my_virtual dynamic-signatures-history-relearn

Clears the dynamic-signatures history on the specified virtual server dynamic-signatures vector.

OPTIONS

name Apply the command to the specified virtual server. It can be optional in some commands/options. In these cases, the command will be applied to all virtual servers.

show command: options are

dns-nxdomain-stat: name is required.

field-fmt: only work with dns-nxdomain-stat.

query-valid-domain [fqdn]: name is required.

run command: options are

auto-threshold-relearn: name is required

dns-nxdomain-relearn: name is optional. The command applies to all virtual servers if name is not specified.

auth-threshold-relearn: name is required.

reset-stats command: options are

dns-nxdomain-stat: name is required.

SEE ALSO

reset-stats, run, show, tmsh

BIG-IP 2018-01-24 security dos virtual(1)

security firewall address-list

NAME

address-list - Configures an address-list for use by firewall rules. An address list is a list of IP-address prefixes to compare against the source-IP address and/or destination-IP address in an IP packet.

MODULE

security firewall

SYNTAX

CREATE/MODIFY

create address-list [name]

modify address-list [[name] | all]

options:

addresses [add | delete | modify | replace-all-with] {
[[ip address]]
}

fqdns [add | delete | replace-all-with] {
[fully qualified domain names]
}

fqdns none

geo [add | default | delete | replace-all-with] {
[[country_code[:state_name/city_name]]]
}

geo none

app-service [name]

description [string]

edit address-list [[name] | all]

options:

all-properties

non-default-properties

DISPLAY

list address-list [[name] | all | [property]]

show running-config address-list [[name] | all | [property]]

DELETE

delete address-list [[name] | all]

DESCRIPTION

You can use the address-list component to define reusable lists of addresses. You can use an address list in any of the following firewalls and firewall rule lists: net self, net route-domain, security firewall global-rules, security firewall rule-list, security firewall management-ip-rules, and ltm virtual. A firewall rule compares all of the addresses in the list to either the source or destination IP in the packet, depending on how you apply the list. If there is a match, the firewall rule takes an action, such as accepting or dropping the packet.

EXAMPLES

```
create address-list alist1 addresses add { 10.10.1.1 10.10.1.2 192.168.24.0/24 }
```

Creates a new address list, "alist1," with two IPv4 addresses and one IPv4 subnet.

```
modify address-list alist1 addresses modify { 10.10.1.1 { description "management IP at wwmed site3" } }
```

Modifies the above address list with a description for the first address.

```
modify alist1 geo add { TR:Istanbul }
```

Modifies the above address list with an addition of a country:city/state.

```
modify address-list alist1 addresses add { 2001:DB8:a::/64 }
```

Modifies the same address list by adding an IPv6 subnet.

```
list address-list alist1
security firewall address-list alist1 {
  addresses {
    10.10.1.1 {
      description "management IP at wwmed site3"
    }
    10.10.1.2 { }
    192.168.24.0/24 { }
    2001:db8:a::/64 { }
  }
}
```

Shows the modified address list.

```
create address-list xyz fqdns add { xyz.com }
```

Creates a new address list, "xyz" with a single fully qualified domain 'xyz.com'.

```
modify address-list xyz addresses add { 2001:DB8:a::/64 } fqdns add { abc.com }
```

Modifies the same address list by adding an IPv6 subnet and another fully qualified domain 'abc.com'.

```
list address-list xyz
security firewall address-list xyz {
  addresses {
    2001:db8:a::/64 { }
  }
  fqdns {
    abc.com { }
    xyz.com { }
  }
}
```

Shows the above address list 'xyz'.

OPTIONS

addresses

Specifies a list of IP addresses and/or subnets to compare against a packet's source or destination address. The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:ca90:ff00:0042:8329" to "2001:db7:3f4a:9dd:ca90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:23ff:678" to "2001::c34a:0:23ff:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

The next keyword specifies the action to take with the addresses (add, delete, modify, or replace the current set of addresses).

add Creates a new address list, which you specify next with IP addresses and/or prefixes in curly braces ({}).

delete

Deletes the address(es) that you specify next, in curly braces ({}).

modify

Makes it possible to replace the optional description(s) for the address(es). You can specify a description in a nested set of curly braces after each address.

replace-all-with

Replaces the current set of IP addresses with the address(es) that you specify next, in curly braces ({}).

fqdns

Specifies a list of fully qualified domain names to compare against packet's destination IP address domain.

The next keyword specifies the action to take with the fqdns (add, delete, or replace the current set of fqdns).

geo Specifies a list of geographic locations that the packet will be compared against.

app-service

Associates this address list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module (see asm) has components for working with iApps.

description

Is your description for this address list.

security firewall config-change-log

NAME

config-change-log - Configures firewall configuration change log setting.

MODULE

security firewall

SYNTAX

Modify the config-change-log component within the security firewall module using the syntax shown in the following sections.

MODIFY

modify config-change-log log-changes [automatic | on | off]

modify config-change-log log-publisher [none | [name]]

DISPLAY

list config-change-log

show running-config config-change-log

DESCRIPTION

You can use the config-change-log component to configure if changes to the firewall rules should be logged or not. The default is to automatically determine if log is needed based on the mode of the on-demand-compilation. If the mode of the on-demand-compilation is 'enabled', the changes will be logged. If change log is enabled, a publisher need to be configured too.

EXAMPLES

modify config-change-log log-changes on log-publisher local-db-publisher

BIG-IP 2014-09-16 security firewall config-change-log(1)

security firewall container-stat

NAME

container-stat - Show the compilation result of firewall rules.

MODULE

security firewall

SYNTAX

show container-stat

DESCRIPTION

You can use the container-stat component to display the compilation result of firewall rules for each container. For firewall rules, a container is uniquely identified by the combination of context type, context name and policy type. The outputs of the command include: the time it takes to compile the rules and to perform overlapping check for each container, the number of micro-rules, the size of the containers in bytes, the amount of memory used for compilation, and the time the container is activated.

EXAMPLES

show security firewall container-stat

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-03-11 security firewall container-stat(1)

security firewall context-stat

NAME

context-stat - Displays and resets firewall statistics of the specified context on the BIG-IP(r) system. You can only use the show and reset-stats command with this component.

MODULE

security firewall

SYNTAX

show context-stat

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

reset-stats context-stat

DESCRIPTION

You can use the context-stat component to display or reset firewall statistics of the specified context.

EXAMPLES

show context-stat

Displays firewall rule's statistics in the system default units.

show context-stat raw

Displays raw firewall rule's statistics.

reset-stats context-stat

Resets firewall statistics for all contexts.

SEE ALSO

show, reset-stats, tmsh

security firewall current-state

NAME

current-state - Show the current state of firewall rules compilation.

MODULE

security firewall

SYNTAX

show current-state

DESCRIPTION

You can use the current-state component to display the current system-wide state of firewall rules compilation. The outputs of the command includes: the mode of on-demand compilation and on-demand rule deploy (enabled or disabled), the rule compiler status (quiescent, pending-compilation, being-compiled, pending-deployment, being-deployed, failed-compilation, failed-deployment, pccd-failed), compilation start time, compilation end time, deployment start time, deployment end time, aggregate number of micro-rules, active blob name, blob creation time, and if the blob MD5 is verified or not.

EXAMPLES

show security firewall current-state

security firewall fqdn-entity

NAME

fqdn-entity - Perform on-demand refresh to query IP mappings for one (or all) configured FQDNs in firewall rules.

MODULE

security firewall

SYNTAX

Use the fqdn-entity component within the security firewall module to perform on-demand refresh to query IP mappings for a specific FQDN (or all FQDNs) configured in firewall rules using the following syntax:

DISPLAY

load fqdn-entity [all | name]

DESCRIPTION

You can use the fqdn-entity component to perform on-demand refresh to query IP mappings for one or all configured FQDNs in firewall rules.

BigIP will periodically refresh IP mappings for each FQDN upon previous mappings expiry time or after refresh-interval as configured in security firewall global-fqdn-policy whichever is greater. fqdn-entity component can be used to refresh the IP mappings irrespective of either the expiry time or the refresh-interval.

EXAMPLES

load fqdn-entity all

Perform on-demand refresh for all the configured FQDNs in firewall rules.

load fqdn-entity f5.com

Perform on-demand refresh for fqdn 'f5.com' configured in one of the firewall rules.

SEE ALSO

security firewall fqdn-info

NAME

fqdn-info - Query run time information for one (or all) configured FQDNs in firewall rules.

MODULE

security firewall

SYNTAX

Use the fqdn-info component within the security firewall module to query run time information for one (or all) configured FQDNs in firewall rules using the following syntax:

DISPLAY

show fqdn-info fqdn [all | name]

DESCRIPTION

You can use the fqdn-info component to query run time information for one or all configured FQDNs in firewall rules. Use option fqdn to query information regarding a specific FQDN or all FQDNs configured in firewall rules.

Following information related to each FQDN is queried using fqdn-info component:

- a) Last Refresh time.
- b) Next Refresh time.
- c) Last Successful Refresh.
- d) DNS Records valid until
- e) IP Addresses

OPTIONS

fqdn Specifies the name of a FQDN. Use 'all' to query information for all configured FQDNs.

EXAMPLES

show fqdn-info fqdn all

Query information for all the configured FQDNs in firewall rules.

show fqdn-info fqdn f5.com

Query information for fqdn 'f5.com' configured in one of the firewall rules.

SEE ALSO

BIG-IP 2014-10-08 security firewall fqdn-info(1)

security firewall global-fqdn-policy

NAME

global-fqdn-policy - Configures the global fqdn policy which is used to resolve FQDN names to IP Address mappings for the FQDN names that are specified in the firewall rules.

MODULE

security firewall

SYNTAX

Modify the global-fqdn-policy component within the security firewall module using the syntax shown in the following sections.

MODIFY

modify global-fqdn-policy

options:

app-service [name]

description [string]

dns-resolver [[resolver_name] | none]

refresh-interval [integer]

edit global-fqdn-policy

options:

- all-properties
- non-default-properties
- one-line
- partition
- recursive

DISPLAY

list global-fqdn-policy
show running-config global-fqdn-policy
options:

- all-properties
- non-default-properties
- one-line
- partition
- recursive

DESCRIPTION

You can use the global-fqdn-policy component to configure a net dns-resolver that will be used by firewall to resolve FQDN names to IP Address mappings. These mappings in turn will be used to match firewall rules (across all policies on all contexts) based on FQDN constraints.

EXAMPLES

modify global-fqdn-policy dns-resolver xyz

Modifies the global-fqdn-policy to use dns resolver object named 'xyz'. Default refresh-interval is 60 seconds.

modify global-fqdn-policy dns-resolver xyz refresh-interval 120

Modifies the global-fqdn-policy to use dns resolver object named 'xyz' and specify periodic refresh rate of 120 seconds (2 minutes) to re-resolve FQDN-to-IP mappings.

list global-fqdn-policy

Displays the current list of global-fqdn-policy contents.

OPTIONS

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description.

dns-resolver

Specifies an existing net dns-resolver. This will be used by firewall to obtain FQDN-to-IP Address mappings which will be used to match firewall rules based on FQDN constraints. Note dns-resolver none can be used to remove the object from global-fqdn-policy if and only if there are no AFM rules with (non empty) FQDN constraints.

refresh-interval

Specifies refresh interval to be used to re-resolve FQDN-to-IP mappings. Unit is in seconds and default is 60 seconds. Minimum allowed is 5 seconds and maximum is 2,764,800 (=32 days) seconds.

SEE ALSO

create, edit, list, modify, security firewall, security firewall policy, net dns-resolver tmsh

BIG-IP 2018-10-12 security firewall global-fqdn-policy(1)

security firewall global-rules

NAME

global-rules - Configures the global network firewall rules. These firewall rules are applied to all packets except those going through the management interface. They are applied first, before any firewall rules for the packet's virtual server, route domain, and/or self IP.

MODULE

security firewall

SYNTAX

MODIFY

```
modify global-rules
options:
  description [string]
  enforced-policy [ [policy_name] | none ]
  staged-policy [ [policy_name] | none ]
  service-policy [ [policy_name] | none ]
```

```
edit global-rules
options:
  all-properties
  non-default-properties
```

```
reset-stats global-rules
enforced-policy-rules { [rule name] }
staged-policy-rules { [rule name] }
```

```
options:
  fw-context-stat
  port-misuse
```

```
DISPLAY
list global-rules
show running-config global-rules
```

```
show global-rules
active
enforced-policy-rules
staged-policy-rules
```

```
options:
  fw-context-stat
  port-misuse
  overlapping-status
```

DESCRIPTION

You can use the global-rules component to configure network firewall policy which is enforced or staged on all IP and ICMP traffic except traffic on the management IP.

EXAMPLES

```
list global-rules
```

```
security firewall global-rules {
  enforced-policy /Common/policy1
}
```

Displays the current list of global rules.

OPTIONS

description

Your description for the global list of firewall rules.

enforced-policy

Specifies an enforced firewall policy. enforced-policy rules are enforced globally.

enforced-policy-rules

Specifies firewall rules enforced on traffic globally via referenced enforced-policy.

overlapping-status

Display detail overlapping information

port-misuse

Used to show or reset global port misuse policy statistics.

fw-context-stat

Used to show or reset firewall statistics for the global rules.

staged-policy

Specifies a staged firewall policy. staged-policy rules are not enforced while all the visibility aspects namely statistics, reporting and logging function as if the staged-policy rules were enforced globally.

staged-policy-rules

Specifies firewall rules staged on traffic globally via referenced staged-policy.

service-policy

Specifies a service policy that would apply to traffic globally. The service policy is applied to all flows, provided if there are no other context specific service policy configuration that overrides the global service policy. For example, when a service policy is configured both at a global level, as well as on a firewall rule, and a flow matches the rule, the more specific service policy configuration in the rule will override the service policy setting at the global level. The service policy associated here can be created using net service-policy command.

security firewall ipi-category-info

NAME ipi-category-info - Query firewall policy names and virtual-server names based on the given ipi-category, also query firewall rules based on ipi-category and firewall policy.

MODULE
security firewall

SYNTAX
Use the ipi-category-info component within the security firewall module to query firewall policies and virtual-servers with ipi category name and query firewall rules with ipi category name and the firewall policy with the following syntax:

DISPLAY
show security firewall ipi-category-info name [name of the ipi-category] [policies | virtuals] show security firewall ipi-category-info name [name of the ipi-category] rules [policy-name]

DESCRIPTION
You can use the ipi-category-info component to query firewall policies or virtual servers based on the given ipi-category. Also to query firewall rules based on the given ipi category and firewall policy.

OPTIONS
policy-name
Specifies the firewall policy-name.

EXAMPLES
show security firewall ipi-category-info name botnets policies

Returns firewall policies that are configured with 'botnets' ipi category

show security firewall ipi-category-info name botnets virtuals

Returns virtual-server names that are configured with 'botnets' ipi category

show security firewall ipi-category-info name botnets rules p1

Returns firewall rules that are under policy p1 with 'botnets' ipi category

SEE ALSO

edit management-ip-rules

```

options:
    all-properties
    non-default-properties

```

DISPLAY

list management-ip-rules

show running-config management-ip-rules

DESCRIPTION

You can use the management-ip-rules component to configure network firewall rules that are applied to all management interface traffic. The network software compares IP packets to the criteria specified in these rules. If a packet matches the criteria then the system takes the action specified by the rule. If a packet does not match a rule then the software compares the packet against the next rule. If a packet does not match any rule the packet is accepted.

For configuration sync management-ip-rules are synced to the devicegroup that has a type field of sync-failover. See "cm config-sync".

MATCHING AN IP PACKET

You can use this TMSH component to match against any or all of the following properties of an IP packet:

```

source address
source port
the packet's source VLAN
destination address

```

destination port
the higher-level protocol in the packet's payload

If you match against more than one of these items, a packet must pass all of your tests to successfully match. For example, if you match against a source subnet and several destination ports, a packet must originate from the given subnet and must also have one of the specified destination ports.

RULE ORDER

Rules are evaluated in the order that you specify. You can use the `list management-ip-rules` command to see the current rule order. As you add or modify rules in this component, you can use the `place-before rule-name` or `place-after rule-name` option to choose the rule's place in the sequence.

Rule order can determine whether or not a packet is dropped. Consider the following rules:

`rule_a`, matches source addresses against 172.16.0.0 and ACCEPTS all packets that match.
`rule_d`, matches source addresses against 172.16.39.0 and DROPS all packets that match.

Also consider a packet from a host at 172.16.39.55. If `rule_a` appears before `rule_d` in the rule list, the packet's source address matches `rule_a` first and the software accepts it. The software never reaches `rule_d` for comparison. If `rule_d` appears first instead, the packet's source address now matches `rule_d`; in this case, the software drops the packet.

EXAMPLES

```
modify management-ip-rules rules add { reject-internal-net { source { addresses replace-all-with {  
172.27.0.0/16 } } action reject place-before first } }
```

Creates a rule entry at the beginning of the list that rejects traffic from the 172.27.0.0 network.

```
modify management-ip-rules rules add { reject-insecure-ports { rule-list block_bad_mgmt place-before first } }
```

Adds a sub rule list to the management-IP firewall. Use the "security firewall rule-list" component to create a custom rule list.

```
list management-ip-rules  
security firewall management-ip-rules {  
  rules {  
    reject-insecure-ports {  
    rule-list block_bad_mgmt  
    }  
    reject-internal-net {  
    action reject  
    source {  
      addresses {  
        172.27.0.0/16 { }  
      }  
    }  
  }  
}
```

Displays the current list of management-firewall rules.

```
modify management-ip-rules rules delete { reject-internal-net }
```

Removes the `reject-internal-net` rule from the management-IP firewall.

OPTIONS

`description`
Your description for the management-firewall rules.

`rules`
Adds, deletes, or replaces a firewall rule.

`add` Creates a new rule, which you specify next with a unique string in curly braces (`{ }`). Use the `place-before` or `place-after` option inside the curly braces to determine the order of the rule. If this is the first rule, use the `replace-all-with` option instead of `add`.

`delete`
Deletes the rule that you specify next, in curly braces (`{ }`).

`modify`
Modifies the existing rule that you specify next, in curly braces (`{ }`). After the rule name, enter the new configuration settings for the rule inside a nested set of curly braces.

`replace-all-with`
Replaces the current set of global rules with the rule(s) that you specify next, in curly braces (`{ }`). Use this option for the first management rule.

`none` Empties the list of management-firewall rules. This implicitly accepts all packets on the management interface.

Enter the name of a rule to be added or modified, then enter an open curly brace (`{`), one or more of the following options, and a closed curly brace (`}`).

`action`
Specifies the action that the system takes when a packet matches the rule.

accept

Specifies that a matching packet should be accepted. The security software stops comparing a matching packet to any other management-firewall rules.

accept-decisively

This option is functionally the same as accept.

drop Specifies that a matching packet should be silently dropped. The security software sends nothing back to the packet source, and it does not compare the packet to any other management-firewall rules.

reject

Specifies that a matching packet should be dropped. For TCP-based protocols, the security software sends a TCP reset (with the RST flag raised) back to the source. For other protocols, reject is equivalent to drop.

app-service

Associates the management-rule list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module has components for working with iApps.

description

Your description for the current rule.

destination

Matches against each packet's destination IP and/or destination port. The next options choose the matching criteria.

address-lists

Specifies a list of IP-address lists (see "security firewall address-list") to compare against the packet's destination address.

This list uses the same add, delete, none, and replace-all-with options described above for rules, as well as a default option.

addresses

Specifies a list of IP addresses and/or subnets to compare against the packet's destination address.

The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:ca90:ff00:0042:8329" to "2001:db7:3f4a:9dd:ca90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:23ff:678" to "2001::c34a:0:23ff:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

port-lists

Specifies a collection of port lists (see "security firewall port-list") to compare against the packet's destination port. If you use this option to specify a port list, a packet only matches if its destination port matches a port on these lists.

This list uses the same add, delete, none, and replace-all-with options described above for rules, as well as a default option.

ports

Specifies a list of ports and port ranges to compare against the packet's destination port.

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

icmp Specifies a list of ICMP types and codes to compare against the packet. You must set the ip-protocol option to "icmp" for this option to function. If you use this option, the current rule only matches ICMP packets that have the ICMP properties you specify here. You can add, delete, or modify (that is, change the description of) any entry in the list, or replace-all-with a new set of entries that you specify between curly braces ({}).

Use the standard integer identifiers to specify an ICMP type. For example: 3 is destination unreachable and 3:1 is destination unreachable with a code of host unreachable. The official list of ICMP types and codes is here: .

ip-protocol

Specifies the IP protocol to compare against the packet. This could be a layer-3 protocol (such as ipv4 or ipv6), or a higher-level protocol like ospf, rdp, or icmp. If you specify this option, a packet only matches if it uses the chosen protocol. Press the key for a full list of valid protocols.

log Specifies whether the security software should write a log entry for all packets that match this rule. You must also enable network filter logging in the "security log profile" component for this option to have any effect. Note that the security software always increments the statistics counter when a packet matches a rule, no matter how you set this option.

place-after [first | last | rule-name]

Specifies that a new rule should be placed after the first rule, the last rule, or the rule-name you

specify. If you are adding individual rules (as opposed to specifying replace-all-with), then you must use place-before or place-after to specify the rule's position in the list.

place-before [first | last | rule-name]

Specifies that a new rule should be placed before the first rule, the last rule, or the rule-name you specify. If you are adding individual rules (as opposed to specifying replace-all-with), then you must use place-before or place-after to specify the rule's position in the list.

rule-list

Specifies a full rule list instead of a customized rule that you might define with the other options. See "security firewall rule-list". If you use this option, then only the schedule and status options are valid; the tmsh software rejects any other options that you attempt to use with rule-list.

schedule

Specifies a schedule for the rule. See "security firewall schedule". If you omit this option, the rule or rule list is enabled all the time.

If the rule refers to a rule-list, the rule-list is enabled according to the schedule. When the rule list is enabled, the security software then honors the schedules defined within the rule-list.

source

Matches against each packet's source IP, source port, and/or source VLAN. The next options choose the matching criteria.

address-lists

Specifies a list of address lists (see "security firewall address-list") to compare against the packet's source address.

This list uses the same add, delete, none, and replace-all-with options described above for rules, as well as a default option.

addresses

Specifies a list of IP addresses and networks to compare against the packet's source address.

The format for an IPv4 address is a.b.c.d. The general format for an IPv6 address is a:b:c:d:e:f:g:h.

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

port-lists

Specifies a collection of port lists (see "security firewall port-list") to compare against the packet's source port. If you use this option to specify a port list, a packet only matches if its source port matches a port on these lists.

This list uses the same add, delete, none, and replace-all-with options described above for rules, as well as a default option.

ports

Specifies a list of ports and port ranges to compare against the packet's source port.

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

vlan

Specifies a list of VLANs, VLAN groups, and tunnels to compare against the packet.

This list uses the same add, delete, none, and replace-all-with options described above for rules, as well as a default option.

status

Specifies whether the rule is enabled, disabled or scheduled. A rule that is enabled is always checked. A rule that is disabled is never checked. A rule that is scheduled is checked according to the corresponding schedule configuration. A rule that is scheduled must have an associated schedule configuration.

uuid Specifies how this rule UUID is assigned: assign a explicit uuid based on RFC-4122, empty UUID (none value), or an auto-generated uuid by system (auto-generated value) based on system wide mode:[uuid-default-autogenerate mode] when creating a rule.

security firewall matching-rule

NAME

matching-rule - Shows the best match firewall rule amongst all the admin configured Network Firewall rules in different contexts (global, route-domain, VIP/SelfIP) given source/destination IP address and port, protocol and user configured vlan name. You can only use the show command with this component.

MODULE

security firewall

SYNTAX

show matching-rule
dest-addr [IP address]
source-addr [IP address]
dest-port [TCP/UDP port]
source-port [TCP/UDP port]
protocol [protocol]
vlan [vlan name]

DESCRIPTION

With user provided VLAN, source/destination IP addresses, TCP/UDP ports and protocol, the command will try to match these parameters against user configured ACL rules in global, route domain, VIP/SelfIP context, and return the best match rules. Both IPv4 and IPv6 addresses and all possible protocols are supported. This command can be used as a diagnostic tool to trouble-shoot BigIP firewall configuration problem. It provides a faster way to identify which ACL rule will have impact to the specified packet stream.

EXAMPLES

show security firewall matching-rule dest-addr 1.1.1.1 dest-port 140 source-addr 2.2.2.2 source-port 141
protocol 10 vlan /Common/internal

Firewall Matching Rule:

Context	Type	Context Name	Policy Name	Rule Name	Action
Global		globalrule	Accept		

Total records returned: 1

security firewall on-demand-compilation

NAME

on-demand-compilation - Configures the compilation mode of firewall rules.

MODULE

security firewall

SYNTAX

MODIFY
modify on-demand-compilation mode [disabled | enabled]

DISPLAY

list on-demand-compilation mode
show running-config on-demand-compilation mode

TRIGGER ON-DEMAND COMPILATION

run on-demand-compilation

DESCRIPTION

You can use the on-demand-compilation component to change the behavior of firewall rule compilation. By default the system will automatically compile the changes at each configuration change. You can change the behavior to manually trigger the compilation by setting the mode to enabled.

EXAMPLES

modify security firewall on-demand-compilation mode enabled

run security firewall on-demand-compilation

SEE ALSO

security firewall on-demand-rule-deploy

NAME

on-demand-rule-deploy - Configures the rule deploy mode of firewall rules.

MODULE

security firewall

SYNTAX

MODIFY

modify on-demand-rule-deploy mode [disabled | enabled]

DISPLAY

list on-demand-rule-deploy mode

show running-config on-demand-rule-deploy mode

TRIGGER ON-DEMAND RULE DEPLOY

run on-demand-rule-deploy

DESCRIPTION

You can use the on-demand-rule-deploy component to change the behavior of firewall rule deployment. By default the system will automatically deploy the changes once the compilation is successful. You can change the behavior to manually trigger the rule deployment by setting the mode to enabled.

EXAMPLES

modify security firewall on-demand-rule-deploy mode enabled

run security firewall on-demand-rule-deploy

  one-line

```

DESCRIPTION

You can use the policy component to configure a shareable and reusable set of network firewall rules which can be associated as enforced or staged with a number of configuration objects of the following types: net self, itm virtual, security firewall global-rules, net route-domain.

EXAMPLES

```

modify policy rules add {
reject-internal-net {
  place-before first
  action reject
  source {
    addresses replace-all-with { 172.27.0.0/16 }
  }
}
}

```

Creates a rule entry at the beginning of the list that rejects traffic from the 172.27.0.0 network.

```
modify policy rules delete reject-internal-net
```

Removes the rule reject-internal-net from the list of rules.

```
create security firewall policy p1 rules add { r1 { source { geo add { US } } action reject place-after first } }
```

Creates a policy with a single rule that rejects all packets from the US.

```
create security firewall policy xyz rules add { r1 { destination { fqdns add { f5.com } } action accept place-after first } }
```

Creates a policy named 'xyz' with a single rule (named 'r1') that accepts all packets with destination IP address in domain 'f5.com'.

```
list policy
```

Displays the current list of policy rules.

```
create policy "New Policy" copy-from "/Common/Existing Policy"
```

Creates a new policy New Policy by copying existing policy /Common/Existing Policy.

OPTIONS

```
description
User defined description.
```

```
copy-from
(CREATE)Specifies the name of an existing policy from which to copy all configuration options.
```

```
rules
Adds, deletes, or replaces a firewall rule.
```

```
action
```

Specifies the action that the system takes when a rule is matched.

accept

Specifies that the current packet should be accepted.

accept-decisively

Specifies that the current packet should be accepted and that packet will not be compared to any other firewall rules in any other context.

drop Specifies that the current packet should be silently dropped. Nothing is sent back to the packet source. The packet is not compared to any other firewall rules.

reject

Specifies that the current packet should be dropped. For TCP based protocols a TCP reset is sent to the source. For other protocols reject is equivalent to drop.

description

User defined description.

destination

address-lists

Specifies a list of address lists (see security firewall address-list) against which the packet will be compared.

addresses

Specifies a list of addresses and networks against which the packet will be compared.

fqdns

Specifies a list of fully qualified domain names to compare against packet's destination IP address domain.

geo Specifies a list of Geo Locations that the packet will be compared against.

ipi-category

Specifies a list of IP-Intelligence category names that the packet will be compared against.

port-lists

Specifies a list of port lists (see security firewall port-list) against which the packet will be compared.

ports

Specifies a list of ports and port ranges against which the packet will be compared.

zones

Specifies a list of zones, (see security firewall zone) against which the packet will be compared.

icmp Specifies a list of ICMP types and codes against which the packet will be compared. The standard integer identifiers are used to specify an ICMP type Example: 3 is destination unreachable and 3:1 is destination unreachable with a code of host unreachable. The list of ICMP types and codes can be found here <http://www.iana.org/assignments/icmp-parameters/icmp-parameters.xml>.

ip-protocol

Specifies the IP protocol against which the packet will be compared.

irule

Specifies the name of the iRule that will be triggered when a packet matches this firewall rule. The firewall rule match raises a FLOW_INIT iRule event.

irule-sample-rate

Specifies the rate at which an iRule specified by irule option will be triggered when a packet matches this firewall rule. The rate is an integer value in the range 0-65535 and specifies how many packets must match this firewall rule before the iRule is triggered. The default value is 1 and causes the iRule to be triggered for every packet that matches this firewall rule. A value of 0 disables iRule triggering.

log Specifies whether the packet will be logged if it matches the rule. Logging must also be enabled in the corresponding logging configuration. (e.g. security log profile global-network when policy assigned to global-rules). Note that the statistics counter is always incremented when a packet matches a rule.

place-after

Specifies that a new rule should be placed after another rule, first or last. If individual rules are being added (as opposed to specifying replace-all-with) then place-before or place-after must be specified.

place-before

Specifies that a new rule should be placed before another rule, first or last. If individual rules are being added (as opposed to specifying replace-all-with) then place-before or place-after must be specified.

rule-list

Specifies a list of rules to evaluate. See security firewall rule-list. If a rule-list is specified then only the schedule and status properties effect the rule.

schedule

Specifies a schedule for the rule. See security firewall schedule. If the rule refers to a rule-

list the rule-list will be enabled according to the schedule. When the rule list is enabled, the schedules defined within the rule-list will be honored.

source
address-lists

Specifies a list of address lists (see security firewall address-list) against which the packet will be compared.

addresses

Specifies a list of addresses and networks against which the packet will be compared.

fqdns

Specifies a list of fully qualified domain names to compare against packet's source IP address domain.

geo Specifies a list of Geo Locations against which the packet will be compared.

ipi-category

Specifies a list of IP-Intelligence category names that the packet will be compared against.

port-lists

Specifies a list of port lists (see security firewall port-list) against which the packet will be compared.

ports

Specifies a list of ports and port ranges against which the packet will be compared.

vlands

Specifies a list of vlans, vlan groups and tunnels against which the packet will be compared.

zones

Specifies a list of zones, (see security firewall zone) against which the packet will be compared.

status

Specifies whether the rule is enabled, disabled or scheduled. A rule that is enabled is always checked. A rule that is disabled is never checked. A rule that is scheduled is checked according to the corresponding schedule configuration. A rule that is scheduled must have an associated schedule configuration.

service-policy

Specifies the service policy configuration to use. (see "net service-policy"). The service policy can be used to set specific policy based configurations like flow timers, which applies to the flows that matches the rule.

uuid Specifies how this rule UUID is assigned: assign a explicit uuid based on RFC-4122, empty UUID (none value), or an auto-generated uuid by system (auto-generated value) based on system wide mode:[uuid-default-autogenerate mode] when creating a rule.

virtual-server

Specifies the virtual server name that will be used for further traffic processing. Option is valid only for global and/or route domain contexts.

security firewall port-list

NAME

port-list - Configures a port-list for use by firewall rules. A firewall rule can match a packet's source port or destination port against one of the ports in a port list, and can take some action (such as ACCEPT or DROP) for a matching packet.

MODULE

security firewall

SYNTAX

CREATE/MODIFY

create port-list [name]

```
modify port-list [[name] | all]
options:
  app-service [name]
  description [string]
  ports [add | delete | modify | replace-all-with] {
    [ [port] | [port] - [port] ]
  }
```

```
edit port-list [[name] | all]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list port-list [[name] | all | [property]]
show running-config port-list [[name] | all | [property]]
```

```
DELETE
delete port-list [[name] | all]
```

DESCRIPTION

You can use the port-list component to define reusable lists of ports for various firewall rules. The network software compares a packet's source port and/or destination port against ports in this list. You can assign a port list to the firewall rules in net self, net route-domain, security firewall global-rules, security firewall rule-list, sys management-ip, and ltm virtual firewall rules.

EXAMPLES

```
create port-list p-list1 ports add { 80 }
```

Creates a new port list with one entry.

```
list port-list
security firewall port-list _sys_self_allow_tcp_defaults {
  ports {
    domain { }
    f5-iquery { }
    https { }
    snmp { }
    ssh { }
  }
}
security firewall port-list _sys_self_allow_udp_defaults {
  ports {
    520 { }
    cap { }
    domain { }
    f5-iquery { }
    snmp { }
  }
}
security firewall port-list p-list1 {
  ports {
    http { }
  }
}
```

Shows all the port lists, including the one created in the previous example.

OPTIONS

app-service

Associates this port list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module has components for working with iApps.

description

Your description for the port list.

ports

Specifies a list of ports to compare against a packet's source or destination port. Use one of the keywords below and then specify the port(s) to add or delete. Specify ranges of ports with a dash between the two ends of the range (for example, 80-88).

add Creates a new port list, which you specify next with port numbers in curly braces ({}).

delete

Deletes the port(s) that you specify next, in curly braces ({}).

modify

Is not supported for this component.

replace-all-with

Replaces the current set of ports with the port(s) that you specify next, in curly braces ({}).

DELETE

delete port-misuse-policy [[name] | all]

DESCRIPTION

You can use the port-misuse-policy component to configure a shareable and reusable set of network port misuse policies which can be associated with a service policy objects. A port misuse policy has one or more rules that match connections by IP transport layer (L4) protocol and port number. Each rule must have a unique L4 protocol and port combination within the policy. When connection matches a policy rule (i.e. L4 protocol/port pair) the first data packet of the connection is tested to conform to application (L7) protocol specified in the rule. If data conforms to the L7 protocol (or test is inconclusive) the policy stops. The connection is allowed to proceed normally and data is processed as if no policy is in use. If data definitely does not conform to the specified L7 protocol the connection is treated according to configuration of the matched rule or the policy if rule uses policy defaults. In this case the rule or policy can drop the connection or allow it to proceed, and can also log an event about L7 protocol mismatch.

Port misuse policy (via service policy) can be associated with objects of the following types: ltm virtual, net route-domain, global. Several port misuse policies can be associated with objects of each type. In addition to service policy specified in the object itself, service policies could be associated with ACL rules of the security firewall policy, if it is associated with the object. When more than one policy is associated with the object the most specific port misuse rule is used. For example, if connection matches an ACL rule which has a service policy with port misuse policy also having a rule matching the connection, that port misuse rule is applied. Otherwise the port misuse rule associated via virtual's service policy is applied, if such rule exists and matches the connection. See also net service-policy.

Port misuse policies could be specified for both virtual server and route domain objects associated with the connection. In this case all policies are applied. If a policy has a matching rule that drops the connection, and connection fails to pass L7 protocol test, the connection is terminated and remaining policies are not applied.

EXAMPLES

```
create security firewall port-misuse-policy web-ports-policy drop-on-l7-mismatch no log-on-l7-mismatch yes
rules add { p80 { ip-protocol tcp port 80 l7-protocol http drop-on-l7-mismatch yes } p8080 { ip-protocol tcp
port 8080 l7-protocol http } }
```

```
list security firewall port-misuse-policy web-ports-policy
security firewall port-misuse-policy web-ports-policy {
  drop-on-l7-mismatch no
  log-on-l7-mismatch yes
  rules {
    p80 {
      drop-on-l7-mismatch yes
      l7-protocol http
      port http
    }
    p8080 {
      l7-protocol http
      port webcache
    }
  }
}
```

Creates port misuse policy with rules for tcp ports 80 and 8080 that test if first data packet looks like HTTP. The rule p80 tests all connections that have destination port TCP 80 and drops them if the first data packet does not look like HTTP. The rule p8080 tests all connections that have destination port TCP 8080 and logs an event if the first data packet does not look like HTTP (because of policy defaults).

```
modify security firewall port-misuse-policy web-ports-policy { rules add { p8888 { port 8888
drop-on-l7-mismatch yes } } }
```

Adds a new rule p8888 to port misuse policy web-ports-policy that tests all connections to TCP port 8888 and drops them and logs an event when the first data packet does not look like HTTP.

```
list security firewall port-misuse-policy
```

Displays the current port misuse policy configuration list.

OPTIONS

description
User defined description.

drop-on-l7-mismatch
Indicates if the connection should be dropped when there is a matching rule in the policy that has drop-on-l7-mismatch set to use-policy-setting and connection that matches that rule fails L7 protocol test. The default is yes.

log-on-l7-mismatch
Indicates if a port misuse event should be logged when there is a matching rule in the policy that has log-on-l7-mismatch set to use-policy-setting and connection that matches that rule fails L7 protocol test. The default is no.

rules
Adds, deletes, or replaces a named port misuse policy rule.

description
User defined description.

drop-on-l7-mismatch
Indicates if the connection should be dropped when it matches this rule but fails L7 protocol test. Allowed values are yes, no, and use-policy-setting. The default is use-policy-setting.

ip-protocol
Specifies the transport layer (L4) IP protocol for matching the connection. The valid protocols are sctp, tcp, and udp. A port and L4 protocol combination must be unique for the policy. The default is tcp.

l7-protocol
Specifies the application layer (L7) protocol for the rule. When the connection matches the rule the first data packet is tested to conform to this protocol. If the test is negative the rule can drop the connection and/or log a port misuse event depending on other options. If the test is positive or inconclusive (not enough data) the connection is handled as if there was no port misuse policy associated with the given object (virtual server or route domain), and policies at other objects are applied. Press the `key` for a full list of valid protocols. The default protocol is http.

log-on-l7-mismatch
Indicates if a port misuse event should be logged when the connection matches this rule but fails L7 protocol test. Allowed values are yes, no, and use-policy-setting. The default is use-policy-setting.

port Specifies the destination port number for matching the connection. The valid values are 1-65535. A port and L4 protocol combination must be unique for the policy.

show running-config rule-list [[name] | all | [property]]

```

DESCRIPTION

You can use the rule-list component to configure network firewall rules to be applied to multiple firewalls. The network software compares IP packets to the criteria specified in these rules. If a packet matches the criteria then the system takes the action specified by the rule. If a packet does not match any rule in the list, the software accepts the packet or passes it to the next rule or rule-list (for example, the system compares the packet to net self-ip rules if the packet is destined for a network associated with a self-ip that has firewall rules defined).

MATCHING AN IP PACKET

You can use this TMSH component to match against any or all of the following properties of an IP packet:

- source address
- source fqdn
- source geo
- source port
- the packet's source VLAN
- destination address
- destination fqdn
- destination geo
- destination port
- the higher-level protocol in the packet's payload

If you match against more than one of these items, a packet must pass all of your tests to successfully match. For example, if you match against a source subnet and several destination ports, a packet must originate from the given subnet and must also have one of the specified destination ports.

RULE ORDER

The network software evaluates firewall rules in the order that you specify. You can use the list management-ip-rules command to see the current rule order. As you add or modify rules in this component, you can use the place-before rule-name or place-after rule-name option to choose the rule's place in the sequence.

Rule order can determine whether or not a packet is dropped. Consider the following rules:

- rule_a, matches source addresses against 172.16.0.0 and ACCEPTS all packets that match.
- rule_d, matches source addresses against 172.16.39.0 and DROPS all packets that match.

Also consider a packet from a host at 172.16.39.55. If rule_a appears before rule_d in the rule list, the packet's source address matches rule_a first and the software accepts it. The software never reaches rule_d for comparison. If rule_d appears first instead, the packet's source address now matches rule_d; in this case, the software drops the packet.

EXAMPLES

```
create rule-list block_bad_mgmt description "ports to be blocked on our management interfaces" rules replace-all-with { reject_telnet { ip-protocol tcp destination { ports add { telnet } } action reject } }
```

Creates a new rule list called block_bad_mgmt. It matches and rejects any TCP packet whose destination port is telnet. The description indicates that the rule is intended for the management-IP firewall.

```
modify rule-list block_bad_mgmt rules add { reject_http { ip-protocol tcp destination { ports add { http } } action reject place-after last } }
```

Modifies the above rule list by blocking HTTP traffic, too.

```
list rule-list block_bad_mgmt
security firewall rule-list block_bad_mgmt {
  description "ports to be blocked on our management interfaces"
  rules {
    reject_telnet {
      action reject
      destination {
        ports {
          telnet { }
        }
      }
    }
    ip-protocol tcp
  }
  reject_http {
    action reject
    destination {
      ports {
        http { }
      }
    }
  }
  ip-protocol tcp
}
}
```

Shows the above rule list, with both rules.

```
modify rule-list rules add { reject-internal-net { place-before first action reject source { addresses replace-all-with { 172.27.0.0/16 } } } }
```

Creates a rule entry at the beginning of the list that rejects traffic from the 172.27.0.0 network.

```
create security firewall rule-list r1 description "Geo Locations to be blocked" rules add { r1 { source { geo add { US } } place-after first action drop } }
```

Creates a new rule list "r1", which matches and rejects any packet with a US source. The description explains the purpose of the rule list.

```
modify security firewall rule-list r1 rules add { r2 { source { geo add { CA } } place-before last action drop } }
```

```
security firewall rule-list r1 {
  description "Geo Locations to be blocked"
  rules {
    r2 {
      action drop
      source {
        geo {
          CA {
            state none
          }
        }
      }
    }
    r1 {
      action drop
      source {
        geo {
          US {
            state none
          }
        }
      }
    }
  }
}
```

Shows the above rule list, with both rules.

```
create security firewall rule-list r1 description "domains to be blocked" rules add { r1 { destination {
```

```
fqdns add { xyz.com} } place-after first action drop } }
```

Creates a new rule list "r1", which matches and rejects any packet with destination IP addresses in domain 'xyz.com'. The description explains the purpose of the rule list.

```
modify security firewall rule-list r1 rules modify { r1 { destination { fqdns add { abc.com } } } }
```

Modifies the above rule list by blocking destination IP addresses in domain 'abc.com' too.

```
list rule-list r1
security firewall rule-list r1 {
description "domains to be blocked"
rules {
  r1 {
    action drop
    destination {
      fqdns {
        abc.com { }
        xyz.com { }
      }
    }
  }
}
```

Shows the above rule list, with the single rule r1.

OPTIONS

app-service

Associates the rule list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module has components for working with iApps.

description

Your description for this list of firewall rules.

rules

Adds, deletes, or replaces a firewall rule.

add Creates a new rule, which you specify next with a unique string in curly braces ({}). Use the place-before or place-after option inside the curly braces to determine the order of the rule. If this is the first rule, use the replace-all-with option instead of add.

delete

Deletes the rule that you specify next, in curly braces ({}).

modify

Modifies the existing rule that you specify next, in curly braces ({}). After the rule name, enter the new configuration settings for the rule inside a nested set of curly braces.

none Empties the list of rules. An empty rule list implicitly accepts all packets. The security software skips this context and assesses packets against the next layer of firewall rules, if there is one (such as those defined for net self-ip, net route-domain or ltm virtual)

replace-all-with

Replaces the current list of rules with the rule(s) that you specify next, in curly braces ({}). Use this option for the first rule in the list.

Enter the name of a rule to be added or modified, then enter an open curly brace ({), one or more of the following options, and a closed curly brace (}).

action

Specifies the action that the system takes when a rule is matched.

accept

Specifies that a matching packet should be accepted. The security software stops comparing a matching packet to any other rules in the list. The software continues comparing the packet to rules in the next appropriate context (such as net self-ip, net route-domain or ltm virtual).

accept-decisively

Specifies that a matching packet should be accepted and should not be compared to any other firewall rules in any other context.

drop

Specifies that a matching packet should be silently dropped. The security software sends nothing back to the packet source. The security software does not compare the packet to any other firewall rules in any other context.

reject

Specifies that a matching packet should be dropped. For TCP-based protocols, the security software sends a TCP reset (with the RST flag raised) back to the source. For other protocols, reject is equivalent to drop.

description

Your description for the current rule.

destination

Matches against each packet's destination IP and/or destination port. The next options choose the

matching criteria.

address-lists

Specifies a list of IP-address lists (see "security firewall address-list") to compare against the packet's destination address.

This list uses the same add, delete, none, and replace-all-with commands described above for rules, as well as a default command.

addresses

Specifies a list of IP addresses and/or subnets to compare against the packet's destination address.

The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:0a90:ff00:0042:8329" to "2001:db7:3f4a:9dd:a90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:0:678" to "2001::c34a:0:0:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

To edit this list, use the same add, delete, modify, none, and replace-all-with commands described above for rules.

fqdns

Specifies a list of fully qualified domain names to compare against packet's destination IP address domain.

To edit this list, use the same add, delete, none, and replace-all-with commands described above for rules.

geo Specifies a list of Geo Locations to compare a packet's source or destination Geo Location.

The format for a Geo Location is a 2 character string for the country code and a string for the state.

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

ipi-category

Specifies a list of IP-Intelligence category names that the packet will be compared against.

port-lists

Specifies a collection of port lists (see "security firewall port-list") to compare against the packet's destination port. If you use this option to specify a port list, a packet only matches if its destination port matches a port on these lists.

If you combine address lists and port lists in the same rule, a packet must have a matching port and a matching address to fully match the rule.

This list uses the same add, delete, none, and replace-all-with commands described above for rules, as well as a default command.

ports

Specifies a list of ports and port ranges to compare against the packet's destination port.

To edit this list, use the same add, delete, modify, none, and replace-all-with commands described above for rules.

icmp Specifies a list of ICMP types and codes to compare against the packet. You must set the ip-protocol option to "icmp" for this option to function. If you use this option, the current rule only matches ICMP packets that have the ICMP properties you specify here. You can add, delete, or modify (that is, change the description of) any entry in the list, or replace-all-with a new set of entries that you specify between curly braces ({}).

Use the standard integer identifiers to specify an ICMP type. For example: 3 is destination unreachable and 3:1 is destination unreachable with a code of host unreachable. The official list of ICMP types and codes is here: .

ip-protocol

Specifies the IP protocol to compare against the packet. This could be a layer-3 protocol (such as ipv4 or ipv6), or a higher-level protocol like ospf or rdp. If you specify this option, a packet only matches if it uses the chosen protocol. Press the key for a full list of valid protocols.

irule

Specifies the name of the iRule that will be triggered when a packet matches this firewall rule. The firewall rule match raises a FLOW_INIT iRule event.

irule-sample-rate

Specifies the rate at which an iRule specified by irule option will be triggered when a packet matches this firewall rule. The rate is an integer value in the range 0-65535 and specifies how many packets must match this firewall rule before the iRule is triggered. The default value is 1 and causes the iRule to be triggered for every packet that matches this firewall rule. A value of 0 disables iRule triggering.

log Specifies whether the security software should write a log entry for all packets that match this rule. You must also enable network filter logging in the "security log profile" component for this

option to have any effect. Note that the security software always increments the statistics counter when a packet matches a rule, no matter how you set this option.

`place-after [first | last | rule-name]`

Specifies that a new rule should be placed after the first rule, the last rule, or the rule-name you specify. If you are adding individual rules (as opposed to specifying `replace-all-with`), then you must use `place-before` or `place-after` to specify the rule's position in the list.

`place-before [first | last | rule-name]`

Specifies that a new rule should be placed before the first rule, the last rule, or the rule-name you specify. If you are adding individual rules (as opposed to specifying `replace-all-with`), then you must use `place-before` or `place-after` to specify the rule's position in the list.

`rule-list`

Specifies a full rule list instead of a customized rule that you might define with the other options. If you use this option, then only the schedule and status options are valid; the `tmsh` software rejects any other options that you attempt to use with `rule-list`.

`schedule`

Specifies a schedule for the rule. See "security firewall schedule". If you omit this option, the rule or rule list is enabled all the time.

If the rule refers to a rule-list, the rule-list is enabled according to the schedule. When the rule list is enabled, the security software then honors any schedules defined within the rule-list.

`source`

Matches against each packet's source IP, source port, and/or source VLAN. The next options choose the matching criteria.

`address-lists`

Specifies a list of address lists (see "security firewall address-list") to compare against the packet's source address.

This list uses the same `add`, `delete`, `none`, and `replace-all-with` commands described above for rules, as well as a default command.

`addresses`

Specifies a list of IP addresses and networks to compare against the packet's source address.

The format for an IPv4 address is `a.b.c.d`. The format for an IPv6 address is `a:b:c:d:e:f:g:h`.

To edit this list, use the same `add`, `delete`, `modify`, `none`, and `replace-all-with` commands described above for rules.

`fqdns`

Specifies a list of fully qualified domain names to compare against packet's source IP address domain.

To edit this list, use the same `add`, `delete`, `none`, and `replace-all-with` commands described above for rules.

`geo` Specifies a list of Geo Locations to compare a packet's source or destination Geo Location.

The format for a Geo Location is a 2 alphabet string for the country code and a string for the state.

To edit this list, use the same `add`, `delete`, `modify`, `none`, and `replace-all-with` options described above for rules.

`ipi-category`

Specifies a list of IP-Intelligence category names that the packet will be compared against.

`port-lists`

Specifies a collection of port lists (see "security firewall port-list") to compare against the packet's source port. If you use this option to specify a port list, a packet only matches if its source port matches a port on these lists.

This list uses the same `add`, `delete`, `none`, and `replace-all-with` commands described above for rules, as well as a default command.

`ports`

Specifies a list of ports and port ranges to compare against the packet's source port.

To edit this list, use the same `add`, `delete`, `modify`, `none`, and `replace-all-with` commands described above for rules.

`vlan`s

Specifies a list of VLANs, VLAN groups, and tunnels to compare against the packet.

This list uses the same `add`, `delete`, `none`, and `replace-all-with` commands described above for rules, as well as a default command.

`status`

Specifies whether the rule is enabled, disabled or scheduled. A rule that is enabled is always checked. A rule that is disabled is never checked. A rule that is scheduled is checked according to the corresponding schedule configuration. A rule that is scheduled must have an associated schedule configuration.

service-policy

Specifies the service policy configuration to use. (see "net service-policy"). The service policy can be used to set specific policy based configurations like flow timers, which applies to the flows that matches the rule.

uuid Specifies how this rule UUID is assigned: assign a explicit uuid based on RFC-4122, empty UUID (none value), or an auto-generated uuid by system (auto-generated value) based on system wide mode:[uuid-default-autogenerate mode] when creating a rule.

virtual-server

Specifies the virtual server name that will be used for further traffic processing. Option is valid only for global and/or route domain contexts.

ips-profile

Specifies IPS profile name used for signature matching and/or protocol compliance checks for flows matching the rule.

classification-policy

Specifies the Classification Policy name that will be enforced.

BIG-IP 2013-03-21 security firewall rule-stat(1)

security firewall schedule

NAME

schedule - Create a schedule that you can apply to firewall rules.

MODULE

security firewall

SYNTAX

CREATE/MODIFY

create schedule [name]

modify schedule [[name] | all]

options:

app-service [name]

daily-hour-end [hour:minute]

daily-hour-start [hour:minute]

date-valid-end [MM/DD/YYYY]

date-valid-start [MM/DD/YYYY]

description [text]

days-of-week [[monday | tuesday | wednesday | thursday | friday | saturday | sunday] ...]

edit schedule [[name] | [glob] | [regex]] ...]

DISPLAY

list schedule [[name] | all | [property]]

DELETE

delete schedule [[name] | all]

show running-config schedule [[name] | all | [property]]

DESCRIPTION

You use the schedule component to specify when to apply a firewall rule. You can specify a start time and an end time, some days of the week, a date when the schedule first starts, and/or a date when the schedule ends forever.

To apply the schedule to a firewall rule or rule list, edit the firewall or rule-list component. These are the firewalls and rule lists where you can apply schedules:

"security firewall global-rules"

"security firewall management-ip-rules"

"net self"

"net route-domain"

"ltm virtual"

"security firewall rule-list"

By default, all firewall rules are continuously active. By applying a schedule to a firewall rule, you reduce the time that the rule is running.

If you create a schedule without any scheduling specifications (such as daily-hour-start), the schedule is always active.

Note you may not delete a schedule that is being used by any firewall rule or rule list.

EXAMPLES

```
create schedule my_schedule1 date-valid-start now date-valid-end 12/31/2016 daily-hour-start 8:00 daily-hour-end 17:00
```

Creates a new schedule which is active between 8am and 5pm every day until December 31, 2016.

```
list schedule>
```

```
security firewall schedule my_schedule1 {
```

```
  daily-hour-end 17:00
```

```
  daily-hour-start 8:00
```

```
  date-valid-end 2016-12-31:00:00:00
```

```
  date-valid-start 2012-12-12:08:40:01
```

```
}
```

```
security firewall schedule workHours {
```

```
  daily-hour-end 18:00
```

```
  daily-hour-start 8:00
```

```
  days-of-week { monday tuesday wednesday thursday friday }
```

```
}
```

Lists two user-configured schedules, including the one that you created above.

```
modify schedule my_schedule1 days-of-week { monday tuesday wednesday }
```

Modifies the schedule named "my_schedule1." This limits the schedule to running only on Mondays, Wednesdays, and Fridays.

OPTIONS

app-service

Associates this schedule with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module has components for working with iApps.

description

Describes the schedule.

daily-hour-end

Specifies the time of day this schedule stops. This end hour must be after the daily-hour-start value. The default is 24:00 (midnight).

A schedule may not contain hours that go past midnight (24:00): for example, a daily-hour-start of 20:00 and daily-hour-end of 02:00 is not allowed. If you need to cover both the late hours and early hours of the day, please create two schedules.

daily-hour-start

Specifies the time of day this schedule starts. This start hour must be before the daily-hour-end value. The default is 0:00 (midnight at the start of the day).

date-valid-end

Specifies the final date for this schedule. The schedule stops firing as of this date. You may specify just the specific date, or a specific date and time for the schedule to end. The date must be after the date-valid-start value. The default is 19:14 1/18/2038 (the latest date expressible with a 32-bit integer).

date-valid-start

Specifies the start date for this schedule. The schedule does not fire before this date and time. You may specify just the specific date, or a specific date and time for the schedule to start. You must specify a date before the date-valid-end value. The default is midnight 1/1/1970 (Unix epoch).

days-of-week

Specifies which days of the week the schedule fires. You must specify at least one day of the week, and you cannot specify any day of the week more than once. The default is all seven days.

security firewall user-domain

NAME

user-domain - Configures a user-domain for use by firewall rules.

MODULE

security firewall

SYNTAX

CREATE/MODIFY

create user-domain [name]

modify user-domain [[name] | all]

options:

domain string

ifmap-service [add | delete | modify | replace-all-with] {

[ip]

[port]

[login]

[password]

}

app-service [name]

description [string]

edit user-domain [[name] | all]

options:

all-properties

non-default-properties

DISPLAY

list user-domain [[name] | all | [property]]

show running-config user-domain [[name] | all | [property]]

DELETE

delete user-domain [[name] | all]

RUN

run user-domain [[name] | all] clear-cache

DESCRIPTION

A user-domain object holds attributes to reach services that provide more information about a user. This information includes the domain for which the service is defined, the identity service that can be used to validate this user and the ifmap service that can be used to obtain more information about the user. User domains also have associated cache data which is utilized by user identity feature for performance improvements. You can use the user-domain component to define reusable configuration that is used to learn about more users used in the firewall rules or clear their associated cache data on demand.

EXAMPLES

```
create user-domain gladiators identity-server add { felix-legions { ip 1.1.1.1 login maximus password meridiem port 10002 } }
```

Creates a new user-domain object that defines a new identity-server for domain gladiators with an identity service felix-legions

```
modify user-domain gladiators ifmap-server add { rome { ip 10.10.10.10 login marcus password aurelius port 10002 } }
```

Modifies the above user domain to add an ifmap server.

```
run user-domain grumpycat clear-cache
```

Clears the user identity cache associated with a specified user domain name.

```
run user-domain all clear-cache
```

Clears the user identity cache for all available user domains.

OPTIONS

domain

Specifies a domain for which the identity and ifmap services are defined.

app-service

Associates this user domain with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module (see asm) has components for working with iApps.

description

User-defined description for this user domain.

clear-cache

Invokes clear-cache functionality for the given user-domain name.

SEE ALSO

edit, list, modify, net self, net route-domain, security firewall global-rules, security firewall management-ip-rules, security firewall rule-list, ltm virtual, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 security firewall user-domain(1)

security firewall user-list

NAME

user-list - Configures a user-list for use by firewall rules. A firewall rule can match a packet sourced from a particular user against one of the users or user-groups in a user list, and can take some action (such as ACCEPT or DROP) for a matching packet. An incoming packet's source IP address is matched in user identity database to get the user and group properties which are then used to perform the rule match.

MODULE

security firewall

SYNTAX

CREATE/MODIFY

create user-list [name]

modify user-list [[name] | all]

options:

app-service [name]

description [string]

user-groups [add | delete | modify | replace-all-with] {
[[user group names...]]
}

users [add | delete | modify | replace-all-with] {

```
[ [user names...] ]  
}
```

edit user-list [[name] | all]
options:
all-properties
non-default-properties

DISPLAY
list user-list [[name] | all | [property]]

DELETE
delete user-list [[name] | all]

DESCRIPTION

You can use the user-list component to define reusable lists of user or user-group names for various firewall rules. The network software compares a packet's source user (mapped by incoming source IP address) and group that user belong to, against users (or user-groups) in this list. You can assign a user list to the firewall rules in net self, net route-domain, security firewall global-rules, security firewall rule-list, and ltm virtual firewall rules.

EXAMPLES

create user-list u-list1 users add { olympus\xyz }

Creates a new user list named u-list1 with one user named xyz in domain olympus.

create user-list u-list2 user-groups add { olympus\eng }

Creates a new user list named u-list2 with one group named eng in domain olympus.

list user-list

Shows all the user lists configured in the system.

OPTIONS

app-service

Associates this user list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module has components for working with iApps.

description

Your description for the user list.

user-groups

Specifies a list of user groups to compare against the groups a user belongs to (which is mapped from the source IP address).

users

Specifies a list of users to compare against a packet's source user (which is mapped from the source IP address).

SEE ALSO

edit, list, modify, net self, net route-domain, security firewall address-list, security firewall rule-list, security firewall global-rules, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008, 2012-2013, 2015-2016. All rights reserved.

BIG-IP 2016-03-14 security firewall user-list(1)

security firewall uuid-default-autogenerate

NAME

uuid-default-autogenerate - Configures system wide firewall rule uuid auto generate mode.

MODULE

security firewall

SYNTAX

MODIFY

modify uuid-default-autogenerate mode [disabled | enabled]

DISPLAY

list uuid-default-autogenerate mode

show uuid-default-autogenerate mode

DESCRIPTION

You can use the `uuid-default-autogenerate` component to change the behavior of how the firewall rule `uuid` get auto generated. By default the system will automatically disable firewall rule `uuid` auto-generating. You can change the behavior to manually trigger the rule `uuid` auto-generating by setting the mode to enabled.

EXAMPLES

modify security firewall `uuid-default-autogenerate` mode enabled

security flowspec-route-injector flowspec-advertised-route-info

NAME

`flowspec-advertised-route-info` - Display FlowSpec routes that are currently being advertised.

MODULE

security `flowspec-route-injector`

SYNTAX

Display `flowspec-advertised-route-info` component within the `security flowspec-route-injector` module using the syntax in the following section.

DISPLAY

show `flowspec-advertised-route-info` `route-domain-id`

DESCRIPTION

Show `flowspec-advertised-route-info` displays FlowSpec routes that are currently being advertised per route domain instance.

OPTIONS

For information about the options that you can use with the command `show`, see `help show`.

DESCRIPTION

profile component under security flowspec-route-injector is used to manage a Security FlowSpec Route Injector profile (unique per route domain instance). Security FlowSpec route injector profile is used by AFM/DHD module to advertise routes based on Source/Destination IP, Source/Destination Port, Protocol etc. for blackholing and scrubbing use cases using BGP FlowSpec mechanism (RFC 5575).

EXAMPLES

```

create profile p1
neighbor add {
    10.128.10.128 {
local-address 10.128.10.169
    }
}
peer-group {
local-as 60000
remote-as 60000
router-id 1.1.1.1
}

```

```
}  
route-domain 0 }
```

Create a security flowspec-route-injector profile p1 for route-domain 0 and add 1 peer neighbor 10.128.10.128. Common attributes that are shared by all neighbors in the profile (unless overridden) are defined using peer-group settings.

modify profile p1 peer-group { graceful-restart enabled graceful-restart-time 120 }

Modify profile p1 and update graceful-restart and graceful-restart-time peer-group attributes.

list policy

Displays the current list of configured security flowspec-route-injector profiles.

OPTIONS

description

User defined description.

advertisement-ttl-from-now

Specifies the duration (in minutes) after which FlowSpec should be withdrawn. The default is 5 minutes. If it is 0, it would be allowed for user to immediately expire the rule (and withdraw from upstream routers).

This is user write-only configuration. It is used for system to calculate expiry time of the rule. It is mutual exclusive with expiry-time.

max-flowspec-routes-limit

Specifies the maximum number of FlowSpec routes that can be advertised simultaneously per FlowSpec profile (or route domain) instance. Minimum allowed value is 100, Maximum allowed value is 10,000 (which is default value too).

neighbor

Add, modify, delete BGP peer neighbor configuration. Each neighbor is uniquely identified / configured using IP Address as the name.

description

User defined description.

adj-out

Enable/Disable BGP adj-rib-out feature. Default is enabled.

bgp-multiple-instance

Enable/Disable BGP multiple instance capability. Default is disabled.

extended-asn-cap

Enable/Disable Extended ASN capability (i.e. send 4-byte ASN). Default is enabled.

graceful-restart

Enable/Disable graceful restart capability. Default is disabled.

graceful-restart-time

Specifies graceful restart time (max time needed for Neighbor(s) to restart).

hold-time

Specifies the hold time (max time that can elapse between messages from peer). Default is 90 seconds.

local-address

Specifies the Local Address (on BigIP) to be used for initiating BGP connection(s) with peers.

local-as

Specifies the BGP Local AS number.

remote-as

Specifies the BGP Remote AS number.

router-id

Specifies the BGP Router ID to be used in BGP OPEN message when initiating BGP connection with peers. Router ID is an IPv4 address.

route-domain

Specifies name of the route domain to be used by the Security FlowSpec Route Injector profile. This is required field at the time of profile creation and is non-mutable after policy creation.

rules

Specifies configuration of rules that can be advertised per FlowSpec profile.

action

Specifies BGP FlowSpec Advertisement Action configuration.

dscp-value

Specifies the BGP FlowSpec DSCP value for advertisement qos action. The default is 0. The valid range is 0 ~ 63 inclusive.

next-hop

Specifies BGP FlowSpec redirection next hop address

rate-limit

Specifies the BGP FlowSpec rate limit (bytes/sec) for advertisement rate limiting action.

asn-community

Specifies the BGP Extended Community value (in the format - AA:NNN, where AA is 16-bit number and NNN is 32-bit number) for redirect-to-VRF support when BGP Flowspec advertisement action is redirect.

type Specifies the BGP FlowSpec Advertisement Action type for this FlowSpec Route Injector profile.
The default is redirect.

alias

Specifies the alias name of this rule.

app-service

The application service that the object belongs to.

creation-time

The time when this rule is created. This is not user configurable field.

description

User defined description.

expiry-time

The time when this rule is going to be expired.

This field is mutual exclusive with advertisement-ttl-from-now. If user specifies advertisement-ttl-from-now, expiry-time will be calculated from it.

last-modified-time

The time when this rule is modified. This is not user configurable field.

remove-config-upon-expiry

Specifies whether or not this rule needs to be automatically removed when reaching expiry time. The default is true. If it is set to false, user needs to manually remove this rule as it is needed.

The maximum allowed expired rules per profile in database is defined by DB variable, flowspec.max.expired_and_saved_rules (min = 0, max = 1000, default = 100).

match

Specifies BGP FlowSpec matching criteria configuration.

destination-address

Specifies the destination address/prefix to match in packets.

destination-ports

Specifies a list of ports that matches destination TCP/UDP ports in packets.

This destination-ports configuration is mutual exclusive with ports field.

dscp-values

Specifies a list of DSCP values to match in packets. The valid range for each of DSCP value in the list must be within 0 ~ 63 inclusive.

icmp-codes

Specifies a list of ICMP codes to match in packets.

icmp-types

Specifies a list of ICMP types to match in packets.

ip-fragments

Specifies a list of IP fragments to match in packets.

ip-protocols

Specifies a set of protocol values that are used to match the IP protocol value byte in IP packets. The valid protocols are ICMP, TCP, UDP, and SCTP. If port object is specified, the valid protocols are TCP, UDP, and SCTP.

packet-lengths

Specifies a list of packet lengths (singleton or a range) to match. Packet Length includes L3 (header) size in addition to payload length.

ports

Specifies a list of ports that matches source OR destination TCP/UDP ports in packets.

This ports configuration is mutual exclusive with destination-ports and source-ports.

source-address

Specifies the source address/prefix to match in packets.

source-ports

Specifies a list of ports that matches source TCP/UDP ports in packets.

This source-ports configuration is mutual exclusive with ports field.

tcp-flags

Specifies lists of TCP flags to match in packets."

bitwise-and-fields

Specifies a bitwise AND list of TCP flags to match in packets."

bitwise-or-fields

Specifies a bitwise OR list of TCP flags to match in packets."

peer-group

Specifies peer group settings that are inherited by each neighbor unless overridden specifically for that neighbor.

adj-out

Enable/Disable BGP adj-rib-out feature. Default is enabled.

bgp-multiple-instance

Enable/Disable BGP multiple instance capability. Default is disabled.

extended-asn-cap

Enable/Disable Extended ASN capability (i.e. send 4-byte ASN). Default is enabled.

graceful-restart

Enable/Disable graceful restart capability. Default is disabled.

graceful-restart-time

Specifies graceful restart time (max time needed for Neighbor(s) to restart).

hold-time

Specifies the hold time (max time that can elapse between messages from peer). Default is 90 seconds.

local-address

Specifies the Local Address (on BigIP) to be used for initiating BGP connection(s) with peers.

local-as

Specifies the BGP Local AS number.

remote-as

Specifies the BGP Remote AS number.

router-id

Specifies the BGP Router ID to be used in BGP OPEN message when initiating BGP connection with peers. Router ID is an IPv4 address.

security-log-profile

Specifies log publisher name used for this FlowSpec Route Injector profile.

security http file-type

NAME

file-type - Lists the available file types that can be used in the context of HTTP Protocol Security.

MODULE

security http

SYNTAX

Retrieve the list of the file-type values using the syntax shown in the following sections.

DISPLAY

list file-type

list file-type [[[name] | [glob] | [regex]] ...]

options:

all

app-service

one-line

DESCRIPTION

Use this command to display the possible values of the file-type object to be used in the context of HTTP Protocol Security. These possible values include predefined and user-defined file types that you can select to have the security profiles allow or disallow.

EXAMPLES

list file-type

Displays all the file types supported by HTTP Protocol Security.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

SEE ALSO

glob, list, regex, security http profile, tmsh

security http mandatory-header

NAME

mandatory-header - Lists the available mandatory headers that can be used in the context of HTTP Protocol Security.

MODULE

security http

SYNTAX

Retrieve the list of the mandatory-header values using the syntax shown in the following sections.

DISPLAY

list mandatory-header

list mandatory-header [[[name] | [glob] | [regex]] ...]

options:

all

app-service

one-line

DESCRIPTION

Use this command to display the possible values of the mandatory-header object to be used in the context of HTTP Protocol Security. These possible values include predefined and user-defined HTTP headers that you can select to be required by the security profiles.

EXAMPLES

list mandatory-header

Displays all the mandatory headers supported by HTTP Protocol Security.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

DELETE

delete profile [name]

DESCRIPTION

You can use the profile component to create, modify, display, or delete an HTTP security profile for use with HTTP Protocol Security functionality.

EXAMPLES

create http my_http_profile defaults-from http_security

Creates a custom HTTP security named my_http_profile that inherits its settings from the system default HTTP security profile.

list profile

Displays the properties of all HTTP security profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

[case-sensitive | case-insensitive]

Specifies whether the security profile treats file types as case sensitive, or not. The default value is case-sensitive. Note: If you create a profile, you can use either property, thereafter it becomes read only. If the security profile is case insensitive, the system stores file types in lowercase in the security profile configuration.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is none.

description

User defined description.

evasion-techniques

Specifies what action the system takes when it detects an evasion technique. Evasion techniques are methods used by attackers to avoid detection of their attack. You can configure the following options for evasion technique checks:

alarm

Specifies, when enabled, that the system logs the request data and displays it in the Protocol Security Statistics screen whenever the system detects an evasion technique. The default value is enabled.

block

Specifies, when enabled, that the system stops requests whenever the system detects an evasion technique. The default value is disabled.

file-types

Specifies which file types the security profile considers legal, and specifies what action the system takes when it detects a request for an illegal file type. You can configure the following options for file types:

alarm

Specifies, when enabled, that the system logs the request data and displays it on the Protocol Security Statistics screen whenever the system detects a request for an illegal file type. The default value is enabled.

[allowed | disallowed]

Indicates whether the values property lists file types that the security profile permits or prohibits. Note: For each security profile you may define either allowed file types or disallowed file types.

block

Specifies, when enabled, that the system stops requests for an illegal file type. The default value is disabled.

values

Adds, deletes, or replaces a set of file types considered either legal or illegal by the security profile. You can either select an available file-type or add a new one.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

http-rfc

Specifies which validations the system should check and what action the system takes when it detects a request that is not formatted properly. You can configure the following options for HTTP protocol checks:

alarm

Specifies, when enabled, that the system logs the request data and displays it in the Protocol Security Statistics screen whenever a request fails one of the enabled HTTP protocol checks. The default value is enabled.

bad-host-header

Specifies, when enabled, that the system inspects requests to see whether they contain a non RFC compliant header value. The default value is enabled.

bad-version

Specifies, when enabled, that the system inspects requests to see whether they request information from a client using an HTTP protocol version 1.0 or higher. The default value is enabled.

block

Specifies, when enabled, that the system stops requests whenever the system detects an evasion technique. The default value is disabled.

body-in-get-head

Specifies, when enabled, that the system examines requests that use the HEAD or GET methods to see whether the requests contain data in their bodies, which is considered illegal. The default value is disabled.

chunked-with-content-length

Specifies, when enabled, that the system examines chunked requests for a content-length header, which is not permitted. The default value is enabled.

content-length-is-positive

Specifies, when enabled, that the system examines requests to see whether their content length value is greater than zero. The default value is enabled.

header-name-without-value

Specifies, when enabled, that the system checks requests for valueless header names, which are considered illegal. The default value is enabled.

high-ascii-in-headers

Specifies, when enabled, that the system inspects request headers for ASCII characters greater than 127, which are not permitted. The default value is disabled.

host-header-is-ip

Specifies, when enabled, that the system verifies that the request's host header value is not an IP address. The default value is disabled.

maximum-headers

Specifies whether the system compares the number of headers in the requests against the maximum number, and if so, how many headers are allowed. The default value is a maximum of 20 headers.

null-in-body

Specifies, when enabled, that the system inspects request bodies to see whether they contain a Null character, which is not allowed. The default value is disabled.

null-in-headers

Specifies, when enabled, that the system inspects request headers to see whether they contain a Null character, which is not allowed. The default value is enabled.

post-with-zero-length

Specifies, when enabled, that the system examines POST method requests for no content-length header, and for a content length of 0. The default value is disabled.

several-content-length

Specifies, when enabled, that the system examines each request to see whether it has more than one content-length header, which is considered illegal. The default value is enabled.

unparsable-content

Specifies, when enabled, that the system examines requests for content that the system cannot parse, which is not permitted. The default value is enabled.

mandatory-headers

Specifies which headers must appear in requests, and specifies what action the system takes when it detects a request without a mandatory header. You can configure the following options for mandatory headers:

alarm

Specifies, when enabled, that the system logs the request data and displays it on the Protocol Security Statistics screen whenever a request does not include a mandatory header. The default value is enabled.

block

Specifies, when enabled, that the system stops requests that do not include a mandatory header. The default value is disabled.

values

Adds, deletes, or replaces a set of headers that must appear in requests to be considered legal by the security profile. You can either select an available mandatory-header or add a new one. Note: The system stores mandatory headers in lowercase in the security profile configuration, regardless of whether it is case sensitive or not.

maximum-length

Specifies the default maximum length settings that the security profile considers legal, and specifies what action the system should take when it detects a request using an illegal length. You can configure the following options for length checks:

alarm

Specifies, when enabled, that the system logs the request data and displays it on the Protocol Security Statistics screen whenever a request fails one of the length checks. The default value is enabled.

block

Specifies, when enabled, that the system stops requests that fail one of the length checks. The default value is disabled.

post-data

Indicates whether there is a maximum acceptable length, in bytes, for the POST data portion of a request, and if so, specifies it. The default value is any (no restriction).

query-string

Indicates whether there is a maximum acceptable length, in bytes, for the query string portion of a request, and if so, specifies it. The default value is 1024 bytes.

request

Indicates whether there is a maximum acceptable length, in bytes, of a request, and if so, specifies it. The default value is any (no restriction).

uri Indicates whether there is a maximum acceptable length, in bytes, for a URL, and if so, specifies it. The default value is 1024 bytes.

methods

Specifies which HTTP methods the security profile considers legal, and specifies what action the system takes when it detects a request using an illegal method. You can configure the following options for methods:

alarm

Specifies, when enabled, that the system logs the request data and displays it on the Protocol Security Statistics screen whenever a request uses an illegal method. The default value is enabled.

block

Specifies, when enabled, that the system stops requests that use an illegal method. The default value is disabled.

values

Adds, deletes, or replaces a set of HTTP methods considered legal by the security profile. You can either select an available http-method or add a new one. Note: HTTP methods are case sensitive even if the security profile is case insensitive.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

response

Specifies information to display when the security profile blocks a client request. You can configure the following options for blocking page:

body Specifies the HTML code the system sends to the client in response to an illegal blocked request. Only if the response type is custom, you can edit this text.

headers

Specifies the set of response headers that the system sends to the client in response to an illegal blocked request. Only if the response type is custom, you can edit this text. Separate each header with a new line (Ctrl-V followed by Ctrl-J).

type Specifies which content, or URL, the system sends to the client in response to an illegal blocked request.

custom

Specifies a modified response text. You can edit the response header and HTML code in the properties headers and body.

default

Specifies the system-supplied response text written in HTML. You cannot edit that text. This is the default value.

redirect

Specifies that the system redirects the user to a specific web page instead of viewing a blocking page. You can edit the redirect web page in the url property.

soap-fault

Specifies the system-supplied response written in SOAP fault message structure. You cannot edit that text. Use this type when a SOAP request is blocked due to an XML related violation.

url Specifies the particular URL to which the system redirects the user. Only if the response type is redirect, you can edit this text. The web page should include a full URL path, for example, <http://www.myredirectpage.com>.

partition

recursive

DESCRIPTION

You can use the blacklist-category component to configure a shareable and reusable blacklist category which can be configured with specific enforcement and logging settings under ip-intelligence policies.

EXAMPLES

modify blacklist-category Malware description "A variety of forms of hostile or intrusive software."

Modifies the blacklist-category description.

list blacklist-category

Displays the current list of blacklist categories.

OPTIONS

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description
User defined description.

bl-match-direction
Indicates whether to match source IPs, destination IPs, or both.

partition
Displays the administrative partition within which the component resides.

security ip-intelligence feed-list

NAME

feed-list - Configures a feed-list for use by firewall. A feed-list is a list of URL feeds from where files are downloaded and the contents (IP-address prefixes) are compared against the source-IP address and/or destination-IP address in an IP packet by DWBL (Dynamic White/Black lists) by IP-Intelligence.

MODULE

security ip-intelligence

SYNTAX

Configure the feed-list component within the security ip-intelligence module using the syntax in the following sections.

CREATE/MODIFY

```
create feed-list [name]
modify feed-list [[name] | all]
options:
  feeds [add | delete | modify | replace-all-with] {
    name [string] {
      options:
        default-blacklist-category [string]
        default-list-type [whitelist | blacklist]
    }
    poll {
      interval [integer]
      user [string]
      url [string]
      password [string]
    }
  }
}
app-service [name]
description [string]
```

```
edit feed-list [[name] | all]
```

```
options:
  all-properties
  non-default-properties
```

```
load feed-list [[name] | all] feeds { name [string] }
```

DISPLAY

```
list feed-list [[name] | all | [property]]
show running-config feed-list [[name] | all | [property]]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

DELETE

```
delete feed-list [[name] | all]
```

DESCRIPTION

You can use the feed-list component to define reusable lists of feeds. You can use a feed list in a security ip-intelligence policy. A policy compares all of the addresses in the list (downloaded from a file at the specified url) to either the source or destination IP in the packet, depending on how you apply the list. If there is a match, the ip-intelligence policy takes an action, such as accepting or dropping the packet.

EXAMPLES

```
create feed-list alist1 feeds add { poll { url http://f5.com/bl.txt }
```

Creates a new feed list, "alist1," with IPv4/IPv6 addresses in the file downloaded from the specified url.

```
modify feed-list alist1 feeds modify { description "DWBL file from f5.com" }
```

Modifies the above feed list with a description.

```
modify feed-list alist1 feeds modify { poll { url https://f5.com/bl.txt }
```

Modifies the same feed by changing the protocol.

```
list feed-list alist1
security ip-intelligence feed-list alist1 {
  feeds {
    url2 {
    poll {
      url https://f5.com/bl.txt
      user user1
      password user1_pwd
    }
  }
  description "DWBL file from f5.com"
}
}
```

Shows the modified feed list.

```
load feed-list alist1 alist2 feeds { feed1 feed2 }
```

Immediately downloads and updates feeds feed1 and feed2 of feed lists alist1 and alist2.

OPTIONS

feeds

Adds, deletes, or replaces feeds. You can configure the following options for a feed:

name Specifies a name for a feed. This option is required for the operations create, delete, modify, and replace-all-with.

add Creates a new feed list.

delete

Deletes the feed list that you specify next, in curly braces ({}).

modify

Makes it possible to replace the optional description(s) for the feed list.

replace-all-with

Replaces the current set of feed list with the a new one that you specify next, in curly braces ({}).

default-list-type

Specifies a default type for this specific entry whether it is a blacklist or whitelist

whitelist

Specifies that this entry is a whitelist.

blacklist

Specifies that this entry is a blacklist.

default-blacklist-category

Default blacklist category type for all blacklist entries that do not have a corresponding category string (eg. Botnet, Spyware, Malware)

poll You can configure the following options under this:

interval

Specifies the frequency at which the url needs to be polled.

user Specifies the user which is used when downloading the url.

url Specifies the URL from where the white/black list will be downloaded. Note: Route domains are not supported when specifying the url.

password

Password for the user.

default-list-type

Specifies a default type for this specific entry whether it is a blacklist or whitelist

whitelist

Specifies that this entry is a whitelist.

blacklist

Specifies that this entry is a blacklist.

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

default-blacklist-category

Default blacklist category type for all blacklist entries that do not have a corresponding category string (eg. Botnet, Spyware, Malware)

description

User defined description for this feed list.

partition

Displays the administrative partition within which the component resides.

security ip-intelligence global-policy

NAME

global-policy - Configures the global ip-intelligence policy. These ip-intelligence policy contents/filters are applied to all packets except those going through the management interface. They are applied first, before any firewall rules for the packet's virtual server, route domain.

MODULE

security ip-intelligence

SYNTAX

Modify the global-policy component within the security ip-intelligence module using the syntax shown in the following sections.

MODIFY

modify global-policy

options:

app-service [name]

description [string]

ip-intelligence-policy [[policy_name] | none]

edit global-policy

options:

all-properties

non-default-properties

one-line

partition

recursive

reset-stats global-policy

options:

ip-intelligence-categories

DISPLAY

list global-policy

show running-config global-policy

options:

all-properties

non-default-properties

one-line

partition

recursive

show global-policy

options:

ip-intelligence-categories

DESCRIPTION

You can use the global-policy component to configure a shareable and reusable set of network firewall DWBL (Dynamic White/Black lists) which can be enforced globally at the system level and the enforcement happens before the route-domain or virtual server level.

EXAMPLES

modify global-policy policy pol1

Modifies the global-policy with policy pol1.

list global-policy

Displays the current list of global-policy contents.

OPTIONS

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description.

policy

Specifies an existing policy. policy contents are enforced at a global level.

partition

Displays the administrative partition within which the component resides.

ip-intelligence-categories

Used to show/ reset statistics on IP intelligence white/ black lists categories.

SEE ALSO

create, edit, list, modify, security ip-intelligence feed-list, security ip-intelligence policy, tmsh

security ip-intelligence info

NAME

info - Query IP Intelligence information about specified IP Address, GEO location or FQDN.

MODULE

security ip-intelligence

SYNTAX

Use the info component within the security ip-intelligence module to query IP Intelligence information about the IP address, GEO location or FQDN using the following syntax.

DISPLAY

show info address [IP address]

fqdn [FQDN name]

geo [GEO_country[:GEO_region]]

options:

virtual-server [name]

route-domain [name]

DESCRIPTION

You can use the info component to query IP Intelligence information about an IP Address, a GEO location, or a FQDN using IP Intelligence policy attached to the selected context. Global context is the default when the command is used without options. To select the virtual server or the route domain context use virtual-server or route-domain option. Only one option can be used. If the specified parameter (IP Address, GEO location or FQDN) is listed in any of the DWBL (Dynamic White/Black List) feeds used by the selected IP Intelligence policy the query shows the list of categories and policy action (drop or allow) for the address. If the policy is configured to query legacy IP Reputation database, that information is also used in the query.

EXAMPLES

show info address 10.123.1.12

Query IP Intelligence information for IP address 10.123.1.12 using global IP Intelligence policy.

show info address 10.123.1.12 virtual-server /Common/vs

Query IP Intelligence information for IP address 10.123.1.12 using IP Intelligence policy configured for virtual server /Common/vs.

show info address fqdn { f5.com }

Query IP Intelligence information for FQDN f5.com using global IP Intelligence policy.

show info address geo { US }

Query IP Intelligence information for United States using global IP Intelligence policy.

show info address geo { US:California }

Query IP Intelligence information for California, United States using global IP Intelligence policy.

OPTIONS

virtual-server

Specifies the name of the virtual server configured with IP Intelligence policy to use in the query. This option cannot be used with the route-domain option.

route-domain

Specifies the name of the route domain configured with IP Intelligence policy to use in the query. This option cannot be used with the virtual-server option.

SEE ALSO

BIG-IP 2018-09-20 security ip-intelligence info(1)

security ip-intelligence policy

NAME

policy - Configures an ip-intelligence policy. It's comprised of three logical groups of settings: list of feed lists, enforcement and logging settings per blacklist category, and default enforcement and logging settings for blacklist categories.

MODULE

security ip-intelligence

SYNTAX

Configure the policy component within the security ip-intelligence module using the syntax in the following sections.

CREATE/MODIFY

create policy [name]

modify policy [name]

options:

app-service [name]

description [string]

blacklist-categories [add | default | delete | replace-all-with] {

[name] {

action [accept | drop | use-policy-setting]

app-service none

description none

log-blacklist-hit-only [no | yes | use-policy-setting]

log-blacklist-whitelist-hit [no | yes | use-policy-setting]

match-direction-override [match-destination | match-source | match-source-and-destination]

}

}

feed-lists [add | default | delete | replace-all-with] { [name] }

default-action [accept | drop]

default-log-blacklist-hit-only [no | yes]

default-log-blacklist-whitelist-hit [no | yes]

edit policy

options:

all-properties

non-default-properties

DISPLAY

```
list policy [ [ [name] | [glob] | [regex] ] ... ]
show running-config policy
show running-config policy [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

DESCRIPTION

You can use the policy component to configure a shareable and reusable enforcement and logging settings on Dynamic White/Black lists of IPs coming from downloaded feeds. The policy can then be enforced on a number of configuration objects of the following types: ltm virtual, security ip-intelligence global-policy, net route-domain.

EXAMPLES

```
create policy pol1 {
  blacklist-categories add {
    Spyware {
      action use-policy-setting
      app-service none
      description none
      log-blacklist-hit-only use-policy-setting
      log-blacklist-whitelist-hit yes
    }
  }
  feed-lists add { alist1 alist2 }
  default-action drop
  default-log-blacklist-hit-only yes
  default-log-blacklist-whitelist-hit no
  description none
  feed-lists none
  partition Common }
```

Creates a policy pol1 with feeds from alist1 and alist2 feed lists, specific enforcement and logging settings for Spyware blacklist category and policy default settings for other categories.

```
modify policy pol1 { feed-lists delete { alist2 } }
```

Removes the feed-list alist2 from the policy pol1.

```
list policy
```

Displays the current list of ip-intelligence policies contents.

OPTIONS

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description.

partition

Displays the administrative partition within which the component resides.

blacklist-categories

Adds, deletes, or replaces blacklist categories.

action

Specifies what enforcement action will be applied if the packet is categorized with this blacklist category. If the packet is categorized with more than one blacklists the most restrictive action will be applied.

log-blacklist-hit-only

Specifies if a log message will be generated if the packet is categorized with this blacklist and the packet's IP listed in no whitelists.

match-direction-override

Overrides the current IP match direction setting for a category. If this value has not been overridden, it will be set to the value of the parent category's bl-match-direction at the time that the category was added to the policy.

log-blacklist-whitelist-hit

Specifies if a log message will be generated if the packet is categorized with this blacklist and the packet's IP is listed in a whitelist.

feed-lists

Adds, deletes, or replaces a feed list. Specifies a list of feed lists (see security ip-intelligence feed-list) against which the packet will be compared.

default-action

Specifies a default enforcement action which will be performed on the matched packet unless an implicit action specified for one of the blacklist categories the packet's IP is categorized with. If the packet's

IP is listed in a white list the action is always accept.

default-log-blacklist-hit-only

Specifies a default blacklist hit only logging action which will be performed on the matched packet unless an implicit action specified for one of the blacklist categories the packet's IP is categorized with.

default-log-blacklist-whitelist-hit

Specifies a default blacklist and whitelist hit logging action which will be performed on the matched packet unless an implicit action specified for one of the blacklist categories the packet's IP is categorized with.

security log antifraud-storage-field

NAME

antifraud-storage-field - Lists the available storage format fields that can be used in the context of Anti-Fraud Security Logging.

MODULE

security log

SYNTAX

Retrieve the list of the antifraud-storage-field values using the syntax shown in the following sections.

DISPLAY

list antifraud-storage-field

list antifraud-storage-field [[[name] | [glob] | [regex]] ...]

options:

all
app-service
id
one-line
support-events

DESCRIPTION

Use this command to display the possible values of the antifraud-storage-field object to be used in the context of Anti-Fraud Security Logging. These possible values are predefined traffic items available for the server to log.

EXAMPLES

list antifraud-storage-field

Displays all the storage fields supported by Anti-Fraud Security Logging.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

id Displays an order ID of the field. This ID should be used to specify that this antifraud-storage-field should be URL-encoded when logging Anti-Fraud events.

support-events

Displays a bit mask representing the Anti-Fraud events that are supported by this antifraud-storage-field.

SEE ALSO

glob, list, regex, security log profile, tmsh

security log network-storage-field

NAME

network-storage-field - Lists the available storage format fields that can be used in the context of Network Security Logging.

MODULE

security log

SYNTAX

Retrieve the list of the network-storage-field values using the syntax shown in the following sections.

DISPLAY

list network-storage-field

list network-storage-field [[[name] | [glob] | [regex]] ...]

options:

all
all-properties
one-line
app-service

DESCRIPTION

Use this command to display the possible values of the network-storage-field object to be used in the context of Network Security Logging. These possible values are predefined traffic items available for the server to log in context of Network event logging (for example, ACL events, TCP Open/Close, TCP/IP error events).

EXAMPLES

list network-storage-field

Displays all the storage fields supported by Network Security Logging.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

SEE ALSO

DELETE
delete profile [name]

DESCRIPTION

You can use the profile component to create, modify, display, or delete a Security log profile for use with Security Logging functionality.

EXAMPLES

create profile my_log_profile

Creates a custom Security log profile named my_log_profile with initial settings.

list profile

Displays the properties of all Security log profiles.

OPTIONS

antifraud

Adds, deletes, or replaces a single Anti-Fraud Security sub-profile. You can configure the following options for Anti-Fraud Security:

encode-fields

Adds, deletes, or replaces a set of antifraud-storage-field IDs for which the system performs URL-encoding before logging.

events

Adds, deletes, or replaces a set of events (alert, login) used by the system to log data. You can configure the following options for each event:

format

Specifies a storage format in Anti-Fraud Security. You can configure the following options for the storage format:

type Specifies a type of the storage format. The options are:

default

Specifies that the log displays a predefined format and antifraud-storage-field fields.

user-defined

Specifies that the log displays any free text that you type in the user-template which can include relevant antifraud-storage-field fields for this event.

rate-limit

This option is used to set the rate for the Anti-Fraud log event that can be logged per second, per virtual-server (per TMM).

user-template

Specifies a user template in the user-defined storage format.

rate-limit-template

Specifies a template for rate-limit event logging.

remote-publisher

Specifies the name of the log publisher used for logging Anti-Fraud events.

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

application

Adds, deletes, or replaces a single Application Security sub-profile. You can configure the following options for Application Security:

facility

Specifies the facility category of the logged traffic in Application Security. Select between local0 and local7.

filter

Adds, deletes, or replaces a set of request filters in Application Security. You can configure the following options for a request filter:

key Specifies a unique key for the request filter. This option is required for the operations create, delete, modify, and replace-all-with. The options are:

request-type

Specifies which kind of requests the system, or server, logs.

protocol

Specifies whether request logging is dependent on the protocol.

response-code

Specifies whether request logging is dependent on the response status code.

http-method

Specifies whether request logging is dependent on the HTTP method.

search-all, search-in-headers, search-in-post-data, search-in-query-string, search-in-request, search-in-uri

Specifies whether the request logging is dependent on a specific string, and if so, the part of the request where the system must find the string. You can select only one of these filters, the default is search-all, which means that the system logs all requests, regardless of string.

values

Adds, deletes, or replaces a set of values in the request filter.

format

Specifies a storage format in Application Security. You can configure the following options for the storage format:

field-delimiter

Specifies a field delimiter in the predefined storage format. You may not use the % character. The default delimiter is the comma character, for CSV.

field-format

Specifies a field format (for each key/value pair) in the predefined storage format. Use %k for key and %v for value. The default format is empty that is interpreted as "%v", for CSV.

fields

Replaces a set of fields in the predefined storage format. The order in the set is important - the server displays the selected traffic items in the log sequentially according to it.

type Specifies a type of the storage format. The options are:

predefined

Specifies that the log displays only the predefined items you select in the fields.

user-defined

Specifies that the log displays any free text that you type in the user-string which can include the predefined items.

user-string

Specifies a user string in the user-defined storage format.

guarantee-logging

Indicates whether to guarantee local logging in Application Security.

guarantee-response-logging

Indicates whether to guarantee local response logging in Application Security. In order to enable it, you must first enable guarantee-logging, and set response-logging to either illegal or all.

local-storage

Enables or disables local storage in Application Security.

logic-operation

Specifies the logic operation on the associated filters in Application Security. The options are:

and Specifies that requests must pass all filters in order for the system, or server, to log the requests.

or Specifies that requests must meet at least one filter in order for the system, or server, to log the requests. This is the default value.

maximum-entry-length

Specifies the maximum entry length in Application Security. The options are:

1k This is the possible length for remote servers that support the udp protocol.

2k This is the default length for remote servers that support the tcp, udp and tcp-rfc3195 protocols.

10k, 64k

These are possible lengths for remote servers that support the tcp and udp protocol.

maximum-header-size

Specifies the maximum headers size in Application Security.

maximum-query-size

Specifies the maximum query string size in Application Security.

maximum-request-size

Specifies the maximum request size in Application Security.

name Specifies a dummy name for enabled Application Security. This option is required for the operations create, delete, modify, and replace-all-with.

protocol

Specifies the protocol supported by the remote server in Application Security. Select either: tcp (the default value), udp, or tcp-rfc3195.

remote-storage

Specifies a remote storage type in Application Security. The options are:

none Specifies that the system does not store traffic on any remote logging server.

remote

Specifies that the system stores all traffic on a remote logging server, like a syslog.

splunk

Specifies that the system stores all traffic on a reporting server (Splunk) using a preconfigured storage format. Key/value pairs are used in the log messages.

arcsight

Specifies that the system stores all traffic on a remote logging server using the predefined ArcSight settings for the logs. The log messages are in Common Event Format (CEF).

report-anomalies

Indicates whether to report detected anomalies in Application Security.

response-logging

Specifies a response logging type in Application Security. The options are:

none Specifies that the system does not log responses. This is the default value.

illegal

Specifies that the system logs responses to illegal requests.

all Specifies that the system logs all responses if the associated request-type filter has the all value.

servers

Adds, deletes, or replaces a set of remote servers in Application Security, by specifying an IP address and service port in the format [IPv4:port] or [IPv6.port].

built-in

Displays whether this profile is predefined or user-defined.

description

User defined description.

dos-application

Adds, deletes, or replaces a single DoS (Application) Protection sub-profile. You can configure the following options for DoS (Application) Protection:

local-publisher

Specifies the name of the local log publisher used for Application DoS attacks. Note: This publisher should have a single local-database destination.

name Specifies a dummy name for enabled DoS (Application) Protection. This option is required for the operations create, delete, modify, and replace-all-with.

remote-publisher

Specifies the name of the remote log publisher used for Application DoS attacks. Note: This publisher should have arcsight or splunk destinations.

bot-defense

Adds, deletes, or replaces a single Bot Defense sub-profile. You can configure the following options for Bot Defense:

name Specifies a dummy name for enabled Bot Defense. This option is required for the operations create, delete, modify, and replace-all-with.

local-publisher

Specifies the name of the local log publisher used for Bot Defense log messages. Note: This publisher should have a single local-database destination.

remote-publisher

Specifies the name of the remote log publisher used for Bot Defense log messages. Note: This publisher should have only splunk destinations.

filter

Following options are available which enable or disable the logging of Bot Defense log messages:

log-illegal-requests

This option is used to enable or disable the logging of illegal requests.

log-challenged-requests

This option is used to enable or disable the logging of challenged requests.

log-legal-requests

This option is used to enable or disable the logging of legal requests.

log-captcha-requests

This option is used to enable or disable the logging of captcha challenged requests.

log-bot-signature-matched-requests

This option is used to enable or disable the logging of reported bot signature requests. =back

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

flowspec

Security FlowSpec log configuration

log-publisher

Specifies the name of the log publisher used for Security FlowSpec log events.

ip-intelligence

You can configure the following options under this:

aggregate-rate

This option is used to set the aggregate rate limit that applies to any ip intelligence log message.

log-publisher

Specifies the name of the log publisher used for IP Intelligence events.

log-translation-fields

This option is used to enable or disable the logging of translated (i.e server side) fields in IP Intelligence log messages. Translated fields include (but not limited to) Source Address/Port, Destination Address/Port, IP Protocol, Route Domain and Vlan.

log-shun

This option is used to enable or disable the logging of shun IP Intelligence events.

log-geo

This option is used to enable or disable the logging of geo location in shun IP Intelligence event.

log-rtbh

This option is used to enable or disable the logging of rtbh IP Intelligence events.

log-scrubber

This option is used to enable or disable the logging of scrubber IP Intelligence events.

port-misuse

You can configure the following options under this:

log-publisher

Specifies the name of the log publisher used for port misuse events.

aggregate-rate

This option is used to set the rate limit that applies to any port misuse log messages.

traffic-statistics

You can configure the following options under this:

log-active-flows

This option is used to enable and disable the logging of number of active flows on client side. The number of flows are logged globally, per virtual server and per route domain periodically if number of active flows increased or decreased.

log-publisher

Specifies the name of the log publisher used for Traffic Statistics logs.

log-reaped-flows

This option is used to enable and disable the logging of number of reaped flows on client side. The number of flows are logged globally, per virtual server and per route domain periodically if number of active flows increased or decreased.

log-missed-flows

This option is used to enable and disable the logging of number of TCP packets (non SYN/ACK) were dropped because of the flow table lookup failed. The number of packets are logged globally, and per route domain periodically.

log-syncookies

This option is used to enable and disable the logging of number of syncookies generated, accepted and rejected in the context globally and per virtual server. These log messages will be generated periodically.

log-syncookies-whitelist

This option is used to enable and disable the logging of number of syncookies whitelist hits, accepted and rejected in the context globally and per virtual server. These log messages will be generated periodically.

network

Add, delete, modify or replace a single Network Security sub-profile. You can configure the following options under this:

filter

Following options are available which enable or disable the logging of corresponding Network events:

log-acl-match-accept

This option is used to enable or disable the logging of packets that match ACL rules configured with action = Accept or action = Accept Decisively.

log-acl-match-drop

This option is used to enable or disable the logging of packets that match ACL rules configured with action = Drop.

log-acl-match-reject

This option is used to enable or disable the logging of packets that match ACL rules configured with action = Reject.

log-ip-errors

This option is used to enable or disable the logging of IP error packets.

log-tcp-errors

This option is used to enable or disable the logging of TCP error packets.

log-tcp-events

This option is used to enable or disable the logging of TCP events on client side. Only 'Established' and 'Closed' states of a TCP session are logged if this option is enabled.

log-translation-fields

This option is used to enable or disable the logging of translated (i.e server side) fields in ACL match and TCP events. Translated fields include (but not limited to) Source Address/Port, Destination Address/Port, IP Protocol, Route Domain and Vlan.

log-geo-always

This option is used to enable or disable the logging of Geographic IP Location information fields in ACL match and TCP logging. Geographic information includes the country code of Source Address and Destination Address.

log-uuid-field

This option is used to enable or disable the logging of ACL rule UUID field in ACL match and TCP logging. If the acl_rule_uuid field is explicitly specified in field-list or user-defined formats, UUID value will be logged regardless of state of this option.

rate-limit

Following options are available to set throttling rate limits for the corresponding logging network events:

acl-match-accept

This option is used to set rate limits for the logging of packets that match ACL rules configured with action = Accept or action = Accept Decisively. This option is effective only if logging of this message type is enabled.

acl-match-drop

This option is used to set rate limits for the logging of packets that match ACL rules configured with action = Drop. This option is effective only if logging of this message type is enabled.

acl-match-reject

This option is used to set rate limits for the logging of packets that match ACL rules configured with action = Reject. This option is effective only if logging of this message type is enabled.

ip-errors

This option is used to set rate limits for the logging of IP error packets. This option is effective only if logging of this message type is enabled.

tcp-errors

This option is used to set rate limits for the logging of TCP error packets. This option is effective only if logging of this message type is enabled.

tcp-events

This option is used to set rate limits for the logging of TCP events on client side. This option is effective only if logging of this message type is enabled.

aggregate-rate

This option is used to set the aggregate rate limit that applies to any network logging message.

format

Specifies the Storage format in Network Security sub-profile. These settings are only used to format the log messages destined to a Remote Syslog server. You can configure the following options for the storage format:

field-list

Specifies a set of fields to be logged. This option is valid when storage format type is field-list. The order in the set is important - the server displays the selected traffic items in the log sequentially according to it. User can pick fields from the following list:
acl_policy_name, acl_policy_type, acl_rule_name, acl_rule_uuid, action, bigip_hostname, context_name, context_type, date_time, dest_fqdn, dest_geo, dest_ip, dest_port, drop_reason, management_ip_address, protocol, route_domain, sa_translation_pool, sa_translation_type, source_fqdn, source_user, src_geo, src_ip, src_port, translated_dest_ip, translated_dest_port, translated_ip_protocol, translated_route_domain, translated_src_ip, translated_src_port,

translated_vlan, vlan.

field-list-delimiter

Specifies the delimiter string in field-list storage format type. The default delimiter is the comma character, for CSV. This option is valid when storage format type is field-list. Special character \$ should not be used in delimiter string as it is reserved for internal usage. Also, the maximum length allowed for field-list-delimiter is 31 characters (excluding NUL terminator).

type Specifies a type of the storage format. The options are:

field-list

Specifies that the log displays only the items you specify in the field-list with field-list-delimiter as the delimiter between the items.

none Default format type. With this option, the messages will be logged in the following format:

"management_ip_address","bigip_hostname","context_type","context_name","src_geo","src_ip", "dest_geo","dest_ip","src_port","dest_por

user-defined

Specifies that the log displays the message as per the user-defined string format.

user-defined

Specifies the format of log message in form of user defined string. This option is valid when storage format type is user-defined. Maximum configurable length is 512 characters. Any of the following items, if wrapped within \${ }, will be substituted with the actual value when generating the log: acl_policy_name, acl_policy_type, acl_rule_name, acl_rule_uuid, action, bigip_hostname, context_name, context_type, date_time, dest_fqdn, dest_geo, dest_ip, dest_port, drop_reason, management_ip_address, protocol, route_domain, sa_translation_pool, sa_translation_type, source_fqdn, source_user, src_geo, src_ip, src_port, translated_dest_ip, translated_dest_port, translated_ip_protocol, translated_route_domain, translated_src_ip, translated_src_port, translated_vlan, vlan.

publisher

Specifies the name of the log publisher used for Network events.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

nat This section is used to configure log settings related to events applicable to firewall NAT feature. Following options are available under this section:

end-inbound-session

Event for end of incoming connection to a translated address. Inbound connections are supported only for dynamic-pat source translation. Following options can be configured for logging this event:

backup-allocation-only

Enable logging this event when translation is done using backup address in the source translation object configured in dynamic-pat mode. This is only applicable when lsn-legacy-mode is enabled.

disabled

Disables logging this event.

enabled

Enables logging this event when translation is done using primary address or backup address in the source translation object.

errors

Event for errors encountered while attempting source or destination translation.

disabled

Disables logging for this event.

enabled

Enables logging for this event.

log-publisher

Specifies the name of log publisher used to log NAT related events to one (or more) remote or local destinations.

lsn-legacy-mode

Specifies whether translation events (and other NAT events) are logged in existing CGNAT/LSN formats (for backward compatibility with LSN events).

log-subscriber-id

When enabled, the subscriber ID associated with a subscriber IP address will be printed in the logs.

quota-exceeded
Event for when client exceeded allocated resource limit.

disabled

Disables logging for this event.

enabled

Enables logging for this event.

rate-limit
Following options are available to set throttling rate limits for the corresponding logging FW NAT events:

aggregate-rate-limit
This option is used to set the aggregate rate for all the FW NAT log events that can be logged per second.

end-inbound-session
This option is used to rate limit the end inbound session log events per second.

end-outbound-session
This option is used to rate limit the end outbound session log events per second.

errors
This option is used to rate limit the errors to be logged per second.

start-inbound-session
This option is used to rate limit the start inbound session log events per second.

start-outbound-session
This option is used to rate limit the start outbound session log events per second.

quota-exceeded
This option is used to rate limit the quota exceeded log events per second.

start-inbound-session
Event for start of incoming connection to a translated address. Inbound connections are supported only for dynamic-pat source translation. Following options can be configured for logging this event:

backup-allocation-only

Enable logging this event when translation is done using backup address in the source translation object configured in dynamic-pat mode.

disabled

Disables logging this event.

enabled

Enables logging this event when translation is done using primary address or backup address in the source translation object.

end-outbound-session
Event for end of outbound translation session, when outbound flow is deleted.

action
Specifies what action is taken at the time of logging the event. Possible options are: backup-allocation-only, disabled and enabled.

elements
Optional elements that can be logged for the event. This is applicable only if Isn-legacy-mode is enabled.

destination

Optional element, if selected, is used to log destination address and port in the applicable log event.

start-outbound-session
Event for start of outbound translation session, when outbound flow is created.

action
Specifies what action is taken at the time of logging the event. Possible options are: backup-allocation-only, disabled and enabled.

elements
Optional elements that can be logged for the event. This is applicable only if Isn-legacy-mode is enabled.

destination

Optional element, if selected, is used to log destination address and port in the applicable log event.

protocol-dns

Add, delete, modify or replace a single Protocol (DNS) Security sub-profile. You can configure the following options under this:

filter

Following options are available which enable or disable the logging of corresponding Network events:

log-dns-drop

This option is used to enable or disable the logging of dropped DNS packets.

log-dns-filtered-drop

This option is used to enable or disable the logging of DNS packets that are dropped due to filtering.

log-dns-malformed

This option is used to enable or disable the logging of malformed DNS packets.

log-dns-malicious

This option is used to enable or disable the logging of malicious DNS packets.

log-dns-reject

This option is used to enable or disable the logging of rejected DNS packets.

format

Specifies the Storage format in Protocol (DNS) Security sub-profile. These settings are only used to format the log messages destined to a Remote Syslog server. You can configure the following options for the storage format:

field-list

Specifies a set of fields to be logged. This option is valid when storage format type is field-list. The order in the set is important - the server displays the selected traffic items in the log sequentially according to it. User can pick fields from the following list: action, attack_type, context_name, date_time, dest_ip, dest_port, dns_query_name, dns_query_type, src_ip, src_port, vlan.

field-list-delimiter

Specifies the delimiter string in field-list storage format type. The default delimiter is the comma character, for CSV. This option is valid when storage format type is field-list. Special character \$ should not be used in delimiter string as it is reserved for internal usage. Also, the maximum length allowed for field-list-delimiter is 31 characters (excluding NUL terminator).

type Specifies a type of the storage format. The options are:

field-list

Specifies that the log displays only the items you specify in the field-list with field-list-delimiter as the delimiter between the items.

none Default format type. With this option, the messages will be logged in the following format:

"date_time", "context_name", "vlan", "dns_query_type", "dns_query_name", "attack_type", "action", "src_ip", "dest_ip", "src_port", "dest_port", "route_domain"

user-defined

Specifies that the log displays the message as per the user-defined string format.

user-defined

Specifies the format of log message in form of user defined string. This option is valid when storage format type is user-defined. Maximum configurable length is 512 characters. Any of the following items, if wrapped within \${ }, will be substituted with the actual value when generating the log: action, attack_type, context_name, date_time, dest_ip, dest_port, dns_query_name, dns_query_type, route_domain, src_ip, src_port, vlan.

name Specifies a dummy name for enabled Protocol (DNS) Security. This option is required for the operations create, delete, modify, and replace-all-with.

publisher

Specifies the name of the log publisher used for DNS events.

protocol-dns-dos-publisher

Specifies the name of the log publisher used for DNS DoS events.

dos-network-publisher

Specifies the name of the log publisher used for DoS Network events.

protocol-sip

Add, delete, modify or replace a single Protocol (SIP) Security sub-profile. You can configure the following options under this:

filter

Following options are available which enable or disable the logging of corresponding protocol sip events:

log-sip-drop

This option is used to enable or disable the logging of dropped SIP packets.

log-sip-global-failures

This option is used to enable or disable the logging of SIP packets that resulted in global failures.

log-sip-malformed

This option is used to enable or disable the logging of malformed SIP packets.

log-sip-redirection-responses

This option is used to enable or disable the logging of SIP packets that resulted in sending redirection response.

log-sip-request-failures

This option is used to enable or disable the logging of SIP request failures.

log-sip-server-errors

This option is used to enable or disable the logging of SIP packets that resulted in server errors.

format

Specifies the Storage format in Protocol (SIP) Security sub-profile. These settings are only used to format the log messages destined to a Remote Syslog server. You can configure the following options for the storage format:

field-list

Specifies a set of fields to be logged. This option is valid when storage format type is field-list. The order in the set is important - the server displays the selected traffic items in the log sequentially according to it. User can pick fields from the following list: action, attack_type, context_name, date_time, dest_ip, dest_port, dns_query_name, dns_query_type, src_ip, src_port, vlan.

field-list-delimiter

Specifies the delimiter string in field-list storage format type. The default delimiter is the comma character, for CSV. This option is valid when storage format type is field-list. Special character \$ should not be used in delimiter string as it is reserved for internal usage. Also, the maximum length allowed for field-list-delimiter is 31 characters (excluding NUL terminator).

type Specifies a type of the storage format. The options are:

field-list

Specifies that the log displays only the items you specify in the field-list with field-list-delimiter as the delimiter between the items.

none Default format type. With this option, the messages will be logged in the following format:

"date_time", "context_name", "vlan", "sip_method_type", "sip_caller", "sip_callee", "attack_type", "action", "src_ip", "dest_ip", "src_port", "dest_port", "route_domain"

user-defined

Specifies that the log displays the message as per the user-defined string format.

user-defined

Specifies the format of log message in form of user defined string. This option is valid when storage format type is user-defined. Maximum configurable length is 512 characters. Any of the following items, if wrapped within \${ }, will be substituted with the actual value when generating the log: action, attack_type, context_name, date_time, dest_ip, dest_port, dns_query_name, dns_query_type, route_domain, src_ip, src_port, vlan.

name Specifies a dummy name for enabled Protocol (SIP) Security. This option is required for the operations create, delete, modify, and replace-all-with.

publisher

Specifies the name of the log publisher used for SIP events.

protocol-sip-dos-publisher

Specifies the name of the log publisher used for SIP DoS events.

protocol-transfer

Adds, deletes, or replaces a single Protocol (Transfer) Security sub-profile. You can configure the following options for Protocol (Transfer) Security:

name Specifies a dummy name for enabled Protocol (Transfer) Security. This option is required for the operations create, delete, modify, and replace-all-with.

publisher

Specifies the name of the log publisher used for Protocol Security log messages. Note: This publisher should have either local-database, local-syslog, remote-syslog, arcsight or splunk single destination.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

BIG-IP 2018-11-27 security log profile(1)

security log protocol-dns-storage-field

NAME

protocol-dns-storage-field - Lists the available storage format fields that can be used in the context of Protocol DNS Security Logging.

MODULE

security log

SYNTAX

Retrieve the list of the protocol-dns-storage-field values using the syntax shown in the following sections.

DISPLAY

list protocol-dns-storage-field

list protocol-dns-storage-field [[[name] | [glob] | [regex]] ...]

options:

all
all-properties
one-line
app-service

DESCRIPTION

Use this command to display the possible values of the protocol-dns-storage-field object to be used in the context of Protocol DNS Security Logging. These possible values are predefined traffic items available for the server to log in the context of DNS event logging (for example, Malformed, Malicious, or Dropped DNS packets).

EXAMPLES

list protocol-dns-storage-field

Displays all the storage fields supported by Protocol DNS Security Logging.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

SEE ALSO

glob, list, regex, security log profile, tmsh

security log protocol-sip-storage-field

NAME

protocol-sip-storage-field - Lists the available storage format fields that can be used in the context of Protocol SIP Security Logging.

MODULE

security log

SYNTAX

Retrieve the list of the protocol-sip-storage-field values using the syntax shown in the following sections.

DISPLAY
list protocol-sip-storage-field
list protocol-sip-storage-field [[[name] | [glob] | [regex]] ...]
options:
all
all-properties
one-line
app-service

DESCRIPTION
Use this command to display the possible values of the protocol-sip-storage-field object to be used in the context of Protocol SIP Security Logging. These possible values are predefined traffic items available for the server to log in the context of SIP event logging (e.g Dropped SIP packets).

EXAMPLES
list protocol-sip-storage-field

Displays all the storage fields supported by Protocol SIP Security Logging.

OPTIONS
app-service
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

security log remote-format

NAME
remote-format - Lists the log format for different remote destinations (such as ArcSight, Splunk etc.) used by various Firewall events (such as Network, IP Intelligence, DoS etc.).

MODULE
security log

SYNTAX
Retrieve the list of the remote-format using the syntax shown in the following sections.

DISPLAY
list remote-format
list remote-format [[[name] | [glob] | [regex]] ...]
options:
all
all-properties
app-service
format
one-line

DESCRIPTION
Use this command to display the actual log format used to send firewall event logs to remote destinations such as ArcSight, Splunk and Syslog. These log formats are used by the log destinations of log publisher configured in different sub-profiles (for example Network, IP Intelligence, DNS, DNS DoS etc.) of a security log profile.

EXAMPLES
list remote-format

Displays the log format for all firewall events.

list remote-format network-arcsight

Displays the format for Network log events (such as ACL matches, TCP events etc.) sent to an ArcSight destination.

list remote-format network-dos-splunk

Displays the format for Network DoS log events sent to a Splunk destination.

list remote-format ip-intelligence-syslog-default

Displays the format for IP Intelligence log events sent to a remote syslog destination.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

format

Displays the remote log format used by the object.

SEE ALSO

glob, list, regex, security log profile, tmsh

COPYRIGHT

security log storage-field

NAME

storage-field - Lists the available storage format fields that can be used in the context of Application Security Logging.

MODULE

security log

SYNTAX

Retrieve the list of the storage-field values using the syntax shown in the following sections.

DISPLAY

list storage-field

list storage-field [[[name] | [glob] | [regex]] ...]

options:

all
app-service
format
id
one-line

DESCRIPTION

Use this command to display the possible values of the storage-field object to be used in the context of Application Security Logging. These possible values are predefined traffic items available for the server to log. The traffic items appear in the final format string as arguments in the printf() function, i.e. "%\$", therefore each storage field has its fixed format (specifier) and id (position).

EXAMPLES

list storage-field

Displays all the storage fields supported by Application Security Logging.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

format

Displays a format of the field (s - string, d - decimal). It corresponds to the conversion specifier in the printf() function.

id Displays an order ID of the field (starting from 1). It corresponds to the position in the argument list of the desired argument in the printf() function.

DELETE
delete destination-translation [name | all]

DESCRIPTION
A destination-translation NAT object is a set of IP Address(es) and port numbers that the BIG-IP system uses as public-side addresses and ports. When this object is assigned to a Security NAT Policy rule (which is associated to a virtual server), any incoming traffic to this virtual server that matches the rule, will have their private destination addresses (and/or ports) translated to a public address and/or port from this destination-translation object.

EXAMPLES
create destination-translation d1 type static-pat addresses add { 10.10.10.0/24 } ports add { 7000-8000 }

Creates the destination-translation object d1 that contains the translation addresses in the range of 10.10.10.0/24, translation port range 7000-8000 and uses static-pat as the translation algorithm.

delete destination-translation d1

Deletes the destination-translation named d1.

OPTIONS

addresses

Specifies the set of translation IP addresses available. This is a collection of either one (or more) IP Address, one (or more) IP prefixes with their prefix lengths and/or IP Address range. All public-side (destination) addresses come from the subnets you enter in this property.

app-service

Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the destination-translation component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ports

Specifies the range of port numbers available for use with translation IP addresses.

type Specifies which kind of translation is performed. Available options are static-nat and static-pat.

static-nat

Using this translation type in the destination-translation, only (destination) IP Address translation is performed (and no port translation) for the incoming client traffic that matches the NAT Policy Rule using this translation object. There is a static (pre-defined) 1:1 mapping between the untranslated IP Address(es) and the translated IP Address(es) specified in this object.

static-pat

Using this translation type in the destination-translation, (destination) port translation is performed for the incoming client traffic that matches the NAT Policy Rule using this translation object. There is a static (pre-defined) 1:1 mapping between the untranslated port(s) and the translated port(s) specified in this object. In addition, if translation address(es) are specified in the destination-translation, it also performs IP Address translation (in the same fashion as done for static-nat).

}
translation {
  destination [name | none]
  source [name | none]
}
next-hop {
  gw [ip address]
  vlan [name | none]
  pool [name | none]
  type [default | pool | gateway | vlan]
}
}
rules none

```

```

edit policy
options:
  all-properties
  non-default-properties

```

```

DISPLAY
list policy
show running-config policy
options:
  all-properties
  non-default-properties
one-line

```

DESCRIPTION

You can use the policy component to configure a shareable and reusable set of nat rules which can be associated with a number of configuration objects of the following types: ltm virtual, security device-context, net route-domain.

EXAMPLES

```

create policy p1 rules add {
r1 {
  place-before first
  ip-protocol tcp
  source {
    addresses replace-all-with { 192.168.10.0/24 }
  }
}
}

```

```

    ports replace-all-with { 10000-19999 }
  }
  destination {
    addresses replace-all-with { 10.10.10.0/24 }
    ports replace-all-with { 80 443 }
  }
  translation {
    destination my_dest_nat
    source my_src_nat
  }
  next-hop {
    gw 10.10.10.10
    pool pool1
    vlan internal
    type vlan
  }
} }

```

Creates a rule entry at the beginning of the policy that matches incoming TCP traffic with source address in the range 192.168.10.0/24, source port in the range 10000-19999, destination address in the range 10.10.10.0/24, destination port 80 or 443 and if matches, performs the source translation as per source-translation object named my_src_nat and destination translation as per destination-translation object named my_dest_nat.

modify policy p1 rules delete r1

Removes the rule r1 from the policy p1.

list policy

Displays the current list of policy rules.

OPTIONS

description
User defined description.

rules
Adds, deletes, or replaces a NAT rule.

description
User defined description.

destination
address-lists
Specifies a list of address lists (see security firewall address-list) against which the packet will be compared.

addresses
Specifies a list of addresses and networks against which the packet will be compared.

port-lists
Specifies a list of port lists (see security firewall port-list) against which the packet will be compared.

ports
Specifies a list of ports and port ranges against which the packet will be compared.

proxy-arp
Enable or disable proxy arp for pre-translation destination addresses.

route-advertisement
Enable or disable route advertisements for pre-translation destination addresses.

ip-protocol
Specifies the IP protocol against which the packet will be compared.

log-profile
Specifies the name of the log profile (see security log profile) that is used to log the translation events triggered by this NAT rule.

place-after
Specifies that a new rule should be placed after another rule, first or last. If individual rules are being added (as opposed to specifying replace-all-with) then place-before or place-after must be specified.

place-before
Specifies that a new rule should be placed before another rule, first or last. If individual rules are being added (as opposed to specifying replace-all-with) then place-before or place-after must be specified.

source
address-lists
Specifies a list of address lists (see security firewall address-list) against which the packet will be compared.

addresses
Specifies a list of addresses and networks against which the packet will be compared.

port-lists

Specifies a list of port lists (see security firewall port-list) against which the packet will be compared.

ports

Specifies a list of ports and port ranges against which the packet will be compared.

vlan

Specifies a list of vlans, vlan groups and tunnels against which the packet will be compared.

next-hop

Specifies next-hop configuration for NAT rule. All these attributes are mutually exclusive.

gw Specifies a gateway address for the route.

vlan Specifies VLAN name (can be VLAN or VLAN group)

pool Specifies a gateway pool, which allows multiple, load-balanced gateways to be used for the route.

type Specifies which option to consider when multiple options were provided under next-hop.

status

Specifies whether the rule is enabled or disabled. A rule that is enabled is always checked. A rule that is disabled is never checked.

translation

Specifies the translation objects.

destination

Specifies the name of destination translation object (see security nat destination-translation). If specified, it is used to perform the destination address/port translation as per its settings. If not specified, the matching traffic's destination address/port are not translated.

source

Specifies the name of source translation object (see security nat source-translation). If specified, it is used to perform the source address/port translation as per its settings. If not specified, the matching traffic's source address/port are not translated.

DELETE

delete source-translation [name | all]

DESCRIPTION

A source-translation NAT object is a set of IP Address(es) and port numbers that the BIG-IP system uses as public-side addresses and ports. When this object is assigned to a Security NAT Policy rule (which is associated to a virtual server), any incoming traffic to this virtual server that matches the rule, will have their private source addresses (and/or ports) translated to a public address and/or port from this source-translation object.

EXAMPLES

```
create source-translation s1 type dynamic-pat pat-mode napt mapping { mode endpoint-independent-mapping
timeout 600 } addresses add { 10.10.20.0/24 } ports add { 4000-5000 } client-connection-limit 100
```

Creates the source-translation object named s1 that contains the translation addresses in the range of (addresses) 10.10.20.0/24, translation port range 4000-5000, with a client connection limit of 100 connections per client. The translated address and port are persisted for 600 seconds. This object operates in NAT mode (Network Address and Port Translation mode), which is the default mode if not specified when type is dynamic-pat.

```
delete source-translation s1
```

Deletes the source-translation object named s1.

OPTIONS

app-service

Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

addresses

Specifies the set of translation IP addresses available in the pool. This is a collection of IP prefixes with their prefix lengths. All public-side addresses come from the subnets you enter in this property.

backup-addresses

Specifies translation IP addresses available in the backup pool which is used by DNAT translation mode if DNAT mode translation fails and falls back to NAT mode. This is a collection of IP prefixes with their prefix lengths.

client-connection-limit

The maximum number of simultaneous translated connections a client or subscriber is allowed to have. This attribute is applicable only if type is set to dynamic-pat.

description

User defined description.

egress-interfaces

The set of interfaces on which the source address translation is allowed or disallowed. If egress-interfaces-enabled is specified, the source address translation is allowed only on the specified set of interfaces. If egress-interfaces-disabled is specified, source address translation is disabled on specified interfaces.

egress-interfaces-disabled

Source address translation is not allowed on the interfaces specified in the egress-interfaces set.

egress-interfaces-enabled

Source address translation is allowed on the interfaces specified in the egress-interfaces set.

exclude-addresses

Specifies the set of addresses excluded from translation IP addresses available in the pool.

exclude-address-lists

Specifies the set of address lists (see security firewall address-list) excluded from translation IP addresses available in the pool.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hairpin-mode

This attribute is applicable only if type is set to dynamic-pat.

Enable or disable hairpinning for incoming connections.

When a client sends a packet to another client in the same private network, hairpin mode sends the packet directly to the source client's private address; the BIG-IP system immediately translates the packet's public-side source address. Rather than going out to the public network and coming back later for translation, the packet takes a hairpin turn at the BIG-IP device.

icmp-echo

Enable or disable ICMP echo on translated addresses.

inbound-mode

This attribute is applicable only if type is set to dynamic-pat.

Modifies the inbound-connection mode for incoming connections to translation endpoints. A translation endpoint is the public-side address and port (X':x') for a private-side address (X:x). You can allow one of the following two algorithms for managing inbound connections:

endpoint-independent-filtering

creates inbound mappings automatically from outbound traffic and allows inbound connections. Consider an outbound mapping from X:x to X':x'. If a connection comes from X:x through X':x', the BIG-IP system automatically creates a reverse mapping from X':x' back to X:x. A public-side station can respond through the X':x' address. This allows the BIG-IP system to provide Endpoint Independent Filtering (EIF) as defined in section 5 of RFC 4787
().

explicit

Allows inbound connections if and only if there exists an inbound mapping to translate public-side source address X':x' to client's private address X:x. Users can create Inbound mappings via iRules or PCP.

none disables inbound connections to translation end-points (X':x'). If there is a mapping of X (a private-side IP address) to X' (a public-side IP), connections can only go out from X through X'. If a public-side recipient tries to answer at the client's public-side X' address, the BIG-IP system does not map X' back to X. The inbound connection never happens.

Port Control Protocol (PCP) is not supported if you use this setting.

eif-timeout

Configurable range of eif-timeout is 3-300 seconds. Default value is 3 seconds. This attribute is only applicable if a) NAT method is Dynamic PAT (any pat-mode : NAT/PBA/DNAT) and b) inbound-mode is set to 'endpoint-independent-filtering'.

pat-mode

Specifies which kind of translation address mapping is performed when type is specified as dynamic-pat. Available options are NATP, Deterministic, and PBA.

NAPT (Network Address Port Translation) assigns translation addresses and ports in round-robin fashion. The algorithm first cycles through translation addresses and then through translation ports.

Deterministic

(DNAT) is a reversible translation method. A given client address and port always translates to a particular public address and port from the source-translation pool. This method has the following restrictions:

it is only available for NAT44 translations,

it does not support connections through DS-Lite tunnels,

subscriber connections must be received over a VLAN with the property, cmp-hash, set to "source ip," the egress to the Internet must be over a VLAN with the property, cmp-hash, set to "dest ip," any security NAT rule ("security nat policy") that uses this must have a source property set to an IP prefix containing fewer than 231 addresses. For example, the source cannot be 0.0.0.0/0.

PBA (Port Block Allocation) assigns 'blocks' of the translation addresses and ports to individual clients. All client connections are restricted to the allocated port blocks. Only block allocations and deallocations are logged in order to reduce the volume of logs.

subscriber connections must be received over a VLAN with the property, cmp-hash, set to "source ip," the egress to the Internet must be over a VLAN with the property, cmp-hash, set to "dest ip,"

You can access your VLAN configurations through the "net vlan" component. You can find the VLANs used by your virtual server by showing or listing the "ltm virtual" component.

name Specifies a unique name for the source-translation component. This option is required for the commands create, delete, and modify.

mapping

These settings are applicable only if type is set to dynamic-pat.

Configure the mapping settings for translation entries. It is the preservation of a public-side IP address for a client from session to session.

mapping.mode

Configure the mapping mode for translation entries. You can enter address-pooling-paired, endpoint-independent-mapping, or none.

address-pooling-paired

causes the BIG IP software to attempt to keep the IP address persistent but not necessarily the port. If a client's private IP address:port combination is X:x, it's public-side address may be X':a in one session, X':b in the next session, X':c in a third session, and so on.

endpoint-independent-mapping

causes the BIG IP software to attempt to keep the IP address and port persistent. If a client's private IP address:port combination is X:x, and it's public-side address is X':x' in the first session, it remains X':x' in all future sessions.

This is called "Endpoint Independent Mapping" in RFC 4787 ().

This is the only supported setting for PCP, which you configure with the pcpc property.

none prevents the BIG IP software from attempting any IP address or port mapping. An address:port combination of X:x is never guaranteed to have the same public-side address or port in two sessions.

mapping.timeout

After the most-recent session where address:port X:x translated to X':x' on the public side, a timer begins. If the timer expires before X:x has another session, X' or x' may be used as the public side of another address:port. Use this parameter to set the timeout (in seconds) for address and port mapping.

pcp A Port Control Protocol (PCP) client can set (or at least learn) its own translation (public-side) IP address and/or port. It can also set the address and/or port of a third-party client. PCP is defined in RFC 6887 (see).

pcp.profile

Specifies the PCP profile to use for this LSN pool. This PCP profile defines the settings to use for communication with PCP clients. Use the create ltm profile pcpc command to create a new PCP profile.

PCP requires a profile (defined with this property) and either a pcpc.selfip or a pcpc.dslite tunnel where clients can send their PCP requests.

If you remove this profile option, you must specifically remove any pcpc.selfip or pcpc.dslite tunnel, too.

pcpc.selfip

Specifies the PCP Server self-IP address for this LSN pool. The virtual server's clients send their PCP packets to this address. Use the create net self command to create a self-IP address, then use that address for this parameter. Choose a self-IP address in a VLAN that is reachable by the virtual server's clients.

pcpc.dslite

Specifies a DS-LITE tunnel for PCP packets. Whenever a client sends a PCP packet through this tunnel, the BIG-IP device uses the PCP profile you choose with the pcpc.profile property.

A DS-LITE tunnel places each IPv4 packet into the payload of an IPv6 packet. The IPv6 packet carries the IPv4 packet between customer equipment and the BIG-IP system, which then removes the IPv4 packet, uses NAT to translate its IPv4 addresses, and sends it to its destination.

You cannot use this property if the `pat-mode` property is set to `Deterministic`.

`port-block-allocation`

Configures the port block settings for PBA mode.

`port-block-allocation.block-idle-timeout`

Configures the time after the last connection using the block is freed that the block assignment expires. The default value is 3600 seconds.

`port-block-allocation.block-lifetime`

Configures the timeout after which the block is no longer used for new port allocations. The block becomes a zombie block. The default is 0 which corresponds to an infinite timeout.

`port-block-allocation.block-size`

Configures the number of ports in a block. The default value is 64.

`port-block-allocation.client-block-limit`

Configures the number of blocks that can be assigned to a single subscriber IP address. The default value is 1.

`port-block-allocation.zombie-timeout`

Configures the timeout after which connections using the zombie block are killed. After connections are killed zombie block is freed after `port-block-allocation.block-idle-timeout`. This parameter is unused unless the `port-block-allocation.block-lifetime` is set. The default value is 0 which corresponds to infinite timeout.

`proxy-arp`

Enable or disable proxy arp for the translated source IP addresses.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`ports`

Specifies the range of port numbers available for use with translation IP addresses.

`route-advertisement`

Enable or Disable Route Advertisement for the translated source IP addresses.

`type` Specifies which kind of translation is performed. Available options are: `static-nat`, `static-pat`, and `dynamic-pat`.

`dynamic-pat`

Using this type, BigIP translates a group of private (internal) IP Addresses to a pool of (one or more) public (external) IP Addresses and also translates ports to reuse the pool of public addresses. BigIP supports 3 different modes for `dynamic-pat` which can be specified using option `pat-mode` as described above.

`static-nat`

Using this translation type in the source-translation, only (source) IP Address translation is performed (and no port translation) for the incoming client traffic that matches the NAT Policy Rule using this translation object. There is a static (pre-defined) 1:1 mapping between the untranslated IP Address(es) and the translated IP Address(es) specified in this object (i.e same translation address (X') is used for all connections originating from the client with untranslated address (X)).

`static-pat`

Using this translation type in the source-translation, (source) port translation is performed for the incoming client traffic that matches the NAT Policy Rule using this translation object. There is a static (pre-defined) 1:1 mapping between the untranslated port(s) and the translated port(s) specified in this object. In addition, if translation address(es) are specified in the source-translation, it also performs IP Address translation (in the same fashion as done for `static-nat`).

security packet-filter default-rules

NAME

default-rules - Configures the default packet-filter rules. These rules are applied to packets if there's no more specific policy for these packets, for example, packets from Route Domain with an attached packet-filter policy will be processed with that Route Domain policy and not default packet-filter policy. Any particular packet is processed with at maximum one packet-filter policy.

MODULE

security packet-filter

SYNTAX

MODIFY

modify default-rules

options:

policy [[policy_name] | none]

edit default-rules

options:

all-properties

non-default-properties

DISPLAY

list default-rules

DESCRIPTION

You can use the default-rules component to configure packet-filter policy which is applied on all IPv6 traffic.

EXAMPLES

list default-rules

```
security packet-filter default-rules {  
  policy policy1  
}
```

Displays the current default policy.

OPTIONS

policy

Specifies an packet-filter policy. policy rules are applied by default.

SEE ALSO

edit, list, modify, security log profile, tmsh, security packet-filter policy

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2018-05-10 security packet-filter default-rules(1)

security packet-filter policy

NAME

policy - Configures packet-filter policy.

MODULE

security packet-filter

SYNTAX

Modify the policy component within the security packet-filter module using the syntax shown in the following sections.

CREATE/MODIFY

create policy [name]

modify policy [name]

options:

description [string]

rules [add | delete | modify | replace-all-with] {

 [name] {

 options:

 action [accept | drop]

 description [string]

 ipv6-extension-headers [add | delete | replace-all-with] {

 [ah | esp | hopopt | ipv6-frag | ipv6-nonxt | ipv6-opts | ipv6-route | mh] {

```

values [add | delete | replace-all-with] {
  [ [value] | [value1-value2] ]
}
}
}
log [no | yes]
status [disabled | enabled]
}
}
rules none

```

```

edit policy
options:
  all-properties
  non-default-properties

```

```

DISPLAY
list policy

```

DESCRIPTION

You can use the policy component to configure a shareable and reusable set of security packet-filter rules which can be associated with a number of configuration objects of the following types: security packet-filter default-rules, net route-domain.

EXAMPLES

```

modify policy policy1 rules add {
drop-frags {
  action drop
  ipv6-extension-headers replace-all-with { ipv6-frag }
} }

```

Creates a rule entry that drops all IPv6 packets specifying Fragment Header.

```

modify policy policy1 rules delete drop-frags

```

Removes the rule drop-frags from the list of rules.

```

create policy xyz rules add { r1 { action drop ipv6-extension-headers replace-all-with { hopopt { values
replace-all-with { 0 } } } } }

```

Creates a policy with a single rule that drops all packets specifying Hop-by-Hop Header with option 0. Packets specifying Hop-by-Hop Header, but without option 0, will not be dropped.

```

create policy xyz rules add { r1 { action drop ipv6-extension-headers replace-all-with { hopopt } } }

```

Creates a policy with a single rule that drops all packets specifying Hop-by-Hop Header with or without any options.

```

list policy

```

Displays the current list of policy rules.

OPTIONS

```

description
User defined description.

```

```

rules
Adds, deletes, or replaces a packet-filter rule.

```

```

action
Specifies the action that the system takes when a rule is matched.

```

```

accept
Specifies that the current packet should be accepted.

```

```

drop Specifies that the current packet should be silently dropped. Nothing is sent back to the
packet source. The packet is still compared to any other rules, so other rule counters may be
incremented.

```

```

description
User defined description.

```

```

ipv6-extension-headers
Specifies a list of IPv6 Extension Header types (only one item per list is currently supported),
against which the packet will be compared

```

```

values
Specifies a list of IPv6 Extension Header options or option ranges against which the packet
will be compared. Specifying values is supported only for some of the IPv6 Extension Header
types: hopopt - values match Hop-by-Hop Options; ipv6-opts - values match Destination Options;
ipv6-route - values match Routing type. If values are omitted - no values are required in
packet to match the rule, so it's enough for a packet to include the IPv6 Extension Header of
the type specified in a rule for rule to match.

```

```

log Specifies whether the packet will be logged if it matches the rule. Logging must also be enabled in
security log profile global-network. Note that the statistics counter is always incremented when a
packet matches a rule.

```

status
Specifies whether the rule is enabled or disabled. If a rule is disabled it has no effect on data packets.

EXAMPLES

list security protocol-inspection compliance

Displays all compliance inspections.

list security protocol-inspection compliance ftp_malformed_param

Displays compliance inspection "ftp_malformed_param".

PROPERTIES

accuracy

Specifies the accuracy of the compliance inspection.

description

Specifies the description of the compliance inspection. Also this parameter is used in logging when compliance inspection is matched.

service

Specifies target-based service.

action

Specifies enforcement action for matched compliance inspection.

direction

Specifies the flow direction for which this compliance inspection will be applied.

log Specifies whether the inspection will be logged if it matches the compliance inspection.

app-service

Specifies app service.

documentation

Specifies compliance inspection documentation.

performance-impact

Specifies performance impact of this compliance inspection.

systems

Specifies systems where this compliance inspection can be matched.

attack-type

Specifies compliance inspection attack type.

id Specifies compliance inspection identifier.

protocol

Specifies transport protocol where this compliance inspection can be matched (udp, tcp, any).

risk Specifies compliance inspection risk.

value

Specifies value for specific compliance check depending on field (see below).

value-type
Specifies value type for specific compliance check.

CREATE/MODIFY

modify security protocol-inspection profile
create security protocol-inspection profile
properties:
app-service [string]
auto-add-new-inspections [bool]
auto-publish-suggestion [bool]
avr-stat-collect [bool]
common-config [string]
common-config-merge-type [string]
compliance-enable [bool]
defaults-from [string]
description [string]
signature-enable [bool]
services { ... }
staging-period [integer]

DISPLAY

list security protocol-inspection profile

DESCRIPTION

Use this command to create/modify protocol inspection profile.

EXAMPLES

create security protocol-inspection profile new_http_profile { default-from protocol_inspection_http }

Create profile "new_http_profile" and clone all configuration from predefined profile protocol_inspection_http.

list security protocol-inspection profile

Displays all protocol inspection profiles.

list security protocol-inspection profile new_http_profile

Displays protocol inspection profile with name new_http_profile.

modify security protocol-inspection profile new_http_profile common-config common_config_name

Attach common-config to the profile.

PROPERTIES

app-service [string]
Specifies app service.

auto-add-new-inspections [bool]
If set, new inspections arrived via IPS IM pkg will be automatically added to this profile for configured service.

auto-publish-suggestion [bool]
If set, after the learning period(staging-period) the action for the inspections will automatically be updated to the suggested action, if exists.

avr-stat-collect [bool]
Specifies if AVR collects data from IPS.

common-config [string]
Specifies common-config to be attached to the profile.

common-config-merge-type [string]
Specifies common-config value merge type.

compliance-enable [bool]
Specifies whether the compliance checks will be enabled for this profile.

signature-enable [bool]
Specifies whether the signature checks will be enabled for this profile.

defaults-from [string]
Specifies parent profile (in time of creating). If this parameter is assigned then new profile will be cloned from parent profile.

description [string]
Specifies profile description.

services
Specifies services for this profile. ...

staging-period
If auto-publish-suggestion is set, this value defines the time period after which inspection action will be automatically updated to suggested action.

list security protocol-inspection service

DESCRIPTION

Use this command to get information about services. This command does not allow you to create/modify services.

EXAMPLES

list security protocol-inspection service

Displays all services.

list security protocol-inspection signature dns

Displays service "dns".

PROPERTIES

app-service

Specifies app service.

description

Specifies service description.

id

Specifies service identifier.

partition

Specifies service partition.

ports

Specifies default service ports in format "80, 81".

SEE ALSO

list, security, tmsh

security protocol-inspection service(1)

security protocol-inspection signature

NAME

signature - Configures the signature inspections.

MODULE

security protocol-inspection signature

SYNTAX

CREATE/MODIFY

modify security protocol-inspection signature
create security protocol-inspection signature
properties:
accuracy [high | low | medium]
description [string]
last-updated [date in format %y-%m-%d:%H:%M:%S]
reference-links [string]
service [string]
action [accept | drop | reject]
direction [any | to-client | to-server]
log [yes | no]
references [string]
sig [string - signature in snort format]
app-service [string]
documentation [string]
performance-impact [high | low | medium]
revision [integer]
systems [string]
attack-type [string]
id [integer]
protocol [any | tcp | udp]
risk [critical | high | low | medium]
user-defined [yes | no]

DISPLAY

list security protocol-inspection signature

DESCRIPTION

Use this command to create/modify custom signatures in snort format.

EXAMPLES

create security protocol-inspection signature new_sig { log yes action drop sig "content:\\"GET\\";
content:\\"HTTP\\";" description "Signature match" }

Create signature "new_sig" which find "GET" and "HTTP" in payload (see details about snort signatures in related documentation). Following actions are applied if signature is matched: drop flow and write message "Signature match".

modify security protocol-inspection signature new_sig { log no action accept sig }

Modify action and logging of previous signature "new_sig". Following actions are applied if signature is matched: accept flow.

list security protocol-inspection signature new_sig

Displays signature new_sig.

list security protocol-inspection signature

Displays all signatures.

PROPERTIES

accuracy

Specifies the accuracy of the signature.

description

Specifies the description of the signature. Also this parameter is used in logging when signature is matched.

last-updated

Specifies date/time when signature has been updated last time.

reference-links

Specifies external references (url) to signature.

references

Specifies external industrial references (cve and bugtraq) to signature.

service

Specifies target-based service.

action

Specifies enforcement action for matched signature.

direction

Specifies flow direction for signature. Signature search will apply only for payload in this direction.

log Specifies whether the inspection will be logged if it matches the signature.

app-service

Specifies app service.

documentation

Specifies signature documentation.

performance-impact

Specifies performance impact of this signature.

revision

Specifies signature revision. For custom signatures, this parameter will be incremented each time you modify this signature.

systems

Specifies systems where this signature can be matched.

attack-type

Specifies signature attack type.

id Specifies signature identifiers.

protocol

Specifies transport protocol where this signature can be matched (udp, tcp, any).

risk Specifies signature risk.

sig Specifies snort signature.

user-defined

Specifies if signature is created by user.

deprecated

Specifies if inspection is now deprecated and will not be matched anymore.

security protocol-inspection updates

NAME
updates - Configures updates.

MODULE
security protocol-inspection updates

SYNTAX
INSTALL
install security protocol-inspection updates
options:
file [string]

DISPLAY
show security protocol-inspection updates

DESCRIPTION
Use this command to install and see all available IM packages.

EXAMPLES
install security protocol-inspection updates file file_name

Install new update from file "file_name".

show security protocol-inspection updates

Show all available updates.

OPTIONS
file Specifies IM package file.

SEE ALSO
show, install, security, tmsh

security scrubber dwbl-scrubber-category-stats

NAME

dwbl-scrubber-category-stats - Show the list of IPs that are associated with a scrubbed category.

MODULE

security scrubber

SYNTAX

show dwbl-scrubber-category-stats

DESCRIPTION

You can use the dwbl-scrubber-category-stats component to display the list of IPs that are associated with a scrubbed category.

EXAMPLES

show security scrubber dwbl-scrubber-category-stats category-name [name] profile-name scrubber-profile-default

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-07-07 security scrubber dwbl-scrubber-category-stats(1)

security scrubber dwbl-scrubber-stat

NAME

dwbl-scrubber-stat - Show scrubber's Dwbl related stats.

MODULE

security scrubber

SYNTAX

Run the show dwbl-scrubber-stat within the security scrubber module using the syntax shown in the following sections.

SHOW

show dwbl-scrubber-stat

options:

destination

expire-time

monitors

observed-rate-bps

observed-rate-cps

observed-rate-pps

route-domain

scrubber-status

scrubber-type

silverline-status

silverline-url

threshold-bps

threshold-cps

threshold-pps

tth

under-attack

DESCRIPTION

You can use the dwbl-scrubber-stat component to display the threshold, observed rate, under attack, time to live, and expire time for each monitor. Each row displays stats related per a monitor. Scrubber module monitors selected virtual servers, categories, route domains, and netflow protected servers.

EXAMPLES

show security scrubber dwbl-scrubber-stat show security scrubber dwbl-scrubber-stat monitors show security scrubber dwbl-scrubber-stat scrubber-status show security scrubber dwbl-scrubber-stat silverline-url silverline-status expire-time under-attack

OPTIONS

destination

Show the column for the destination configured on the scrubber.

expire-time

Show the column for the current expiration time on the scrubber.

monitors

Show the columns related to the monitor configuration: threshold-bps, observed-rate-bps, threshold-cps, observed-rate-cps, threshold-pps, observed-rate-pps.

observed-rate-bps

Show the column for the current observed BPS on the monitor.

observed-rate-cps

Show the column for the current observed CPS on the monitor.

observed-rate-pps

Show the column for the current observed PPS on the monitor.

route-domain

Show the column for the Route Domain configured on the monitor.

scrubber-status

Show the columns related to the current status of the scrubber: under-attack, expire-time, silverline-status.

scrubber-type

Show the column for the type of monitor configured for the scrubber.

silverline-status

Show the column for the current status of Silverline.

silverline-url

Show the column for the URL configured for Silverline.

threshold-bps

Show the column for the BPS threshold configured for the scrubber.

threshold-cps

Show the column for the CPS threshold configured for the scrubber.

threshold-pps

Show the column for the PPS threshold configured for the scrubber.

ttn Show the column for the TTL configured for the scrubber.

under-attack

Show the column for whether an attack has been detected.

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2016. All rights reserved.

BIG-IP 2018-01-10 security scrubber dwbl-scrubber-stat(1)

security scrubber profile

NAME

profile - Configures a scrubber profile for use by firewall. A scrubber-profile-default specifies monitors and method (how and where) to be monitored and scrubbed.

MODULE

security scrubber

SYNTAX

Configure the scrubber-profile-default component within the security scrubber profile module using the syntax in the following sections.

MODIFY

modify profile [name]
options:

recursive

OPTIONS

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description.

advertisement-ttl

Defines the scrubbing duration for all monitored entities in seconds.

scrubber-categories

Defines how a blacklist-category to be scrubbed.

OPTIONS

advertisement-method

Defines a method to use to scrub a blacklist-category.

bgp-flowspec-advertisement-action

Specifies the BGP FlowSpec Advertisement Action to be used for scrubbing Blacklist category. The default is redirect

bgp-flowspec-dscp-value

Specifies the BGP FlowSpec DSCP value for advertisement qos action.

bgp-flowspec-rate-limit

Specifies the BGP FlowSpec rate limit (bytes/sec) for advertisement rate limiting action.

bgp-flowspec-redirect-asn-community

Specifies the BGP Extended Community value (in the format - AA:NNN, where AA is 16-bit number and NNN is 32-bit number) for redirect-to-VRF support when BGP Flowspec advertisement action is redirect.

blacklist-category

Identifies a blacklist-category to be scrubbed.

next-hop

Defines the nexthop to be used for scrubbing/redirecting traffic for IPv4 shuns.

next-hop-v6

Defines the nexthop to be used for scrubbing/redirecting traffic for IPv6 shuns.

route-domain-name

Identifies a route-domain to be used for route advertisement.

OPTIONS

absolute-threshold

Specifies aggregate maximum bandwidth threshold in Mbps.

advertisement-method

Defines a method to use to scrub a NetFlow protected server object.

app-service

The application service that the object belongs to.

bgp-flowspec-advertisement-action

Specifies the BGP FlowSpec Advertisement Action to be used for scrubbing NetFlow protected server. The default is redirect.

bgp-flowspec-dscp-value

Specifies the BGP FlowSpec DSCP value for advertisement qos action.

bgp-flowspec-rate-limit

Specifies the BGP FlowSpec rate limit (bytes/sec) for advertisement rate limiting action.

bgp-flowspec-redirect-asn-community

Specifies the BGP Extended Community value (in the format - AA:NNN, where AA is 16-bit number and NNN is 32-bit number) for redirect-to-VRF support when BGP Flowspec advertisement action is redirect.

cps-absolute-threshold

Specifies aggregate maximum connection threshold in CPS (Connection Per Second).

cps-percentage-threshold

Specifies aggregate maximum connection rate (CPS) threshold as a percentage of NetFlow capacity.

next-hop

Specifies BGP redirection next hop property.

nps-name

Specifies the name of the specified NetFlow protected server.

percentage-threshold

Specifies aggregate maximum bandwidth (BPS) threshold as a percentage of NetFlow capacity.

pps-absolute-threshold

Specifies aggregate maximum packet threshold in PPS (Packet Per Second).

pps-percentage-threshold

Specifies aggregate maximum packet rate (PPS) threshold as a percentage of NetFlow capacity.

OPTIONS

absolute-threshold

Defines bandwidth threshold which triggers scrubbing for selected route domain.

advertisement-method

Defines a method to use to scrub a route domain.

bgp-flowspec-advertisement-action

Specifies the BGP FlowSpec Advertisement Action to be used for scrubbing a route domain. The default is redirect.

bgp-flowspec-dscp-value

Specifies the BGP FlowSpec DSCP value for advertisement qos action.

bgp-flowspec-rate-limit

Specifies the BGP FlowSpec rate limit (bytes/sec) for advertisement rate limiting action.

bgp-flowspec-redirect-asn-community

Specifies the BGP Extended Community value (in the format - AA:NNN, where AA is 16-bit number and NNN is 32-bit number) for redirect-to-VRF support when BGP Flowspec advertisement action is redirect.

percentage-threshold

Defines bandwidth threshold which triggers scrubbing for selected route domain. The percentage is calculate based on route-domain bandwidth value.

next-hop

Defines the nexthop to be used for scrubbing/redirecting IPv4 traffic.

next-hop-v6

Defines the nexthop to be used for scrubbing/redirecting IPv6 traffic.

route-domain-name

Identifies a route-domain to be used for route advertisement.

excluded-vlans

Identifies VLANs to be excluded from traffic monitoring.

scrubber-rd-network-prefix

Defines subnets which to be used for scrubbing/redirecting traffic. If is defined than the scrubbing for parent route-domain would be ignored.

OPTIONS

bgp-flowspec-advertisement-action

Specifies the BGP FlowSpec Advertisement Action to be used for scrubbing route domain subnets. The default is redirect.

bgp-flowspec-dscp-value

Specifies the BGP FlowSpec DSCP value for advertisement qos action.

bgp-flowspec-rate-limit

Specifies the BGP FlowSpec rate limit (bytes/sec) for advertisement rate limiting action.

bgp-flowspec-redirect-asn-community

Specifies the BGP Extended Community value (in the format - AA:NNN, where AA is 16-bit number and NNN is 32-bit number) for redirect-to-VRF support when BGP Flowspec advertisement action is redirect.

dst-ip

Defines subnet to be used for redirection.

mask

Defines subnet mask to be used for redirection.

next-hop

Defines the nexthop to be used for scrubbing/redirecting traffic.

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

scrubber-virtual-server

Defines how and when a virtual server to be scrubbed.

OPTIONS

absolute-threshold

Defines a bandwidth threshold which triggers scrubbing for a selected virtual server.

advertisement-method

Defines a method to use to scrub a virtual server.

bgp-flowspec-advertisement-action

Specifies the BGP FlowSpec Advertisement Action to be used for scrubbing a virtual server. The default is redirect.

bgp-flowspec-dscp-value
Specifies the BGP FlowSpec DSCP value for advertisement qos action.

bgp-flowspec-rate-limit
Specifies the BGP FlowSpec rate limit (bytes/sec) for advertisement rate limiting action.

bgp-flowspec-redirect-asn-community
Specifies the BGP Extended Community value (in the format - AA:NNN, where AA is 16-bit number and NNN is 32-bit number) for redirect-to-VRF support when BGP Flowspec advertisement action is redirect.

percentage-threshold
Defines bandwidth threshold which triggers scrubbing for selected route domain. The percentage is calculate based on defined virtual server bandwidth value.

next-hop
Defines the nexthop to be used for scrubbing/redirection traffic for IPv4 VS destination addresses.

next-hop-v6
Defines the nexthop to be used for scrubbing/redirection traffic for IPv6 VS destination addresses.

vs-name
Identifies a virtual server to be used for route advertisement.

app-service
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

OPTIONS

url
Used to communicate with Silverline system.

user-id
Defines silverline user's user identification.

user-passwd
Defines silverline user's password.

security scrubber unredirect

NAME

unredirect - Stop scrubbing for a monitored entity. A unredirect command enables a user to stop redirection(scrubbing) for a selected monitored entity such as category, virtual server, or route domain.

MODULE

security scrubber

SYNTAX

Configure the redirect component within the security scrubber module using the syntax shown in the following sections.

RUN

```
run security scrubber unredirect
options:
  profile [scrubber-profile-default]
  unredirect-category [string]
  unredirect-netflow-protected-server [string]
  unredirect-route-domain [string]
  unredirect-virtual-server [string]
```

DESCRIPTION

You can use the unredirect component to stop traffic redirection (scrubbing) for a selected monitored entity.

EXAMPLES

```
run security scrubber unredirect scrubber-profile scrubber-profile-default unredirect-category
run security scrubber unredirect scrubber-profile scrubber-profile-default unredirect-virtual-server
run security scrubber unredirect scrubber-profile scrubber-profile-default unredirect-route-domain
```

show running-config profile
options:
  all-properties
  non-default-properties
  one-line

```

DESCRIPTION

You can use the profile component to configure a shareable and reusable set of ssh profile rules.

EXAMPLES

```

create profile profile1 auth-info add {
auth1 {
  proxy-server-auth {
    private-key "abcd"
    public-key "1234"
  }
  proxy-client-auth {
    private-key "efgh"
    public-key "5678"
  }
} }

```

Creates a ssh profile with auth-info of client facing auth and server facing auth.

```

modify profile profile1 actions add {
action1 {
  sftp-up-action {
    control disallow log yes
  }
  shell-action {
    control terminate log yes
  }
} }

```

Modify existing profile by adding default actions of shell action and sftp action.

```

modify profile profile1 rules add {
rule1 {
  actions add {
    action1 {
      sftp-up-action {
        control disallow log yes
      }
      shell-action {
        control terminate log yes
      }
    }
  }
  identity-groups add {
    "grp1" "grp2"
  }
  identity-users add {
    "usr1" "usr2"
  }
  description "rule1 and action1"
} }

```

Modify existing profile by adding rule1 to it with command actions and user and group identity info.

list profile

Displays the current list of profile rules.

OPTIONS

```

description
User defined profile description.

```

timeout

User defined timeout value.

lang-env-tolerance

Set the tolerance level for LANG environment variable settings. Only applicable when "other-action" is set to "disconnect" or "terminate". "common" allows only "en_US.UTF-8", while "any" allows any standard locale.

rules

Adds, deletes, or replaces a profile rule.

description

User defined rule description.

actions

Specifies the rule actions that the system takes when a profile is applied.

shell-action

Specifies the rule shell action info.

sub-system-action

Specifies the rule sub system info.

sftp-up-action

Specifies the rule sftp up action info.

sftp-down-action

Specifies the rule sftp up action info.

scp-up-action

Specifies the rule scp up action info.

scp-down-action

Specifies the rule scp up action info.

rexec-action

Specifies the rule rexec action info.

local-forward-action

Specifies the rule local forward action info.

remote-forward-action

Specifies the rule local forward action info.

x11-forward-action

Specifies the rule x11 forward action info.

agent-action

Specifies the rule agent action info.

other-action

Specifies the rule other action info.

identity-users

Specifies the rule users identity.

identity-groups

Specifies the rule groups identity.

actions

Specifies the profile default actions that the system takes when a profile is applied.

shell-action

Specifies the rule shell action info.

sub-system-action

Specifies the rule sub system info.

sftp-up-action

Specifies the rule sftp up action info.

sftp-down-action

Specifies the rule sftp up action info.

scp-up-action

Specifies the rule scp up action info.

scp-down-action

Specifies the rule scp up action info.

rexec-action

Specifies the rule rexec action info.

local-forward-action

Specifies the rule local forward action info.

remote-forward-action

Specifies the rule local forward action info.

x11-forward-action
Specifies the rule x11 forward action info.

agent-action
Specifies the rule agent action info.

other-action
Specifies the rule other action info.

auth-info
Specifies the authentication info of public key and private key for this profile.

proxy-server-auth
Specifies a set of private/public keys that can be used to authenticate proxy (BigIP) host server to the real clients during the initial key exchange of the SSH session between real clients and BigIP acting as a proxy server. A SSH Profile MUST have at least 1 set of private/public key configured for proxy server authentication.

private-key
Specifies the private key of the authentication algorithm (RSA, DSS etc) used for the proxy server authentication.

public-key
Specifies the public key of the authentication algorithm (RSA, DSS etc) used for the proxy server authentication.

proxy-client-auth
Specifies a set of private/public keys that can be used to support 'publicKey' based client authentication as defined in RFC 4252 (The Secure Shell (SSH) Authentication Protocol). Note that this is optional in a SSH profile and is only required to support 'publicKey' based client authentication (as defined in section 7 of the above mentioned RFC).

private-key
Specifies the private key of the authentication algorithm (RSA, DSS etc) used for the proxy client authentication.

public-key
Specifies the public key of the authentication algorithm (RSA, DSS etc) used for the proxy client authentication.

real-server-auth
Specifies public key that can be used to authenticate real host server to the proxy (BigIP) client during the initial key exchange of the SSH session between BigIP acting as a proxy client and a real ssh (backend) server. If user does not configure any public key for the real server authentication in a SSH profile, all (backend) real servers are always trusted.

public-key
Specifies the public key of the authentication algorithm (RSA, DSS etc) used for the real server authentication.

BIG-IP 2017-10-30 security ssh profile(1)

security zone

NAME
zone - Configures firewall zones.

MODULE
security

SYNTAX
Zones are reusable objects that are used to classify traffic in firewall policy. Zone is defined as consisting of one or more Vlans, and traffic matching one of the zone member Vlans belongs to the Zone. Zone object can be used as a "source" or "destination" specifier in Firewall policy rules to either mean originating from, or destined-to traffic. Modify the zone component within the security zone module using the syntax shown in the following sections.

CREATE/MODIFY
create zone [name]
options:

```
    copy-from [string]
modify zone [name]
options:
  vlags [add | delete | modify | replace-all-with] {
    [ vlan_name ]
  }
  vlags none
```

edit zone

```
    DISPLAY
list zone
show running-config zone
options:
  all-properties
  non-default-properties
  one-line
```

DESCRIPTION

You can use the zone component to configure a shareable and reusable set of network firewall zones which can be associated as enforced or staged with a number of configuration objects of the following types: security firewall policy.

EXAMPLES

```
    modify zone vlags add {
vlan-1 { }
vlan-2 { } }
```

Creates a zone configuration that includes vlan-1 and vlan-2 as members.

```
list zone
```

Displays the current list of zones.

OPTIONS

copy-from
(CREATE)Specifies the name of an existing policy from which to copy all configuration options.

vlags
Adds, deletes, or replaces a zone vlan member. Specifies one or more vlans against which the packet will be compared, when used with security firewall policy rules.

SEE ALSO

create, edit, list, modify, security firewall policy, tmsh

sys

sys air-filter-reset

NAME

air-filter-reset - Resets the air filter alert timer

MODULE

sys

SYNTAX

Reset the air filter alert timer air-filter-reset component within the sys module using the following syntax.

DISPLAY

```
run air-filter-reset
```

DESCRIPTION

You can use the air-filter-reset component to reset the air filter alert time. The primary usage of this command is to reset the timer after the air filter has been replaced.

EXAMPLES

```
run air-filter-reset
```

Resets the air filter alert timer.

SEE ALSO
tmsh

COPYRIGHT

BIG-IP 2017-03-07 sys air-filter-reset(1)

sys alert lcd

NAME
alert - Manages outstanding alerts.

MODULE
sys

SYNTAX
Manages the outstanding alerts on the system when used with the syntax below.

DISPLAY
show alert lcd

MODIFY
reset-stats alert lcd
reset-stats alert lcd [priority { alert | critical | emergency | error | info | warning }]

DESCRIPTION
You can use the lcd component to display or clear the lcd alerts for the system. The clear lcd alerts can be issued with the priority option followed by the priority value in which case only alerts with matching priority are cleared.

EXAMPLES
show alert lcd

Displays lcd alerts.

reset-stats alert lcd

Clears all lcd alerts.

SEE ALSO
reset-stats, show, sys alert lcd, tmsh

sys aom

NAME
aom - Manages Always On Management subsystem

MODULE
sys

SYNTAX
Manages the Always On Management(AOM) subsystem when used with the syntax below.

DISPLAY
aom list

MODIFY
aom [readonly | webui | media-redirection | vkvm | ipmi] [enabled | disabled]

DESCRIPTION

You can use the aom component to manage the AOM access for the system. All AOM controls are disabled by default. These commands are not supported on all platforms.

readonly reduces the AOM menu to status only, the AOM cannot be used to change the system.

webui controls access to the AOM web services, when enabled this opens port 443 on the AOM for HTTPS. This option is not available on all platforms.

media-redirection controls if the AOM can access a virtual media server to allow the user to mount a file or iso image from a remote system to the AOM. Only allowed when webui is enabled. Media-redirection opens up ports 5120/5124(CDMEDIA) 5122/5126(FDMEDIA) and 5123/5127(HDMEDIA) on the AOM. This option is not available on all platforms.

vkvm controls AOM webui Virtual Keyboard, Video and Mouse redirection. Only allowed when webui is enabled. This opens up port 7578/7582. This option is not available on all platforms.

ipmi controls ipmi access over LAN. When enabled ipmi commands into the AOM over the network port 623(IPMI) and 52123(SSHSOL) are allowed.

EXAMPLES

list sys aom all-properties

Displays aom configuration.

modify sys aom ipmi enabled

Allows IPMI access into the Always On Management subsystem.

SEE ALSO

modify, list, tmsh

BIG-IP 2016-03-29 sys aom(1)

sys appiq config

NAME

config - Configures this BIG-IP for AppIQ feature.

MODULE

sys appiq

SYNTAX

Automatically configures AppIQ feature on this box with given ECM host IP.

MODIFY

modify config

options:

host-ip [ip address]

DISPLAY

list config

options:

all-properties

DESCRIPTION

When run for the first time, this command automatically creates necessary configuration objects to establish communication between BIG-IP and ECM cluster. The command can be reused to change the configured host IP of the ECM cluster.

OPTIONS

host-ip

Specifies an IPv4/6 address for the ECM host. By default, this value is "any6" and AppIQ is disabled. Upon setting this value, the feature is enabled.

User can later delete automatically created and configured AppIQ logging profiles under System configuration to disable the feature. Please note that the command needs to be re-run to enable the feature if the configuration is manually removed/changed.

SEE ALSO

list, modify, tmsh

COPYRIGHT

sys application apl-script

NAME

apl-script - Provides scripts that can be included by an application template.

MODULE

sys application

SYNTAX

Configure the apl-script component within the sys application module using the syntax in the following sections.

EDIT

```
create apl-script [name]
modify apl-script [name]
options:
  apl-checksum [[string] | none]
  apl-signature [[string] | none]
  description [[string] | none]
  ignore-verification [true | false]
edit apl-script [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
```

DISPLAY

```
list apl-script
list apl-script [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete apl-script [name]
```

GENERATE

Note: generate cryptographic signature or checksum based on apl script text.

```
generate sys application apl-script [name]
```

```
options:
  checksum
  signature
```

DESCRIPTION

An APL script contains APL that can be directly included into application templates. APL scripts provide a convenient way to build libraries of common presentation elements. For detailed description of application presentation language elements, See help page of sys application template

EXAMPLES

The following is a fairly simple example of an APL script and a template that makes use of the APL script. The APL script defines a user type that can then be used multiple times in different templates.

```
sys application apl-script com.f5.apl.example {
  define string port validator "PortNumber"
}
```

```
sys application template example_template {
  actions {
  definition {
    presentation {
      include "com.f5.apl.example"
    section my_section {
      string address1
      port portnum1
      string address2
      port portnum2
    }
  }
}
```

```
generate my_script checksum
```

Generate a checksum for the script text and add the checksum as a property.

generate my_script signature signing-key my_key

Generate a signature for the script text using the specified private key and add the signature as a property.

Note: For a script which includes a checksum or signature to successfully load, the script text contents must match the stored checksum or signature.

To temporarily stop the verification of signature or checksum and still retain the checksum or signature, the ignore-verification attribute must be set to true. This is done by editing the script and adding the ignore-verification attribute.

To completely clear the signature or checksum, simply set the attribute script-signature or script-checksum to empty string "". By doing so, the script will be processed as if it was never signed or checksummed.

```
modify apl-script my_script {
description none
script {
}
ignore-verification true
script-checksum 74778e7b13016e0b9329a17f8d2da601
total-signing-status checksum
verification-status checksum-verified }
```

OPTIONS

You can use these options with the apl-script command:

checksum

Generate a checksum for the script text and add the checksum to the script as a property. Only for use with the generate command.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

script

Contains the APL text that can be imported into application templates.

signature

Generate a signature for the script text using the specified private key and add the signature to the script as a property. Only for use with the generate command.

signing-key

The private key to use for signing the script. Only for use with the signature option.

SEE ALSO

create, delete, edit, glob, list, modify, regex, sys application template and generate.

COPYRIGHT

BIG-IP 2016-03-14 sys application apl-script(1)

sys application custom-stat

NAME

custom-stat - Provides derived statistics for iStats.

MODULE

sys application

SYNTAX

Configure the custom-stat component within the sys application module using the syntax in the following sections.

```
EDIT
create custom-stat [key]
modify custom-stat [key]
options:
  app-service [[string] | none]
  keyspace [string]
  formula [string]
  measure [string]
edit custom-stat [ [ [key] | [glob] | [regex] ] ... ]
options:
  all-properties

DISPLAY
list custom-stat
list custom-stat [ [ [key] | [glob] | [regex] ] ... ]

DELETE
delete custom-stat [key]
```

DESCRIPTION
Statistics are derived for objects in the given keyspace based on the given formula, producing the given measure.

EXAMPLES
create sys application custom-stat myKey
keyspace sys.application.service
measure conns_per_min
formula "rate counter conns 60"

Creates a derived iStat.

OPTIONS
You can use these options with the custom-stat component:

app-service
Specifies the name of the application service to which the object belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

formula
Specifies the first token in the formula indicates the computation to be made. Currently only rates are supported.

rate

rate computes the rate of change of the source measure over the last seconds.
This is applicable only to numeric measures. The derived measure is of type gauge.

keyspace
Specifies that a derived iStat will be computed for all objects in the given keyspace for which the formula is computable (the source measure of the correct type exists).

measure
Specifies the name of the derived measure to be created. The type of the derived measure is dependent on the formula.

SEE ALSO
create, modify, sys application service

COPYRIGHT

BIG-IP 2012-10-19 sys application custom-stat(1)

sys application service

NAME
service - Configures traffic management application services.

MODULE
sys application

SYNTAX

Modify the service component within the sys application module using the syntax shown in the following sections.

CREATE/MODIFY

```
create service [name]
modify service [name]
options:
  description [string]
  device-group [[string] | default | non-default | none]
  execute-action [name]
  lists [add | delete | modify | replace-all-with] {
    [name] {
      options:
    }
  }
  value { [string]... }
  value none
  encrypted [yes | no]
}
lists none
strict-updates [disabled | enabled]
tables [add | delete | modify | replace-all-with] {
  [name] {
    options:
  }
  column-names { [name] ... }
  encrypted-columns { [name] ... }
  rows { { row { [value] ... } row { [value] ... } ... } }
  rows none
}
tables none
template [name]
traffic-group [[string] | default | non-default | none]
variables [add | delete | modify | replace-all-with] {
  [name] {
    options:
  }
  value [string]
  encrypted [yes | no]
}
variables none

metadata
  [add | delete | modify] {
    [metadata_name ... ] {
  }
  value [ "value content" ]
  persist [ true | false ]
}
```

```
edit service [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list service
list service [ [ [name] | [glob] | [regex] ] ... ]
show running-config service
show running-config service [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

Note: Application Service objects are always created in a subfolder of the current folder. Make sure the correct path is used to display the service. E.G list myapplication.app/myapplication

DELETE

```
delete service [name]
```

OPTIONS

You can use these options with the service component:

description
User defined description.

device-group
Specifies the name of the device group to which the application service is assigned. If this property is modified with the default keyword, the value of the parent folder or partition will be used and the inherited-devicegroup property will be set to true.

execute-action
Runs the specified template action associated with the service.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

lists

Provides the set of list variables and values that are passed to template scripts.

metadata

Associates user defined data, each of which has name and value pair and persistence. The default value is persistent, which means the data will be saved into the config file.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

strict-updates

Specifies whether configuration objects contained in the application service can be directly modified outside the context of the system's application service management interfaces.

tables

Provides the set of table variables and values that are passed to template scripts.

template

The template defines the configuration for the application service. Generic application service has no template associated with it. This can be changed after the service has been created to move the service to a new template. A templated application service can be converted to a generic application service by setting new template to none or empty string. Similarly a generic application service can be made templated by associating it with the existing template.

template-modified

Indicates that the application template used to deploy the service has been modified. The application service should be updated to make use of the latest changes.

template-prerequisite-errors

Indicates any missing prerequisites associated with the template that defines this application.

traffic-group

The name of the traffic group that the application service is assigned to. If this property is modified with the "default" keyword, the value of the parent folder or partition will be used and the inherited-trafficgroup property will be set to true.

variables

The set of atomic variables and values that are passed to template scripts.

SEE ALSO

create, delete, edit, glob, list, modify, regex, tmsn

 Note: generate cryptographic signature or checksum based on template fields - html-help, implemenation, macro and presentation in definition section.

```

generate template [name]
options:
  checksum
  signature

```

```

SAVE/LOAD
save template [name] file [filename]
load template [filename]

```

DESCRIPTION

Application templates allow a user to define a custom interface for easily creating complex configurations. The user can create multiple templates for various types of configurations. Once built, the user can use a template to create an application, which is a specific set of configuration objects (such as Virtual IP addresses, pools, and so forth), that work together to perform some task.

The template is composed of two primary parts, the presentation and the implementation.

The presentation section describes a form (a set of questions and user interface elements) that the user must fill out in order to create an application.

The implementation section describes how the values collected from the user (the form variables) are used to generate the actual configuration objects which are part of the application.

The presentation section of the template is written in a simple language called Application Presentation Language or APL. The implementation section of the template is written in TCL and provides access to tmsh scripting commands.

APPLICATION LIFECYCLE

Before describing in detail how a template is written, it is important to explain how the resulting template will be used. Since templates are used to create and edit applications, it makes sense to review the application lifecycle.

Application Creation

The user selects which template to use for his application. The system presents an empty form, based on the template's presentation script that the user fills out and submits. The system collects and stores the form variables in a newly created application object. Configuration objects are generated based on the form variables by the template's implementation script.

Application Editing

The user selects an existing application that he would like to change. The system reloads the form associated with the template that was used to create the application and refills all form variables using the previous user input, which is gathered from the application object. The user edits the form and submits it. The template's implementation script is run again to compute a new set of configuration objects for the application. The system alters the current configuration objects associated with the application to match the newly computed set of configuration objects, including creating, modifying, and deleting objects as needed.

Application Deletion

The user selects an application to delete. All configuration objects associated with the application are removed.

APPLICATION TEMPLATE LANGUAGE

The application template language describes the user interface presented to a user making a new application, or editing an existing application. It describes what questions to ask, how the questions are presented (for example, a free form field or a list of options), and the names of the variables used to store the values the user inputs.

It consists of a set of primitive form elements (string, choice, etc), a set of grouping and organization

constructs (section, table, etc), methods for hiding or displaying portions of the form based on the values of other portions (optional), a method to associate human-readable text with various form elements (text) and methods for creating user defined types(define group, define section, etc) for reuse of application presentation language elements.

Primitive Elements

Primitive elements represent the actual user interface components. The system displays each primitive element as part of the form, and associates it with a form variable. The following lists the basic primitive types:

choice

A list of options from which the user can select (a drop-down menu).

```
choice [default "" ] [display "" ] { "", "", ... }
```

editchoice

Multiple choices are available that the user can select, or a new value can be entered if the choices are not acceptable.

```
choice [default "" ] [display "" ] { "", "", ... }
```

multichoice

Similar to a basic choice element except that multiple items may be selected from the available choices.

```
choice [default "" ] [display "" ] { "", "", ... }
```

password

Similar to a string element except the contents may be obscured to prevent others from seeing the value.

```
password [default "" ] [display "" ] [required]
```

string

A basic text box into which the user can enter an arbitrary string.

```
string [default "" ] [display "" ] [required] [validator "" ]
```

Each primitive element is associated with a variable name, which defines where the value collected by the form is stored. In addition, primitive elements can have additional parameters such as a default value, a validation method that provides for additional requirements (for example, the string must be an IP address).

The following defines the format for the string primitive values, using normal BNF syntax:

Â· default - A sensible default value to which the string is initialized when a new application is created.

Â· display - Directs the renderer how to display the element. This can be small, medium, large, xlarge, or xxlarge.

Â· required - If present, a valid value must be entered before the application can be created.

Â· validator - The name of a well known validation method.

Section

The section construct is used to group form variables (primitives) into logical sections for display.

Each section is named, and header text can be defined for a section using the text construct.

Every variable must be inside a section. The format for a section is:

```
section { }
```

For example, to represent the data associated with a virtual IP:

```
section vip
```

```
{
  string address
  string port default "80" display "small"
}
```

Table

The table construct is similar to section, except that it represents a grouping of elements that can be repeated zero or more times. The syntax for table and section are identical.

```
table { }
```

For example, to collect a list of nodes from a user to populate a pool, you can add any number of nodes, each of which has an address and port:

```
section pool
```

```
{
  table members
  {
    string address
    string port default "80" display "small"
  }
}
```

The table above is displayed using a JavaScript-editing widget that enables you to add and remove pool members. Each member contains two form variables: address and port.

Optional

The optional construct allows the form elements to be hidden or shown based on the state of other form elements. The syntax of the optional construct is:

```
optional () { }
```

The expression in the optional construct is evaluated during the display of the form. The content section is displayed or hidden, based on its value.

To dynamically hide parts of the presentation based on the answer to a earlier question, use the variable name in the expression:

```
section chooseopts {
  choice show_section_1 {"yes", "no"}
}
section section1
{
  optional (chooseopts.show_section_1 == "yes")
  {
    string str
  }
}
```

User defined types

The define construct allows the creation of user-defined types out of primitive types. The defined type can then be used multiple times independently at different places. This is especially useful in conjunction with the include element because types can be defined in the included application presentation language script and then used where necessary in the template. For more details on application presentation language script, See help sys application apl-script.

For example, user defined choice type can be defined as below and can be reused at multiple sections:

```
define choice yesno {
  "Yes", "No"
}
section ssl_section {
  yesno use_ssl
}
section optimizations {
  yesno use_wa
  yesno offload_ssl
}
```

The define group construct allows the creation of user-defined type to allow the user to group multiple elements of existing types together. The defined type can be reused multiple times independently similar to the above.

For example IPAddress and port can be grouped into a user-defined type and reused in multiple sections:

```
define group addrport {
  string addr required validator "IpAddress"
  string port
}
section http_section {
  addrport server
}
section sip_section {
  addrport client
  addrport server
}
```

Localization

The text element lets you define the localized text labels for sections, table, row and other sub-elements.

For message element, body text can be localized in addition to the label. Similarly for the choice, editchoice and multichoice element, display text associated with each choice value can be localized. The syntax for the text element is:

```
text [""] {
  ""
  . ""
  . "" ""
  . "" { "" => "", "" => "", ... }
}
```

Depending on the locale used (setting in the browser), particular text label, body text or choice display text will be shown to the user.

For example, string, message and choice display texts can be localized as below.

```
section http
{
  message intro
```

```

string address
string port default "80" display "small"
choice pools default "pool1" { "pool1", "pool2", "pool3" }
choice profile default "http" tcl {
    set choices "no\n"
    append choices "http\n"
    append choices [tmsh::run_proc f5.app_utils:get_items ltm profile http]
    return $choices
}
}

text {
    vs "HTTP Application"
    vs.intro "Introduction" "This template supports simple web server implementations"
    vs.address "What IP address do you want to use for this virtual server?"
    vs.port "What port do you want to use for this virtual server?"
    vs.pools "Use pool.." { "Internal" => "pool1", "Public cloud" => "pool2", "Private data center" => "pool3" }
    vs.profile "Use profile.." { "Do not use profile" => "no", "Use F5's recommended profile" => "http" }
}

text "de_AU" {
    vs "HTTP-Anwendung"
    vs.intro "Einführung" "Diese vorlage unterstützt einfache web-server-implementierungen"
    vs.address "Welche ip-adresse mochten Sie für diesen virtuellen Server zu verwenden?"
    vs.port "Welchen port willst du für diesen virtuellen Server zu verwenden?"
    vs.pools "Verwenden pool.." { "intern" => "pool1", "Privat Rechenzentrum" => "pool3", "Öffentliche Cloud" => "pool2" }
    vs.profile "Mit profil.." { "Verwenden sie kein profil" => "no", "Verwenden von F5 empfohlen profil" => "http" }
}

```

A user from Austria will see the german text, all other locales will see the default (locale-less) text.

While localizing choice value display text, users are allowed to use different ordering of choice values in each locale. If TCL is used to populate the choices, then best effort is made to match what is returned in the TCL to the given localized choice value. In the above example, the embedded TCL script for profile will return two static choices (no and http) followed by the list of all http profiles. These static choices are localized, but not the other results. When the TCL results contain a mix of localized and non-localized choices, the localized choices will always be listed first in the order specified in the text element.

With the localization, message body and static choices will become optional in the declaration. If the message body is provided in both the declaration and in text element, the body in the text element will override the body in the variable declaration. Same applicable for the display text of choice value provided in declaration. The recommended syntax for choice, editchoice and multichoice element is to give just the choice values in the variable declaration, and give the display text of the choices in the text element.

TMSH SCRIPTING SUPPORT

Once the user finishes editing an application, the form variables are saved, and the implementation section of the associated template is run. The implementation section is an ordinary TCL script and can use the standard set of tmsh scripting extensions. In addition, there are a few template-specific additions.

First, access to the form variable is done using the syntax, where
 is the name of the section to
 which the variable belongs, and is the name of the form variable:

```
$::
```

```
—
```

Next, a table can be iterated over, and for each list element, the components of the list can be gathered using the tmsh::get_field_value command. For example, for the pool member example described in the section regarding the list, you can use the following syntax:

```

foreach member $::pool_members {
    set the_addr [tmsh::get_field_value $member address]
    set the_port [tmsh::get_field_value $member port]
    # Do something with the_addr and the_port
}

```

This means for variable access can also be used within a script macro. Expansion of a macro is done using the tmsh::expand_macro command. Usage:

```
tmsh::expand_macro [macro] [name_value_pair_list]
```

The variables defined in the presentation are automatically available from within the macro. If additional variables are needed from within the macro, they can be specified via name_value_pair_list. Variables defined this way will take precedence over duplicate variables defined in the presentation.

TMSH BUILT-IN VARIABLES

Specific details on application and application template is provided to implementation section using built-in variables. Following are the variables available for use.

tmsh::app_name
 Stores the user-provided application name string.

tmsh::app_name_path
 Stores the path name of application in configuration database.

tmsh::app_template_name
 Stores the user-provided application template name including the path in configuration database.

tmsh::app_template_action
Stores the application template action name.

EXAMPLES

The following template example shows both the presentation and implementation sections. (It lacks some features, such as use of optional, defaults, validators, etc.)

```
presentation {
  section basic
  {
    choice ssl_enabled { "true", "false" }
    string addr
    string more_stuff
    table servers
    {
      string addr
      string port
      string ratio
    }
  }
  text
  {
    basic "Some example questions"
    basic.ssl_enabled "Should SSL be enabled?"
    basic.addr "What address should we use for the VIP?"
    basic.servers.addr "Address"
    basic.servers.port "Port"
  }
}

implementation {
  if { $::basic__ssl_enabled }
  {
    set profile_name [format "%s_%s" $tmsh::app_name clientssl]
    tmsh::create ltm profile client-ssl $profile_name
    append profile_name " http"

    set destination "$::basic__addr:https"
    set monitor https
  }
  else
  {
    set profile_name http
    set destination "$::basic__addr:http"
    set monitor http
  }
}

set pool_name [format "%s_%s" $tmsh::app_name pool]

set members \{
  foreach server $::basic__servers {
    append members [tmsh::get_field_value $server addr]
    append members ":"
    append members [tmsh::get_field_value $server port]
    append members " { ratio "
    append members [tmsh::get_field_value $server ratio]
    append members "}"
    append members " "
  }
}
append members \}

tmsh::create ltm pool $pool_name \
  members replace-all-with $members \
  monitor $monitor

set vs_name [format "%s_%s" $tmsh::app_name virtual]
tmsh::create ltm virtual $vs_name \
  destination $destination \
  profiles replace-all-with "{ $profile_name }" \
  snat automap \
  pool $pool_name \
  http-class none
}
```

generate my_app checksum

Generate a checksum for the template definition and add the checksum as a property.

generate my_app signature signing-key my_key

Generate a signature for the template definition using the specified private key and add the signature as a property.

Note: For a template which includes a checksum or signature to successfully load, the definition contents must match the stored checksum or signature.

To temporarily stop the verification of signature or checksum and still retain the checksum or signature, the ignore-verification attribute must be set to true. This is done by editing the script and adding the ignore-verification attribute.

To completely clear the signature or checksum, simply set the attribute script-signature or script-checksum to empty string "". By doing so, the script will be processed as if it was never signed or checksummed.

```
sys application template my_tmpl {
actions {
  definition {
html-help {

}
implementation {
  # insert tmsb script
}
presentation {
  # insert apl script
}
role-acl none
run-as none
}
description "This is my template"
ignore-verification true
script-checksum 74778e7b13016e0b9329a17f8d2da601
total-signing-status checksum
verification-status checksum-verified }
```

OPTIONS

actions

Adds, deletes, or replaces a set of template actions. You can configure the following options for an action:

html-help

The help for the application template action formatted as HTML.

implementation

The script that is run to create the configuration objects associated with the application.

name The name of the application template action.

presentation

The questions that must be answered to create an application from the template.

role-acl

The list of roles that are allowed to run the action.

run-as

The user account that will be used to run the implementation script. If no account is specified, the script is run as the calling user.

checksum

Generate a checksum for the template definition and add the checksum to the template as a property. Only for use with the generate command.

signature

Generate a signature for the template definition using the specified private key and add the signature to the template as a property. Only for use with the generate command.

signing-key

The private key to use for signing the template. Only for use with the signature option.

description

User defined description.

metadata

Associates user defined data, each of which has name and value pair and persistence. The default value is persistent, which saves the data into the config file.

partition

Displays the administrative partition within which the application template resides.

prerequisite-errors

A message indicating if there are any errors with the prerequisites for the template on the current BIG-IP system. If there are errors no applications can be created from this template. If there are no errors then the template is valid.

requires-modules

Adds, deletes, or replaces the list of modules that are required to be provisioned for this template to work.

requires-bigip-version-max

Specifies the maximum version of BIG-IP software required by this template.

requires-bigip-version-min

Specifies the minimum version of BIG-IP software required by this template.

THIRD PARTY TCL LIBRARY USAGE

A selection of third party libraries have been tested to work within the CLI script environment. These include MD5, BASE64, SHA1/SHA256, HTTP, TLS, TCL Perl, LDAP client, and XML parser. The TCL packages can only reside in the /use/share/compat-tcl8.4 directory.

Important: Only these tested packages are supported currently.

The following example shows how the Tcl package command can make use of the XML parser:

```
cli script /Common/use_xml {

proc script::EStart {tag attlist args} {
    array set attr $attlist
    puts "Element \"$tag\" started with [array size attr] attributes"
}

proc script::PCData text {
    incr ::count [string length $text]
}

proc script::run {} {
    namespace eval :: {
        set count 0
    }
    puts "running use_xml...\n"
    set pkg_name xml
    if {[catch {package require $pkg_name 3.2}]} {
        puts "No package found: $pkg_name!\n"
    }
    else {
        puts "Found package: $pkg_name!\n"
        set parser [xml::parser]
        $parser configure -elementstartcommand script::EStart -characterdatacommand script::PCData
        set fp [open "/shared/test.xml" r]
        set text [read $fp]
        $parser parse $text
        puts "The document contains $::count characters"
        close $fp
    }
}
```

Here are some additional examples:

```
cli script /Common/use_sha1 {
proc script::run {} {
    set pkg_name sha1
    if {[catch {package require $pkg_name}]} {
        puts "No package found: $pkg_name!\n"
    }
    else {
        puts "Found package: $pkg_name!\n"
        puts "TCL does SHA1 now:"
        puts [sha1::sha1 -hex "TCL does SHA1"]
    }
}
```

```
cli script /Common/use_base64 {
proc script::run {} {
    set pkg_name base64
    if {[catch {package require $pkg_name}]} {
        puts "No package found: $pkg_name!\n"
    }
    else {
        puts "Found package: $pkg_name!\n"
        set chemical [encoding convertto utf-8 "C\u2088H\u2081\u2080N\u2084O\u2082"]
        set encoded [base64::encode $chemical]
        set caffeine [encoding convertfrom utf-8 [base64::decode $encoded]]
        puts "Caffeine: $caffeine"
    }
}
```

NAME

availability - Display summary of system availability.

MODULE

sys availability

SYNTAX

Display summary of system availability.

DISPLAY

show sys availability

options:

field-fmt

RESET

reset-stats sys availability

DESCRIPTION

Displays a summary of the availability metrics for the BIG-IP(r) system or blade. The metrics represent the

amount of time spent in a given state.

States

Available

The total time BIG-IP(r) has been active or standby for one or more traffic-groups.

Maintenance

The total time BIG-IP(r) has spent offline for maintenance, e.g., state administratively set to offline, rebooting, powered off. This will also include the time running in software which does not log system availability.

Unavailable

The total time BIG-IP(r) is operationally offline and unable to accept traffic or failover.

Unknown

The total time for which the system is unable to determine availability state. This could be due to gaps present in availability logs or when the system is unable to write to the availability log.

EXAMPLES

show sys availability

Displays summary of system availability metrics.

reset-stats sys availability

Resets system availability metrics.

OPTIONS

field-fmt

Displays the summary of system availability metrics in field format where the value is total time in seconds spent in given state.

SEE ALSO

sys failover, cm traffic-group, reset-stats, show, tmsh

non-default-properties

one-line

show running-config cluster

show running-config cluster [option name]

options:

one-line

show cluster

show cluster [option name]

options:

all-properties

field-fmt

DESCRIPTION

You can use the cluster component to modify the configuration of the primary blade in a cluster. When you do this, the system automatically propagates the changes to the other blades in the cluster. This is known as cluster synchronization.

EXAMPLES

modify cluster default address 192.168.217.44/24

Sets the floating management IP address for the cluster default to an IP address of 192.168.217.44.

list cluster my_cluster

Displays the properties of the cluster named my_cluster.

OPTIONS

address

Specifies an IP address for the cluster or cluster member. The default value is none.

alt-address Specifies an optional, additional IP address for the cluster or cluster member in support of dual-stack addressing. The default value is none. Note: The IP address specified must compliment the family of the IP address held in address. I.e. Without loss of generality, if address holds an IPv6 address, then alt-address must hold an IPv4 address or none at all. Symmetrically, if address holds an IPv4 address, then alt-address must hold an IPv6 address or none at all.

disabled

Disables the specified cluster member. The default value is enabled.

enabled

Enables the specified cluster member. This is the default value.

members

Specifies the cluster members to be acted on by the command. A cluster member is a slot into which you insert a blade. The cluster member is identified by the number assigned to the slot.

min-up-members

Specifies the minimum number of cluster members that must be up for the cluster to remain Active. The default value is 0.

min-up-members-enabled

When set to yes, specifies that when the number of cluster members that are active is below the value of the option min-upmembers, the cluster fails over to its peer. The default value is no.

Enable this parameter when you configure a redundant pair.

Important: Make sure that you modify the value of the min-up-members option appropriately when you take blades down in a cluster. Otherwise, you can get into the condition where disabling a cluster member brings the cluster below the value of the option min-up-members, which can cause the cluster to fail over to its peer.

name

Specifies a name for the cluster. This option defaults to the value default.

priming

Prevents a cluster member from proceeding to the RUNNING cluster quorum state, which is useful when a blade is in a reboot loop. The default value is disabled.

sys config-diff

NAME

config-diff - Displays the differences between two specified single configuration files (SCFs).

MODULE

sys

SYNTAX

Display information using the config-diff component within the sys module with the syntax in the following section.

DISPLAY

show config-diff [file name] [file name]

DESCRIPTION

You can use the config-diff component to display the differences between two previously created SCF files.

EXAMPLES

show config-diff my.scf your.scf

Displays information about the differences between two specified files.

OPTIONS

file name

Specifies the name of an SCF file that you want to compare to another SCF file.

SEE ALSO

show, tmsh

delete config file [file name]

DISPLAY

list config file

DESCRIPTION

The system applies all configuration changes that you make from within tmsh to the running configuration. To save the running configuration to the system configuration files, use the command sequence save config. Additionally, you can replace the running configuration with the configuration in the system configuration files using the command sequence load config.

If any of these options are not specified, save/load config will save or load the configuration in all partitions on this system:

- Â· binary
- Â· default
- Â· file
- Â· from-terminal
- Â· partitions

EXAMPLES

save config

Saves the running configuration in all partitions by overwriting the system configuration files.

In Virtual Editions with f5-swap-eth installed, saves the mapping of Ethernet device names and MAC addresses to /etc/ethmap to make the working BIG-IP still work after adding/deleting virtual NIC(s). It also works for save config partitions all.

save config base

Saves the running base configuration in all partitions by overwriting the system base configuration files.

save config binary

Saves all running configuration by overwriting the system binary configuration database file.

save config current-partition

Saves the running configuration in current update partition by overwriting the system configuration files.

save config wait

Save request waits if another save operation is in progress.

save config file my_file tar-file my_tar_file no-passphrase

Saves all running configuration to the specified file, my_file, and all the user provided disk files referred to by the configuration into my_tar_file. From v12.1.0 onwards the no-passphrase option should be explicitly specified for saving the unencrypted SCF and SCF.tar.

save config file my_file passphrase my_password

Saves all running configuration to the specified file, my_file and encrypt it with my_password.

save config partitions { my_partition }

Saves the running configuration in my_partition by overwriting the system configuration files.

save config partitions all

Saves the running configuration in all partitions by overwriting the system configuration files.

save config user-only

Saves only user account configuration by overwriting the system configuration files.

load config

Replaces the running configuration in all partitions with the configuration in the system configuration files.

load config base

Replaces the running base configuration in all partitions with the configuration in the system base configuration files.

load config current-partition

Replaces the running configuration in current update partition with the configuration in the system configuration files.

load config merge file my_file

Loads the specified configuration from my_file, which modifies the running configuration.

load config replace file my_file

Loads the specified configuration from my_file, which modifies the running configuration, overwrites certain elements that may be conflicting.

load config verify file my_file

Validates the specified configuration in my_file to see whether they are valid to replace the running configuration. The running configuration will not be changed.

load config verify merge file my_file

Validates the specified configuration in my_file to see whether they are valid to be merged into the running configuration. The running configuration will not be changed.

load config verify replace file my_file

Validates the specified configuration in my_file to see whether they are valid to be merged into the running configuration with some elements replaced. The running configuration will not be changed.

load config default

Sets system configuration back to factory default settings.

load config file my_file tar-file my_tar_file

Replaces all running configurations with the configuration in the specified file, my_file and the disk files referred to by the configuration are retrieved from my_tar_file.

load config file my_file files-folder my_files_folder

Replace all running configuration with the configuration in the specified file, my_file and the disk files referred to by the configuration is taken from the directory tree under my_files_folder.

load config file my_file passphrase my_password

Replaces all running configuration with the configuration in the specified encrypted file, my_file and decrypt it with my_password.

While searching for disk files under the specified folder, the order of search is first by file name as in cache-path, and then by object-name. If more than one file is found for a name, then the relative path in the cache-path is used to make the selection.

That is, while looking for

Looks for file(s) named B.

If none are found, looks for file(s) named "xxx"

When more than one file is found, looks for a copy that matches paths in the order:

B>

B>

load config partitions { x }

Replace the running configuration in partition x with the configuration in the system configuration files.

load config partitions all

Replace the running configuration in all partitions with the configuration in the system configuration files.

load config from-terminal

Replace the running configuration with what is entered from the terminal.

1. Type the initial command. 2. The system responds with a confirmation prompt, type Y to confirm.

Replace the running configuration? (y/n) y

3. Type in the replacement configuration entries.

```
net self-allow {
  defaults {
    igmp:any
    ospf:any
    pim:any
    tcp:161
    tcp:22
    tcp:4353
    tcp:443
    tcp:53
    udp:1026
    udp:161
    udp:4353
    udp:520
    udp:53
  }
}
net stp-globals {
  config-name 00-01-D7-B5-67-00
}
sys management-ip 172.27.41.70/24 { }
sys management-route default {
  gateway 172.27.41.254
}
sys provision ltm {
  level nominal
}
```

```
....
ltm pool pool1 {
    slow-ramp-time 200
}
.....
^D
```

4. Use Ctrl+D to submit the changes or Ctrl+C to cancel the changes.

delete config file myfile

Delete myfile in default directory, /var/local/scf/.

list config file

Display files in default directory, /var/local/scf/.

OPTIONS

base Indicates the base configuration. This option cannot be specified with the binary, default, gtm-only, and user-only options.

binary
Indicates binary configuration. This option may not be specified with any other options.

default
Indicates factory default configuration. This option cannot be specified with any other options.

file Loads or saves a configuration from the specified file. For save, a file with a relative path is saved in the default directory, /var/local/scf. For load, in shell mode, the default directory, /var/local/scf, is used for a file with a relative path. In bash mode, for a file with a relative path, the current directory is searched first. If the file can't be found in the current directory, /var/local/scf is searched.

This option can be used with binary, default, from-terminal and partitions options.

passphrase
Specifies a password to save or load an encrypted configuration file. This option can only be used with option file.

tar-file
Loads or saves disk files referred to by the configuration from the specified tar file. A file with a relative path is looked up, relative to the current directory.

files-folder
Loads disk files referred to by the configuration from the folder tree under the specified folder. Disk files by name are searched for recursively. When there is more than one file with the same name, the relative path of the file from the cache-path is used for selection.

from-terminal
Specifies that the configuration will be input from the terminal in the same format as the system configuration files in . **Use Ctrl+D to submit the changes and Ctrl+C to cancel the changes.**

This option cannot be specified with default, file and partitions.

gtm-only
Indicates the Global Traffic Manage (GTM) configuration. This option cannot be specified with the base, exclude-gtm, and user-only options.

exclude-gtm
Indicates the BIG-IP configuration, excluding GTMs. This is only valid with the file option. This option cannot be specified with the base, gtm-only, and user-only options.

merge
Loads the configuration from the specified file or from the terminal, which modifies the running configuration. If merging from the terminal, it requires Ctrl+D to complete the operation. This option is only valid with the file or from-terminal options.

partitions
Indicates the partitions in which configuration components reside. This option cannot be specified with the default, file, from-terminal, or merge options.

user-only
Indicates the configuration including user account information only. This option cannot be specified with the base, default, exclude-gtm, or gtm-only options.

time-stamp
Inserts a time-stamp in a file name. This is only valid with the file option.

verify
Validates the specified configuration from file(s) or from the terminal without changing the running configuration.

wait Specifies that tmsh should wait for another instance of tmsh to finish saving the configuration before proceeding. If wait is not specified and another instance of tmsh is in the process of saving the configuration, the command exits tmsh immediately (because the other instance of tmsh is already saving the configuration).

BIG-IP 2019-01-14 sys config(1)

sys connection

NAME

connection - Sets idle timeout for, displays, and deletes active connections on the BIG-IP(r) system.

MODULE

sys

SYNTAX

Use the connection component within the sys module to manage connections using the following syntax.

MODIFY

modify connection

options:

idle-timeout [integer]
flow-accel-type software-only

DISPLAY

show connection

option:

all-properties
age [integer]
cs-client-addr [IP address/prefixlen]
cs-client-port [[integer] | [service]]
cs-server-addr [IP address/prefixlen]
cs-server-port [[integer] | [service]]
connection-id [integer]
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
protocol [name]
save-to-file [filename]
ss-client-addr
ss-client-port [[integer] | [service]]
ss-server-addr
ss-server-port [[integer] | [service]]
type [any | mirror | self | mptcp]

DELETE

delete connection

option:

age [integer]
cs-client-addr [IP address]
cs-client-port [[integer] | [service]]
cs-server-addr [IP address]
cs-server-port [[integer] | [service]]
connection-id [integer]
protocol [name]
ss-client-addr [IP address]
ss-client-port [[integer] | [service]]
ss-server-addr [IP address]
ss-server-port [[integer] | [service]]
type [any | mirror | self | mptcp]

DESCRIPTION

You can use the connection component to set the idle timeout for or delete active connections to the BIG-IP system based on a specified filter. Additionally, you can display information about the active connections to the system.

You can specify the option using either a number or a service (80 or http).

Important: If you do not specify a port or service, the system deletes all connections that match just the IP address. If you do not specify an IP address, the system deletes all connections including mirrored connections.

EXAMPLES

show connection all-properties

Displays information about all active connections to the system.

modify connection idle-timeout 300

Changes the amount of idle time before a connection is disconnected to five minutes (300 seconds).

modify connection flow-accel-type software-only

Flush all hardware accelerated connections from the hardware to be software only connections.

OPTIONS

age Specifies, in seconds, the minimum idle time of the active connections that you want to display or delete.

cs-client-addr/prefixlen

Specifies the client-side remote IP address of the active connections that you want to display or delete. Subnet addresses are allowed with prefix lengths up to /24 and /56 for IPv4 and IPv6 respectively.

cs-client-port

Specifies the clientside remote port of the active connections that you want to display or delete.

cs-server-addr/prefixlen

Specifies the clientside local IP address of the active connections that you want to display or delete. Subnet addresses are allowed with prefix lengths up to /24 and /56 for IPv4 and IPv6 respectively.

cs-server-port

Specifies the clientside local port of the active connections that you want to display or delete.

connection-id

Specifies the MPTCP connection ID of the active connections that you want to display or delete.

idle-timeout

Specifies the interval, in seconds, that a connection can remain idle before the system closes the connection.

protocol

Specifies the protocol of the active connections that you want to display or delete.

save-to-file

Specifies the file which connection information can be save to. With this option, it can write a file larger than 2GB.

ss-client-addr

Specifies the serverside local IP address of the active connections that you want to display or delete.

ss-client-port

Specifies the serverside local port of the active connections that you want to display or delete.

ss-server-addr

Specifies the serverside remote IP address of the active connections that you want to display or delete.

ss-server-port

Specifies the serverside remote port of the active connections that you want to display or delete.

type Specifies the type of active connections that you want to display or delete. The possible values are:

any Specifies all active connections.

mirror

Specifies only mirrored connections.

self Specifies the connection with which you are accessing the system.

mptcp

Specifies the MPTCP type of connections.

BIG-IP 2018-05-31 sys connection(1)

NAME

console - Configures the serial console for the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the console component within the sys module using the syntax in the following section.

MODIFY

modify console

options:

baud-rate [integer]

DISPLAY

show console

DESCRIPTION

You can use the console component to configure the serial console on the BIG-IP system.

OPTIONS

baud-rate

Specifies the baud rate for the serial console. Select from the following options:

• 9600

• 19200 (default)

• 57600

• 115200

For information about the options that you can use with the command show, see help show.

BIG-IP 2010-12-02 sys console(1)

sys core

NAME

enhancedcorefiles - Configures management of core files for the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the core component within the sys module using the following syntax.

MODIFY

modify core

options:

tmm-manage [true|false]

tmm-max [1-100]

tmm-action [skip|rotate]

mcpd-manage [true|false]

mcpd-max [1-100]

mcpd-action [skip|rotate]

bigd-manage [true|false]

bigd-max [1-100]

bigd-action [skip|rotate]

retention [1-365]

edit core

options:

all-properties

non-default-properties

DISPLAY

list core

list core [option]

show running-config sys core
show running-config sys core [option]
options:
all-properties
non-default-properties
one-line

DESCRIPTION

You can use this component to configure the creation of core files that the system will use to generate core files.

EXAMPLES

modify sys core tmm-manage true

Configures the TMOS system to manage tmm corefiles.

OPTIONS

process-manage
Whether or not this process' core files are managed by this component.

process-max
Maximum number of core files that may exist in /shared/cores for this process before the process-action is taken.

process-action
Action to take when number of core files is at its maximum. Possible actions are "skip" which will skip creation of the core file. "rotate" will delete the oldest core file before creation of the new core file.

retention
Integer representing number of days before deletion.

SEE ALSO

BIG-IP 2019-04-25 sys core(1)

sys cpu

NAME

cpu - Displays statistics about the Traffic Management Microkernel (TMM) service, specifically, CPU cycles.

MODULE

sys

SYNTAX

Display statistics for the cpu component within the sys module using the syntax in the following section.

DISPLAY
show cpu
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
global

DESCRIPTION

You can use the cpu component to display the CPU cycles for the system. You can also specify the unit value in which the system displays statistics.

EXAMPLES

show cpu

Displays TMM processor statistics in the system default units.

show cpu raw

Displays raw TMM processor statistics.

SEE ALSO

show, tmsh

sys crypto acceleration-strategy

NAME

acceleration-strategy - Control crypto operations offloading on the BIG-IP(r) system (hybrid mode).

MODULE

sys crypto

SYNTAX

Configure offload strategy

LIST

list acceleration-strategy

DESCRIPTION

Display the configured setting.

EXAMPLES

list sys crypto acceleration-strategy

MODIFY

modify acceleration-strategy [fixed-ratio]

DESCRIPTION

Set the fixed-ratio policy setting as a value in the interval 0-1000. The value 1000 means that cryptographic operations will be processed by available hardware accelerator(s). A value 700 means that 70% of cryptographic operations will be processed by available hardware accelerator(s), while remaining 30% of operations will be processed on CPU.

Currently only the following operations are subject to this policy: ECDSA signing, RSA encrypt or verify, and ECDH.

EXAMPLES

modify sys crypto acceleration-strategy fixed-ratio 700

In the above example, 70% (700 out of 1000) of relevant cryptographic requests are processed by hardware accelerator(s), if available, while 30% (300 out of 1000) of relevant cryptographic requests will be sent to the CPU.

SHOW

show acceleration-strategy

DESCRIPTION

Display acceleration-strategy statistics.

EXAMPLES

show sys crypto acceleration-strategy

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys crypto allow-key-export

NAME

allow-key-export - Specifies whether or not to allow private key export.

LIST/MODIFY

list allow-key-export
modify allow-key-export

options:
value [enabled | disabled]

EXAMPLES

list sys crypto allow-key-export value

modify sys crypto allow-key-export value enabled

modify sys crypto allow-key-export value disabled

BIG-IP 2017-07-20 sys crypto allow-key-export(1)

sys crypto ca-bundle-manager

NAME

ca-bundle-manager - Certificate Authority (CA) certificate bundle manager on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

A ca-bundle-manager manages cryptographic ca-bundles using the syntax given in the following sections.

CREATE/MODIFY

```
create ca-bundle-manager [name]
modify ca-bundle-manager [name]
options:
  description [string]
  exclude_bundle
    [add | delete | replace-all-with] ] {
[cert file obj] ...
  }
  exclude_url
    [add | delete | replace-all-with] ] {
[url] ...
  }
  include_bundle
    [add | delete | replace-all-with] ] {
[cert file obj] ...
  }
  include_url
    [add | delete | replace-all-with] ] {
[url] ...
  }
  proxy-server [ [hostname] | [ipv4] | [ipv6] ]
  proxy-port [ port number ]
  trusted-ca-bundle [certificate file object]
  update-interval [days]
  time-out [seconds]
  update-now [yes | no]
```

LIST

```
list ca-bundle-manager [name]
options:
  -hidden
```

DELETE

```
delete ca-bundle-manager [name]
```

DESCRIPTION

You can use the ca-bundle-manager component to automatically update and install CA-bundles on the system from two sources - local certificate file objects and remote URL resources, using set include/exclude operations. The set include/exclude operations are equivalent to mathematical set addition/subtraction operations. For example, the user may use include-bundle and include-url options to combine CA-certificates from various sources, and use exclude-bundle and exclude-url options to remove certain CA-certificates from the final CA-bundle file. The generated CA-bundle file will be installed as a certificate-file-object on the system, and used as trusted CA-bundle by other modules. Additionally, the user may set the update frequency of the CA-bundle, or use web proxy for downloading the remote URL resources. By default, a newly created CA-bundle manager does not create or update the managed CA-bundle object unless it has a positive update interval or being explicitly told to do so by the update-now option. Additionally, the calculated CA-bundle must contain at least two CA certificates to be installed on the system.

EXAMPLES

```
modify sys crypto ca-bundle-manager bmgr include-bundle add { ca-bundle.crt } include-url add {
https://ca.f5net.com/ca-bundle.crt } trusted-ca-bundle trusted-ca-chain.crt update-interval 30
```

Creates a ca-bundle-manager bmgr from two sources, one is a locally installed certificate file object ca-bundle.crt, and the other is from remote URL resource <https://ca.f5net.com/ca-bundle.crt> using trusted CA bundle . bmgr is refreshed from the two sources every 30 days.

modify sys crypto ca-bundle-manager bmgr update-now yes

Extending from above example, this command triggers an immediate update of the generated ca-bundle from its sources.

list sys crypto ca-bundle-manager bmgr -hidden

Shows all the properties of the ca-bundle-manager bmgr, including the hidden fields.

delete sys crypto ca-bundle-manager bmgr

Deletes the ca-bundle-manager bmgr from the system. Note that the generated ca-bundle certificate file object is not removed, and can still be used.

OPTIONS

description

Specifies user defined description.

include-bundle

Specifies a list of certificate file objects to include for generating the new ca-bundle.

include-url

Specifies a list of remote ca-bundles at the URLs to include for generating the new ca-bundle.

exclude-bundle

Specifies a list of certificate file objects to exclude from the new ca-bundle.

exclude-url

Specifies a list of remote ca-bundles at the URLs to exclude from the new ca-bundle.

partition Displays the administrative partition within which this ca-bundle-manager resides.

proxy-server Specifies the host name or IP address of the proxy server for accessing remote URL resources.

Only HTTP proxy is supported. Optional http:// may be prepended.

proxy-port Specifies the port number of the proxy server for accessing remote URL resources. Default is 3128.

trusted-ca-bundle

Specifies the trusted CA certificate bundle when downloading ca-bundles from the other URLs.

update-interval

Specifies the update interval in days to refresh the remote ca-bundles at the URLs. Default value is 0, which means the generated ca-bundle is not dynamically updated.

time-out

Specifies the time-out period in seconds to download the remote ca-bundles at the URLs. The value ranges between 1 and 3600 (1 hour). The default value is 8 seconds.

update-now

Specifies whether the ca-bundle-manager should immediately refresh its generated ca-bundle from all its sources and recalculate its certificate contents. The default value is no.

updated-by

Specifies a read-only attribute from which this ca-bundle-manager was last updated.

managed-bundle

Specifies a read-only attribute, which indicates the ca-bundle certificate file object name, managed by this ca-bundle-manager.

SEE ALSO

sys crypto cert-order-manager

NAME

cert-order-manager - Certificate order manager on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

A cert-order-manager Manages the collection of Certificate Authority (CA) requirements for making certificate

orders using the syntax given in the following sections.

CREATE/MODIFY

create cert-order-manager [name]

modify cert-order-manager [name]

options:

app-service [[string] | none]
additional-headers [[string] | none]
authority [comodo | digicert | godaddy | symantec]
auto-renew [yes | no]
base-url [URL | none]
ca-cert [certificate file object]
client-cert [certificate file object | none]
client-key [certificate key file object | none]
client-key-passphrase [[string] | none]
edit-order-info
internal-proxy [internal proxy object]
login-name [[string] | none]
login-password [[string] | none]
order-info [string]
validity-days [days | none]

LIST

list cert-order-manager [name]

DELETE

delete cert-order-manager [name]

DESCRIPTION

cert-order-manager A component holds the Certificate Authority's (CA) specific requirements for making certificate orders. The user needs to select a CA from the supported list, configure the necessary authentication information, and order the information specific to the selected CA.

EXAMPLES

```
create sys crypto cert-order-manager certmgr authority comodo login-name cert-admin@myorg.com login-password
default ca-cert ca-bundle.crt internal-proxy iproxy-caapi additional-headers "customerUri:myorg-auto-poc"
order-info "{ orgId 5678 serverType -1 certType 136 }"
```

Creates a certificate order manager certmgr for certificate authority comodo. For CA account login authentication username cert-admin@myorg.com and password default is used. ca-bundle.crt is used for authenticating a TLS connection to a CA server and validating the certificate issued by the CA. customerUri:myorg-auto-poc provides customer Uri issued by comodo for the certificate requesting organization. In order info { orgId 5678 serverType -1 certType 136 } organization identity orgId 5678 is provided by comodo, and certType 136 is the certificate product type offered by comodo for the organization.

```
list sys crypto cert-order-manager certmgr
```

Shows all the properties of the cert-order-manager certmgr.

```
delete sys crypto cert-order-manager certmgr
```

Deletes the cert-order-manager certmgr from the system.

OPTIONS

additional-headers

Specifies additional headers required for the certificate authority with expected format "key:value,...". For example: (comodo) "customerUri:mycomp-auto-poc"

authority

Specifies a certificate authority.

auto-renew

Enable/Disable the certificate automatic renewals. By default, the automatic certificate renewal is enabled.

base-url

Specifies the base-url for reaching the CA. This is an optional field which gets populated with default values for a specific certificate authority.

ca-cert

Specifies the CA certificate to be used for authenticating the TLS connection with the CA server. ca-cert is also used for validating an issued certificate from CA before accepting into the system.

client-cert

Specifies the client authentication certificate used for accessing the CA account. This is a required field for certain CA accounts.

client-key

Specifies the client authentication key used for accessing the CA account. This is a required field for certain CA accounts.

client-key-passphrase

Specifies the optional key passphrase required for decrypting the client-key.

edit-order-info

Provides an editor for creating and modifying the order-info configuration. This should be the last property since selecting save and exit from the editor automatically submits the configuration.

internal-proxy

Specifies the internal proxy object that should be used for reaching the CA server.

login-name

Specifies the login name for accessing the CA account. This is a required field for certain CA accounts.

login-password

Specifies the login password for accessing the CA account. This is a required field for certain CA accounts.

order-info

Specifies a string containing necessary information for making certificate orders with CA. Format and fields of order-info varies with the CA.

validity-days

Specifies certificate validity in days. The default value is 365 days.

sys crypto cert-validation-response ocs

NAME

ocsp - Manages the OCSF response of a certificate when it has OCSF validation enabled.

MODULE

sys crypto cert-validation-response

SYNTAX

Use the ocsf component within the sys.crypto.cert-validation-response module to manage the cached OCSF response of a given certificate.

DELETE

delete ocsf

options:

certificate [name]

DESCRIPTION

You can use the ocsf component to delete the cached OCSF response of a given certificate. The response is automatically re-fetched, and the certificate status is updated subsequently.

OPTIONS

certificate

Specifies the name of the certificate whose OCSF response you want to delete.

SEE ALSO

delete, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys crypto cert-validator crl

NAME

crl - Configures a CRL cert-validator.

MODULE

sys crypto cert-validator

SYNTAX

Configure the `crl` component using the syntax shown in the following sections.

CREATE/MODIFY

`create crl [name]`

`modify crl [name]`

options:

`internal-proxy [none | [string]]`

`strict-revocation-check [disabled | enabled]`

`reset-stats crl [name]`

DISPLAY

`list crl [name]`

`show crl [name]`

DELETE

`delete server-ssl [all | [name]]`

options:

`recursive`

DESCRIPTION

You can use the `crl` component to create, modify, display or delete a custom CRL cert-validator.

EXAMPLES

`create cert-validator crl my_crl internal-proxy my_intp`

Creates a CRL cert-validator named `my_crl` using the internal proxy named `my_intp`.

OPTIONS

`internal-proxy`

Specifies the internal proxy to define the route for reaching CRL distribution points to fetch CRL files.

`strict-revocation-check`

If enabled, the certificate status won't be checked until the CRL fetching and caching is complete. If disabled, the certificate status will be immediately considered as unknown if the CRL fetching and caching is not complete yet. The default value is disabled.

SEE ALSO

`sys crypto cert-validator ocsp`, `sys internal-proxy`

BIG-IP 2017-12-11 `sys crypto cert-validator crl(1)`

sys crypto cert-validator ocsp

NAME

`ocsp` - Configuration of the OCSP cert-validator.

MODULE

`sys crypto`

SYNTAX

Configure the `ocsp` component within the `sys.crypto.cert-validator.ocsp` module using the syntax shown in the following sections. This object is associated with a certificate object to enable an OCSP request for updating the certificate status.

CREATE/MODIFY

`create ocsp [name]`

`modify ocsp [name]`

options:

`cache-error-timeout [integer]`

`cache-timeout [indefinite | [integer]]`

`concurrent-connections-limit [integer]`

`clock-skew [integer]`

`description [string]`

`dns-resolver [name]`

`proxy-server-pool [name]`

DISPLAY

list ocsf [name]

DELETE

delete [all | [name]]
options:
recursive

DESCRIPTION

You can use the ocsf component to create, modify, display or delete a custom OCSF cert-validator.

The OCSF cert-validator is associated with a certificate object.

EXAMPLES

create cert-validator my_ocsf dns-resolver name

Creates an OCSF cert-validator named my_ocsf using the DNS resolver specified by name.

OPTIONS

cache-error-timeout

Specifies the lifetime of an error response in the cache, in seconds. The default value is 3600 seconds.

cache-timeout

Specifies the lifetime of the OCSF response in the cache, in seconds. The actual time period for which the response is cached is the minimum of the response validity period and the cache-timeout. The default value is indefinite, indicating that the response validity period takes precedence.

concurrent-connections-limit

Specifies the maximum number of connections per second allowed for the OCSF cert-validator.

clock-skew

Specifies the tolerable absolute difference in the clocks of the responder and the BIG-IP, in seconds. The default value is 300.

description

User defined description.

dns-resolver

Specifies the DNS resolver object used for fetching the OCSF response.

partition

Displays the administrative partition within which this validator resides.

proxy-server-pool

Specifies the proxy server pool used for fetching the OCSF response.

responder-url

Specifies the absolute URL that overrides the OCSF responder URL obtained from the certificate's AIA extension(s). This should be an HTTP-based URL.

route-domain

Specifies the route domain for fetching an OCSF response using HTTP forward proxy.

sign-hash

Specifies the hash algorithm used for signing the OCSF request. The default value is sha256.

signer-cert

Specifies the certificate corresponding to the key used for signing the OCSF request.

signer-key

Specifies the key used for signing the OCSF request.

signer-key-passphrase

Specifies the passphrase of the key used for signing the OCSF request.

status-age

Specifies the maximum allowed lag time for the 'thisUpdate' time in the OCSF response that the BIG-IP accepts. If this maximum is exceeded, the response is dropped. If this value is set to 0, this validation is skipped. The default value is 86400 seconds.

strict-resp-cert-check

If enabled, the responder's certificate is checked for an OCSF signing extension. The default value is disabled.

timeout

Specifies the time interval (in seconds) that the BIG-IP waits for before ending the connection to the OCSF responder. The default value is 8.

trusted-responders

Specifies the certificates used for validating the OSCP response when the responder's certificate has been omitted from the response.

BIG-IP 2017-01-20 sys crypto cert-validator ocspl(1)

sys crypto cert

NAME

cert - Manage cryptographic certificates on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Manage cryptographic certs using the syntax in the following section.

CREATE

```
create cert [name]
options:
  city [string]
  common-name [string]
  consumer
    [enterprise-manager | iquery | iquery-big3d | itm | webserver]
  country [string]
  email-address [string]
  key [string]
  lifetime [days]
  organization [string]
  ou [string]
  state [string]
  subject-alternative-name [string]
```

INSTALL

```
install cert [name]
options:
  cert-validation-options [none | ocspl]
  cert-validators [none | [cert_validator_name]]
  consumer
    [enterprise-manager | iquery | iquery-big3d | itm | webserver]
  from-editor
  from-local-file [filename]
  from-url [URL]
  issuer-cert [none | [issuer_cert_name]]
  no-overwrite
```

MODIFY

```
modify cert [name]
options:
  cert-validation-options [none | ocspl]
  cert-validators [none | [cert_validator_name]]
  issuer-cert [none | [issuer_cert_name]]
```

DELETE

```
delete cert [name]
```

DESCRIPTION

You can use the cert component to create, install, and delete cryptographic certificates, and bundles.

EXAMPLES

```
create cert example key testkey.key common-name "My Company Inc." country "US"
```

Generates a self signed certificate named "example.crt". A key with the specified name "testkey.key" in this case must be installed on the system in order for this operation to succeed. The cert extension (".crt") will be appended to the created cert name if it is not already provided in the name.

```
create cert /myfolder/example key testkey.key common-name "My Company Inc." country "US"
```

Similar to above, but creates the cert "example.crt" in the folder "/myfolder" instead of the default "/Common". The specified folder "/myfolder" must already exist in order for this operation to succeed.

create cert server2 key server2.key common-name "My Company Inc." country "US" consumer webserver

Generates a self-signed certificate named server2.crt. The consumer attribute, "webserver", is used to cause the files to be placed directly in the path which can be found by the BIG-IP system httpd. A pre-existing key named "server2.key" must exist in the web server's key path in order for this operation to succeed. Please note that for non LTM consumer's key and cert names must be the same.

install cert example from-editor

Opens an interactive editor session into which can be pasted a certificate for import into the BIG-IP system. A certificate file-object will be created with the name example which contains the contents saved from the editor session.

install cert example from-local-file /tmp/example.crt

Obtains a certificate from the file located at /tmp/example.crt.

install cert example from-url http://example.com/example.crt

Obtains a certificate from a remote host, based on the URI specified.

modify sys crypto cert leaf.crt issuer-cert issuer.crt cert-validators add { my_ocsp1 } cert-validation-options { ocsp }

Assigns issuer certificate issuer.crt to the certificate leaf.crt, associates the OCSP certificate validator my_ocsp to the certificate, and enables the OCSP certificate validator for this certificate.

delete cert example.crt

Deletes the certificate "example.crt" from the system.

OPTIONS

cert-validation-options

Specifies the option used for validating the certificate status.

cert-validators

Specifies the name of the cert-validators used for validating the certificate status. Each cert-validation type can only have one cert-validator.

city Specifies the x509 city field to be used in creation of the certificate.

common-name

Specifies the x509 common-name to be used in creation of the certificate.

consumer

Specifies the system component by which a certificate will be consumed. The default behavior is to create file-objects for use by ltm components. This is the same as specifying "ltm" for this property. If a component other than "ltm" is specified then files will be installed/created in locations where the specified components can find them. For example, for component "webserver", certificates will be placed in the webserver's ssl directories.

country

Specifies the x509 country to be used in creation of the certificate. The country must be a 2 letter country code.

email-address

Specifies the x509 email-address to be used in creation of the certificate.

fingerprint

Displays the SHA-256 fingerprint of the certificate.

from-editor

Specifies that the certificate should be obtained from a text editor session. This allows certificates to be imported via cut-n-paste from another location as long as they are in a text representation.

from-local-file

Specifies a local file path from which a certificate is to be copied.

from-url

Specifies a URI which is to be used to obtain a certificate for import into the system.

The URL syntax is protocol dependent. Supported schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE."

issuer-cert

Specifies the name of the issuer certificate for this certificate.

no-overwrite

Specifies option of not overwriting a certificate if it is in the scope.

key Specifies a key from which a certificate should be generated when using the create command.

organization

Specifies the x509 organization to be used in creation of the certificate.

ou Specifies the x509 organizational unit to be used in creation of the certificate.

state
Specifies the x509 state or province of the certificate.

subject-alternative-name
Specifies standard X.509 extensions as shown in RFC 2459. Allowed values e.g. DNS:example.com, IP:192.168.1.1, IP:12:34, email:user@example.com, URI:http://www.example.com

BIG-IP **2017-05-01** **sys crypto cert(1)**

sys crypto check-cert

NAME
check-cert - Examines certificates and displays or logs any that have expired on the BIG-IP(r) system.

MODULE
sys crypto

SYNTAX
Run a check on the expiration date of LTM certificates, in the sys crypto module by using the syntax below.

RUN
run check-cert [certificate-file-name]
options:
 ignore-large-cert-bundles [enabled | disabled]
 log [enabled | disabled]
 stdout [enabled | disabled]
 verbose [enabled | disabled]

DESCRIPTION
You can use the check-cert command to check the expiration date of certificate(s) and print the results to the screen and/or log them to /var/log/ltn.

OPTIONS
ignore-large-cert-bundles
Specifies whether or not to ignore large certificate bundles which contain more than 20 certificates. By default it will not be ignored, i.e., it will still check every certificate bundle if this option is not specified.

log Specifies whether results should be logged or not. By default they will be logged.

stdout
Specifies whether results should be printed to STDOUT or not. By default they will be printed.

verbose
Specifies whether verbose output should be emitted or not, such as information about all certificates being checked rather than just those which return unfavorable results. By default verbose output is disabled.

EXAMPLES
run check-cert

Checks all certificate file-objects known by MCPD, and displays information about any certificates which have expired or which are close to expiration. By default this information is printed to the screen and logged to /var/log/ltn.

run check-cert default.crt

Runs the check on the specific certificate "default.crt"

run check-cert verbose

Displays expiration information about all certificates, not just those that have expired or have impending expirations.

run check-cert ignore-large-cert-bundles enabled

Ignore the certificate bundles with large size (the ones containing more than 20 certificates).

run check-cert log disabled

Prints the results to screen but does not log them.

run check-cert stdout disabled

Logs the results to /var/log/ltm, but does not print them to the screen.

sys crypto client

NAME

client - Manage remote crypto clients.

MODULE

sys crypto

SYNTAX

Manage crypto clients using the syntax in the following section.

CREATE/MODIFY

create client [name]

modify client [name]

options:

addr [ip address]

connection-reset

[disabled | enabled]

heartbeat [integer]

max-retries [integer | infinite]

port [integer]

profiles [add | delete | replace-all-with] { [profile_name ...] }

profiles [none]

req-timeout [integer]

retry-interval [integer]

DISPLAY

list client

list client [[[name] | [globl] | [regex]] ...]

show client

show client [[[name] | [globl] | [regex]] ...]

DELETE

delete client [name]

DESCRIPTION

You can use the client component to manage remote crypto clients.

EXAMPLES

create client example addr 10.1.1.1 port 12100 profiles add { serverssl tcp }

Creates a remote crypto client named "example" that will use a remote crypto server with the IP address "10.1.1.1" on port "12100". The remote crypto client will use SSL over a TCP connection to communicate with the remote crypto server.

OPTIONS

addr Specifies the IP address of the remote crypto server.

connection-reset

Resets the connection to the remote crypto server.

(enabled | disabled)

Specifies the state of the remote crypto client. The default value is enabled.

heartbeat

Specifies the number of seconds to wait before sending a heartbeat request. A value of 0 disables the sending of heartbeat requests. The default value is 30 seconds.

max-retries

Specifies the maximum number of times to retry connecting to the remote crypto server.

If the maximum retries value is infinite, the crypto client retries connecting until a connection is made.

The default value is infinite.

port Specifies the port used by the remote crypto server.

profiles
Specifies a list of profiles that the remote crypto client will use to communicate with remote the remote crypto server.

req-timeout
Specifies the timeout in milliseconds for crypto requests to complete. The default value is 5000 milliseconds.

retry-interval
Specifies the interval in seconds between attempts to connect to the remote crypto server. The default value is 10 seconds.

SEE ALSO

BIG-IP 2015-01-16 sys crypto client(1)

sys crypto crl

NAME

crl - Manage certificate revocation lists on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Manage crls using the syntax in the following section.

INSTALL

```
install crl [name]
options:
  ca-file [filename]
  consumer
    [enterprise-manager | iquery | iquery-big3d | ltm | webserver]
  from-editor
  from-local-file [filename]
  from-url [URL]
```

DELETE

```
delete crl [name]
```

DESCRIPTION

You can use the crl component to install, and delete certificate revocation lists. The file-objects created by these operations can be used in other BIG-IP system configuration blocks such as ssl profiles.

EXAMPLES

```
install crl example from-editor
```

Opens an interactive editor session into which can be pasted a crl for import into the BIG-IP system. A crl file-object will be created with the name example which contains the contents saved from the editor session.

```
install crl example from-local-file /tmp/example.crl
```

Obtains a crl from the file located at /tmp/example.crl and installs it as example.crl. The crl extension (".crl") will be appended to the installed crl name if it is not already provided in the name.

```
install crl /myfolder/myexample from-local-file /tmp/example.crl
```

Similar to above, but installs the crl "myexample.crl" in folder "/myfolder" instead of the default "/Common". The specified folder "/myfolder" must already exist in order for this operation to succeed.

```
install crl example from-url http://example.com/example.crl
```

Obtains a crl from a remote host, based on the URI specified.

delete crl example.crl

Deletes the certificate revocation list "example.crl" from the system.

OPTIONS

consumer

Specifies the system component by which the certificate revocation list will be consumed. The default behavior is to create file-objects for use by Itm components. This is the same as specifying "Itm" for this property. If a component other than "Itm" is specified then files will be installed/created into locations where the specified components can find them. For example, for component "webserver", crls will be placed in the webserver's ssl directories.

from-editor

Specifies that the crl should be obtained from a text editor session. This allows crls to be imported via cut-n-paste from another location as long as they are in a text representation.

from-local-file

Specifies a local file path from which the crl is to be copied.

from-url

Specifies a URI which is to be used to obtain the crl for import into the configuration of the system.

The URL syntax is protocol dependent. Supported schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE."

SEE ALSO

BIG-IP **2013-03-21** **sys crypto crl(1)**

sys crypto csr

NAME

csr - Manage cryptographic certificate signing requests on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Manage cryptographic CSRs using the syntax in the following section.

CREATE

create csr [name]

options:

challenge-password [string]

admin-email-address [string]

city [string]

common-name [string]

consumer

[enterprise-manager | iquery | iquery-big3d | Itm | webserver]

country [string]

email-address [string]

key [string]

organization [string]

ou [string]

state [string]

subject-alternative-name [string]

SHOW

show csr

LIST

list csr [name]

DELETE

delete csr [name]

DESCRIPTION

You can use the csr component to create, show, list and delete cryptographic certificate signing requests.

EXAMPLES

create csr example key testkey.key common-name "My Company Inc." country "US" challenge-password "abcd"

Generates a certificate signing request named "example.csr" with provided common-name, country and challenge-password attributes. A key with the specified name "testkey.key" in this case must be installed on the system in order for this operation to succeed. The csr extension (".csr") will be appended to the created csr name if it is not already provided in the name.

create csr /myfolder/example key testkey.key common-name "My Company Inc." country "US" challenge-password "abcd"

Similar to above, but creates the csr "example.csr" in the folder "/myfolder" instead of the default "/Common". The specified folder "/myfolder" must already exist in order for this operation to succeed.

create csr server2 key server2.key common-name "My Company Inc." country "US" consumer webserver

Generates a certificate signing request named "server2.csr". The consumer attribute, "webserver", is used to cause the files to be placed directly in the path which can be found by the BIG-IP system httpd. A pre-existing key named "server2.key" must exist in the web server's key path in order for this operation to succeed.

show csr

Shows the number of certificate signing requests installed in the system.

list csr example.csr

Lists all details of the certificate signing request "example.csr". A csr with the specified name "example.csr" in this case must already be installed on the system in order for this operation to succeed. Because only one certificate signing request name is specified in the list command, it will also display the contents of the certificate signing request file.

list csr example1.csr example2.csr

Lists all details of the certificate signing requests "example1.csr" and "example2.csr". Because more than one certificate signing request name is specified in the list command, it will not display the contents of the certificate signing request files.

list csr

Lists details of all certificate signing requests that are configured in the system. This command does not display the contents of the certificate signing request files.

delete csr example.csr

Deletes the certificate signing request "example.csr" from the system.

OPTIONS

challenge-password

Specifies the PKCS#9 challenge-password field to be used in creation of the certificate signing request.

admin-email-address

Specifies the administrator email-address to be used in creation of the certificate signing request.

city Specifies the x509 city field to be used in creation of the certificate signing request.

common-name

Specifies the x509 common-name to be used in creation of the certificate signing request.

consumer

Specifies the system component by which a certificate signing request will be consumed. The default behavior is to create file-objects for use by Itm components. This is the same as specifying "Itm" for this property. If a component other than "Itm" is specified then files will be installed/created in locations where the specified components can find them. For example, for component "webserver", certificate signing requests will be placed in the webserver's ssl directories.

country

Specifies the x509 country to be used in creation of the certificate signing request. The country must be a 2 letter country code.

email-address

Specifies the x509 email-address to be used in creation of the certificate signing request.

key Specifies a key from which a certificate signing request should be generated when using the create command.

organization

Specifies the x509 organization to be used in creation of the certificate signing request.

ou Specifies the x509 organizational unit to be used in creation of the certificate signing request.

state

Specifies the x509 state or province to be used in creation of the certificate signing request.

subject-alternative-name

Specifies standard X.509 subject alternative extensions as shown in RFC 2459 to be used in creation of the certificate signing request. Examples of allowed types are : DNS:example.com, IP:192.168.1.1, IP:12:34, email:user@example.com, URI:http://www.example.com

sys crypto encrypted-attributes

NAME

encrypted-attributes - Displays all objects in the MCP binary database that contain items encrypted with the master key for the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Display a list of objects with attributes encrypted with the master-key in the binary database using the syntax in the following section.

DISPLAY

show encrypted-attributes
options:
field-fmt

DESCRIPTION

You can use the encrypted-attributes command to help diagnose master-key problems in the BIG-IP(r) system. Only users with the Administrator role or the Resource Administrator role can view the list of objects with encrypted attributes.

EXAMPLES

show encrypted-attributes

Displays, in a table, information about the system's objects with encrypted-attributes including type, object name, attribute name, and whether or not the encrypted value in the binary database can be decrypted with the current master-key.

show master-key field-fmt

Displays, in field format, information about the system's objects with encrypted-attributes.

OPTIONS

For information about the options that you can use with the command show, see help show.

sys crypto fips external-hsm

NAME

external-hsm - Configures parameters for external HSM FIPS hardware.

MODULE

sys crypto fips

DESCRIPTION

You can use the external-hsm command to set parameters about the HSM vendor name and the password to login to the external HSM hardware.

SYNTAX

Configures FIPS external-hsm within the sys crypto fips module using the syntax in the following section.

CREATE

create external-hsm

modify external-hsm vendor [thales | safenet | auto | none]

modify external-hsm password [password]

modify external-hsm pkcs11-lib-path [path to pkcs#11 library provided by the vendor]

modify external-hsm num-threads [no. of threads]

DISPLAY

sys crypto fips key

NAME

key - Manage FIPS keys

MODULE

sys crypto fips

SYNTAX

Manage cryptographic keys within the sys crypto fips module using the syntax in the following section.

SHOW

show key [key ID]

options:

field-fmt

all-properties

include-public-keys

DELETE

delete key [key ID]

DESCRIPTION

You can use the key component to show and delete cryptographic keys contained in the FIPS hardware.

EXAMPLES

show key

Displays the list of all private keys stored in the FIPS hardware and their meta-data.

show key bef8221fd25a27cda51b3904bc2f5fb8

Displays information specifically about the FIPS key with the key ID "bef8221fd25a27cda51b3904bc2f5fb8".

show key field-fmt

Displays, in field format, information about private keys stored in the FIPS hardware.

show key all-properties

Displays all information about the FIPS contained private keys, including: handle, a numerical value used by the FIPS hardware to identify individual keys; modulus-length, the cryptographic modulus length of the key; and modulus, the modulus associated with the key, displayed as a string of hex octets separated by colons.

show key include-public-keys

Displays the list of all private and public keys stored in the FIPS hardware and their meta-data. Note that public keys are not displayed by default and need not exist for normal operation of FIPS hardware.

delete key bef8221fd25a27cda51b3904bc2f5fb8

Deletes the FIPS key with the key ID "bef8221fd25a27cda51b3904bc2f5fb8" from the system.

OPTIONS

include-public-keys

Specifies that public keys should be selected for output in addition to private.

For information about the options that you can use with the command show, see help show.

DELETE

delete key [name]

DESCRIPTION

You can use the key component to create, show, list, install, and delete cryptographic keys and associated cryptographic objects. The file-objects created by these operations can be used in other BigIP configuration blocks such as ssl profiles.

EXAMPLES

create key mykey

Generates a 2048-bit (default-sized) RSA key file object named "mykey.key". The appropriate extension will be added to the generated key/cert if not already a part of the provided name.

create key mykey key-type ec-private curve-name prime256v1

Generates a prime256v1 curve name EC private key file object named "mykey.key". The appropriate extension will be added to the generated key/cert if it is not already a part of the provided name.

create key /myfolder/mykey

Similar to the above action except it creates the key "mykey.key" in the folder "/myfolder" instead of the default "/Common". The specified folder "/myfolder" must already exist in order for this operation to succeed.

create key example gen-cert gen-csr common-name "My Company Inc." country "US"

Generates a 2048-bit (default-sized) RSA key file object named "example.key" and a self signed certificate named "example.crt". Also, a certificate signing request will be printed to the console for use in obtaining a signed certificate from a certificate authority, if desired.

create key my gen-cert gen-csr prompt-for-password common-name "My Company Inc." country "US"

Similar to the above action when creating key "my.key" except it also prompts for a password to be used as a challenge password in the certificate authority signing procedure.

create key server2 gen-cert gen-csr common-name "My Company Inc." country "US" consumer webserver

Generates a key and self signed certificate identified by server2. The consumer attribute, "webserver", is used to cause these files to be placed directly in the paths which can be found by the BigIP's httpd.

create key server gen-csr common-name "My Company Inc." country "US" cert-order-manager add { certmgr { order-type new } }

Generates a key and CSR identified by server. Associates cert-order-manager object "certmgr" with the key and

makes a "new" certificate order to the CA.

show key

Shows the number of keys installed in the system.

show key cert-order-manager

Shows certificate order statistics if a cert-order-manager object is associated with key.

list key example.key

Lists all details of the key named "example.key". A key with the specified name "example.key" in this case must already be installed on the system in order for this operation to succeed.

list key

Lists all details of all keys installed in the system.

install key example from-editor

Opens an interactive editor session into which it a key for import into the BIGIP system can be pasted. A key file-object will be created with the name example which contains the contents saved from the editor session.

install key example from-local-file /tmp/example.key

Obtains a key from the file located at /tmp/example.key.

install key example from-url http://example.com/my.key

Obtains a key from a remote host that is based on the URI specified.

delete key example.key

Deletes the key "example.key" from the system.

OPTIONS

challenge-password

Specifies the challenge password to create the certificate request key.

admin-email-address

Specifies the administrator email-address to be used in creation of the certificate request associated with the given key.

city Specifies the x509 city field to be used in creation of the certificate associated with the given key.

common-name

Specifies the x509 common-name to be used in creation of the certificate associated with the given key.

consumer

Specifies the system component by which a key and/or associated cryptographic file will be consumed. The default behavior is to create file-objects for use by Itm components. This is the same as specifying "Itm" for this property. If a component other than "Itm" is specified then files will be installed/created into locations where the specified components can find them. For example, for component "webserver", keys and certs will be placed in the webserver's ssl directories.

country

Specifies the x509 country to be used in creation of the certificate associated with the given key. The country must be a 2 letter country code.

curve-name

Specifies the curve name to be used in creation of the elliptic curve (EC) key. This option only applies when generating EC keys. The default value is prime256v1.

email-address

Specifies the x509 email-address to be used in creation of the certificate associated with the given key.

from-editor

Specifies that the key should be obtained from a text editor session. This allows keys to be imported via cut-n-paste from another location as long as they are in a text representation.

from-local-file

Specifies a local file path from which a key is to be copied.

from-url

Specifies a URI which is to be used to obtain a key for import into the configuration of the system.

The URL syntax is protocol dependent. Supported schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE."

from-nethsm

Specifies an option to import an existing key from network-HSM to BIG-IP config. The key label is specified as the key name to identify the key to be imported from network-HSM.

no-overwrite

Specifies the option for not overwriting a key if it is in the scope.

gen-certificate

Specifies that in addition to generating a key, a self-signed certificate will also be created. If this option is specified then x509 attributes should also be specified. Minimally, you must also specify a common-name.

gen-csr

Specifies that a certificate signing request should be generated along with the key. The CSR will be displayed to the terminal for the purposes of use in getting a certificate signed by an outside authority. X509 attributes must also be specified.

key-size

Specifies the size, in bits, of the key to be generated. This option does not apply when generating EC keys.

key-type

Specifies the type of cryptographic key to be generated. Default is rsa-private.

lifetime

Specifies the certificate life time to be used in creation of the certificate associated with the given key.

organization

Specifies the x509 organization to be used in creation of the certificate associated with the given key.

ou Specifies the x509 organizational unit to be used in creation of the certificate associated with the given key.

prompt-for-password

Specifies that a password should be prompted for and then used as a challenge password in generation of the CSR (Certificate Signing Request).

security-type

Specifies the level of security used in storing the key in question. For example, a security-type of FIPS means that the key should be stored on a FIPS card if one is available.

state

Specifies the x509 state or province of the certificate associated with the given key.

passphrase

Specifies an optional passphrase with which the key has been protected. It may be used by consumers of the key in the data-plane or control-plane to decrypt it.

subject-alternative-name

Specifies standard X.509 extensions as shown in RFC 2459. Allowed values e.g. DNS:example.com, IP:192.168.1.1, IP:12:34, email:user@example.com, URI:http://www.example.com

cert-order-manager

Specifies an optional cert-order-manager to be associated with the key.

check-status

Specifies that it checks the status of a certificate order. This command triggers an immediate status check query with CA for a current pending certificate order.

order-id

Specifies the order id for a certificate order. This order id is provided by the CA and the bigip stores it in the order-id field. Order id is required for certificate renewal and revoke. If the first certificate was not originally ordered from the bigip, the user needs to enter the order-id manually before making a certificate renewal or revoke.

order-passphrase

Specifies the order challenge passphrase. This is a CA specific requirement. Some CA's require a challenge passphrase for making a certificate order.

order-type

Specifies the type of certificate order to authority.

new : Make a new certificate order to the CA.

renew : Make a certificate renewal order to the CA.

revoke : Make a certificate revoke order to the CA.

cancel : Tries to cancel the previous certificate order.

revoke-reason

Specifies the reason for certificate revoke.

sys crypto master-key

NAME

master-key - Displays the configuration of the master key for the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Display the configuration of the master-key component within the sys crypto module using the syntax in the following section.

DISPLAY

show master-key

options:

field-fmt

MODIFY

modify master-key

options:

prompt-for-password

RUN

run master-key diagnostic

DESCRIPTION

You can use the master-key command to manipulate the system master key. Users with the Administrator role or the Certificate Manager role can set the key to a value of their choosing by using the 'prompt-for-password' option during a modify operation. All other roles, including Resource Administrators, are prohibited from setting the master key.

Use the 'diagnostic' option of the run command to test the key integrity.

EXAMPLES

show master-key

Displays, in a table, information about the system's master key.

show master-key field-fmt

Displays, in field format, information about the system's master key.

run master-key diagnostic

Loads the device key. Uses the device key to decrypt the master key file to test the integrity of the keys. On success, there is no output. There will be a response only if there is an error.

modify master-key prompt-for-password

Create a master-key based on a word or phrase of your choosing. You can use this to manually synchronize several devices without having to copy keys between them.

OPTIONS

For information about the options that you can use with the command show, see help show.

BIG-IP 2016-03-14 sys crypto master-key(1)

sys crypto pkcs12

NAME

pkcs12 - Install pkcs12 keys and certificates on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Install keys and certificates from pkcs12 files using the syntax in the following section.

INSTALL

install pkcs12 [name]

options:

consumer

[enterprise-manager | iquery | iquery-big3d | itm | webserver]

from-local-file [filename]

from-url [URL]

key-passphrase

key-security-type

[fips | password | normal]

passphrase [passphrase]

no-overwrite

DESCRIPTION

You can use the pkcs12 component to install cryptographic keys and certificates from pkcs12 formatted files. The file-objects created by these operations can be used in other BigIP configuration blocks such as ssl profiles.

EXAMPLES

install pkcs12 example from-local-file /tmp/example.p12

Obtains a pkcs12 from the file located at /tmp/example.p12, and installs the key and certificate from that file as file-objects named "example.key" and "example.crt" respectively.

install pkcs12 /myfolder/example from-local-file /tmp/example.p12

Similar to above, but installs the key "example.key" and cert "example.crt" in folder "/myfolder" instead of the default "/Common". The specified folder "/myfolder" must already exist in order for this operation to succeed.

install pkcs12 example prompt-for-password from-local-file /tmp/example.p12

Same as above but also prompts for a password which is to be used to decrypt the pkcs12 file.

install pkcs12 my from-url http://example.com/my.p12

Obtains a pkcs12 file from a remote host, based on the URL specified.

install pkcs12 server consumer webserver from-local-file /tmp/example.p12

Obtains a pkcs12 file from /tmp/example.p12 and installs the key and certificate from that file as file-objects that can be used by the "webserver". The consumer attribute, "webserver", is used to cause these files to be placed directly in the paths which can be found by the BigIP's httpd.

OPTIONS

consumer

Specifies the system component by which a key and associated certificate from a PKCS12 file will be consumed. The default behavior is to create file-objects for use by Itm components. This is the same as specifying "Itm" for this property. If a component other than "Itm" is specified then files will be installed/created into locations where the specified components can find them. For example, for component "webserver", keys and certs will be placed in the webserver's ssl directories.

from-local-file

Specifies a local file path from which the contents of the PKCS12 are to be read.

from-url

Specifies a URI which is to be used to obtain a PKCS12 for import into the configuration of the system.

The URL syntax is protocol dependent. Supported schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE."

key-passphrase

Specifies the passphrase to be used to encrypt the key.

key-security-type

Specifies the security type of the key. Default is set to "normal".

passphrase

Specifies the passphrase to be used to decrypt the PKCS12 file.

no-overwrite

Specifies option of not overwriting key/certificate if they are in the scope.

SEE ALSO

install, tmsh

sys crypto server

NAME

server - Manage remote crypto servers.

MODULE

sys crypto

SYNTAX

Manage crypto servers using the syntax in the following section.

CREATE/MODIFY

create server [name]

modify server [name]

options:

addr [ip address]

clients [add | delete | replace-all-with] { [ip_addr/prefixlen ...] }

clients [none]

[disabled | enabled]

port [integer]

profiles [add | delete | replace-all-with] { [profile_name ...] }

profiles [none]

DISPLAY

list server

list server [[name] | [globl] | [regex]] ...]

show server

show server [[name] | [globl] | [regex]] ...]

DELETE

delete server [name]

DESCRIPTION

You can use the server component to manage remote crypto servers.

EXAMPLES

create server example addr 10.1.1.1 port 12100 profiles add { clientssl tcp }

Creates a remote crypto server named "example" that will listen for remote crypto clients on IP address "10.1.1.1" and port "12100". The remote crypto server will use SSL over a TCP connection to communicate with remote crypto clients.

OPTIONS

addr Specifies the IP address of the remote crypto server.

clients

Specifies a list of allowed client IP addresses and subnets. An empty list allows all clients.

(enabled | disabled)

Specifies the state of the remote crypto server. The default value is enabled.

port Specifies the port used by the remote crypto server.

profiles

Specifies a list of profiles that the remote crypto server will use to communicate with remote crypto clients.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

sys daemon-ha

NAME

daemon-ha - Configures high availability for a BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the daemon-ha component within the sys module using the syntax in the following sections.

MODIFY

modify daemon-ha [name]

options:

heartbeat [enabled | disabled]

heartbeat-action [go-offline | go-offline-downlinks-restart |

go-offline-restart | reboot | restart | restart-all]

running [enabled | disabled]

edit daemon-ha [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list daemon-ha

list daemon-ha [[[name] | [glob] | [regex]] ...]

show running-config daemon-ha

show running-config daemon-ha [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

not-running-action

one-line

running-timeout

DESCRIPTION

You can use the daemon-ha component to configure the daemons on the system that handle high availability for the BIG-IP system.

EXAMPLES

modify daemon-ha bigd running disabled

Disables the bigd daemon.

list daemon-ha bigd running-timeout

Displays the running timeout of the bigd daemon.

OPTIONS

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

heartbeat

Specifies whether heartbeat monitoring is enabled for the specified daemon. If monitoring is enabled and the daemon does not maintain its heartbeat the action specified by the value of the heartbeat-action option is taken.

The default value is enabled for all daemons, except the named daemon, which is disabled by default.

heartbeat-action

Specifies the action the system takes if the specified daemon does not maintain its heartbeat.

The default value is dependent on the specified daemon, the most common default value is restart.

name Specifies a unique name for the component. This option is required for the command modify.

not-running-action

Specifies the action that the system takes if the daemon is not running. This option is read-only.

The default value is dependent on the specified daemon, the most common default value is go-offline-downlinks.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

running

Specifies whether the running-timeout and non-running-action options are enabled. The default value is dependent on the specified daemon, the most common default value is enabled.

Note: This feature is implemented only for the daemons: tmm, mcpd, bcm56xxd, bigd, gtmd, clusterd, tmrouted, bd, datasyncd and tmrouted.

running-timeout

Specifies the amount of time (in seconds) that must elapse before the specified daemon is considered to be not running. This option is read-only.

The default value is dependent on the specified daemon.

SEE ALSO

edit, glob, list, modify, regex, show, tmsh

sys daemon-log-settings clusterd

NAME

clusterd - Changes the log-level of or displays information about the daemon clusterd.

MODULE

sys daemon-log-settings

SYNTAX

Configure the clusterd component within the sys daemon-log-settings module using the syntax in the following sections.

MODIFY

modify clusterd

options:

log-level [critical | debug | error | informational | notice | warning]

edit clusterd

options:

all-properties
non-default-properties

DISPLAY

list clusterd

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the clusterd component to change the level of the messages about the clusterd daemon that appear in the system logs. Additionally, you can display information about the daemon.

EXAMPLES

list clusterd

Displays information about the clusterd daemon.

modify clusterd log-level critical

Changes the level of the messages about the clusterd daemon that display in the system log to critical.

OPTIONS

log-level

Specifies the level of log messages for the specified daemon that you want to display in the system log.

SEE ALSO

edit, list, modify, tmsh

COPYRIGHT

DESCRIPTION
You can use the icrd component to change the audit level of the icrd daemon.

EXAMPLES
list icrd

Displays audit log level of the icrd daemon.

modify icrd audit all

Changes the audit level of the icrd daemon to all. This means that all commands executed by the icrd daemon get audited

OPTIONS

audit

Specifies the audit level of log messages for the icrd daemon in the audit logs.

SEE ALSO

sys daemon-log-settings tmm

NAME	tmm - Changes the log-level of or displays information about the Traffic Management Microkernel (tmm).
MODULE	sys daemon-log-settings
SYNTAX	Configure the tmm component within the sys daemon-log-settings module using the syntax in the following

sections.

MODIFY

modify tmm

options:

arp-log-level [debug | error | informational | notice | warning]
http-compression-log-level [debug | error | informational | notice | warning]
http-log-level [debug | error | informational | notice | warning]
ip-log-level [debug | informational | notice | warning]
irule-log-level [debug | error | informational | notice | warning]
layer4-log-level [debug | informational | notice]
net-log-level [critical | debug | error | informational | notice | warning]
os-log-level [alert | critical | debug | emergency | error | informational | notice | warning]
pva-log-level [debug | informational | notice]
ssl-log-level [alert | critical | debug | emergency | error | informational | notice | warning]

edit tmm

options:

all-properties
non-default-properties

DISPLAY

list tmm

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the tmm component to change the level of the messages about the tmm that appear in the system logs. Additionally, you can display information about the tmm.

EXAMPLES

list tmm

Displays information about the tmm.

modify tmm http-compression-log-level critical

Changes the level of the messages about HTTP compression that display in the system log to warning.

OPTIONS

arp-log-level

Specifies the lowest level of ARP messages from the tmm daemon to include in the system log. The default value is warning.

http-compression-log-level

Specifies the lowest level of HTTP compression messages from the tmm daemon to include in the system log. The default value is error.

http-log-level

Specifies the lowest level of HTTP messages from the daemon to include in the system log. The default value is error.

ip-log-level

Specifies the lowest level of IP address messages from the tmm daemon to include in the system log. The default value is warning.

irule-log-level

Specifies the lowest level of iRule messages from the tmm daemon to include in the system log. The default value is warning.

layer4-log-level

Specifies the lowest level of Layer 4 messages from the tmm daemon to include in the system log. The default value is notice.

net-log-level

Specifies the lowest level of network messages from the tmm daemon to include in the system log. The default value is warning.

os-log-level

Specifies the lowest level of operating system messages from the tmm daemon to include in the system log. The default value is notice.

pva-log-level

Specifies the lowest level of PVA messages from the tmm daemon to include in the system log. The default value is informational.

ssl-log-level

Specifies the lowest level of SSL messages from the tmm daemon to include in the system log. The default

value is warning.

sys datastor

NAME

datastor - Configures the data storage used for optimization.

MODULE

sys

SYNTAX

Configure the datastor component within the sys module using the syntax in the following sections.

MODIFY

modify datastor

options:

dedup-cache-weight [integer]

description [string]

disk [disabled | enabled]

high-water-mark [integer]

low-water-mark [integer]

web-cache-weight [integer]

DISPLAY

list datastor

show running-config datastor

options:

all-properties

cache-size

non-default-properties

one-line

store-size

DESCRIPTION

You can use the datastor component to configure disk I/O operations and optimized page cache for frequently accessed sectors. Note that symmetric data deduplication is one consumer of this storage space.

EXAMPLES

list datastor all-properties

Displays the data storage settings.

modify datastor disk disabled

Disables data storage on the disk.

OPTIONS

cache-size

Displays the size of the data storage in megabytes (MB).

dedup-cache-weight

Specifies the relative weight of the dedup cache for the Acceleration Manager module. The default value is 10.

description

User defined description.

disk Enables or disables the use of the disk (in addition to memory) for data storage.

If you enable or disable data storage on the disk, you must then restart the datastor service from the command line using the command sequence `bigstart restart datastor`.

high-water-mark

Specifies the percentage of full cache above which pruning starts. The valid range is 60 - 100 percent. The default value is 92.

low-water-mark

Specifies the percentage of full cache below which pruning stops. The valid range is 10 - 90 percent. The default value is 80.

store-size
Displays the amount of space for each disk path specified.

web-cache-weight
Specifies the relative weight of the web cache for the Acceleration Manager module. The default value is 10.

SEE ALSO

wom deduplication, list, modify, show, tmsh

BIG-IP 2012-12-06 sys datastor(1)

sys db

NAME

db - Displays or modifies bigdb database entries.

MODULE

sys

SYNTAX

Configure the db component within the sys module using the syntax in the following sections.

MODIFY

modify db [name] value [database variable value]
modify db [name] reset-to-default

DISPLAY

list db
list db [[[name] | [glob] | [regex]] ...]
options:
all-properties
default-value
non-default-properties
one-line
value
value-range

show running-config db
show running-config db [[[name] | [glob] | [regex]] ...]
options:
all-properties

DESCRIPTION

You can use the db component to modify and retrieve the data that is stored in the bigdb configuration database.

Important: After you change a bigdb database variable using the db component, you must run the command sequence save config. If you do not, the next time that you run the command sequence load [config base | config], the value of the bigdb database variable may be reset to the value in the stored configuration.

Note that tmsh only displays bigdb database entries when you explicitly request them.

EXAMPLES

modify db Connection.SynCookies.Threshold value 16384

Sets the database entry, SYN Check(tm) Activation Threshold, to the given value.

modify db Connection.SynCookies.Threshold reset-to-default

Sets the database entry, SYN Check(tm) Activation Threshold, back to the default value.

list log.mcpd.level

Displays the properties of the database entry log.mcpd.level:

OPTIONS

default-value
Displays the system-supplied default value of the database entry.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies the unique name of the database variable. This option is required for the command modify.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-to-default
Resets the database variable back to its default value.

value
Specifies the value to which you want to set the specified database entry.

value-range
Displays the type of data that you can use with the value option. The options are:

integer
IP address
list of valid values
management IP address
string
unsigned integer

SEE ALSO
glob, list, modify, regex, show, tmsh

sys default-config

NAME
default-config - Loads the default configuration of the BIG-IP(r) system stored in the configuration files to the running configuration of the system.

MODULE
sys

SYNTAX
Configure the default-config component within the sys module using the following syntax.

MODIFY
load default-config

DESCRIPTION
You can use the default-config component to load the default system configuration to the running configuration. This results in the user-defined configuration being removed from the running configuration.

EXAMPLES
load default-config

Loads the default configuration stored on the system to the running configuration of the system.

SEE ALSO
load, tmsh

COPYRIGHT

BIG-IP 2010-03-11 sys default-config(1)

sys diags ihealth-request

NAME

ihealth-request - Displays the BIG-IP(r) iHealth qkview upload request status, errors and progress.

MODULE

sys diags

SYNTAX

Display the ihealth-request component within the sys diags module using the syntax in the following section.

DISPLAY

list sys diags ihealth-request
all-properties
one-line

show sys diags ihealth-request
raw

DESCRIPTION

You can use the ihealth-request component to display the status of the iHealth upload feature.

EXAMPLES

list ihealth-request

Displays iHealth upload request status.

OPTIONS

ihealth-start-time

This is the start time of the ihealth request in seconds since 1970-01-01 00:00:00 UTC.

ihealth-finish-time

This is the finish time of the ihealth request in seconds since 1970-01-01 00:00:00 UTC.

error

This is the error status of the ihealth request: (one of none, creds, qkview-error, qkview-timeout, ihealth-unreach, ihealth-process, ihealth-sr-format, ihealth-timeout, ihealth-resolv ihealth-invalid-opts, ihealth-missing-user-password, ihealth-login-failed, ihealth-missing-qkview-file, qkview-invalid-opts, ihealth-miscellaneous-error).

status

This is the status of the ihealth upload process (one of none, running, analyzing or uploading).

progress

This is the progress in percent of the upload process.

type This is the type of the diagnostics request (one of none, ihealth, qkview or tcpdump).

qk-progress

This is the percent complete of a qkview in the process of being generated.

qk-progress-msg

Warnings and non fatal errors while running qkview

qkview-filename

This is the filename of the last qkview file generated, if there is one.

qkview-date

This is the date of the last qkview file generated, if there is one.

qkview-size

This is the file size of the last qkview file generated, if there is one.

qkview-user

This is the user name of the account that created the last qkview file generated, if there is one.

tcpdump-filename

This is the filename of the last tcpdump file generated, if there is one.

tcpdump-date

This is the date of the last tcpdump file generated, if there is one.

tcpdump-size

This is the file size of the last tcpdump file generated, if there is one.

For information about the options that you can use with the command list, see help list.

SEE ALSO

list, tmsh, qkview

BIG-IP 2019-05-07 sys diags ihealth-request(1)

sys diags ihealth-result

NAME

ihealth-result - Displays the BIG-IP(r) iHealth qkview upload results.

MODULE

sys diags

SYNTAX

Display the ihealth-result component within the sys diags module using the syntax in the following section.

DISPLAY

list ihealth-result

options:

all-properties

one-line

show ihealth-result

options:

field-fmt

DESCRIPTION

You can use the ihealth-result component to display the result history of the iHealth upload feature.

EXAMPLES

list ihealth-result

Displays iHealth upload result history for the system.

OPTIONS

time-checked

This is the date and time that the qkview was uploaded to iHealth.

check-user

This is the iHealth user name (email address) used to access the iHealth service.

result

This is the result returned from iHealth.

sr This is the Support Request number uploaded to the iHealth service with the qkview file.

description

This is the description uploaded to the iHealth service with the qkview file.

size This is the size of the qkview file uploaded to the iHealth service.

id This is the iHealth ID number returned from the iHealth service for the qkview file.

warnings

This is the the total number of warnings returned by the iHealth service.

criticals

This is the the total number of critical warnings returned by the iHealth service.

For information about the options that you can use with the command list, see help list.

SEE ALSO

list, tmsh, qkview

BIG-IP 2017-01-16 sys diags ihealth-result(1)

sys diags ihealth

NAME

ihealth - Displays the BIG-IP(r) iHealth qkview upload settings.

MODULE

sys diags

SYNTAX

Display and modify the ihealth component within the sys diags module using the syntax in the following section.

MODIFY

modify ihealth

options:

user

password

expiration

options

no-ihealth

DISPLAY

list ihealth

options:

all-properties

one-line

show ihealth

options:

field-fmt

DESCRIPTION

You can use the ihealth component to display or modify the configuration of the iHealth upload feature.

EXAMPLES

list ihealth

Displays iHealth upload configuration information for the system.

modify ihealth expiration 180

Modify the expiration of iHealth upload history to 180 days.

modify ihealth options "-t 180"

Add a time limit of 180 seconds for qkview module execution.

modify ihealth no-ihealth true

Prevent any qkviews generated on this device from being uploaded to iHealth.

OPTIONS

user This is the iHealth user name (email address) used to access the iHealth service.

password

This is the iHealth password used to access the iHealth service.

expiration

This is the number of days to retain iHealth upload history. The default is 30, and the maximum is 365.

options

This is a command line string to specify qkview options.

no-ihealth

This switch causes a tag to be inserted into qkview files that instructs the iHealth service to deny their uploading.

For information about the options that you can use with the command list, see help list.

SEE ALSO

list, tmsh, qkview

BIG-IP 2018-10-04 sys diags ihealth(1)

sys disk application-volume

NAME

application-volume - Configures an application volume instance.

MODULE

sys disk

SYNTAX

Configure the application-volume component in the sys disk module using the syntax shown in the following sections.

DISPLAY

show application-volume [name]

list application-volume [name]

DELETE

delete application-volume [name]

DESCRIPTION

The application-volume component provides better granularity for managing disks. Physical disks can now be shared by several application-volumes. An application-volume is physically confined to one logical disk. The visibility of the application-volume can be confined to a particular software volume set or it can be global. No application-volume properties are allowed to be modified through tmsh or iControl(r) interfaces.

EXAMPLES

delete application-volume mysqldb_MD1.3

Deletes an application-volume named mysqldb_MD1.3.

show application-volume mysqldb_MD1.3

Displays the configuration details of the application-volume mysqldb_MD1.3 in a table.

OPTION

logical-disk [name]

Specifies the name of the logical disk in which the application-volume will be created.

owner [unassigned/datastor/mysql/vcmp]

Specifies the owner for which this application-volume is assigned. unassigned - is the default option and means the volume is not in use and nobody owns it.

preservability [discardable/precious]

Specifies the if application-volume can be discarded by software (for example, during module provisioning). discardable - is the default option.

resizeable [false/true]

Specifies the if application-volume can potentially be resized. false - is the default option.

size [integer]

Specifies the size of the application-volume.

volume-set-visibility-restraint [name]

Specifies the name of the volume set to which the application-volume is constrained, if any.

SEE ALSO

delete, show, list, tmsh, sys provision, sys disk logical-disk

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2013, 2016. All rights reserved.

BIG-IP 2016-03-14 sys disk application-volume(1)

sys disk directory

NAME

directory - Manages resizing of system directories.

MODULE

sys disk

SYNTAX

Configure the directory component in the sys disk module using the syntax shown in the following sections.

MODIFY
modify directory [directory_name]
options:
 new-size [new_size]

SHOW
show directory

DESCRIPTION
The directory component assists in resizing system directories. It allows system administrators to increase the size of 4 system directories (/config, /shared, /var, /var/log). This allows more flexible management of the system resources and path for growing the directory sizes on case per case basis.

EXAMPLES
modify directory /shared new-size 35000

Increases the size of /shared system directory to 35 MiB.

show directory

Displays a table with currently scheduled directories for resizing. If there are no such directories the output is empty.

SEE ALSO
modify, show, tmsb

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2013. All rights reserved.

BIG-IP 2013-11-20 sys disk directory(1)

sys disk logical-disk

NAME
logical-disk - Manages logical disks.

MODULE
sys disk

SYNTAX
Configure the logical-disk component in the sys disk module using the syntax shown in the following sections.

MODIFY
modify logical-disk [name]
 options:
 vg-reserved [integer]
 mode [none/mixed/datastor]

DISPLAY
list logical-disk [name]

DESCRIPTION
The logical-disk component provides better granularity for managing disks. A physical disk can now be shared by one or more logical disks. A logical disk is physically confined to one physical disk.

EXAMPLES
modify logical-disk foo mode mixed vg-reserved 200

Modifies the logical disk foo mode property to mixed and the vg-reserved property size to 200 MiB.

list logical-disk foo

Displays the configuration details of the logical disk named foo.

OPTION
mode [none/mixed/datastor/control]
Specifies the current mode of the logical disk. The options are:

control - Indicates that the logical disk is part of a RAID array.

datastor - Indicates that the entire disk is committed to the datastor module.

mixed - Indicates that the disk contains multiple volumes for software and/or multiple volumes for application data.

none - Indicates that the disk is not in use. This is the default option.

size [integer]

Specifies the size (MiB) of the logical disk.

vg-free [integer]
Specifies the usable free space (MiB) available in the logical disk.

vg-in-use [integer]
Specifies the total logical disk space (MiB) in use.

vg-reserved [integer]
Specifies the reserved logical disk space (MiB). This space is NOT available for provisioning.

SEE ALSO
modify, list, tmsh, sys provision, sys disk logical-disk

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2013, 2016. All rights reserved.

BIG-IP **2016-03-14** **sys disk logical-disk(1)**

sys dns

NAME
dns - Configures the Domain Name System (DNS) for the BIG-IP(r) system.

MODULE
sys

SYNTAX
Modify the dns component within the sys module using the syntax shown in the following sections.

MODIFY
modify dns
options:
 description [string]
 include [string]
 name-servers [add | delete | replace-all-with] {
 [IP address] ...
 }
 name-servers none
 number-of-dots [integer]
 search [add | delete | replace-all-with] {
 [domain] ...
 }
 search none

edit dns
options:
 all-properties
 non-default-properties

DISPLAY
list dns
list dns [option]
show running-config dns
show running-config dns [option]
options:
 all-properties
 non-default-properties
 one-line

DESCRIPTION
You can use the dns component to manage configurations by server grouping, in this case, DNS servers.

EXAMPLES
modify dns name-servers add { 192.168.10.20 192.168.10.22 }
Adds DNS name servers with the IP addresses, 192.168.10.20 and 192.168.10.22, to the BIG-IP system.

modify dns search add { siterequest.com store.siterequest.com london.siterequest.com }
Adds the host names, siterequest.com, store.siterequest.com, and london.siterequest.com, to the DNS search configuration for the BIG-IP system.

Note: When DNS searches for the host, siterequest, which is not a fully qualified domain name, it uses the IP address of the first match, in this case, siterequest.com.

show running-config dns
Displays the running configuration of the dns component.

OPTIONS

description

User defined description.

include

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using the include option. If you use this option incorrectly, you put the functionality of the system at risk.

name-servers

Configures a group of DNS name servers for the BIG-IP system.

number-of-dots

Configures the number of dots needed in a name before an initial absolute query will be made.

search

Configures a list of domain names in a specific order. DNS uses that order when searching for host names that are not fully qualified. You can use this option to delete domain names in the list.

SEE ALSO

edit, list, modify, tmsh

sys dynad instrumentation

NAME

instrumentation - Display and configure the instrumentation available for the BIG-IP(r) DynaD feature.

MODULE

sys dynad

SYNTAX

Display and modify the instrumentation component within the sys dynad module using the syntax in the following section.

MODIFY

modify sys dynad instrumentation [name]

options:

active

DELETE

delete sys dynad instrumentation [name]

DISPLAY

list sys dynad instrumentation

list sys dynad instrumentation [name]

options:

all-properties

one-line

active

DESCRIPTION

You can use the instrumentation component to display or modify the configuration of the DynaD feature.

EXAMPLES

list sys dynad instrumentation

Display all the instrumentation available for use by the DynaD feature.

list sys dynad instrumentation [name]

Display a specific instrumentation available for use by the DynaD feature.

modify sys dynad instrumentation [name] active true

Activate the specified instrumentation.

delete sys dynad instrumentation [name]

Remove the specified instrumentation from the file system.

OPTIONS

active

Indicates the state of the instrumentation. The system will be instrumented when set to 'true'.

For information about the options that you can use with the command list, see help list.

SEE ALSO

list, tmsh, dynad

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2018-02-22 sys dynad instrumentation(1)

sys dynad key

NAME

key - Encryption key used for the BIG-IP(r) DynaD feature.

MODULE

sys dynad

SYNTAX

Manage the key component within the sys dynad module using the syntax in the following section.

GENERATE

generate sys dynad key

DELETE

delete sys dynad key

DISPLAY

list sys dynad key

options:

all-properties

one-line

key

blob

DESCRIPTION

You can use the key component to manage the encryption key used by the DynaD feature.

EXAMPLES

generate sys dynad key

Create a new encryption key and blob.

delete sys dynad key

Delete the existing encryption key and blob.

list sys dynad key

Display the entire key component.

OPTIONS

key Display the encryption key used to load DynaD instrumentation.

blob Display the encrypted blob used by F5 support to prepare DynaD instrumentation.

For information about the options that you can use with the command list, see help list.

SEE ALSO

list, tmsh, dynad

COPYRIGHT

BIG-IP 2017-11-03 sys dynad key(1)

sys dynad rpm

NAME

rpm - Display and install instrumentation rpms for the BIG-IP(r) DynaD feature.

MODULE

sys dynad

SYNTAX

Manage instrumentation with the rpm component within the sys dynad module using the syntax in the following section.

INSTALL

install sys dynad rpm [package]

options:

force

UNINSTALL

uninstall sys dynad rpm [package]

DELETE

delete sys dynad rpm [package]

DISPLAY

list sys dynad rpm

list sys dynad rpm [package]

options:

all-properties

one-line

arch

description

path

release

version

show sys dynad rpm

show sys dynad rpm [package]

DESCRIPTION

You can use the rpm component to view and install DynaD instrumentation packages. DynaD instrumentation packages must be placed in the /shared/rpms directory to be used by the BIG-IP(r) system.

Note that installation can only occur when the DynaD feature is inactive.

EXAMPLES

list sys dynad rpm

Display all the rpms available for installation.

list sys dynad rpm [package]

Display a specific rpm available for installation.

install sys dynad rpm [package]

Install the specified instrumentation rpm.

install sys dynad rpm force [package]

Forcibly install the specified instrumentation rpm.

uninstall sys dynad rpm [package]

Remove the specified instrumentation package from the rpm database.

delete sys dyad rpm [package]

Delete the specified instrumentation package from the BIG-IP(r) file system.

show sys dynad rpm

Display all previously installed instrumentation rpms.

OPTIONS

force

Forcibly install the specified package regardless of most errors. This option is useful if an RPM needs to be reinstalled.

arch Displays the architecture of the instrumentation contained in the package.

description
Displays the description of the instrumentation contained in the package.

path Displays the local path to the package.

release
Displays the release number of the package.

version
Displays the version number of the package.

For information about the options that you can use with the command list, see help list.

SEE ALSO
list, tmsh, dynad

sys dynad settings

NAME
Settings - Display and configure global settings for the BIG-IP(r) DynaD feature.

MODULE
sys dynad

SYNTAX
Display and modify the settings component within the sys dynad module using the syntax in the following section.

MODIFY
modify sys dynad settings
options:
development-mode

DISPLAY
list sys dynad settings
options:
all-properties
one-line
development-mode

DESCRIPTION
You can use the settings component to display or modify the global settings for the DynaD feature.

EXAMPLES
list sys dynad settings

Display all the settings available to the DynaD feature.

modify sys dynad settings development-mode true

Enable development mode.

OPTIONS
development-mode
Development-mode can be used to place the DynaD feature into a promiscuous operating mode. Allowing it to bypass various validation checks performed on installed scripts.

For information about the options that you can use with the command list, see help list.

SEE ALSO
list, tmsh, dynad

sys ecm config

NAME

config - Configures Elastic Compute Manager cluster.

MODULE

sys ecm

SYNTAX

Modify the configuration for ECM module using the syntax shown in the following sections.

MODIFY

modify config

options:

seed-ip [string]

dns-resolver [string]

edit config

options:

all-properties

non-default-properties

DISPLAY

list config

options:

auth [string]

seed-ip [string]

dns-resolver [string]

status [string]

OPTIONS

You can use these options with the config component:

auth Displays the authorization credentials to access ECM cluster. Authorization credentials are obtained by registering the BIG-IP with the ECM cluster. Refer to register command within the ECM module.

seed-ip

Specifies the host name or IP address of the seed node of the ECM cluster.

dns-resolver

Specifies the BIG-IP DNS resolver to use for host name resolution.

status

Displays the status

BIG-IP 2017-05-24 sys ecm register(1)

sys failover

NAME

failover - Configures failover for a BIG-IP(r) unit in a redundant system configuration.

MODULE

sys

SYNTAX

Change the failover state within the sys module using the syntax in the following section.

MODIFY

run failover

options:

device [string]

no-persist

offline

online

persist

standby

traffic-group [[string] | default | non-default | none]

DISPLAY

show failover

options:
cable

DESCRIPTION

Failover is the process where a standby unit in a redundant system configuration takes over when a software or hardware failure is detected on the active unit.

EXAMPLES

run failover standby

Causes the active unit or cluster to go into the standby state forcing the other unit or cluster in the redundant system configuration to become active.

run failover offline

Causes the active unit or cluster to go into the Forced Offline state.

run failover online

Changes the status of a unit or cluster from Forced Offline to either Active or Standby, depending upon the status of the other unit or cluster in a redundant system configuration.

show failover

Displays the failover state of the BIG-IP system (active, standby, offline, forced_offline) and how long it has been in that state.

run failover standby device my_bigip

Specifies that the my_bigip device should become the active device for all traffic groups currently active on this device.

run failover standby traffic-group traffic_grp01

Specifies that the traffic group named traffic_grp01 should fail over to the Standby state. The traffic group will then become Active on another device.

run sys failover offline no-persist

Changes the status of a unit to Forced Offline and indicates that the change will not be persisted after a system restart.

run sys failover offline persist

Changes the status of a unit to Forced Offline and indicates that the change will be persisted after a system restart.

OPTIONS

Use these options to control failover of the system:

device

Specifies the device that should next become the active device for the specified traffic group or all traffic groups (if a traffic group is not specified). This option may only be specified with the standby option.

no-persist

Does not persist the change in status of a unit. The option is valid only with the offline state.

offline

Changes the status of a unit or cluster to Forced Offline. If persist or no-persist options are not specified, the default action is to persist the offline status of the unit between system restarts.

online

Changes the status of a unit or cluster from Forced Offline to either Active or Standby, depending upon the status of the other unit or cluster in a redundant system configuration.

persist

Persists the change in status of a unit. The option is valid only with the offline state.

standby

Specifies that the active unit or cluster fails over to a Standby state, causing the standby unit or cluster to become Active.

traffic-group

Specifies the traffic-group that should fail over to the Standby state, the traffic-group will become Active on another device. This option may only be specified with the standby option.

Use this option to display the failover cable status of the system:

cable

Displays the status that the failover daemon detects on the serial cable from its failover peer. It also shows what the failover peer detects on the serial cable. An active BIG-IP system will see a zero from its failover peer. A standby BIG-IP system will see a one from its failover peer.

SEE ALSO

run, tmsh

BIG-IP 2017-03-13 sys failover(1)

sys feature-module

NAME

feature-module - Enables or disables a feature module on the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the feature-module component within the sys module using the syntax in the following sections.

MODIFY

modify feature-module

modify feature-module [[all]]

options:

enabled | disabled

edit feature-module

[[glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list feature-module

list feature-module

[[glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DESCRIPTION

You can use the feature-module component to modify the availability of any licensed feature modules on your system.

EXAMPLES

list feature-module

Displays the current feature module of the system.

OPTIONS

all Specifies that you are enabling or disabling all of the available modules.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

edit, glob, list, modify, regex, show, tmsh, provision

COPYRIGHT

sys file apache-ssl-cert

NAME

apache-ssl-cert - Manages an Apache SSL certificate file.

MODULE

sys file

SYNTAX

Configure the apache-ssl-cert component within the sys file module using the syntax shown in the following sections.

CREATE

create apache-ssl-cert [name]

options:

source-path [URL]

DISPLAY

list apache-ssl-cert

list apache-ssl-cert [[[name] | [glob] | [regex]] ...]

DELETE

delete apache-ssl-cert [name]

DESCRIPTION

You can use the apache-ssl-cert component to create, delete, or list an SSL certificate.

EXAMPLES

create apache-ssl-cert new-cert source-path http://cert-server/cert_store/certs/cert1.crt

Downloads the certificate from the given URL into file-store, creates an SSL certificate file named new-cert, and saves the given URL in the source-path attribute.

create apache-ssl-cert new-cert source-path file://shared/save/cert1.crt

Specifies the location of the file on the local disk (use this when the file has already been created on the local disk).

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

bundle-certificates

Lists data about all the certificates in the bundle, if the certificate file is a bundle. This option must be explicitly specified; otherwise, this field will be none.

certificate-key-curve-name

Specifies the Elliptical Curve name of the cryptographic key associated with this certificate. This field will be set to none if an Elliptical Curve key is not present.

certificate-key-size

Specifies the number of bits in the key associated with this certificate.

checksum

Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

create-time

Specifies the time at which the file-object was created.

created-by

Specifies the user who originally created the file-object.

expiration-date

Specifies the date at which this certificate expires. Stored as a POSIX time.

expiration-string

Specifies a string representation of the expiration date of the certificate.

fingerprint

Displays the SHA-256 fingerprint of the certificate.

is-bundle

Specifies whether the certificate file is a bundle (that is, whether it contains more than one certificate).

issuer

Specifies X509 information of the certificate's issuer. If the cert is a bundle, this displays the issuer information for the primary (first) cert in the bundle.

key-type

Specifies the type of cryptographic key associated with this certificate.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

partition
Specifies the administrative partition where the certificate resides.

revision
Identifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

serial-number
Specifies the certificate's serial number.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]
This attribute takes a URL, for example:

source-path http://cert-server/cert_store/certs/vs_132.crt

source-path https://cert-server/cert_store/certs/vs_132.crt

source-path ftp://username:password@server/cert_store/certs/vs_132.crt

subject
Specifies X509 information of the certificate's subject. If the cert is a bundle, this displays the subject information for the primary (first) cert in the bundle.

subject-alternative-name
Specifies a standard X.509 extension as shown in RFC 2459.

updated-by
Specifies the user who last updated the file-object.

version
Specifies the X509 version of the certificate.

SEE ALSO

create, delete, glob, list, ltm profile client-ssl, ltm profile server-ssl, modify, regex, tmsh

BIG-IP **2017-11-16** **sys file apache-ssl-cert(1)**

sys file browser-capabilities-db

NAME

browser-capabilities-db - Manages a browser capabilities DB file.

MODULE

sys file

SYNTAX

Configure the browser-capabilities-db component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create browser-capabilities-db [name]

modify browser-capabilities-db [name]

options:

source-path [URL]

DISPLAY

list browser-capabilities-db

list browser-capabilities-db [[[name] | [glob] | [regex]] ...]

DELETE

delete browser-capabilities-db [name]

DESCRIPTION

You can use the browser-capabilities-db component to create, delete, list or modify an browser capabilities DB file.

EXAMPLES

create browser-capabilities-db dcdb source-path file:/shared/images/dcdb

Loads the browser capabilities file from the given path on the local disk into file-store and creates an file named dcdb.

OPTIONS

checksum

A cryptographic hash or checksum of the file contents for use in verification of file integrity.

create-time

Specifies the time at which the file-object was created.

created-by

Specifies the user who originally created the file-object.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [path]

This attribute takes an absolute path on the local disk, for example:

source-path file:/shared/images/filename

updated-by

Specifies the user who last updated the file-object.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2014-12-29 sys file browser-capabilities-db(1)

sys file data-group

NAME

data-group - Manages an external data group file.

MODULE

sys file

SYNTAX

Manage the data-group component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create data-group [name]

modify data-group [name]

options:

app-service [[string] | none]

data-group-description [string]

data-group-name [name]

separator [string]

source-path [URL]

type [integer | ip | string]

edit data-group [[[name] | [glob] | [regex]] ...]

DISPLAY

list data-group

list data-group [[[name] | [glob] | [regex]] ...]

DELETE

delete data-group [name]

DESCRIPTION

You can use the data-group component to create, edit, delete, list or modify an external data group file.

EXAMPLES

create data-group new-dg source-path http://file-server/data-groups/acl.class type string

Downloads the data-group file from the given URL into file-store, creates an external-data-group file named new-dg, and saves the given URL in the source-path attribute.

create data-group new-dg source-path http://file-server/data-groups/acl.class type string data-group-name dg data-group-description "created for rule xyz"

Downloads the data-group file from the given URL into file-store, creates an external-data-group file named new-dg, saves the given URL in the source-path attribute, and creates an external data group within the Itm data-group module named dg with the given description.

create data-group new-dg source-path file:/shared/save/Test.cls type ip

Specifies the location of the file on the local disk (use this when the file has already been created on the local disk).

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by

Specifies the user who originally created the file-object.

create-time

Specifies the time at which the file-object was created.

data-group-description

Specifies the description of the external data group that will be created within the Itm data-group module and reference the given data group file. This is optional in the create command.

data-group-name

Specifies the name of the external data group that will be created within the Itm data-group module and reference the given data group file. This is optional in the create command.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

The latest revision of the file. The revision starts with 1 and gets incremented on each update.

separator

Specifies a separator to use when defining the data group. The default value is :=.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

source-path http://file-server/data-groups/AUL_1.cls

source-path https://file-server/data-groups/CNN.x

source-path ftp://username:password@server/data-groups/latest.class

source-path file:/shared/save/Test.dat

type Specifies the kind of data in the group. This option is required by the create command.

Possible values for type are:

• integer

• ip

• string

updated-by

Specifies the user who last updated the file-object.

SEE ALSO

create, delete, edit, glob, list, Itm data-group external, modify, regex, tmsh

sys file device-capabilities-db

NAME

device-capabilities-db - Manages a device capabilities DB file.

MODULE

sys file

SYNTAX

Configure the device-capabilities-db component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create device-capabilities-db [name]

modify device-capabilities-db [name]

options:

app-service [[string] | none]

source-path [file:/PATH/FILE]

DISPLAY

list device-capabilities-db

list device-capabilities-db [[[name] | [glob] | [regex]] ...]

DELETE

delete device-capabilities-db [name]

DESCRIPTION

You can use the device-capabilities-db component to create, delete, list or modify an device capabilities DB file.

EXAMPLES

create device-capabilities-db dcdb source-path file:/shared/images/dcdb

Loads the device capabilities file from the given path on the local disk into file-store and creates an file named dcdb.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

A cryptographic hash or checksum of the file contents for use in verification of file integrity.

create-time

Specifies the time at which the file-object was created.

created-by

Specifies the user who originally created the file-object.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [path]

This attribute takes an absolute path on the local disk, for example:

source-path file:/shared/images/filename

updated-by

Specifies the user who last updated the file-object.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

sys file external-monitor

NAME

external-monitor - Manages an external monitor file.

MODULE

sys file

SYNTAX

Manage the external-monitor component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create external-monitor [name]

modify external-monitor [name]

options:

app-service [[string] | none]

source-path [URL]

edit external-monitor [[[name] | [glob] | [regex]] ...]

DISPLAY

list external-monitor

list external-monitor [[[name] | [glob] | [regex]] ...]

DELETE

delete external-monitor [name]

DESCRIPTION

You can use the external-monitor component to create, edit, delete, list or modify an external-monitor file.

EXAMPLES

create external-monitor new-mon source-path http://file-server/external-monitors/mon_app1

Downloads the monitor file from the given URL into file-store, creates an external-monitor file named new-mon, and saves the given URL in the source-path attribute.

create external-monitor new-mon source-path file:/shared/save/Test.mon

Specifies the location of the file on the local disk (use this when the file has already been created on the local disk).

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by

Specifies the user who originally created the file-object.

create-time

Specifies the time at which the file-object was created.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical

value.

revision

The latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

source-path http://file-server/external-monitors/monitor_service

source-path https://file-server/external-monitors/custom_mon.1

source-path ftp://username:password@server/external-monitors/tested.mon

updated-by

Specifies the user who last updated the file-object.

SEE ALSO

create, delete, edit, glob, list, ltm monitor external, modify, regex, tmsh

COPYRIGHT

sys file ifile

NAME

ifile - Manages an iFile file.

MODULE

sys file

SYNTAX

Manage the ifile component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create ifile [name]

modify ifile [name]

options:

app-service [[string] | none]

source-path [URL]

edit ifile [[[name] | [glob] | [regex]] ...]

DISPLAY

list ifile

list ifile [[[name] | [glob] | [regex]] ...]

DELETE

delete ifile [name]

DESCRIPTION

You can use the ifile component to create, edit, delete, list or modify an iFile file.

EXAMPLES

create ifile new-ifile source-path http://tmp/text.txt

Downloads the iFile file from the given URL into file-store and creates an ifile file named new-ifile. Saves the given URL in the source-path attribute.

Supported URL schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE"

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

A cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by

Specifies the user who originally created the file-object.

create-time
Specifies the time at which the file-object was created.

last-update-time
Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision
The latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]
This attribute takes a URL, for example:

source-path http://file-server/ifiles/AUL_1.cls

source-path https://file-server/ifiles/CNN.x

source-path ftp://username:password@server/ifiles/latest.class

updated-by
Specifies the user who last updated the file-object.

sys file lwtunneltbl

NAME
lwtunneltbl - Manages an lwtunneltbl file.

MODULE
sys file

SYNTAX
Manage the lwtunneltbl component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY
create lwtunneltbl [name]
modify lwtunneltbl [name]
options:
app-service [[string] | none]
source-path [URL]

edit lwtunneltbl [[[name] | [glob] | [regex]] ...]

DISPLAY
list lwtunneltbl
list lwtunneltbl [[[name] | [glob] | [regex]] ...]

DELETE
delete lwtunneltbl [name]

DESCRIPTION
You can use the lwtunneltbl component to create, edit, delete, list or modify an lwtunneltbl file.

EXAMPLES
create lwtunneltbl new-ifile source-path http://tmp/text.txt

Downloads the lwtunneltbl file from the given URL into file-store and creates an lwtunneltbl file named new-ifile. Saves the given URL in the source-path attribute.

Supported URL schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE"

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

A cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by

Specifies the user who originally created the file-object.

create-time

Specifies the time at which the file-object was created.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

The latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

source-path http://file-server/ifiles/AUL_1.cls

source-path https://file-server/ifiles/CNN.x

source-path ftp://username:password@server/ifiles/latest.class

updated-by

Specifies the user who last updated the file-object.

BIG-IP **2015-10-01** **sys file lwtunneltbl(1)**

sys file rewrite-rule

NAME

rewrite-rule - Manages a HTML content rewrite rule.

MODULE

sys file

SYNTAX

Configure the rewrite-rule component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create rewrite-rule [name]

modify rewrite-rule [name]

options:

local-path [URL]

edit rewrite-rule [[[name] | [glob] | [regex]] ...]

DISPLAY

list rewrite-rule

list rewrite-rule [[[name] | [glob] | [regex]] ...]

DELETE

delete rewrite-rule [name]

DESCRIPTION

You can use the rewrite-rule component to create, edit, delete, list or modify a HTML content rewrite rule.

EXAMPLES

create rewrite-rule new-rule local-path /shared/tmp/my_rewrite_rule

Creates a new HTML content rewrite rule using file located by local-path and saves path in the local-path attribute.

OPTIONS

checksum

Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by

Specifies the user who originally created the file-object.

create-time

Specifies the time at which the file-object was created.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

local-path [path]

This attribute takes a path, for example:

local-path /shared/tmp/my_rewrite_rule

updated-by

Specifies the user who last updated the file-object.

SEE ALSO

create, delete, edit, glob, list, ltm profile html, modify, regex, tmsh

COPYRIGHT

BIG-IP 2013-04-12 sys file rewrite-rule(1)

sys file ssl-cert

NAME

ssl-cert - Manages a SSL certificate file.

MODULE

sys file

SYNTAX

Configure the ssl-cert component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create ssl-cert [name]

options:

app-service [[string] | none]

source-path [URL]

modify ssl-cert [name]

options:

app-service [[string] | none]

cert-validation-options [none | ocsp]

cert-validators [none | [cert_validator_name]]

issuer-cert [none | [issuer_cert_name]]

source-path [URL]

edit ssl-cert [[[name] | [glob] | [regex]] ...]

DISPLAY

list ssl-cert

list ssl-cert [[[name] | [glob] | [regex]] ...]

DELETE

delete ssl-cert [name]

DESCRIPTION

You can use the ssl-cert component to create, edit, delete, list or modify an SSL certificate.

EXAMPLES

create ssl-cert new-cert source-path http://cert-server/cert_store/certs/cert1.crt

Downloads the certificate from the given URL into file-store, creates an SSL certificate file named new-cert, and saves the given URL in the source-path attribute.

create ssl-cert new-cert source-path file:/shared/save/cert1.crt

Specifies the location of the file on the local disk (use this when the file has already been created on the local disk).

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

bundle-certificates

Lists data about all the certificates in the bundle, if the certificate file is a bundle. This option must be explicitly specified; otherwise, this field will be none.

cert-validation-options

Specifies the option used for validating the certificate status.

cert-validators

Specifies the name of the cert-validators used for validating the certificate status. At most one cert-validator can be configured for each cert-validation type.

certificate-key-size

Specifies the number of bits in the key associated with this certificate.

checksum

Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

create-time

Specifies the time at which the file-object was created.

created-by

Specifies the user who originally created the file-object.

expiration-date

Specifies the date at which this certificate expires. Stored as a POSIX time.

expiration-string

Specifies a string representation of the expiration date of the certificate.

fingerprint

Displays the SHA-256 fingerprint of the certificate.

is-bundle

Specifies whether the certificate file is a bundle (that is, whether it contains more than one certificate).

issuer

Specifies X509 information of the certificate's issuer. If the cert is a bundle, this displays the issuer information for the primary (first) cert in the bundle.

issuer-cert

Specifies the name of the issuer certificate for this certificate.

key-type

Specifies the type of cryptographic key associated with this certificate.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

serial-number

Specifies the certificate's serial number.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

source-path http://cert-server/cert_store/certs/vs_132.crt

source-path https://cert-server/cert_store/certs/vs_132.crt

source-path ftp://username:password@server/cert_store/certs/vs_132.crt

subject

Specifies X509 information of the certificate's subject. If the cert is a bundle, this displays the subject information for the primary (first) cert in the bundle.

subject-alternative-name

Specifies a standard X.509 extension as shown in RFC 2459.

updated-by

Specifies the user who last updated the file-object.

version

Specifies the X509 version of the certificate.

SEE ALSO

BIG-IP 2017-05-05 sys file ssl-cert(1)

sys file ssl-crl

NAME

ssl-crl - Manages a SSL CRL file.

MODULE

sys file

SYNTAX

Configure the ssl-crl component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create ssl-crl [name]

modify ssl-crl [name]

options:

app-service [[string] | none]

source-path [URL]

edit ssl-crl [[[name] | [glob] | [regex]] ...]

DISPLAY

list ssl-crl

list ssl-crl [[[name] | [glob] | [regex]] ...]

DELETE

delete ssl-crl [name]

DESCRIPTION

You can use the ssl-crl component to create, edit, delete, list or modify an SSL CRL file.

EXAMPLES

create ssl-crl new-crl source-path http://cert-server/cert_store/CRLs/latest.crl

Downloads the CRL file from the given URL into file-store, creates an SSL CRL file named new-crl, and saves the given URL in the source-path attribute.

create ssl-crl new-crl source-path file://shared/save/copy_10.crl

Specifies the location of the file on the local disk (use this when the file has already been created on the local disk).

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by

Specifies the user who originally created the file-object.

create-time

Specifies the time at which the file-object was created.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

source-path http://cert-server/cert_store/CRLs/backup_10.crl

source-path https://cert-server/cert_store/CRLs/jan_2010.crl

source-path ftp://username:password@server/cert_store/CRLs/latest.crl

updated-by

Specifies the user who last updated the file-object.

SEE ALSO

create, delete, edit, glob, list, ltm profile client-ssl, ltm profile server-ssl, modify, regex, tmsh

COPYRIGHT

sys file ssl-key

NAME

ssl-key - Manages a SSL certificate key file.

MODULE

sys file

SYNTAX

Configure the ssl-key component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create ssl-key [name]

modify ssl-key [name]

options:

app-service [[string] | none]

source-path [URL]

passphrase [passphrase]

edit ssl-key [[[name] | [glob] | [regex]] ...]

DISPLAY

list ssl-key

list ssl-key [[[name] | [glob] | [regex]] ...]

DELETE

delete ssl-key [name]

DESCRIPTION

You can use the ssl-key component to create, edit, delete, list or modify an SSL certificate key file.

EXAMPLES

create ssl-key new-key source-path http://cert-server/cert_store/certs/cert1.key

Downloads the certificate-key file from the given URL into file-store and creates an SSL certificate key file named new-key. Saves the given URL in the source-path attribute.

create ssl-key new-key source-path file:/shared/save/cert1.key

Specifies the location of the file on the local disk. Use this when the file has already been created on the local disk.

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

A cryptographic hash or checksum of the file contents for use in verification of file integrity.

create-time

Specifies the time at which the file-object was created.

created-by

Specifies the user who originally created the file-object.

key-size

Specifies the size of the cryptographic key associated with this file object, in bits.

key-type

Specifies the cryptographic type of the key in question. That is, which algorithm this key is compatible with.

The options are:

rsa-private

The key is an RSA private key.

dsa-private

The key is a DSA based private key.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

passphrase [passphrase]

Specifies an optional passphrase with which the key has been protected. It may be used by consumers of the key in the data-plane or control-plane to decrypt it.

revision

Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

security-type

Specifies the type of security used to handle or store the key.

The options are:

normal

The key resides in a standard form on the file-system. This is the default value.

fips The key is protected by a FIPS device on the system and is only applicable to devices with FIPS support.

password

Specifies that the key is protected by a passphrase and stored in encrypted form.

nethsm

The key is protected by a FIPS device outside the system.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

source-path http://cert-server/cert_store/certs/vs_132.key

source-path https://cert-server/cert_store/certs/vs_132.key

source-path ftp://username:password@server/cert_store/certs/vs_132.key

updated-by
Specifies the user who last updated the file-object.

SEE ALSO

sys fipsuser

NAME

FIPS - Manage FIPS User Table

MODULE

sys fipsuser

SYNTAX

Manage FIPS user table with the sys fipsuser module using the syntax in the following section.

LIST

list sys fipsuser [fips-user-id]

DELETE

delete sys fipsuser {fips-user-id| all}

DESCRIPTION

You can use the fipsuser component to list or delete the one entry comprising the FIPS Cryptographic Username and encrypted password, contained in table fipsuser.

EXAMPLES

list sys fipsuser

Displays the list of the FIPS Cryptographic Username and password stored in the FIPS User Table fipsuser. The password is shown encrypted and base-64 encoded.

delete sys fipsuser f5cu

Deletes the FIPS entry for the FIPS Cryptographic Username f5cu. This removes the Username and encrypted password.

delete sys fipsuser all

Deletes all FIPS Cryptographic Usernames and corresponding passwords from the table fipsuser. This empties the table.

OPTIONS

None

SEE ALSO

list, delete, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys fix-connection

NAME

fix-connection - Displays FIX connection statistics.

MODULE

sys

SYNTAX

DISPLAY

show fix-connection

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

all-properties

save-to-file

DESCRIPTION

You can use the fix-connection component to display statistics about FIX connections.

EXAMPLES

show fix-connection

Displays FIX connection statistics in the system default units.

OPTIONS

For information about the options that you can use with the command show, see help show.

COPYRIGHT

BIG-IP 2014-05-19 sys fix-connection(1)

sys folder

NAME

folder - Configure folders (directory structure) on the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the folder component within the sys module using the syntax in the following sections.

CREATE/MODIFY

create folder [name]

modify folder [name]

options:

app-service [[string] | none]

description [string]

device-group [[string] | default | non-default | none]

no-ref-check [false | true]

traffic-group [[string] | default | non-default | none]

DISPLAY

list folder

list folder [[name] | [glob] | [regex] | [recursive]]

DELETE

delete folder [name]

DESCRIPTION

The folder system enables users to create logical containers for the purpose of granular control of synchronization to other devices in a device group.

The folder system is hierarchical, with folders and sub-folders, in a parent-to-child relationship. The highest level folder in the system is called root. For every administrative partition on the BIG-IP system, there is a top-level folder. Top-level folders always have root as the parent. Users can create sub-folders to any folder in the system.

EXAMPLES

create sys folder sub-folder1 device-group dg1 traffic-group none

Creates a new sub-folder to the current working folder called sub-folder1, associates the folder with a device-group called dg1, and sets the traffic-group to no association.

modify sys folder /Common/sub-folder1/subfolder2 description "store pools for the B2 server configuration"

Changes the description property of the folder indicated by its full name.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

device-group

Adds this folder and all configuration items in this folder to a device group for device failover or config-sync purposes. The options are:

default

Indicates that this folder should use the device group setting of its parent folder. If the parent folder's associated device group is changed, this folder's device group will change as well.

non-default

Disassociates this folder from its parent folder's device group setting. This folder's device group field can then be set independently of the parent folder's field.

hidden

Folders may be hidden by setting this property to true. The -hidden command-line option will allow you to view hidden folders, but is not required to use or modify a folder. The -hidden command-line option only affects output from the list command and the results of tab completing a configuration item. If set to false, the folder will always be visible as long as the user has the appropriate permissions.

inherited-devicegroup

Specifies, when set to true, that this folder uses the device group setting of its parent folder. If the parent folder's associated device group is changed then this folder's device group will change as well. This field is read-only.

inherited-traffic-group

Specifies, when set to true, that this folder uses the traffic group setting of its parent folder. If the parent folder's associated traffic group is changed then this folder's traffic group will change as well. This field is read-only.

no-ref-check

Specifies whether strict device group reference validation is performed on configuration items in the folder. The options are:

false

Requires configuration items in the folder to sync to a super-set of the devices that are associated with any configuration that refers to configuration items in the folder. This is the default value.

true Disables this check. It is then assumed that any dependent configuration items contained in the folder will be created locally on the other devices.

traffic-group

Adds this folder and its configuration items to an existing traffic group. The values default and non-default work as they do for the device-group option.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

sys fpga firmware-config

NAME

firmware-config - Configures the FPGA firmware to be used by the system.

MODULE

sys fpga

SYNTAX

Configure the firmware-config component within the sys fpga module using the syntax shown in the following sections.

MODIFY

modify firmware-config

options:

type [l4-performance-fpga | l7-intelligent-fpga | standard-balanced-fpga | traffic-acceleration-fpga]

DISPLAY

list firmware-config

options:

all-properties

non-default-properties

one-line

DESCRIPTION

You can use the firmware-config component to configure the PFGA firmware type to use.

EXAMPLES

list firmware-config

Displays properties of the current FPGA firmware configuration.

modify firmware-config type

Modify the type of the current FPGA firmware configuration. The default is standard-balanced-fpga.

OPTIONS

type The type for FPGA firmware current used on the system.

l4-performance-fpga: High throughput fpga firmware. **l7-intelligent-fpga:** eFAD and L7 intelligent fpga firmware. **standard-balanced-fpga:** The balanced standard fpga firmware. **traffic-acceleration-fpga:** traffic acceleration fpga firmware.

SEE ALSO

BIG-IP 2017-09-05 sys fpga turboflex-profile(1)

sys geoip

NAME

geoip - Loads the GeoIP data files.

MODULE

sys

SYNTAX

Use the geoip component within the gtm module to load the GeoIP data files using the syntax in the following sections.

LOADING

load geoip

DESCRIPTION

The BIG-IP system ships with three default database files that are stored in the /usr/share/GeoIP/v2 directory. The three files are: F5GeoIP.dat, F5GeoIPISP.dat, and F5GeoIPv6.dat.

You can download and install updated GeoIP database files using the procedure available from the F5 download site. The installation places the updated database files in the share/GeoIP/v2 directory.

When you run the load geoip command sequence, the system loads the GeoIP files from disk into the running configuration. If you have downloaded and installed updated database files, those files are loaded from the /shared/GeoIP/v2 directory. Otherwise, the default database files are loaded from the /usr/share/GeoIP/v2 directory. Note that if both directories contain the same files, the files in shared/GeoIP/v2 are loaded.

EXAMPLES

load geoip

Loads the GeoIP files from disk into the running configuration.

SEE ALSO

load, tmsh

COPYRIGHT

sys global-settings

NAME

global-settings - Configures the global system settings for a BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the global-settings component within the sys module using the syntax in the following sections.

MODIFY

modify global-settings

options:

aws-access-key [string]
aws-secret-key [string]
aws-api-max-concurrency [integer]
file-blacklist-path-prefix [string]
file-blacklist-read-only-path-prefix [string]
file-whitelist-path-prefix [string]
console-inactivity-timeout [integer]
custom-addr [IP address]
description [string]
failsafe-action [go-offline | reboot | restart-all |
go-offline-restart-tm | failover-restart-tm]
file-local-path-prefix [local path prefix]
gui-audit [disabled | enabled]
gui-expired-cert-alert [disabled | enabled]
gui-security-banner [disabled | enabled]
gui-security-banner-text [string]
gui-setup [disabled | enabled]
host-addr-mode [custom | management | state-mirror]
hostname [string]
hosts-allow-include [string]
lcd-display [disabled | enabled]
net-reboot [disabled | enabled]
password-prompt [string]
mgmt-dhcp [dhcpv4 | dhcpv6 | disabled | enabled]
quiet-boot [disabled | enabled]
remote-host [add | delete | replace-all-with] {
[name]... {

options:

addr [IP address]
hostname [string]
}
}
remote-host none
username-prompt [string]

edit global-settings

options:

all-properties
non-default-properties

DISPLAY

list global-settings

list global-settings [option]

show running-config global-settings

show running-config global-settings [option]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the global-settings component to set up the BIG-IP system.

EXAMPLES

modify system remote-host add { bigip151 {addr 172.27.226.151 hostname bigip151.saxon.net} }

Sets up a remote host named bigip151 with an IP address of 172.27.226.151 and a hostname of bigip151.saxon.net.

list global-settings all-properties

Displays all of the properties of the global system settings.

OPTIONS

aws-access-key

Amazon Web Services (AWS) supplied access key needed to make secure requests to AWS. The default value is none.

aws-secret-key

Amazon Web Services (AWS) supplied secret key needed to make secure requests to AWS. The default value is none.

aws-api-max-concurrency

Maximum concurrent connections allowed while making Amazon Web Service (AWS) api calls. The default value is 1.

file-blacklist-path-prefix

Specifies the path prefixes that are disallowed for certain commands. The blacklist takes precedence over the whitelist. It is used by the tmsh save/load sys config file command to disallow saving or loading configuration. Example: The path prefix /shared/tmp/ is included both in the whitelist and blacklist. Since, it is present in the blacklist, the configuration cannot be saved or loaded from the /shared/tmp/ location. The paths are specified in braces separated by spaces in quotes. ex: "{/shared/3dns}/{/shared/bin/}".

file-blacklist-read-only-path-prefix

Specifies the read-only path prefixes that are disallowed for certain commands. It is used by the tmsh save/load sys config file command to disallow saving or loading configuration. It is a read-only attribute with value "{/etc/shadow}".

file-whitelist-path-prefix

Specifies the path prefixes that are valid for certain commands. It is used by the tmsh save/load sys config file command for saving or loading configuration. The paths are specified in braces separated by spaces in quotes. ex: "{/var/local/scf/} {/tmp/} {/shared/} {/config/}".

console-inactivity-timeout

Specifies the number of seconds of inactivity before the system logs off a user that is logged on. The default value is 0 (zero), which means that no timeout is set. The valid range is 0 - 2147483647.

custom-addr

Specifies an IP address for the system. The default value is ::. The host-addr-mode option must be set to custom in order for this setting to take effect.

description

Specifies a user defined description. The default value is no description.

failsafe-action

Specifies the action that the system takes when the switch board fails. The default value is go-offline-restart-tm.

failover-restart-tm

Specifies that when the switch board fails the system restarts the traffic management system and fails over to the other unit in a redundant pair.

go-offline

Specifies that when the switch board fails the system goes offline.

go-offline-restart-tm

Specifies that when the switch board fails the system goes offline and restarts the traffic management system.

reboot

Specifies that after the active cluster fails over to its peer, it reboots while the peer processes the traffic.

restart-all

Specifies that when the switch board fails the system restarts all system services.

file-local-path-prefix

Specifies a list of folder prefixes that can be applied for file objects. This is a space separated list of folder prefixes, contained in curly braces. Example: "{file:///shared/}" or "{file:///fileobjectfolder/} {/shared/}". By default the folders are "/shared/" and "/tmp/", represented as "{/shared/} {/tmp/}".

gui-audit

Specifies whether or not system GUI log audit messages. If you disable this option, system GUI will not log audit messages. The default value is disabled.

gui-expired-cert-alert

Specifies whether or not system GUI identify in use expired certificates and alert the user. If you

disable this option, system GUI will not monitor in use certificates. The default value is enabled.

gui-security-banner

Specifies whether the system presents on the login screen the text you specify in the gui-security-banner-text option. If you disable this option, the system presents an empty frame in the right portion of the login screen. The default value is enabled.

gui-security-banner-text

Specifies the text to present on the login screen when the gui-security-banner option is enabled. The default value is Welcome to the BIG-IP Configuration Utility.

Note: To enter a carriage return in the text type Ctrl-V followed by Ctrl-J. Additionally, you must escape special characters, such as a question mark(?), with a back slash.

gui-setup

Enables or disables the Setup utility in the browser-based Configuration utility. The default value is enabled.

Note: When you configure a system using tmsh, disable this option. Disabling this option allows the system administrators to use the browser-based Configuration utility without having to run the Setup utility.

host-addr-mode

Specifies the type of host address you want to assign to the system. The default value is management. The options are:

custom

Use this value to specify a custom IP address for the system using the custom-addr option.

management

Indicates that the host address is the management port of the system.

state-mirror

Use this value when the host address of the system is shared by the other system in a redundant pair. In case of system failure, the traffic to the other system is routed to this system.

hostname

Specifies a local name for the system. The default value is bigip1.

hosts-allow-include

Warning: Do not use this parameter without assistance from the F5 Technical Support team. The system does not validate the commands issued when you use the hosts-allow-include option. If you use this option incorrectly, you put the functionality of the system at risk.

lcd-display

Enables or disables the LCD display on the front of the system. The default value is enabled.

net-reboot

Enables or disables the network reboot feature. The default value is disabled.

If you enable this feature and then reboot the system, the system boots from an ISO image on the network, rather than from an internal media drive. Use this option only when you want to install software on the system, for example, for an upgrade or a re-installation.

Note: An enabled value reverts to disabled after you reboot the system a second time.

password-prompt

Specifies the text to present above the password field on the system's login screen.

mgmt-dhcp

Specifies whether the system uses DHCPv4/DHCPv6 clients for acquiring the management interface IP addresses. The option takes 4 possible values: dhcpv4, dhcpv6, disabled, enabled. dhcpv4 and dhcpv6 options only enable DHCPv4 or DHCPv6 client respectively. enabled and disabled options enable/disable both DHCPv4 and DHCPv6 clients.

If this option is enabled, manually specified IP addresses for the management interface may be overwritten if the network also contains a DHCP server (for the given IP protocol). If this option is disabled, no DHCP server will be applied to the management interface, however any previously acquired address will still be used. The default value is enabled for VE and disabled for all other platforms. When this option is enabled, manual changes like create/delete on sys management-ip will not be allowed. For dhcpv4/dhcpv6 values, this only applies to the management-ip entries matching the IP protocol. For example, for dhcpv4 value, user can't manually change IPv4 management-ip but user can change IPv6 management-ip.

quiet-boot

Enables or disables the quiet boot feature. The default value is enabled. When enabled, the system suppresses informational text on the console during the boot cycle.

remote-host

Configures a remote host in the /etc/hosts file. The default value is none. You must enter both an IP address and a fully qualified domain name (FQDN) or alias for each host that you want to add to the file.

username-prompt

Specifies the text to present above the user name field on the system's login screen.

sys ha-group

NAME

ha-group - Configures the high availability (HA) scoring mechanism for a unit in a traffic group of BIG-IP(r) systems.

MODULE

sys

SYNTAX

Configure the ha-group component within the sys module using the following syntax.

CREATE/MODIFY

```
create ha-group [name]
modify ha-group [name]
options:
  active-bonus [integer]
  app-service [[string] | none]
  clusters none
  clusters [add | delete | modify | replace-all-with] {
    [name] {
      app-service [[string] | none]
      attribute percent-up-members
      threshold [integer]
      minimum-threshold [integer]
      sufficient threshold [integer | all]
      weight [integer]
    }
  }
  description [string]
  [disabled | enabled]
  pools none
  pools [add | delete | modify | replace-all-with] {
    [name] {
      app-service [[string] | none]
      attribute percent-up-members
      threshold [integer]
      minimum-threshold [integer]
      sufficient threshold [integer]
      weight [integer]
    }
  }
  trunks none
  trunks [add | delete | modify | replace-all-with] {
    [name] {
      app-service [[string] | none]
      attribute percent-up-members
      threshold [integer]
      minimum-threshold [integer]
      sufficient threshold [integer]
      weight [integer]
    }
  }
}
```

DISPLAY

```
list ha-group
list ha-group [name]
options:
  all
  all-properties
  current-module
  one-line
```

DELETE

```
delete ha-group [name]
```

DESCRIPTION

You can use the ha-group component to configure a high availability (HA) group that determines the HA scoring mechanism for a unit in a traffic group. This mechanism compares the relative health of the two or more units

in the traffic group and the system with the highest score becomes the active unit. Note Use the attribute ha-group of the traffic group to make the association.

EXAMPLES

```
create ha-group group1 pools add { ftp_pool { attribute percent-up-members weight 70 } }
```

Creates a HA group, named group1, that includes the pool named ftp_pool, and uses the attribute percent-up-members and a weight of 70 to determine the HA score for a unit in a traffic group.

```
list ha-group group1
```

Displays the configuration of the HA group, group1.

OPTIONS

active-bonus

Specifies a number to add to the unit's HA score when the unit is active. This option ensures that the state of a unit is dependent upon the history of its state. The default value is 10 (ten). The range is 0 - 100.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

attribute

Specifies an attribute of the component that you want to use for the HA scoring mechanism. Percent-up-members is the only available attribute for HA scoring for the clusters, pools, and trunks options.

clusters

Specifies the clusters that you want to configure for the HA group. You can only configure a cluster on a chassis.

description

User defined description.

[disabled | enabled]

Enables or disables the HA group in the HA table. The default value is enabled.

name Specifies the name of the component that you want to configure. This option is required when you create, modify, or delete a HA group. This option is also required when you configure clusters, pools, or trunks for the HA group.

pools

Specifies the pools that you want to configure for the HA group.

threshold

Deprecated. Use minimum-threshold instead.

minimum-threshold

Specifies the minimum number of up interfaces in a trunk, up pool members in a pool, or up cluster members in a cluster below which the specified component does not contribute to the HA score for the unit. The default value is 0 (zero), which indicates this option is disabled. The value may not exceed the number of members of the trunk, pool, or cluster.

sufficient-threshold

Specifies the sufficient number of up interfaces in a trunk, up pool members in a pool, or up cluster members in a cluster above which the specified component is considered at 100% for its contribution to the HA score for the unit. The default value is all (or 0). The value may not exceed the number of members of the trunk, pool, or cluster.

trunks

Specifies the trunks that you want to configure for the HA group.

weight

The value of this option is multiplied by the percent of up cluster, pool, or trunk members, and is added to the HA score. The default value is 10. The range is 10 - 100.

BIG-IP 2016-04-08 sys ha-group(1)

NAME

ha-status - Displays information about the high availability (HA) status of a unit in a redundant pair.

MODULE

sys

SYNTAX

Display information about the ha-status component within the sys module using the following syntax.

DISPLAY

show ha-status

options:

all-properties

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

failure

field-fmt

DESCRIPTION

You can use the ha-status component to display information about the high availability status of a unit in a redundant pair.

EXAMPLES

show ha-status

Display information about the HA status of the unit.

OPTIONS

failure

Display only the objects that present a failure condition.

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

COPYRIGHT

sys host-info

NAME

host-info - Displays statistics about the host.

MODULE

sys

SYNTAX

Configure the host-info component within the sys module using the syntax in the following sections.

DISPLAY

show host-info

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

global

DESCRIPTION

You can use the host-info component to display statistics about the host, including CPU count, active CPU count, processor mode, memory usage, and more.

EXAMPLES

show host-info

Displays host statistics in the system default units.

show host-info raw

Displays raw host statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

non-default-properties

DISPLAY

list httpd

list httpd [option name]

show running-config httpd

show running-config httpd [option name]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the httpd component to configure the HTTP daemon for the system.

Important: F5 Networks recommends that users of the Configuration utility exit the utility before changes are made to the system using the httpd component. This is because making changes to the system using this component causes a restart of the httpd daemon. Additionally, restarting the httpd daemon creates the necessity for a restart of the Configuration utility.

EXAMPLES

modify httpd { ssl-certfile [string] ssl-certkeyfile [string] }

Changes the SSL certificate and the SSL key. Note that when you change the SSL key, you must also change the SSL certificate.

modify httpd auth-pam-idle-timeout 43200

Sets the PAM idle timeout to half a day (in seconds).

modify httpd allow replace-all-with {172.27.0.0/255.255.0.0}

Replaces the existing list of hosts that can connect to the httpd daemon with the hosts in the range, 172.27.0.0/255.255.0.0.

OPTIONS

allow

Configures IP addresses and hostnames for the HTTP clients from which the httpd daemon accepts requests. The default value is All.

Warning: Using the value none resets the httpd daemon to allow NO HTTP clients access to the system; therefore, F5 Networks recommends that you do not use the value none.

auth-name

Specifies the name for the authentication realm. The default value is BIG-IP.

auth-pam-dashboard-timeout

Specifies whether idle timeout while viewing the dashboard is enforced or not. The default value is off.

auth-pam-idle-timeout

Specifies the number of seconds of inactivity that can elapse before the GUI session is automatically logged out. The default value is 1200 seconds.

auth-pam-validate-ip

Specifies whether the check for consistent inbound IP for the entire web session is enforced or not. The default value is on.

description

User defined description.

fast-cgitimeout

Specifies, in seconds, the timeout for FastCGI. The default value is 300 seconds.

fips-cipher-version

Read-only field for internal use. Non-zero value indicates that ssl-ciphersuite has been set to FIPS 140-2 compliant defaults. The value 1 indicates that the ciphersuite is "ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-SHA:ECDHE-RSA-AES256-SHA:EC" User changes to ssl-ciphersuite will not affect this field. This field is relevant only when FIPS 140-2 compliance is enabled in the license.

hostname-lookup

The default value is off.

include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

log-level

Specifies the minimum httpd message level to include in the system log. The default value is warn.

redirect-http-to-https

Specifies whether the system should redirect HTTP requests targeted at the configuration utility to HTTPS. The default value is disabled.

request-header-max-timeout

Specifies, in seconds, the maximum time allowed to receive all of the request headers, if the request-header-min-rate option is used, in which case the timeout is extended as more data arrives. Ignored if request-header-min-rate is not used. A value of 0 means no limit. The default value is 40.

request-header-min-rate

Specifies, in bytes per second, the minimum average rate at which the request headers must be received. A value of 0 means no limit. The default value is 500.

request-header-timeout

Specifies, in seconds, the time allowed to receive all of the request headers. A value of 0 means no limit. If you use the request-header-min-rate option, this represents the initial value for the timeout, which will be extended as more data arrives. The default value is 20.

Warning: This includes the time needed to complete the initial SSL handshake. If the user's browser is configured to query certificate revocation lists and the CRL server is not reachable, the initial SSL handshake may take a significant time until the browser gives up waiting for the CRL.

request-body-max-timeout

Specifies, in seconds, the maximum time allowed to receive all of the request body, if the request-body-min-rate option is used, in which case the timeout is extended as more data arrives. Ignored if request-body-min-rate is not used. A value of 0 means no limit. The default value is 0.

request-body-min-rate

Specifies, in bytes per second, the minimum average rate at which the request body must be received. A value of 0 means no limit. The default value is 500.

request-body-timeout

Specifies, in seconds, the time allowed for reading all of the request body. This includes the time needed to do any SSL renegotiation. A value of 0 means no limit. If you use the request-body-min-rate option, this represents the initial value for the timeout, which will be extended as more data arrives. The default value is 60.

ssl-ca-cert-file

Specifies the name of the file that contains the SSL Certificate Authority (CA) certificate file. The default value is none.

ssl-certchainfile

Specifies the name of the file that contains the SSL certificate chain. The default value is none.

ssl-certfile

Specifies the name of the file that contains the SSL certificate. The default value is /etc/httpd/conf/ssl.crt/server.crt.

Note that the path to the file must start with either /etc/httpd/conf/ssl.crt/ or /config/httpd/conf/ssl.crt/, unless the path is a relative path. If the path is a relative path, then it must start with conf/ssl.crt/.

ssl-certkeyfile

Specifies the name of the file that contains the SSL certificate key. The default value is /etc/httpd/conf/ssl.key/server.key.

Note that the path to the file must start with either /etc/httpd/conf/ssl.key/ or /config/httpd/conf/ssl.key/, unless the path is a relative path. If the path is a relative path, then it must start with conf/ssl.key/.

When you change the key file, you must also change the certificate file. For example, use the following command sequence to change the key: `modify httpd { ssl-certfile [string] ssl-certkeyfile [string] }`

ssl-ciphersuite

Specifies the ciphers that the system uses. The default value is

"ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-SHA:ECDHE-RSA-AES256-SHA:EC

ssl-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the ssl-include option incorrectly, you put the functionality of the system at risk.

ssl-protocol

The list of SSL protocols to accept on the management console. A space-separated list of tokens in the format accepted by the Apache mod_ssl SSLProtocol directive.

The default value is all -SSLv2 -SSLv3.

ssl-port

The SSL port to run the management console. It is a number in the range of 1 and 65535.

The default value is 443.

ssl-ocsp-default-responder

Specifies the default responder URI for OCSP validation. The default is http://localhost.localdomain.

The value for the default responder should always be preceded with http://.

ssl-ocsp-enable

Specifies OCSP validation of the client certificate chain. The default is off.

ssl-ocsp-override-responder

Specifies the force use of default responder URI for OCSP validation. The default is off.

ssl-ocsp-responder-timeout

Specifies the maximum allowable time in seconds for OCSP response. The default is 300 seconds.

ssl-ocsp-response-max-age

Specifies the maximum allowable age ("freshness") for OCSP responses. The default value (-1) does not enforce a maximum age, which means that OCSP responses are considered valid as long as their nextUpdate field is in the future.

ssl-ocsp-response-time-skew

Specifies the maximum allowable time skew in seconds for OCSP response validation. The default is 300 seconds.

ssl-verify-client

Specifies if the client certificate needs to be verified for SSL session establishment. The default is no.

ssl-verify-depth

Specifies maximum depth of CA certificates in client certificate verification. The default is 10.

sys hypervisor-info

NAME

hypervisor-info - Used inside of a vCMP guest to display proposed configuration information passed in from the vCMP hypervisor.

MODULE

sys

SYNTAX

Access the hypervisor-info component within the sys module using the syntax in the following sections.

DISPLAY

show hypervisor-info
options:

field-fmt

DESCRIPTION

You can use the hypervisor-info component to display vCMP guest configuration information proposed by the vCMP hypervisor. Note that this component will only display information when used from inside a vCMP guest. On any other BIG-IP system, the show command will produce no output.

These values will override the default values for any of the corresponding configuration items inside the guest:

Proposed Address - The management IP, as configured via tmsh sys management-ip on appliances and via tmsh sys cluster on clusters.

Proposed Gateway - The default gateway, as configured via tmsh sys management-route.

Proposed Hostname - The hostname, as configured via tmsh sys global-settings.

Proposed Netmask - The management netmask. See "Proposed Address" above.

EXAMPLES

show hypervisor-info

Displays hypervisor configuration information in default units.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

BIG-IP 2016-03-14 sys hypervisor-info(1)

sys ical event

NAME

event - Generate an Event on the BIG-IP(r) system.

MODULE

sys ical

SYNTAX

Generate the event component within the sys ical module using the syntax shown in the following sections.

GENERATE

```
generate event
options:
name [string]
context {
{
name [string]
value [string]}
}
}
```

DESCRIPTION

You may use the generate event command to construct a free-form Event in the system which will be sent to interested Event Handlers.

EXAMPLES

generate event name EMPLOYEE context { { first_name Sam } { last_name Shepard } }

Construct an event named "EMPLOYEE" that contains two pieces of information as name/value pairs. An Event Handler must be subscribed to the event by the name "EMPLOYEE" or by both event name and all the contexts in a context group.

OPTIONS

context

Specifies a set of name/value pairs that convey the information of the Event.

name The Events name; does not have to be unique, but may not be empty.

SEE ALSO

create, delete, edit, list, modify, show, sys ical event-handler, sys ical script, tmsb

COPYRIGHT

BIG-IP 2016-03-14 sys ical event(1)

sys ical handler periodic

NAME

periodic - Make or configure a periodic handler for the BIG-IP(r) system.

MODULE

sys ical handler

SYNTAX

Modify the periodic component within the sys ical handler module using the syntax shown in the following sections.

CREATE/MODIFY

create periodic [name]

modify periodic [name]

options:

arguments {

{

name [string]

value [string]

}

...

}

description [string]

first-occurrence [date/time]

interval [integer]

last-occurrence [date/time]

script [script name]

status [active | inactive]

mv periodic [[[source-name] [destination-name]] |

[[name] to-folder [folder-name]] |

[[name...name] to-folder [folder-name]]]

options:

to-folder

DISPLAY

list periodic

list periodic [[[name] | [glob] | [regex]] ...]

show periodic

show periodic [[[name] | [glob] | [regex]] ...]

DELETE

delete periodic [name]

DESCRIPTION

You can create a periodic handler to run scripts automatically based on clock time.

EXAMPLES

create periodic my_handler1 script script1 first-occurrence now+1h interval 45 arguments { { name user value j.han } { name role value manager } }

Create a new periodic handler that will execute script1 every 45 seconds. The handler will wait one hour before beginning, but continue to execute indefinitely. Each 45 seconds, when the script executes, the provided arguments will be passed into the script as EVENT::context() data.

mv periodic /Common/my_periodic to-folder /Common/my_folder

Moves a periodic ical handler named my_periodic to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

arguments

Specifies a set of name/value pairs that will be passed to the script at the start of each execution on each interval.

The use of arguments is optional and may be changed at any time.

description
A user defined description of the item.

first-occurrence
A specific date and time for this handler to begin executing. If not specified, the current date and time of creation will be used.

interval
The number of seconds between each time this handler should execute.

last-occurrence
A specific date and time for this handler to stop executing. If not specified, the script will run indefinitely.

script
The iCall Tcl script the handler when execute at each time interval. Note that this script must be an object in sys ical script; a cli script will not work.

status
Specify either active or inactive. Active is the default value.

When the handler status is active, the handler accepts events and executes the script as expected. However, when the status is inactive, the handler will no longer accept incoming events and the script will not execute. Use the inactive status when you wish to keep the handler as a configuration item and do not wish to delete it, but also do not wish the handler to run.

to-folder
A periodic ical handler can be moved to any folder under /Common, but configuration dependencies may restrict it from moving out of /Common.

SEE ALSO
create, delete, edit, list, modify, mv, show, sys ical event, sys ical script, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 sys ical handler periodic(1)

sys ical handler perpetual

NAME
perpetual - Make or configure a perpetual handler for the BIG-IP(r) system.

MODULE
sys ical handler

SYNTAX
Modify the perpetual component within the sys ical handler module using the syntax shown in the following sections.

CREATE/MODIFY
create perpetual [name]
modify perpetual [name]
options:
description [string]
script [script name]
status [active | inactive | suspend]
subscriptions [add | delete | modify | replace-all-with] {
[subscription name] {
options:
event-name [event name]
filters [add | delete | modify | replace-all-with] {
[filter name] {
options:
value [string]
match-algorithm [accept-all | exact | glob | regex | subnet]
}
}
}
}
restart perpetual [name]
start perpetual [name]
stop perpetual [name]

mv perpetual [[[source-name] [destination-name]]] |

```
[ [name] to-folder [folder-name] ] |
[ [name...name] to-folder [folder-name] ] ]
```

options:
to-folder

DISPLAY

list perpetual
list perpetual [[[name] | [glob] | [regex]] ...]
show perpetual
show perpetual [[[name] | [glob] | [regex]] ...]

DELETE

delete perpetual [name]

DESCRIPTION

You can create a perpetual handler to run continuously executing code and to receive events by specifying subscriptions.

EXAMPLES

```
create perpetual my_handler1 script script1 subscriptions add { sub1 { event-name LTM_POOL_UP } }
```

Creates a new perpetual handler run the program defined in "script1". Anytime an event called "LTM_POOL_UP" is generated in the system, a copy will be sent to my_handler1.

```
mv perpetual /Common/my_perpetual to-folder /Common/my_folder
```

Moves a perpetual icall handler named my_perpetual to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

description

A user defined description of the item.

script

The iCall Tcl script the handler will execute upon creation. The user is responsible for creating a script with perpetual execution. If the script is changed, the handler will not change its executing code until the handler is restarted or put into inactive and then active status.

Note that this script must be an object in sys icall script; a cli script will not work.

status

Specify active, inactive, or suspend. Active is the default value.

Inactive status indicated that the handler is to no longer execute and to no longer receive events. The handler's state is lost and all pending events are deleted. Use this status to eliminate a handler in the system but to keep its information stored.

The handler may also be set to suspend which will keep the handler script executing, but the system will send no new events to the handler. Events waiting to be processed remain in queue.

subscriptions

Create one or more subscription items to specify the conditions of this handler's execution. The handler subscribes generally to events by the event name, and specifically to data by using filters. The use of filters is optional.

The handler will be sent events by the system as defined by the subscription property, but the code inside the handler must use EVENT::get_next function in order to receive the data into the handler. See sys icall script for more information.

to-folder

A perpetual icall handler can be moved to any folder under /Common, but configuration dependencies may restrict it from moving out of /Common.

SEE ALSO

create, delete, edit, list, modify, mv, show, sys icall event, sys icall script, tmsh

COPYRIGHT

BIG-IP **2016-03-14** **sys icall handler perpetual(1)**

sys icall handler triggered

NAME

triggered - Make or configure an event-triggered handler for the BIG-IP(r) system.

MODULE

sys icall handler

SYNTAX

Modify the triggered component within the sys icall handler module using the syntax shown in the following sections.

CREATE/MODIFY

```
create triggered [name]
modify triggered [name]
options:
  description [string]
  script [script name]
  status [active | inactive]
  subscriptions [add | delete | modify | replace-all-with] {
    [subscription name] {
      options:
        event-name [event name]
        filters [add | delete | modify | replace-all-with] {
          [filter name] {
            options:
              value [string]
            match-algorithm [accept-all | exact | glob | regex | subnet]
          }
        }
      }
    }
  }
```

```
mv triggered [ [ [source-name] [destination-name] ] |
  [ [name] to-folder [folder-name] ] |
  [ [name...name] to-folder [folder-name] ] ]
options:
  to-folder
```

DISPLAY

```
list triggered
list triggered [ [ [name] | [glob] | [regex] ] ... ]
show triggered
show triggered [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete triggered [name]
```

DESCRIPTION

You can create a triggered handler to automatically run a script when a specified event occurs.

EXAMPLES

```
create triggered my_handler1 script script1 subscriptions add { pools { event-name LTM_POOL_UP filters add {
pool_name { value pool1 } node_name { value node1 } } } }
```

Creates a new triggered handler that will execute the script called "script1" when an event called "LTM_POOL_UP" is generated in the system and contains the contexts { pool_name, pool1 } and { node_name, node1 }.

```
mv triggered /Common/my_triggered to-folder /Common/my_folder
```

Moves a triggered icall handler named my_triggered to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

description

A user defined description of the item.

script

The iCall Tcl script the handler will execute when invoked by an appropriate event. Note that this script must be an object in sys icall script; a cli script will not work.

status

Specify either active or inactive. Active is the default value.

When the handler status is active, the handler accepts events and executes the script as expected. However, when the status is inactive, the handler will no longer accept incoming events and the script will not execute. Use the inactive status when you wish to keep the handler as a configuration item and do not wish to delete it, but also do not wish the handler to run.

subscriptions

Specify one or more subscriptions to define the conditions of this handler's execution. The handler subscribes generally to events by the event name, and specifically to data by using filters. The use of filters is optional.

A handler that specifies more than one subscription will execute when any one subscription is matched to an event.

to-folder

A triggered icall handler can be moved to any folder under /Common, but configuration dependencies may restrict it from moving out of /Common.

SEE ALSO

create, delete, edit, list, modify, mv, show, sys ical event, sys ical script, tmsb

COPYRIGHT

BIG-IP 2016-03-14 sys ical handler triggered(1)

sys ical istats-trigger

NAME

istats-trigger - Configure an iStats trigger to generate a user defined event for the iCall feature on the BIG-IP(r) system.

MODULE

sys ical

SYNTAX

Modify the istats-trigger component within the sys ical module using the syntax shown in the following sections.

CREATE/MODIFY

create istats-trigger [name]

modify istats-trigger [name]

options:

description [string]

duration [integer]

event-name [string]

istats-key [string]

range-max [integer]

range-min [integer]

repeat [integer]

mv istats-trigger [[[source-name] [destination-name]] |

[[name] to-folder [folder-name]] |

[[name...name] to-folder [folder-name]]]

options:

to-folder

DISPLAY

list istats-trigger

list istats-trigger [[[name] | [glob] | [regex]] ...]

DELETE

delete istats-trigger [name]

DESCRIPTION

You can create an istats-trigger to automatically generate a Control Plane iRules event under the conditions specified in the properties.

EXAMPLES

mv istats-trigger /Common/my_istats_trigger to-folder /Common/my_folder

Moves an istats-trigger named my_istats_trigger to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

description

A user defined description of the item.

duration

Duration in seconds. The value "0" means trigger instantly when in range.

event-name

The name of the event that will be generated.

istats-key

Specify the items and thresholds to define when this istats-trigger will generate an event.

range-max

Trigger event only if value is less-than-or-equal to range-max.

range-min

Trigger event only if value is greater-than-or-equal to range-min. Note that if 0 is included in the

specified range, then the iStats key must be explicitly initialized with "istats set [key] 0" in order for the trigger to fire.

repeat
Repeat interval in seconds. The value "none" means do not resend the event unless the value falls outside the range and then re-enters it.

to-folder
An istats-trigger can be moved to any folder under /Common, but configuration dependencies may restrict it from moving out of /Common.

SEE ALSO

BIG-IP 2016-03-14 sys icall istats-trigger(1)

sys icall publisher

NAME

publisher - Show the services publishing events on a BIG-IP(r) system

MODULE

sys icall

SYNTAX

Show the available publishers within the sys icall module using the syntax shown in the following sections.

DISPLAY

show publisher [field-fmt]
show publisher [[[name] | [glob] | [regex]] ...] [field-fmt]

DESCRIPTION

This command lets you display the publishers on the system, as well as the events that they publish and the contexts that those events are guaranteed to contain.

By default these are shown in a tabular form; use the field-fmt option to show them in a format similar to listing other objects in tmsh.

If a published event includes no contexts, then a single line will be shown with a - in the context column. If a publisher publishes no events, then a single line will be shown with a - in the event column.

OPTIONS

field-fmt

By default, the events will be shown in a tabular format. This overrides the command to print the publishers in object format like the list command does for other objects.

SEE ALSO

show, tmsh, sys icall event, sys icall handler periodic, sys icall handler perpetual, sys icall handler triggered, sys icall istats-trigger, sys icall script

COPYRIGHT

BIG-IP 2014-06-27 sys icall publisher(1)

sys icall script

NAME

script - Manage a Tcl script used by handlers during execution on the BIG-IP(r) system.

MODULE

sys icall

SYNTAX

Manage the script component within the sys icall module using the syntax shown in the following sections.

CREATE/MODIFY/EDIT

```
create script [name]
modify script [name]
edit script [name]
options:
  definition
  description [string]
  events [add | delete | modify | replace-all-with] {
    [event name] {
      contexts [add | delete | modify | replace-all-with] {
        [context name]
      }
    }
  }
}
```

```
mv script [ [ [source-name] [destination-name] ] |
  [ [name] to-folder [folder-name] ] |
  [ [name...name] to-folder [folder-name] ] ]
options:
  to-folder
```

DISPLAY

```
list script
list script [name]
```

DELETE

```
delete script [name]
```

Note: You must remove all references to the icall script before deletion.

DESCRIPTION

You can use this script component to manage Tcl scripts which are used by event handlers upon execution.

Caution: If you add a handler to a shared configuration on a set of BIG-IP appliances, then care must be used in making changes to configuration items. A handler's script which makes config changes on more than one device may cause inconsistencies that must be manually resolved.

EXAMPLES

```
create script my_script1
```

Create a new icall script item called "my_script1". Upon pressing enter, the user will enter the text editor in order to edit the Tcl script. Note that this configuration item may only be modified while in the edit view.

```
mv script /Common/my_script to-folder /Common/my_folder
```

Moves an icall script named my_script to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

definition

Holds the Tcl code.

description

User defined description.

events

Register events with the system that this script creates.

to-folder

An icall script can be moved to any folder under /Common, but configuration dependencies may restrict it from moving out of /Common.

EVENT ACCESSORS

In addition to all the tmsh:: commands provided by the system to use in the Tcl scripts (please see help cli script), the commands below are provided to access event specific information.

Hint: When you use a tmsh:: command, call it inside of Tcl catch to receive any error messages returned, and to allow the script to exit gracefully if needed. Without Tcl catch, the script may crash and end the process.

The following Tcl variables may be used in triggered handlers. (The \$ is not part of the variable name but is the lookup operator for the Tcl variable.):

\$EVENT::context([name])

An array variable containing the value of each context, keyed by the context name.

\$EVENT::creation_time

The date and time the event was generated.

\$EVENT::event_name

The name of the event that was generated.

`$EVENT::handler_name`

The name of the event handler that matched the event being handled.

`$EVENT::script_name`

The name of the currently running script.

For use in perpetual handlers:

`EVENT::get_next [-timeout [milliseconds]]`

The timeout parameter is optional. If the timeout is set, then `EVENT::get_next` will return 0 if no event matches before the timeout hits. Otherwise, the `EVENT::get_next` will return 1, and the above variables in the `EVENT::` namespace will be replaced with the data from the new event.

SCRIPT EXAMPLES

The following script will print out all the information of an event.

```
puts "*** start of event ***"
```

```
foreach var [info vars EVENT::*] {
  set varname [namespace tail $var]
  if { [array exists $var] } {
    puts "$varname: "
    foreach { k v } [array get $var] { ;#k = key v = value
    puts "$k:$v"
    }
  } else {
    puts "$varname: [set $var]"
  }
}
```

The next script will allow events to hold bash commands and have the script execute them. The script would be required to run inside an event handler that subscribed to the appropriate event and filtered on the words "utility" and "arguments".

```
set bash_cmd $EVENT::context(utility) append bash_cmd " " $EVENT::context(arguments)
```

```
if { [catch { exec /bin/bash -c $bash_cmd } result] } {
  puts "error executing bash command: $bash_cmd" } else {
  puts $result }
```

BIG-IP **2016-03-14** `sys icall script(1)`

sys icmp-stat

NAME

`icmp-stat` - Displays and resets ICMP statistics on the BIG-IP system.

MODULE

`sys`

SYNTAX

Configure the `icmp-stat` component within the `sys` module using the syntax in the following section.

MODIFY

`reset-stats icmp-stat`

DISPLAY

`show icmp-stat`

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the `icmp-stat` component to display and reset ICMP statistics. The statistics you can view are standard ICMP statistics, including ICMPv4 packets and errors, and ICMPv6 packets and errors.

OPTIONS

For information about the options that you can use with the command `show`, see `help show`.

For information about the options that you can use with the command `reset-stats`, see `help reset-stats`.

SEE ALSO

`reset-stats`, `show`, `sys icmp-stat`, `tmsb`

BIG-IP 2011-04-25 `sys icmp-stat(1)`

sys icontrol-soap

NAME

`icontrol-soap` - Configures the iControl SOAP daemon for the BIG-IP(r) system.

MODULE

`sys`

SYNTAX

Configure the `icontrol-soap` component within the `sys` module using the following syntax.

CREATE/MODIFY

`modify icontrol-soap`

`options:`

`allow [add | delete | none |replace-all-with] {`
 All or IP address ...
`}`

`edit icontrol-soap`

`options:`

`all-properties`
`non-default-properties`

DISPLAY

`list icontrol-soap`

`list icontrol-soap [option name]`

`show running-config icontrol-soap`

`show running-config icontrol-soap [option name]`

`options:`

`all-properties`
`non-default-properties`
`one-line`

DESCRIPTION

You can use the `icontrol-soap` component to configure the iControl SOAP for the system.

Important: F5 Networks recommends that users of the Configuration utility exit the utility before changes are made to the system using the `icontrol-soap` component. This is because making changes to the system using this component causes a restart of the `icontrol-soap` daemon. Additionally, restarting the `icontrol-soap` daemon creates the necessity for a restart of the Configuration utility.

EXAMPLES

`modify icontrol-soap allow replace-all-with {9.9.9.9}`

Reduces the allowed IP address that can access iControl SOAP to 9.9.9.9

OPTIONS

`allow`

Configures IP addresses for iControl SOAP clients from which the `icontrol-soap` daemon accepts requests. The value may be either a full IP address or a Perl Compatible Regular Expression to allow connections from a specific subnet. The default value is `All`.

Warning: Using the value `none` resets the `icontrol-soap` daemon to allow all iControl SOAP clients access to the system; therefore, F5 Networks recommends that you do not use the value `none`.

SEE ALSO

`edit`, `list`, `modify`, `show`, `tmsb`

sys integrity status-check

NAME
status-check - Checks and verifies the integrity of the BIG-IP BIOS and kernel using the tpm-status utility.

MODULE
sys integrity

SYNTAX
Run a check on the system's integrity status in the sys integrity module by using the syntax below.

RUN
run status-check
options:
-h Print help for the tpm-status command.
-c Attempt to continue after reaching an error.
-o Output the PCR measurements to a given file after measurement. The file will be overwritten if pre-existing.
-a Append the PCR measurements to a given file after measurement.
-v [0|1|2|3] Modify the verbosity of the tpm-status utility from 0 (not verbose) to 3 (very very verbose). Default value: 0.
-q Generates a file containing system information needed for Remote Attestation. File is located at /var/log/pcrs.json.
Note: Options -o and -a are mutually exclusive. Files may only be written to areas allowed by tmsh.

DESCRIPTION
You can use the status-check command to check the system's integrity status.

EXAMPLES
run status-check

Runs the tpm-status utility and returns the integrity status. It shall be one of VALID, INVALID, UNAVAILABLE, or PENDING.

run status-check -v 3

Runs the tpm-status utility with very very verbose output then returns the integrity status.

SEE ALSO
run, tmsh

sys internal-proxy

NAME
internal-proxy - Configuration of the internal proxy.

MODULE
sys

SYNTAX
Configure the internal-proxy component within the sys.internal-proxy module using the syntax shown in the following sections. This object is used by other services such as CRL cert-validator, for defining how to send/receive the outbound traffic for the service.

CREATE/MODIFY
create internal-proxy [name]
modify internal-proxy [name]
options:
description [string]
dns-resolver [name]

proxy-server-pool [name]
route-domain [name]

DISPLAY
list internal-proxy [name]

DELETE
delete [all | [name]]
options:
recursive

DESCRIPTION
You can use the internal-proxy component to configure a custom internal proxy.

EXAMPLES
create sys internal-proxy my_intp dns-resolver my_dnsr

Creates an internal proxy named my_intp using the DNS resolver my_dnsr.

OPTIONS
dns-resolver
Specifies the DNS resolver object used for sending out the traffic.

proxy-server-pool
Specifies the proxy server pool used for reaching servers.

route-domain
Specifies the route domain for for reaching servers using HTTP forward proxy.

SEE ALSO
sys crypto cert-validator crl

COPYRIGHT

BIG-IP 2017-12-11 sys internal-proxy(1)

sys ip-address

NAME
ip-address - Displays the IP addresses currently associated with a configuration object on a BIG-IP(r) system.

MODULE
sys

SYNTAX
Display the IP addresses associated with a BIG-IP system configuration object using the syntax in the following section.

DISPLAY
show ip-address
options:
[all-properties | field-fmt]

DESCRIPTION
You can use the ip-address component to display the location on the BIG-IP system of the IP addresses associated with a configuration object. The system displays the following information:

Entry
Displays the IP address and any associated configuration. For example, for a Local Traffic Manager pool member, the entry is the member's IP address and port number, 10.1.1.1:80.

Component
Displays the type of component associated with the IP address. For example, for a Local Traffic Manager pool, the entry is ltm pool.

Object-ID
Displays the name of a configuration object associated with the IP address. For example, for a Local Traffic Manager pool named my_pool, the entry is my_pool.

Property
When you specify the all-properties option, displays the name of the property that contains the IP address value. Note that if the IP address is an object identifier the system displays n/a.

EXAMPLES

show ip-address

Displays the IP addresses currently associated with a BIG-IP system configuration object.

OPTIONS

For information about the options that you can use with the command **show**, see **help show**.

SEE ALSO

show, **tmsh**

sys ipfix element

NAME
element - Configures element for IPFIX logging.

MODULE
sys ipfix

SYNTAX
Configure the IPFIX component within the sys ipfix module using the syntax shown in the following sections.

CREATE/MODIFY
create element [name]
modify element [name]
options:
all
app-service [[string] | none]
data-type
[boolean | datetime-microseconds |
 datetime-milliseconds | datetime-nanoseconds |
 datetime-seconds | float32 | float64 |
 ipv4-address | ipv6-address | macaddress |
 octetarray | signed16 | signed32 | signed64 |
 signed8 | string |
 unsigned16 | unsigned32 |
 unsigned64 | unsigned8]
description [string]
enterprise-id [integer]
id [integer]
size [integer]

DISPLAY
list element
list element [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line

DELETE
delete element [name]

Note: Default elements loaded at boot time may not be deleted.

DESCRIPTION
You can use the element component to configure elements for the IPFIX logging interface.

EXAMPLES
create element myelement id 345 enterprise-id 543 data-type string size 128

Creates a element named myelement with element id 345, enterprise-id 543, data-type string and data size of 128.

delete element myelement

Deletes the element named myelement.

list element myelement

Displays properties of the element named myelement.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the element belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the element. Only the application service can modify or delete the element.

data-type

Specifies the data type of the element.

description

User defined description.

enterprise-id

Specifies the enterprise-id for the IPFIX element being configured between 0 and 4294967295. An enterprise id value of 0 is used to define standardized IANA Information Elements.

id Specifies the element id for the IPFIX element being configured between 1 and 65535. Values greater than 32767 will be considered NETFLOW-only Information Elements; since the high bit of the 16-bit value is set for those values.

size Specifies the IPFIX element data size between 1 and 1900 for data-types octetarray and string. The default is 0; and means variable for these two data-types.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique alphanumeric name for the component. Preferably camel casing. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

sys ipfix irules

NAME

irules - Displays or resets statistics for irules that use IPFIX logging destinations.

MODULE

sys ipfix

SYNTAX

Specify the irules component within the sys ipfix module using the syntax in the following section.

MODIFY

reset-stats irules

DISPLAY

show irules

DESCRIPTION

You can use the irules component to display a global set of statistics for the iRules that use IPFIX destinations, like memory allocation and outstanding counts for templates, messages and destinations. You can also reset the IPFIX iRules statistics to zero at any time.

OPTIONS

For information about the options that you can use with the command show, see help show.

For information about the options that you can use with the command `reset-stats`, see `help reset-stats`.

SEE ALSO

`reset-stats`, `show`, `sys log-config destination ipfix`, `sys ipfix destination`, `sys ipfix element`, `tmsh`

sys iprep-status

NAME

`iprep-status` - Displays the status of an IP reputation database. In the BIG-IP(R) Configuration Utility, this database is referred to as the IP Address Intelligence database.

MODULE

`sys`

SYNTAX

Display information about the `iprep-status` component within the `sys` module using the following syntax.

DISPLAY

`show iprep-status`
options:
 `current-module`
 `field-fmt`
 `running-config`

DESCRIPTION

You can use the `iprep-status` component to display status information about the IP reputation database. The reputation database (referred to as IP Address Intelligence in the Config Utility) is available from third-party vendors. An IP intelligence database is a list of IP addresses that have a questionable reputation. The status information returned includes:

- the date and time that the BIG-IP system last contacted the vendor server
- the date and time that the BIG-IP system last received an update
- the total number of IP address in the database
- the number of IP addresses in the most recent update

Note: When the system has an IP Intelligence license and the database variable `db iprep.autoupdate` is enabled (default), the database is automatically downloaded and stored in the binary file:

`/var/lpRep/F5lpRep.dat`

The database contains information that maps IP addresses or ranges of IP addresses to one or more reputation categories. After every update, the `lpRep` data file is loaded from disk into the running configuration.

EXAMPLES

`show iprep-status`

Displays current status information for the IP reputation database.

OPTIONS

For information about the options that you can use with the command `show`, see `help show`.

SEE ALSO

`show`, `tmsh`

BIG-IP 2016-03-14 `sys iprep-status(1)`

sys license

NAME

license - Manage the BIG-IP(r) system licensing information.

MODULE

sys

SYNTAX

Manage the license component within the sys module using the syntax in the following section.

INSTALL

install license

options:

add-on-keys { [key] ...}
license-server [[host name] | [IP address]]
license-server-port [number]
no-certificate-update
registration-key [key]
show-difference
verbose

DISPLAY

show license

options:

detail

REVOKE

revoke license

options:

license-server [[host name] | [IP address]]
license-server-port [number]
verbose

DESCRIPTION

You can use the license component to do the following:

Display detailed licensing and version information for the system, including the registration key, licensing dates, platform ID, suggested service check date, and the installed active modules.

Install and update the system license.

Revoke the existing license (only for VE instances; the registration key may subsequently be re-used to relicense this or another VE instance).

EXAMPLES

show license

Displays the system software licensing information.

show license detail

Displays the system software licensing information, including optional modules and active features.

install license

Reactivate an existing license.

revoke license

System returns to an unlicensed state; the previous registration key may be re-used on this or another VE.

OPTIONS

add-on-keys

Specifies additional feature modules to be included in the license. If add-on keys are not specified the system will use the add-on keys in the current license file.

license-server

Specifies the host name or IP address of the license server. The default value is 65.61.115.202 (activate.f5.com).

license-server-port

Specifies the IP port of the license server. The default value is 443.

no-certificate-update

Do not perform the certificate update check when contacting the Licensing Server.

registration-key

Specifies the license registration key. If the registration key is not specified the system will use the registration key in the current license file.

show-difference

Displays a comparison between the existing license and the pending license, and prompts to allow the user to keep the existing license or install the pending license.

verbose

Display status as the license is being installed.

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

sys log-config destination alertd

NAME

alertd - Modify the AlertD destination.

MODULE

sys log-config destination

SYNTAX

Modify the AlertD component within the sys log-config destination module using the syntax shown in the following sections.

MODIFY

modify alertd [name]

options:

all

description [string]

DISPLAY

list alertd

list alertd [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

Note: There is only one AlertD destination, alertd; this destination cannot be created or deleted.

DESCRIPTION

You can use this destination component to modify the AlertD destination for the common logging interface. There is only one AlertD destination; it cannot be deleted. You can use this destination to send logs directly to the AlertD daemon, bypassing syslog-ng.

EXAMPLES

list alertd alertd

Displays properties of the AlertD destination.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the modify command.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

glob, list, modify, regex, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys log-config destination arcsight

NAME

arcsight - Formats incoming logs into the ArcSight format for delivery by a forwarding destination.

MODULE

sys log-config destination

SYNTAX

Configure the ArcSight component within the sys log-config destination module using the syntax shown in the following sections.

CREATE/MODIFY

```
create arcsight [name]
modify arcsight [name]
options:
  all
  app-service [[string] | none]
  description [string]
  forward-to [string]
```

DISPLAY

```
list arcsight
list arcsight [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete arcsight [name]
```

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create ArcSight formatting destinations for the common logging interface. ArcSight log destinations currently only deliver log messages from the Network Firewall Module or the Application Security Module.

EXAMPLES

```
create arcsight my_dest forward-to another_dest
```

Creates an ArcSight destination named `my_dest` which forwards to another destination `another_dest`. `another_dest` must be a Local Syslog, Local Database, Remote Syslog, or Remote High Speed Log destination.

```
delete arcsight my_dest
```

Deletes the destination named `my_dest`. Destinations cannot be deleted when in use by a publisher.

```
list arcsight my_dest
```

Displays properties of the destination named `my_dest`.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is `none`. **Note:** If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

description

User defined description.

forward-to

Specifies a Local Syslog, Local Database, Remote Syslog, or Remote High Speed Log destination. This is required for the create and modify commands.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2013-04-12 sys log-config destination arcsight(1)

sys log-config destination ipfix

NAME

ipfix - Formats log messages into IPFIX messages and sends them to a specified pool of IPFIX Collectors

MODULE

sys log-config destination

SYNTAX

CREATE/MODIFY

create ipfix [name]

modify ipfix [name]

options:

all

app-service [[string] | none]

description [string]

pool-name [string]

protocol-version [ipfix | netflow-9]

template-delete-delay [integer]

template-retransmit-interval [integer]

transport-profile [profile name]

serverssl-profile [profile name]

DISPLAY

list ipfix

list ipfix [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DELETE

delete ipfix [name]

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create IPFIX forwarding destinations for the common logging interface.

The IPFIX protocol is designed for logging IP-transmission events. RFC 5101

() specifies the protocol, and RFC 5102

() describes the information model for IPFIX logs. IPFIX logs are raw,

binary-encoded strings with their fields and field lengths defined by IPFIX templates. IPFIX collectors are external devices that can receive IPFIX templates and use them to interpret IPFIX logs.

EXAMPLES

create ipfix my_dest pool-name my_pool

Creates a destination named my_dest which sends IPFIX messages to the pool named my_pool.

delete ipfix my_dest

Deletes the destination named my_dest. Destinations cannot be deleted when in use by a publisher or another destination.

list ipfix my_dest

Displays properties of the destination named my_dest.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is **none**.

Note: If the **strict-updates** option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

description

A user defined description for this logging destination.

glob Displays the items that match the **glob** expression. See help **glob** for a description of **glob** expression syntax.

name Specifies a unique name for the component. This option is required for the commands **create**, **delete**, and **modify**.

pool-name

Specifies the LTM pool that receives messages from the IPFIX destination. This option is required for the **create** command. The pool should contain one or more IPFIX collectors; use the "itm pool" component to set up an LTM pool.

protocol-version

Specifies the protocol version used to encode IPFIX messages sent by this logging destination. The possible values are **ipfix** and **netflow-9**. The default is **ipfix**.

template-delete-delay

This feature is not implemented.

template-retransmit-interval

Specifies the time interval, in seconds, after which this IPFIX logging destination must resend all active IPFIX Templates to the pool of IPFIX collectors.

The logging destination periodically retransmits all of its IPFIX templates at the interval you set in this property. These retransmissions can be helpful if the transport-profile is **UDP**, a lossy transport mechanism. They can also be useful for debugging a network session with a network analyzer, such as **Wireshark**.

The default value is 30 seconds.

transport-profile

Specifies the name of a profile for the transport protocol to be used by this IPFIX logging destination. You can use any existing **TCP**-based or **UDP**-based profile. The default value is the default **udp** profile.

You can use the **itm** profile **tcp** command (see "itm profile tcp") to create a **TCP** profile, or **itm** profile **udp** (see "itm profile udp") to create a **UDP** profile.

serverssl-profile

Specifies the name of a server-side **SSL** profile to be used by this IPFIX Log Destination. The default is not to use a server-side **SSL** profile. If one is specified, the IPFIX Log Destination must be configured to use **TCP** as the transport protocol, and will use **SSL** over **TCP** to communicate with the configured IPFIX collectors.

You can use the **itm** profile **server-ssl** command (see "itm profile server-ssl") to create a server-side **SSL** profile.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an **@** sign (**@**[regular expression]) to indicate that the identifier is a regular expression. See help **regex** for a description of regular expression syntax.

SEE ALSO

itm pool, **itm profile tcp**, **itm profile udp**, **create**, **delete**, **glob**, **list**, **modify**, **regex**, **tmsh**

BIG-IP 2016-03-14 **sys log-config destination ipfix(1)**

sys log-config destination local-database

NAME

local-database - Modify the Local Database destination.

MODULE

sys log-config destination

SYNTAX

Modify the Local Database component within the sys log-config destination module using the syntax shown in the following sections.

MODIFY

modify local-database [name]

options:

all

description [string]

DISPLAY

list local-database

list local-database [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

Note: There is only one Local Database destination, local-db. This destination cannot be created or deleted.

DESCRIPTION

You can use this destination component to modify the Local Database destination for the common logging interface. There is only one Local Database destination that cannot be deleted.

EXAMPLES

list local-database local-db

Displays properties of the Local Database destination.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the modify command.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

glob, list, modify, regex, tmsh

COPYRIGHT

BIG-IP 2013-04-10 sys log-config destination local-database(1)

sys log-config destination local-syslog

NAME

local-syslog - Configures the Local Syslog destination.

MODULE

sys log-config destination

SYNTAX

Modify the Local Syslog component within the sys log-config destination module using the syntax shown in the following sections.

MODIFY

modify local-syslog [name]

options:

all

default-facility [local0 | local1 | local2 | local3 | local4 | local5 | local6 | local7]

default-severity [alert | crit | debug | emerg | err | info | notice | warn]

description [string]

DISPLAY

```
list local-syslog
list local-syslog [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

Note: There is only one Local Syslog destination, local-syslog. This destination cannot be created or deleted.

DESCRIPTION

You can use this destination component to modify the Local Syslog destination for the common logging interface. There is only one Local Syslog destination which cannot be deleted.

EXAMPLES

```
list local-syslog local-syslog
```

Displays properties of the Local Syslog destination.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

default-facility

Specifies the facility given to log messages received that do not already have one. The default value is local0. The options are local0, local1, local2, local3, local4, local5, local6, and local7.

default-severity

Specifies the severity given to log messages received that do not already have one. The default value is info. The options are debug, info, notice, warn, err, crit, alert, and emerg.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the modify command.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

BIG-IP 2013-04-12 sys log-config destination local-syslog(1)

sys log-config destination management-port

NAME

management-port - Sends received messages to a specified IP address and port through the management interface.

MODULE

sys log-config destination

SYNTAX

Configure the Management Port Log component within the sys log-config destination module using the syntax shown in the following sections.

CREATE/MODIFY

```
create management-port [name]
modify management-port [name]
options:
  all
  app-service [[string] | none]
  description [string]
  ip-address [ ip address ]
  port [ port ]
  protocol [ tcp | udp ]
```

DISPLAY

list management-port

list management-port [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DELETE

delete management-port [name]

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create Management Port Log forwarding destinations for the common logging interface.

EXAMPLES

create management-port my_dest ip-address 1.2.3.4 port 99 protocol udp

Creates a destination named my_dest which forwards to the address 1.2.3.4:99 using the UDP protocol.

delete management-port my_dest

Deletes the destination named my_dest. Destinations cannot be deleted when in use by a publisher or another destination.

list management-port my_dest

Displays properties of the destination named my_dest.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is none. **Note:** If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

ip-address

Specifies the IP address that will receive messages from the specified destination.

port Specifies the port of the IP address that will receive messages from the specified destination.

protocol

Specifies the protocol used to send messages to the specified destination. The default value is tcp. The options are tcp and udp.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

COPYRIGHT

BIG-IP 2015-07-22 sys log-config destination management-port(1)

sys log-config destination remote-high-speed-log

NAME

remote-high-speed-log - Sends received messages to a specified pool.

MODULE

sys log-config destination

SYNTAX

Configure the Remote High Speed Log component within the sys log-config destination module using the syntax shown in the following sections.

CREATE/MODIFY

create remote-high-speed-log [name]

modify remote-high-speed-log [name]

options:

all

app-service [[string] | none]

description [string]

distribution [adaptive | balanced | replicated]

pool-name [string]

protocol [tcp | udp]

DISPLAY

list remote-high-speed-log

list remote-high-speed-log [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DELETE

delete remote-high-speed-log [name]

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create Remote High Speed Log forwarding destinations for the common logging interface.

EXAMPLES

create remote-high-speed-log my_dest pool-name my_pool

Creates a destination named my_dest which forwards to the pool my_pool.

delete remote-high-speed-log my_dest

Deletes the destination named my_dest. Destinations cannot be deleted when in use by a publisher or another destination.

list remote-high-speed-log my_dest

Displays properties of the destination named my_dest.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is none. **Note:** If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

description

User defined description.

distribution

Specifies the distribution method used by the Remote High Speed Log destination to send messages to pool members. The default method is adaptive: connections to pool members will be added as required to provide enough logging bandwidth. This can have the undesirable effect of logs accumulating on only one pool member when it provides sufficient logging bandwidth on its own. balanced sends each successive log to a new pool member, balancing the logs among them according to the pool's load balancing method. replicated replicates each log to all pool members, for redundancy.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

pool-name

Specifies the Itm pool that receives messages from the Remote High Speed Log destination. This option is required for the create command.

protocol

Specifies the protocol used to send messages to the specified pool. The default value is tcp. The options are tcp and udp.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

COPYRIGHT

BIG-IP 2014-12-18 sys log-config destination remote-high-speed-log(1)

sys log-config destination remote-syslog

NAME

remote-syslog - Configures Remote Syslog destinations to format log messages into Syslog format and forward them to a Remote High-Speed Log destination.

MODULE

sys log-config destination

SYNTAX

Configure the Remote Syslog component within the sys log-config destination module using the syntax shown in the following sections.

CREATE/MODIFY

create remote-syslog [name]

modify remote-syslog [name]

options:

all

app-service [[string] | none]

default-facility [local0 | local1 | local2 | local3 | local4 | local5 | local6 | local7]

default-severity [alert | crit | debug | emerg | err | info | notice | warn]

description [string]

format [legacy-bigip | rfc3164 | rfc5424]

remote-high-speed-log [string]

DISPLAY

list remote-syslog

list remote-syslog [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

DELETE

delete remote-syslog [name]

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create Remote Syslog formatting destinations for the common logging interface.

EXAMPLES

create remote-syslog my_dest remote-high-speed-log another_dest

Creates a destination named my_dest which forwards to another destination another_dest. another_dest may not be another Remote Syslog destination.

delete remote-syslog my_dest

Deletes the destination named my_dest. Destinations cannot be deleted when in use by a publisher or another destination.

list remote-syslog my_dest

Displays properties of the destination named my_dest.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is

none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

default-facility

Specifies the facility given to log messages received that do not already have a facility listed. The default value is local0. The options are local0, local1, local2, local3, local4, local5, local6, and local7.

default-severity

Specifies the severity given to log messages received that do not already have a severity listed. The default value is info. The options are debug, info, notice, warn, err, crit, alert, and emerg.

description

User defined description.

format

Specifies the syslog format received messages are formatted into. The default value is rfc3164. The options are legacy-bigip, rfc3164, and rfc5424. For more information, see the respective RFCs.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

remote-high-speed-log

Specifies the forwarding destination to send logs in the syslog format. This option is required for the create command. It may only be a remote high speed log destination or a management port destination.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

DELETE

delete splunk [name]

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create Splunk formatting destinations for the common logging interface.

EXAMPLES

create splunk my_dest forward-to another_dest

Creates a destination named **my_dest** which forwards to another destination **another_dest**. **another_dest** must be a Local Syslog, Local Database, Remote Syslog, or Remote High Speed Log destination.

delete splunk my_dest

Deletes the destination named **my_dest**.

list splunk my_dest

Displays properties of the destination named **my_dest**. Destinations cannot be deleted when in use by a publisher.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is none. **Note:** If the **strict-updates** option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

description

User defined description.

forward-to

Specifies a Local Syslog, Local Database, Remote Syslog, or Remote High Speed Log destination to receive Splunk formatted log messages. This is required for the creation of a Splunk destination.

glob Displays the items that match the glob expression. See help **glob** for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands **create**, **delete**, and **modify**.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (**@**[regular expression]) to indicate that the identifier is a regular expression. See help **regex** for a description of regular expression syntax.

SEE ALSO

create, **delete**, **glob**, **list**, **modify**, **regex**, **tmsh**

DISPLAY

list filter

list filter [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties
one-line

DELETE

delete filter [name]

DESCRIPTION

You can use the filter component to configure the filters for the common logging interface.

EXAMPLES

create filter my_filter publisher my_pub

Creates a filter named my_filter with the publisher my_pub.

delete filter my_filter

Deletes the filter named my_filter.

list filter my_filter

Displays properties of the filter named my_filter.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the filter belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the filter. Only the application service can modify or delete the filter.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

level

The minimum severity level of logs to be filtered. The severity levels in increasing order are debug, info, notice, warn, err, crit, alert, and emerg. The default value is debug.

message-id

A refinement for filtering out specific logs. The default value is none. This is an eight digit hex number. The proper hex value can be obtained from an existing log message by extracting the eight digit value.

For example, the message-id for the example log message below is highlighted.

Oct 9 15:38:20 bigip1 notice mcpd[21498]: 01070410:5: Removed subscription with subscriber id logstatd

name Specifies a unique name for the component. This option is required for the commands **create**, **delete**, and **modify**.

publisher
A publisher to send filtered log messages. The default value is **none**.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an **@** sign (**@**[regular expression]) to indicate that the identifier is a regular expression. See **help regex** for a description of regular expression syntax.

source
The stream of log messages that will be filtered by the created/modified filter. The default value is **all**.

SEE ALSO
create, **delete**, **glob**, **list**, **modify**, **regex**, **tmsh**

BIG-IP **2019-09-11** **sys log-config filter(1)**

sys log-config publisher

NAME
publisher - Configures lists of destinations for the common logging interface.

MODULE
sys log-config

SYNTAX
Configure the publisher component within the **sys log-config** module using the syntax shown in the following sections.

CREATE/MODIFY
create publisher [name]
modify publisher [name]
options:
 all
 app-service [[string] | none]
 description [string]
 destinations [add | delete | none | replace-all-with] {
 [[destinations]]
 }
}

DISPLAY
list publisher
list publisher [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line

DELETE
delete publisher [name]

Note: You must remove all references to a publisher before you can delete the publisher. Default publishers may not be deleted.

DESCRIPTION
You can use the publisher component to configure publishers for the common logging interface.

EXAMPLES
create publisher my_pub destinations add {
 destination_1
 destination_2
}

Creates a publisher named **my_pub** with two destinations, **destination_1** and **destination_2**.

delete publisher my_pub

Deletes the publisher named **my_pub**.

list publisher my_pub

Displays properties of the publisher named my_pub.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the publisher belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the publisher. Only the application service can modify or delete the publisher.

description

User defined description.

destinations

Adds, deletes, or replaces a set of destinations.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

BIG-IP 2013-04-10 sys log-config publisher(1)

sys log-rotate

NAME

log-rotate - Configures log rotation for the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the log-rotate component within the sys module using the syntax in the following sections.

MODIFY

modify log-rotate

options:

common-backlogs [integer]

common-include [string]

description [string]

ilx-include [string]

ilx-rotations [string]

ilx-schedule [string]

ilx-size [string]

include [string]

max-file-size [integer]

mysql-include [string]

syslog-include [string]

tomcat-include [string]

wa-include [string]

edit log-rotate

options:

all-properties

non-default-properties

DISPLAY

list log-rotate

list log-rotate [option]

show running-config log-rotate

show running-config log-rotate [option]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can configure the system to rotate the log files after a specified length of time. This helps to clear the hard drive of unneeded log files.

EXAMPLES

modify log-rotate common-backlogs 7

Specifies that the system saves seven copies of the common log files.

list log-rotate all-properties

Displays the configuration of the log-rotate component.

OPTIONS

common-backlogs

Specifies the number of logs that you want the system to save. Select a number from the valid range of 1 - 100. The default value is 24.

common-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the common-include option incorrectly, you put the functionality of the system at risk.

description

User defined description.

ilx-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

ilx-rotations

The default value is 10.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

ilx-schedule

The default value is daily.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

ilx-size

The value is specified in kilobytes. The default value is 10240 kilobytes.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

max-file-size

The max size of rotated log files in kB. The default value is 1024000.

syslog-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the syslog-include option incorrectly, you put the functionality of the system at risk.

tomcat-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the tomcat-include option incorrectly, you put the functionality of the system at risk.

wa-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the wa-include option incorrectly, you put the functionality of the system at risk.

BIG-IP 2016-07-29 sys log-rotate(1)

sys log

NAME

log - Displays various system log files.

MODULE

sys

SYNTAX

Configure the log component within the sys module using the syntax in the following sections.

DISPLAY

show log

show log [audit | daemon | gtm | kernel | itm | mail | messages |
security | tmm | user | webui]

options:

lines [integer]

range [date range]

DESCRIPTION

You can use the log component to display various logs.

EXAMPLES

show log

Displays a list of logs that you can view.

show log gtm

Displays the Global Traffic Manager log.

show log gtm lines 100 range 2/19/2006:15:04:00--epoch

Displays no more than 100 lines of the Global Traffic Manager log that were logged before the 19th of February 2006 at 3:04 pm.

OPTIONS

audit

Displays a log of configuration changes.

daemon

Displays the Unix daemon logs.

gtm Displays the Global Traffic Manager logs.

kernel

Displays Linux Kernel messages.

lines

Specifies how many lines of the log that you want the system to display at one time.

itm Displays Local Traffic Manager logs.

mail Displays mail daemon logs.

messages

Displays application messages.

range

Specifies the date range of the log information that you want the system to display.

security
Displays security-related messages.

tmm Displays Traffic Manager Micro-kernel logs.

user Displays various user process logs.

webui
Displays Configuration utility logs.

SEE ALSO

BIG-IP 2013-04-12 sys log(1)

sys mac-address

NAME
mac-address - Displays all MAC addresses currently associated with a configuration object on a BIG-IP(r) system, including all dynamically-discovered MAC addresses.

MODULE
sys

SYNTAX
Display the MAC addresses associated with a BIG-IP system configuration using the syntax in the following section.

DISPLAY
show mac-address
options:
field-fmt

DESCRIPTION
You can use the mac-address component to display the location on the BIG-IP system of the MAC addresses associated with a configuration object. The system displays the following information, which identifies the location of the MAC address in the configuration.

Entry
Displays the MAC address.

Component
Displays the type of component associated with the MAC address, for example, net interface.

Object-ID
Displays the name of a configuration object associated with the MAC address, for example, 2.1.

Property
Displays the name of the property that contains the MAC address value. Note that if the MAC address is an object identifier the system displays n/a.

EXAMPLES
show mac-address

Displays all MAC addresses currently associated with a BIG-IP system configuration object.

OPTIONS
For information about the options that you can use with the command show, see help show.

SEE ALSO
show, tmsh

COPYRIGHT

BIG-IP 2010-03-11 sys mac-address(1)

sys management-dhcp

NAME

management-dhcp - Configures dhcp settings for the management interface (MGMT). The changes in this object are reflected in dhclient's next lease renewal cycle and doesn't effect the current lease. User can force the changes to take effect right away by restarting dhclient.

MODULE

sys

SYNTAX

Configure the management-dhcp component within the sys module using the syntax in the following sections.

MODIFY

```
modify management-dhcp [name]
options:
  client-id [string]
  description [string]
  hostname [string]
  request-options [add | delete | modify | replace-all-with]
  send-options [add | delete | modify | replace-all-with]
  supersede-options
    [add | delete | modify | replace-all-with] {
      [name] ... {
        value
      }
    }
  }
}
```

```
supersede-options none
```

```
edit management-dhcp [name]
```

```
options:
  all-properties
```

DISPLAY

```
list management-dhcp
list management-dhcp [name]
show running-config sys management-dhcp
show running-config sys management-dhcp [name]
options:
  all-properties
  one-line
```

DESCRIPTION

Specifies DHCP client settings for the management interface. These settings will be used to retrieve an IP address for the management interface if mgmt-dhcp is enabled.

EXAMPLES

```
modify management-dhcp default request-options add ntp-servers
```

Adds ntp-servers to the lists of options requested by the management interface DHCP client.

OPTIONS

client-id

Specifies the client identifier to send to the DHCP server.

description

User defined description.

hostname

Specifies the hostname to send to the DHCP server.

request-options

Specifies the options to request from the DHCP server. Adding or removing an option will be reflected at next lease renewal with dhcp server or upon restarting DHCP client.

send-options

Specifies the options to send to the DHCP server.

supersede-options

Specifies dhclient options for which BIG-IP should always use a locally-configured value or values rather than whatever is provided by the DHCP server in the lease.

SEE ALSO

edit, list, modify, show, sys management-ip, sys management-route, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2018-01-11 sys management-dhcp(1)

sys management-ip

NAME

management-ip - Configures the ip address and netmask for the management interface (MGMT).

MODULE

sys

SYNTAX

Configure the management-ip component within the sys module using the syntax in the following sections.

CREATE/MODIFY

```
create management-ip [ip address/netmask]
create management-ip [ip address/prefixlen]
modify management-ip [ip address/prefixlen]
options:
description
```

DISPLAY

```
list management-ip
show running-config management-ip
options:
all-properties
one-line
```

DELETE

```
delete management-ip [ip address/netmask]
delete management-ip [ip address/prefixlen]
```

DESCRIPTION

Specifies network settings for the management interface.

The management interface is available on all switch platforms and is designed for management purposes. You can access the browser-based Configuration utility and command line configuration utility through the management port. You cannot use the management interface in traffic management VLANs. You can configure only one IP address on the management interface.

After you make any changes using the management-ip component, issue the following command sequence to save the changes to the bigip_base.conf file: save sys config.

To configure management-ip firewall rules, see security firewall management-ip-rules.

Note: modify only allows modification of the description field. If you wish to change the IP address of the management interface, please see the example below.

EXAMPLES

```
create management-ip 10.2.3.4/255.255.0.0
```

Creates the IP address 10.2.3.4 on the management interface.

```
create management-ip 10.2.3.4/16
```

Creates the IP address 10.2.3.4 on the management interface.

```
delete sys management-ip 10.2.3.4/25; create sys management-ip 10.2.3.5/25
```

Changes the IP address of the management interface. Note: modify does not allow a user to change the IP address directly.

OPTIONS

[ip address/netmask]

Specifies the IPv4 address and netmask. DHCP should be set to 'disabled' or 'dhcpv6' before creating IPV4 management-ip.

[ip address/prefixlen]

Specifies the IPv6 address and prefix length. DHCP should be set to 'disabled' or 'dhcpv4' before creating IPV6 management-ip.

description

User defined description.

dhcp-enabled

Specifies if the ip address has been configured by DHCP.

SEE ALSO

log-level [level]

logical-routing-type [none | backhaul]

port [port number]

tunnel-floating-addresses [IP address(es)]

tunnel-local-address [IP address]

tunnel-maintenance-mode [active | passive]

DISPLAY

list management-ovsdb

show running-config management-ovsdb

options:

all-properties

one-line

bfd-disabled

bfd-enabled

bfd-route-domain

ca-cert-file

cert-file

cert-key-file

controller-addresses

description

disabled

enabled

flooding-type

log-level

logical-routing-type

port

tunnel-floating-addresses

tunnel-local-address

tunnel-maintenance-mode

DESCRIPTION

Specifies the configurations for the OVSDB server.

EXAMPLES

modify management-ovsdb controller-addresses add { 10.0.0.1 }

Specifies 10.0.0.1 as the controller address.

list management-ovsdb all-properties

Displays the OVSDB server configurations.

OPTIONS

bfd-disabled

Disable the BFD sessions between the BIG-IP and replicators.

bfd-enabled

Enable the BFD sessions between the BIG-IP and replicators.

bfd-route-domain

Specifies the route-domain on which the VXLAN tunnel of VNI 0 is created for the BFD sessions between the BIG-IP and replicators.

ca-cert-file

Specifies the name of the CA certificate file.

cert-file

Specifies the name of the certificate file.

cert-key-file

Specifies the name of the certificate key file.

controller-addresses

Specifies the IP address(es) of the controller.

disabled

Disables OVSDb management.

enabled

Enables OVSDb management.

flooding-type

Specifies the flooding type to use to transmit unknown destination frames.

log-level

Specifies the log level for OVSDb management. The log file is located at /var/log/vxland.log.

logical-routing-type

Specifies the logical routing type.

port Specifies the OVSDb connection port. The default port is 6640.

tunnel-floating-addresses

Specifies the floating endpoint address(es) for the tunnels. The addresses need to be a self IP address associated with a floating traffic-group.

tunnel-local-address

Specifies the local endpoint address for the tunnels created by the controller. A valid IP address for the tunnel local endpoint is required when OVSDb management is enabled.

tunnel-maintenance-mode

Specifies whether the tunnels are created automatically (active) or manually (passive).

description

User defined description.

sys management-proxy-config

NAME

management-proxy-config - Configures proxy configuration for database download.

MODULE

sys

SYNTAX

Configure a management-proxy-config component within the sys module using the syntax shown in the following sections.

CREATE/MODIFY
create management-proxy-config [name]
modify management-proxy-config [name]
options:
 description [string]
 proxy-ip-addr [ip address]
 proxy-port [port]
 username [string]
 password [string]

edit management-proxy-config [name]
options:
 all-properties
 non-default-properties

DISPLAY
list management-proxy-config [name]
options:
 all-properties
 non-default-properties
 one-line

DELETE
delete management-proxy-config [name]

DESCRIPTION
Configures proxy configuration for database download. The management-proxy-config consists of the object name, proxy ip address (proxy-ip), proxy port (proxy-port), username and password. You can have only one proxy configuration specified.

EXAMPLES
create management-proxy-config test-proxy { proxy-ip-addr 10.10.10.10 proxy-port 1010 username test password test }

Creates the proxy configuration with name test-proxy and uses the specified proxy-ip-addr 10.10.10.10 and proxy-port 1010 with supplied credentials username/password test/test for database download.

modify management-proxy-config test-proxy { proxy-port 1012 }

Modify the proxy configuration for database download to use proxy port 1012.

delete management-proxy-config test-proxy

Delete the test-proxy configuration for database download.

OPTIONS
 description
 User defined description.

 proxy-ip-addr
 Specifies proxy IP to be used for database download.

 proxy-port
 Specifies proxy port to be used for database download (default value is 3128).

 username
 Specifies username for proxy configuration to be used for database download.

 password
 Specifies password for proxy configuration to be used for database download.

COPYRIGHT

show running-config management-route [[[name | default
| default-inet6] | [glob] | [regex]] ...]

options:

all-properties
one-line

DELETE

delete management-route [name]

DESCRIPTION

Specifies route settings for the management interface. You must configure a route on the management interface if you want to access the management network on the BIG-IP(r) system by connecting from another network.

The management interface is available on all switch platforms and is designed for management purposes. You can access the browser-based Configuration utility and command line configuration utility through the management port. You cannot use the management interface in traffic management VLANs.

EXAMPLES

create management-route default gateway 10.10.10.254

Sets the management interface default gateway IP address to 10.10.10.254.

create management-route myMgmtRoute network 10.10.10.0/24 gateway 10.10.10.254

Creates a management route named myMgmtRoute for the subnet 10.10.10.0/24 whose gateway IP address is 10.10.10.254.

modify management-route 10.10.10.0/24 gateway 172.24.74.62

Changes the management interface to subnet 10.10.10.0/24, and the gateway to 172.24.74.62.

OPTIONS

default

Specifies that the system forwards packets to the destination through the default IP address and netmask, 0.0.0.0 0.0.0.0.

default-inet6

Specifies that the system forwards packets to the destination through the default version 6.0 IP address and netmask.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

[ip address/netmask]

Specifies the IP address and netmask through which the system forwards packets to the destination. You can use either of these formats: 0.0.0.0/0 or 0.0.0.0 0.0.0.0.

gateway

Specifies that the system forwards packets to the destination through the gateway with the specified IP address.

mtu Specifies the maximum transmission unit (MTU) for the management interface. The value of the MTU is the largest size that the BIG-IP system allows for an IP datagram passing through the management interface.

network

The subnet and netmask to be used for the route. This is an optional field; if empty the name should be

of the form [ip address/netmask].

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

type Specifies that traffic should be delivered to the management interface (interface) or be dropped by the system (blackhole).

sys mcp-state

NAME

mcp-state - Displays information about the mcpd daemon.

MODULE

sys

SYNTAX

Display information about the mcpd daemon using mcp-state component within the sys module using the syntax in the following section.

DISPLAY

show mcp-state
options:
field-fmt

DESCRIPTION

You can use the mcp-state component to display the current state of the mcpd daemon.

EXAMPLES

show mcp-state

Displays, in a table, information about the state of the mcpd daemon.

show mcp-state field-fmt

Displays, in field format, information about the state of the mcpd daemon.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

sys memory

NAME

memory - Displays system memory information and statistics.

MODULE

sys

SYNTAX

Configure the memory component within the sys module using the syntax in the following sections.

DISPLAY

show memory

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

global

DESCRIPTION

You can use the memory component to display information about the system memory.

EXAMPLES

show memory gig

Displays memory statistics in gigabytes.

show memory raw

Displays raw memory statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

sys nethsm async-queue-stat

NAME

async-queue-stat - Display or reset Network HSM pkcs11d daemon async queue statistics

MODULE

sys

SYNTAX

Display and reset the async-queue-stat component within the sys nethsm module using the syntax in the following section.

MODIFY

reset-stats async-queue-stat

DISPLAY

show async-queue-stat

options:

(default | field-fmt)

DESCRIPTION

You can use the async-queue-stat component to display Network HSM pkcs11d async-queue statistics like queued operations and queue times. You can also reset the Network HSM pkcs11d async-queue statistics to zero at any time.

OPTIONS

For information about the options that you can use with the command show, see help show.

For information about the options that you can use with the command reset-stats, see help reset-stats.

SEE ALSO

sys ntp

NAME

ntp - Configures the Network Time Protocol (NTP) daemon for the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the **ntp** component within the **sys** module using the following syntax.

MODIFY

modify ntp

options:

description [string]
include [string]
restrict [add | delete | replace-all-with] {
[string] {
address [IP address]
default-entry [enabled | disable]
description [string]
ignore [enabled | disable]
kod [enabled | disable]
limited [enabled | disable]
low-priority-trap [enabled | disable]
mask [IP address]
no-modify [enabled | disable]
non-ntp-port [enabled | disable]
no-peer [enabled | disable]
no-query [enabled | disable]
no-serve-packets [enabled | disable]
no-trap [enabled | disable]
no-trust [enabled | disable]
ntp-port [enabled | disable]
version [enabled | disable]
}
}
restrict none
servers [add | delete | replace-all-with] {
[hostname | IP address] ...
}
servers none
timezone [string]

edit ntp

options:

all-properties
non-default-properties

DISPLAY

list ntp

list ntp [option]

show running-config ntp

show running-config ntp [option]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use this component to configure the NTP servers for the system.

EXAMPLES

modify ntp servers add {192.168.1.245}

Adds the NTP server with the IP address, 192.168.1.245, to the system.

modify ntp servers replace-all-with {time.f5net.com}

Replaces the existing list of NTP servers with a single host, time.f5net.com.

modify ntp timezone "America/Los_Angeles"

Sets the system time to Pacific Standard Time.

modify ntp restrict add { basicrestrict { default-entry enable ignore enable } }

Adds a default restriction denying all packets.

OPTIONS

description

User defined description.

include

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using the include option. If you use this option incorrectly, you put the functionality of the system at risk.

restrict

Specifies a set of access restrictions.

address

The address for the entry. See also, the mask option. The default value is 0.0.0.0.

default-entry

Specifies whether the entry is the default entry. The default value is disabled.

description

User defined description.

ignore

Specifies whether all packets will be ignored. The default value is disabled.

kod Specifies whether a kod (kiss of death) packet will be sent when an access violation occurs. The default value is disabled.

limited

Specifies whether service will be denied if packet spacing limits are violated. The default value is disabled.

low-priority-trap

Specifies whether lower priority traps will be overridden by normal priority traps. The default value is disabled.

mask The mask for the entry. See also, the address option. The default value is 0.0.0.0.

no-modify

Specifies whether ntpq and ntpdc queries that attempt to modify the server are allowed. The default value is disabled.

non-ntp-port

When enabled, the restrict entry will be matched only if the source port is not the standard NTP UDP port (123). The default value is disabled.

no-peer

Specifies whether packets will be denied if they mobilize a new association. The default value is disabled.

no-query

Specifies whether ntpq and ntpdc queries will be denied. The default value is disabled.

no-serve-packets

Specifies whether all queries except ntpq and ntpdc will be denied. The default value is disabled.

no-trap

Specifies whether to decline the mode 6 control message trap service to matching hosts. The default value is disabled.

no-trust

Specifies whether to reject packets that are not cryptographically authenticated. The default value is disabled.

ntp-port

When enabled, the restrict entry will be matched only if the source port is the standard NTP UDP port (123). The default value is disabled.

version

Specifies whether packets will be rejected if they do not match the local NTP version. The default values is disabled.

servers

Configures NTP servers for the BIG-IP system.

timezone

Specifies the time zone that you want to use for the system time.

sys outbound-smtp

NAME

outbound-smtp - Configures outgoing email for the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the outbound-smtp component within the sys module using the following syntax.

MODIFY

modify outbound-smtp

options:

description [string]

from-line-override [string]

mailhub [string]

rewrite-domain [string]

edit outbound-smtp

options:

all-properties

non-default-properties

DISPLAY

list outbound-smtp

list outbound-smtp [option]

show running-config outbound-smtp

show running-config outbound-smtp [option]

options:

all-properties

non-default-properties

one-line

DESCRIPTION

You can use this component to configure the outgoing SMTP server that the system will use to send automated email.

EXAMPLES

modify outbound-smtp mailhub smtp.yoursite.com:587

Configures the TMOS system to send outgoing email through the specified SMTP server.

OPTIONS

description

User defined description.

from-line-override

Specify whether From field's domain can be overridden.

mailhub

The SMTP server to use to send outgoing automated email.

rewrite-domain

The domain name in the From address to use when sending outgoing automated email.

SEE ALSO

edit, list, modify, tmsh

COPYRIGHT

sys performance all-stats

NAME

all-stats - Resets or displays all performance statistics.

MODULE

sys performance

SYNTAX

Reset or display all performance statistics for the system within the sys_performance module using the syntax in the following sections. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

MODIFY

reset-stats all-stats

DISPLAY

show all-stats

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

(detail | historical)

DESCRIPTION

You can use the all-stats component to reset or display all system performance statistics.

Note that tmsh only displays performance statistics when you explicitly request them.

EXAMPLES

show all-stats detail

Displays detailed information about system performance in the system default units.

reset-stats all-stats

Resets all performance statistics for the system.

OPTIONS

For information about the options that you can use with the command show, see help show.

For information about the options that you can use with the command reset-stats, see help reset-stats.

SEE ALSO

reset-stats, show, sys performance connections, sys performance gtm, sys performance ramcache, sys performance system, sys performance throughput, tmsh

COPYRIGHT

sys performance connections

NAME

connections - Displays connection performance information.

MODULE

sys performance

SYNTAX

Display statistics for the connections component within the sys_performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY

show connections

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
(detail | historical)

DESCRIPTION

You can use the connections component to display information about system performance, including details about new and active connections and HTTP requests.

You can reset the connection performance statistics using the all-stats component.

EXAMPLES

show connections gig detail

Displays detailed information about connection performance in gigabytes.

show connections historical

Displays historical performance information about connections.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, sys performance all-stats, sys performance gtm, sys performance ramcache, sys performance system, sys performance throughput, tmsh

sys performance dnsexpress

NAME

dnsexpress - Displays performance information for the DNS-Express.

MODULE

sys performance

SYNTAX

Display statistics for the dnsexpress component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY

show dnsexpress

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
(historical)

DESCRIPTION

You can use the dnsexpress component to display information about system performance, including the number of queries, responses, zone transfer messages, and NOTIFYs.

EXAMPLES

show dnsexpress historical

Displays historical performance information for DNS-Express.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, sys performance all-stats, sys performance connections, sys performance ramcache, sys performance system, sys performance throughput, tmsh

BIG-IP 2014-10-22 sys performance dnsexpress(1)

sys performance dnssec

NAME

dnssec - Displays performance information for the DNSSEC signing.

MODULE

sys performance

SYNTAX

Display statistics for the dnssec component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY

show dnssec

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

(historical)

DESCRIPTION

You can use the dnssec component to display information about system performance, including the number of queries for specific DNSSEC types and zone transfer signing.

EXAMPLES

show dnssec historical

Displays historical performance information for DNSSEC signing.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, sys performance all-stats, sys performance connections, sys performance ramcache, sys performance system, sys performance throughput, tmsh

BIG-IP 2014-10-22 sys performance dnssec(1)

sys performance gtm

NAME

gtm - Displays performance information for the Global Traffic Manager.

MODULE

sys performance

SYNTAX

Display statistics for the gtm component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY

show gtm

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

(detail | historical)

DESCRIPTION

You can use the gtm component to display information about system performance, including details about the Global Traffic Manager, including number of requests, resolutions, persisted connections, and those returned to DNS.

You can reset the Global Traffic Manager performance statistics using the all-stats component.

EXAMPLES

show gtm detail

Displays detailed performance information about the Global Traffic Manager in the system default units.

show gtm historical

Displays historical performance information about the Global Traffic Manager.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, sys performance all-stats, sys performance connections, sys performance ramcache, sys performance system, sys performance throughput, tmsh

BIG-IP 2012-03-26 sys performance gtm(1)

sys performance ramcache

NAME

ramcache - Displays RAM cache performance information.

MODULE

sys performance

SYNTAX

Display statistics for the ramcache component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY

show ramcache

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

historical

DESCRIPTION

You can use the ramcache component to display RAM cache utilization information.

You can reset the RAM cache performance statistics using the all-stats component.

EXAMPLES

show ramcache default

Displays ramcache performance information in the system default units.

show ramcache historical

Displays historical ramcache performance information.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, sys performance all-stats, sys performance connections, sys performance gtm, sys performance system, sys performance throughput, tmsh

sys performance system

NAME

system - Displays system performance information.

MODULE

sys performance

SYNTAX

Display statistics for the system component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY

show system

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

(detail | historical)

DESCRIPTION

You can use the system component to display CPU and memory usage information.

You can reset the system performance statistics using the all-stats component.

EXAMPLES

show system detail

Displays detailed system performance information in the system default units.

show system historical

Displays historical system performance information.

OPTIONS

For information about the options that you can use with the command show, see help show.

BIG-IP **2012-03-26** **sys performance system(1)**

sys performance throughput

NAME

throughput - Displays performance information about traffic throughput.

MODULE

sys performance

SYNTAX

Display statistics for the throughput component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY

show throughput

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

(detail | historical)

DESCRIPTION

You can use the throughput component to display information about traffic throughput, including client, server, compression, and SSL transactions.

You can reset the throughput performance statistics using the all-stats component.

EXAMPLES

show throughput gig detail

Displays detailed throughput performance information in gigabits per second.

show throughput historical

Displays historical throughput performance information.

OPTIONS

For information about the options that you can use with the command show, see help show.

BIG-IP 2012-03-26 sys performance throughput(1)

sys pfman consumer

NAME

consumer - Manage the state of pfman health status consumers.

MODULE

sys pfman

SYNTAX

Manage pfman administered consumers using the syntax in the following section.

MODIFY

modify consumer [guest-name]
parameter:
state [up|down|reset]

DISPLAY

list consumer
list consumer [guest-name]

DESCRIPTION

You can use the consumer component to manage the state of guest access to device health status services.

EXAMPLES

modify consumer tesseract-guest down

Transitions to 'down' the communication link between the hypervisor and guest pfmand daemons. When 'down', the guest is unable to send requests to the hypervisor, nor will it receive status updates.

modify consumer tesseract-guest up

Transitions to 'up' the communication link between the hypervisor and guest pfmand daemons. When 'up', the guest can send requests to the hypervisor, and receive status updates.

modify consumer tesseract-guest reset

Transitions to 'down', then to 'up', the communication link between the hypervisor and guest pfmand daemons.

list consumer tesseract-guest

Lists the current status of the guest called "tesseract-guest".

list consumer

Lists the current status of all guests.

SEE ALSO

list, modify, tmsb

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-04-21 sys pfman consumer(1)

sys pfman device

NAME

device - Manage the state of a pfman controlled device status.

MODULE

sys pfman

SYNTAX

Manage pfman administered devices using the syntax in the following section.

MODIFY

modify device [pci_device]
parameter:
state [up|down|reset]

DISPLAY

list device
list device [pci_device]

DESCRIPTION

You can use the device component to manage the state of device reset and health status reporting.

EXAMPLES

modify device 04:00.0 down

This will cause pfmand to "down" the device. A device in the "down" state will not return to use until the device returns to "up" status. All associated tmm instances will be informed of the device status change to "down".

modify device 86:00.0 up

This causes pfmand to attempt to bring a "down" device back to the "up" status. When successful, all associated tmm instances will be informed of the device status change to "up".

modify device 86:00.0 reset

Instructs pfmand to issue a reset of device 86:00.0.

list device 85:00.0

Lists the status of device 85:00.0.

list device

Lists the status of all devices.

SEE ALSO

sys proc-info

NAME

proc-info - Display CPU and memory usage for each process.

MODULE

sys

SYNTAX

Display proc-info component within the sys module using the syntax in the following section.

DISPLAY

show proc-info
show proc-info process_name
options:
(default | field-fmt | all | kil | meg | gig | raw | exa | peta | tera | zetta | yotta)

DESCRIPTION

Show proc-info displays CPU and memory usage for each process and the process associated module name. This can be used to debug which process or module uses more resource.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

COPYRIGHT

BIG-IP 2011-02-16 sys proc-info(1)

sys provision

NAME

provision - Configures provisioning on the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the provision component within the sys module using the syntax in the following sections.

MODIFY

modify provision [afm | apm | asm | avr | cgnat | fps | gtm | ilx | lc |
itm | pem | swg | urldb | sslo | vcmp]

options:

cpu-ratio [integer]
disk-ratio [integer]
level [custom | dedicated | minimum | nominal | none]
memory-ratio [integer]

edit provision

[[[afm | apm | asm | avr | cgnat | fps | gtm | ilx | lc | itm | pem |
swg | urldb | sslo | vcmp] [glob] [regex]] ...]

options:

all-properties
non-default-properties

DISPLAY

list provision

[[[afm | apm | asm | avr | cgnat | fps | gtm | ilx | lc | itm | pem |
swg | urldb | sslo | vcmp] [glob] [regex]] ...]

show running-config provision

[[[afm | apm | asm | avr | cgnat | fps | gtm | ilx | lc | itm | pem |
swg | urldb | sslo | vcmp] [glob] [regex]] ...]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the provision component to modify the allocation of resources to the licensed modules on your system.

EXAMPLES

modify provision asm level minimum

Provisions the minimum amount of resources for the BIG-IP Application Security Manager.

list provision

Displays the current provisioning of the system.

Using Transactions

1. create / cli transaction
2. modify / sys provision itm level minimum
3. modify / sys provision gtm level nominal
4. submit / cli transaction

The previous four steps create a transaction to modify the provisioning of a unit to provision the Local Traffic Manager at the minimum level and the Global Traffic Manager at the nominal level.

1. create / cli transaction

2. modify / sys provision ltm level none
3. modify / sys provision gtm level dedicated
4. submit / cli transaction

The previous four steps create a transaction to modify the provisioning of a unit to dedicate all of the unit's resources to the Global Traffic Manager when currently only the Local Traffic Manager is provisioned.

OPTIONS

afm Specifies that you are provisioning the BIG-IP Advanced Firewall Manager. When the Advanced Firewall Manager is provisioned, the tmsh module security is enabled.

apm Specifies that you are provisioning the BIG-IP Access Policy Manager. When the Access Policy Manager is provisioned, the tmsh module apm is enabled.

asm Specifies that you are provisioning the BIG-IP Application Security Manager. When asm is provisioned the tmsh module asm is enabled.

avr Specifies that you are provisioning the BIG-IP Application Visibility and Reporting. When Application Visibility and Reporting is provisioned the tmsh module analytics is enabled.

cpu-ratio
Use this option only when the level option is set to custom. F5 Networks recommends that you do not modify this option. The default value is none.

disk-ratio
Use this option only when the level option is set to custom. F5 Networks recommends that you do not modify this option. The default value is none.

fps Specifies that you are provisioning the BIG-IP Fraud Protection Service. When fps is provisioned the tmsh module security anti-fraud is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

gtm Specifies that you are provisioning the BIG-IP Global Traffic Manager. When gtm is provisioned the tmsh module gtm is enabled.

ilx Specifies that you are provisioning BIG-IP iRules Language Extensions.

lc Specifies that you are provisioning the BIG-IP Link Controller. When Link Controller is provisioned the tmsh module gtm is enabled.

level
Specifies the level of resources that you want to provision for a module. The options are:

custom
F5 Networks does not recommend that you specify this level.

dedicated
Specifies that all resources are dedicated to the module you are provisioning. For all other modules, the level option must be set to none.

minimum
Specifies that you want to provision the minimum amount of resources for the module you are provisioning.

nominal
Specifies that you want to share all of the available resources equally among all of the modules that are licensed on the unit.

none Specifies that you do not want to provision any resources for this module.

ltm Specifies that you are provisioning the BIG-IP Local Traffic Manager.

memory-ratio
Use this option only when the level option is set to custom. F5 Networks recommends that you do not modify this option. The default value is none.

pem Specifies that you are provisioning the BIG-IP Policy Enforcement Manager. When Policy Enforcement Manager is provisioned the tmsh module pem is enabled.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

swg Specifies that you are provisioning the BIG-IP Secure Web Gateway. When Secure Web Gateway is provisioned, the assumption is that Access Policy Management is already provisioned and tmsh component apm url-filter is enabled;

urldb
Specifies that you are provisioning the BIG-IP Secure Web Gateway with minimum resource mode. Mainly used for SSL orchestration use cases. The tmsh module urldb cannot be provisioned in BIG-IP when the tmsh module swg is already provisioned and vice-versa.

sslo Specifies that you are provisioning the BIG-IP SSL Otrchestrator.

vcmp Specifies that you are provisioning the BIG-IP Virtual CMP. When Virtual CMP is provisioned the tmsh module vcmp is enabled.

BIG-IP 2020-02-12 sys provision(1)

sys pva-traffic

NAME

pva-traffic - Displays and resets Packet Velocity(r) ASIC (PVA) traffic statistics for the system.

MODULE

sys

SYNTAX

Configure the pva-traffic component within the sys module using the following syntax.

MODIFY

reset-stats pva-traffic

DISPLAY

show pva-traffic

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

global

DESCRIPTION

You can use the pva-traffic component to display traffic statistics, including bits in and out, packets in and out, current, maximum, and total connections, and other miscellaneous statistics.

The BIG-IP(r) system has one PVA accelerator; however, when you run the command show pva-traffic, the system displays a PVA statistics entry for each Traffic Management Microkernel (TMM).

EXAMPLES

show pva-traffic

Displays PVA traffic statistics for the system.

show pva-traffic raw

Displays PVA traffic statistics for the system in raw data form.

OPTIONS

For information about the options that you can use with the command show, see help show.

For information about the command reset-stats, see help reset-stats.

SEE ALSO

reset-stats, show, sys tmm-traffic, sys traffic, tmsh

BIG-IP 2011-04-25 sys pva-traffic(1)

sys raid array

NAME

array - Configures an array of hard disks on the BIG-IP(r) system.

MODULE

sys raid

SYNTAX

Configure the array component within the sys raid module using the syntax in the following sections.

MODIFY

modify array [name] [[add | remove] [hard disk name]]

DISPLAY

show array

show array [name]

options:

field-fmt

DESCRIPTION

You can use the array component to add a hard disk to or remove a hard disk from an array of disks, or to display information about an array of disks.

EXAMPLES

show array

Displays information about all of the arrays that are configured on the system.

modify array MD1 remove HD2

Removes hard disk, HD2 from array, MD1.

OPTIONS

hard disk name

Specifies the name of the hard disk that you want to add to or remove from the array. This option is required for the command modify.

name Specifies the name of the array. This option is required for the command modify.

SEE ALSO

modify, show, tmsh

BIG-IP 2010-03-11 sys raid array(1)

sys raid bay

NAME

bay - Manages a BIG-IP(r) system disk drive bay.

MODULE

sys raid

SYNTAX

Manage the bay component within the sys raid module using the syntax in the following sections.

MODIFY

modify bay [1 | 2]

options:

flash-led

no-flash-led

DISPLAY

show bay [1 | 2]

options:

field-fmt

DESCRIPTION

You can use the bay component to display information about a system bay, signal the LED on a bay to flash, or signal the LED on a bay to stop flashing. The LED is helpful for identifying the location of a specific disk, see sys raid disk.

EXAMPLES

modify bay 1 flash-led

Signal the system to make the LED on bay 1 flash.

show bay

Displays information about the system bay.

show bay field-fmt

Displays information about the system bay in a field format.

OPTIONS

flash-led

Signal the LED on the bay to flash.

no-flash-led

Signal the LED on the bay to stop flashing.

For information about the field-fmt option, see help show.

SEE ALSO

show, sys raid disk, tmsh

BIG-IP 2011-08-29 sys raid bay(1)

sys raid disk

NAME

disk - Displays information about the BIG-IP(r) system disks.

MODULE

sys raid

SYNTAX

Display information about the disk component within the sys raid module using the syntax in the following sections.

DISPLAY

show disk [name]

options:

field-fmt

all-properties

DESCRIPTION

You can use the disk component to display information about the system disks including name, serial number, and whether the disk is a member of an array of disks. When "all-properties" option is specified, the media wear-out information of the disk is also shown. This include the wear-out indicator, space available, power-on hours, and estimated remaining life.

EXAMPLES

show disk

Displays information about all of the system disks.

show disk HD1 field-fmt

Displays information, in a field format, about disk, HD1.

show disk SSD1 all-properties

Displays all information (including the media wear-out information) about disk, SSD1.

OPTIONS

name Specifies the name of the disk for which you want to display information.

SEE ALSO

show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 sys raid disk(1)

sys ready

NAME

ready - Display the ready status for processing config/license/provision commands.

MODULE

sys

SYNTAX

Display the ready status for processing config/license/provision commands using the syntax in the following section.

DISPLAY

show ready
options:
field-fmt

DESCRIPTION

You can use the ready component to display whether or not the BIG-IP is ready to handle actions such as:

config

Adding or modifying the system's configuration, such as adding a pool member.

license

Apply or update licensing.

provision

Modify resource provisioning, such as enabling or disabling modules

EXAMPLES

show ready

Sys::BIG-IP Ready:

config yes
license yes
provision yes

show ready field-fmt

```
sys bigip-ready {  
  config-ready yes  
  license-ready yes  
  provision-ready yes  
}
```

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

BIG-IP 2017-05-18 sys ready(1)

sys scriptd

NAME

scriptd - Configure the scriptd daemon

MODULE

sys

SYNTAX

Configure the scriptd daemon within the sys module using the syntax in the following sections.

MODIFY

modify scriptd

options:

log-level [alert | crit | debug | emerg | err | info | notice | warn]

max-script-run-time [seconds]

DISPLAY

list scriptd

show running-config scriptd

options:

all-properties

DESCRIPTION

You can use the scriptd component to configure the scriptd daemon. The scriptd daemon runs app application template implementation scripts when an application service is created or updated (see sys application template and sys application service).

EXAMPLES

list scriptd

Displays scriptd configuration.

modify scriptd max-script-run-time 120

Updates the maximum time, in seconds, that a script is allowed to run.

OPTIONS

log-level

Specifies the syslog level at which scriptd will generate log messages.

max-script-run-time

Specifies, in seconds, the maximum amount of time that a script is allowed to run before scriptd will kill the script. The default value is 300. The minimum value is 5.

SEE ALSO

list, modify, show, sys application template, sys application service, tmsh

BIG-IP 2012-04-19 sys scriptd(1)

sys service

NAME

service - Manages services on the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the service component within the sys module using the syntax in the following sections.

MODIFY

modify service [name]

options:

[add | disable | enable | reinit | remove]

restart service [name]

start service [name]

stop service [name]

options:

force

DISPLAY

list service

list service [name]

show running-config service

show running-config service [name]

options:

all-properties

show service

options:

memstat

DESCRIPTION

You can use the service component to add, disable or enable, start, stop, restart, reinitialize, remove, or display information about a service.

Note that the tmsh connection to mcpd will be dropped if you stop or restart the mcpd service. The next tmsh command will prompt you to try again. Alternatively you can quit tmsh and login again.

EXAMPLES

list service

Displays information about the services available on the BIG-IP system.

restart service mcpd

Restarts the mcpd daemon.

OPTIONS

add Adds the specified service.

disable

Disables the specified service.

enable

Enables the specified service.

memstat

Displays memory usage statistics for the specified service.

reinit

Reinitializes the specified service.

remove

Removes the specified service.

SEE ALSO

list, modify, restart, show, start, stop, tmsh

sys sflow global-settings http

NAME

http - Manages the global HTTP sFlow configuration on the BIG-IP system.

MODULE

sys sflow global-settings

SYNTAX

Configure the http component within the sys sflow global-settings module using the syntax shown in the following sections.

MODIFY

modify http
options:

description [string]
poll-interval [integer]
sampling-rate [integer]

DISPLAY

list http
options:
all-properties
non-default-properties
one-line

DESCRIPTION

You can use the http component to modify or list the global HTTP sFlow configuration on the BIG-IP system.

Note: You can modify the global HTTP sFlow configuration on the BIG-IP system, only if you are assigned either the Resource Administrator or Administrator user role.

EXAMPLES

modify http poll-interval 60 sampling-rate 1500

Sets the poll-interval to 60 seconds and the sampling-rate to 1500 packets for all monitored HTTP data sources on the BIG-IP system.

OPTIONS

description
User defined description.

poll-interval

Specifies the maximum interval in seconds between polling by the sFlow agent of all monitored HTTP data sources on the BIG-IP system. The default value is 10.

sampling-rate

Specifies the ratio of packets observed at all HTTP data sources to the samples generated. For example, a sampling rate of 2000 specifies that 1 sample will be randomly generated for every 2000 packets observed. The default value is 1024.

SEE ALSO

list, modify, tmsh

sys sflow receiver

NAME

receiver - Manages sFlow receivers configured on the BIG-IP system.

MODULE

sys sflow

SYNTAX

Configure the receiver component within the sys sflow module using the syntax shown in the following sections.

CREATE/MODIFY

```
create receiver [name]
modify receiver [name]
options:
  address [ip address]
  app-service [[string] | none]
  description [string]
  max-datagram-size [integer]
  port [ip port]
  state [disabled | enabled]
```

DISPLAY

```
list receiver
list receiver [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  one-line
```

DELETE

```
delete receiver [name]
```

DESCRIPTION

You can use the receiver component to create, delete, list, or modify an sFlow receiver object on the BIG-IP system.

Note: You can add an sFlow receiver to the BIG-IP system, only if you are assigned either the Resource Administrator or Administrator user role.

EXAMPLES

```
create receiver my_receiver address 10.10.10.10
```

Creates an sFlow receiver object named `my_receiver` with an IP address of 10.10.10.10, where the port, max-datagram-size, and state options are set to default values.

```
create receiver my_receiver address 10.20.10.20 port 1234 state enabled
```

Creates an sFlow receiver object named `my_receiver` with an IP address of 10.20.10.20, a port of 1234, and the max-datagram-size option set to default value. The state of the receiver is enabled.

```
modify receiver my_receiver state enabled
```

Changes the state of sFlow receiver object named `my_receiver` to enabled.

OPTIONS

address

Specifies the IP address on which the sFlow receiver listens for UDP datagrams. This option is required for the create command.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

max-datagram-size

Specifies the maximum size in bytes of the UDP datagram the sFlow receiver accepts. The default value is 1400.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

port Specifies the port on which the sFlow receiver listens for UDP datagrams. The default value is the standard sFlow port, 6343.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

state

Specifies the state of the receiver. The sFlow samples will be collected and sent to the receiver when enabled. The default value is disabled.

sys smtp-server

NAME

smtp-server - Configure the SMTP server connection.

MODULE

sys

SYNTAX

Create or modify an SMTP server access configuration using the syntax in the following sections.

CREATE / MODIFY

modify smtp-server [name]

create smtp-server [name]

options:

app-service [[string] | none]

[authentication-enabled | authentication-disabled]

encrypted-connection [none | tls | ssl]

local-host-name [string]

smtp-server-host-name [string]

smtp-server-port [integer]

from-address [string]

username [string]

password [string]

DISPLAY

list smtp-server

show running-config smtp-server

options:

all-properties

DESCRIPTION

You can use the smtp-server component to configure an SMTP server connection.

EXAMPLES

list smtp-server

Displays the SMTP configuration.

modify smtp-server smtp1 authentication-enabled encrypted-connection ssl local-host-name example.f5.com from-address example@f5.com smtp-server-host-name mail.server.com username user password pass

Configures SMTP server connection with username=user and password=pass to be authenticated against the SMTP server mail.server.com. SSL encryption will be used for all communication with the SMTP server. Email messages will be sent out with the address example@f5.com in the "Reply-To" address.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

[authentication-enabled | authentication-disabled]

Enables or disables authentication against the configured SMTP server.

encrypted-connection

Specifies which type of encrypted connection the SMTP server requires in order to send mail. The default value is none.

local-host-name

Specifies the host name used in SMTP headers in the format of a fully qualified domain name. This setting does not refer to the BIG-IP system's Hostname.

smtp-server-host-name

Specifies the SMTP server host name in the format of a fully qualified domain name.

smtp-server-port

Specifies the SMTP port number. The default value is 25.

from-address

Specifies the email address that the email is being sent from. This is the "Reply-to" address that the recipient sees.

username
Specifies the user name that the SMTP server requires when validating a user.

password
Specifies the password that the SMTP server requires when validating a user. This password is stored in an encrypted form.

SEE ALSO
list, create, modify, show, tmsh

COPYRIGHT

```

DESCRIPTION

You can use the `snmp` component to configure the `snmpd` daemon for the BIG-IP system.

Important: F5 Networks recommends that users of the Configuration utility exit the utility before changes are made to the system using the command sequence `tmsh sys snmp`. This is because making changes to the system using this command causes a restart of the `snmpd` daemon. Likewise, restarting the `snmpd` daemon creates the necessity for a restart of the Configuration utility.

EXAMPLES

```
modify snmp sys-contact admin@company.com
```

Modifies the configuration to indicate that the person who administers the `snmpd` daemon for the system can be reached using the email address, `admin@company.com`.

```
modify snmp sys-location "central office"
```

Modifies the configuration to indicate that the physical location of the system is the central office.

```
modify snmp snmpv1 disabled
```

Disables `snmpV1` agent support.

```
modify snmp snmpv2c disabled
```

Disables `snmpV2c` agent support.

```
modify snmp agent-trap disabled
```

Disables agent traps.

```
modify snmp allowed-addresses add {10.10.0.0/255.255.240.0}
```

Adds a range of SNMP clients to the `/etc/hosts.allow` file.

```
modify snmp traps add { tv1 { version 1 community public host 192.168.1.240 port 162 } }
```

Adds an SNMP version 1 trap, `tv1`, to the system. The destination IP address of `tv1` is `192.168.1.240`, the port is `162`, and the community that has access to `tv1` is `public`. The default port is `162`.

```
modify snmp traps add { tv2 {version 2c community public host 192.168.1.241 port 162} }
```

Adds an SNMP version 2 trap, `tv2`, to the system. The destination IP address of `tv2` is `192.168.1.241`, the port is `162`, and the community that has access to `tv2` is `public`. The default port is `162`. The default version is `2c` (version 2).

```
modify snmp traps add { trap_v3_1 { version 3 host 192.168.1.242 port 162 security-level auth-no-privacy security-name mySecurityName auth-protocol md5 auth-password myAuthPassword } }
```

Adds an SNMP version 3 trap, `trap_v3_1`, with authentication capabilities to the system. The destination IP address of `trap_v3_1` is `192.168.1.242`, the port is `162`, the security level is the authentication without privacy, the security name is `mySecurityName`, the authentication protocol is `MD5`, and the authentication password is `myAuthPassword`. The default port is `162`.

```
modify snmp traps add { trap_v3_2 { version 3 host 192.168.1.243 port 162 security-level auth-privacy security-name mySecurityName auth-protocol sha auth-password myAuthPassword privacy-protocol aes privacy-password myPrivacyPassword } }
```

Adds an SNMP version 3 trap, `trap_v3_2`, with authentication and privacy capabilities to the system. The destination IP address of `trap_v3_2` is `192.168.1.243`, the port is `162`, the security level is the authentication and privacy, the security name is `mySecurityName`, the authentication protocol is `SHA`, the authentication password is `myAuthPassword`, the privacy protocol is `AES`, and the privacy password is `myPrivacyPassword`. The default port is `162`.

```
modify snmp v1-traps add { ts { community public host 10.20.5.11 port 162 } }
```

Adds an SNMP version 1 trap, `ts`, to the system. The destination IP address of `ts` is `10.20.5.11`, the port is `162`, and the community that has access to `ts` is `public`. The default port is `162`.

```
modify snmp v2-traps add { t2s { community public host 10.20.5.12 port 162 } }
```

Adds an SNMP version 2 trap, `t2s`, to the system. The destination IP address of `t2s` is `10.20.5.12`, the port is `162`, and the community that has access to `t2s` is `public`. The default port is `162`.

```
modify snmp users add { myUser1 { username myUser1 access ro security-level auth-no-privacy auth-protocol md5 auth-password myAuthPassword privacy-protocol } }
```

Adds an SNMP version 3 user with the user name, `myUser1`, to the system. The access to the management information base (MIB) of `myUser1` is read-only, the security level is the authentication without privacy, the authentication protocol is `MD5`, and the authentication password is `myAuthPassword`.

```
modify snmp users add { myUser2 { username myUser2 oid-subset .1.3.6.1.4.1.3375 auth-protocol md5 auth-password myAuthPassword privacy-protocol none } }
```

Adds an SNMP version 3 user with the user name, `myUser2`, to the system. The access to the management information base (MIB) of `myUser2` is read-only (by default) and restricted to every object below `.1.3.6.1.4.1.3375` object identifier in the MIB tree, the security level is the authentication without privacy,

the authentication protocol is MD5, and the authentication password is myAuthPassword.

```
modify snmp users add { myUser3 { username myUser3 access ro security-level auth-privacy auth-protocol sha  
auth-password myAuthPassword privacy-protocol des privacy-password myPrivacyPassword } }
```

Adds an SNMP version 3 user with the user name, myUser3, to the system. The access to the management information base (MIB) of myUser3 is read-only, the security level is the authentication and privacy, the authentication protocol is SHA, the authentication password is myAuthPassword, the privacy protocol is DES, and the privacy password is myPrivacyPassword.

```
modify snmp users add { myUser4 { username myUser4 access ro security-level no-auth-no-privacy auth-protocol  
none privacy-protocol none } }
```

Adds an SNMP version 3 user with the user name, myUser4, to the system. The access to the management information base (MIB) of myUser4 is read-only without the authentication and privacy settings.

```
modify snmp communities add { community1 { community-name mycommunity access ro source 192.168.1.246 oid-  
subset 5 ipv6 disabled } }
```

Creates a community specification named community1 for the BIG-IP system. community1 includes a community, named mycommunity, that provides read-only access to the host at 192.168.1.246. This host cannot be an IPv6 address. The oid for this community is 5.

```
modify snmp communities add { new-name { community-name public source default oid-subset 1 access ro } }
```

Replaces the default community specification for the BIG-IP system. Using this command, the default community includes a community, named public, that provides read-only access to the default host. The oid for this community is 1.

```
modify snmp communities delete { mycommunity }
```

Deletes the community named mycommunity.

```
modify snmp load-max1 0 load-max5 0 load-max15 0
```

Disables monitoring of snmpd load average on the BIG-IP system.

OPTIONS

snmpv1

Specifies, when enabled, that the snmpd daemon supports snmpV1 queries. The default value is enabled.

snmpv2c

Specifies, when enabled, that the snmpd daemon supports snmpV2c queries. The default value is enabled.

agent-addresses

Indicates that the SNMP agent is to listen on the specified address. F5 Networks recommends that you do not change this setting without fully understanding the impact of the change.

agent-trap

Specifies, when enabled, that the snmpd daemon sends traps, for example, start and stop traps. The default value is enabled.

allowed-addresses

Configures the IP addresses of the SNMP clients from which the snmpd daemon accepts requests. An SNMP client is a system that runs the SNMP manager software for the purpose of remotely managing the BIG-IP system. The default value is 127.

auth-trap

Specifies, when enabled, that the snmpd daemon generates authentication failure traps. The default value is disabled.

bigip-traps

Specifies, when enabled, that the BIG-IP system sends device warning traps to the trap destinations. The default value is enabled.

community

Configures a community for the snmpd daemon. Note that you must include a community key, and you must enclose the attributes in braces.

The options are additive and include:

access

Specifies the community access level to the MIB. The access options are ro (read-only) or rw (read-write). The default value is ro.

community name

Specifies the name of the community that you are configuring for the snmpd daemon. This option is required. The default value is public.

description

User defined description.

ipv6 Specifies to enable or disable IPv6 addresses for the community that you are configuring. The default value is disabled.

oid-subset

Specifies to restrict access by the community to every object below the specified object identifier

(OID).

source

Specifies the source addresses with the specified community name that can access the management information base (MIB). The default value is default, which means allow any source address to access the MIB.

description

User defined description.

disk-monitors

Checks the disks mounted at the specified path for available disk space.

The options are:

description

User defined description.

minspace

Specifies the minimum disk space threshold in either kB or percentage based on the value of the minspace-type option. If the available disk space is less than this amount, the associated entry in the 1.3.6.1.4.1.2021.9.1.100 MIB table is set to (1) and a descriptive error message is returned to queries of 1.3.6.1.4.1.2021.9.1.101.

minspace-type

Specifies a minimum disk space measurement type of either size in kB, or percent. Note that the value of the minspace option is based on the value of this option.

path Specifies the path to the disk that the system checks for disk space. This option is required.

include

Warning: Do not use this parameter without assistance from the F5 Technical Support team. The system does not validate the commands issued using the include parameter. If you use this parameter incorrectly, you put the functionality of the system at risk.

l2forward-vlan

Specifies the VLANs for which you want the snmpd daemon to expose Layer 2 forwarding information. Layer 2 forwarding is the means by which frames are exchanged directly between hosts, with no IP routing required. The default value is none.

The options are:

all The snmpd daemon exposes Layer 2 forwarding information for all VLANs.

Warning: When you set this option to all, the system can create a very large table of statistics and potentially affect system performance.

none Indicates that this option is not set.

Important: The default is not the same as setting this option to the string "none," which indicates that you do not want the snmpd daemon to expose Layer 2 forwarding for any VLAN.

VLAN name

Specifies the names of the VLANs for which the snmpd daemon exposes Layer 2 forwarding information. The snmpd daemon overwrites the value of the sysL2ForwardAttrVlan object identifier (OID) with the specified VLAN names. Once you set this parameter, users cannot change the value of the sysL2ForwardAttrVlan OID using the SNMP set method.

load-max1

Specifies the maximum 1-minute load average of the machine. If the load exceeds this threshold, the associated entry in the 1.3.6.1.4.1.2021.10.1.100 MIB table is set to (1) and a descriptive error message is returned to queries of 1.3.6.1.4.1.2021.10.1.101.

Note that when you specify a 0 (zero) for all three of the load-max1, load-max5, and load-max15 options, the system does not monitor the load average.

load-max5

Specifies the maximum 5-minute load average of the machine. If the load exceeds this threshold, the associated entry in the 1.3.6.1.4.1.2021.10.1.100 MIB table is set to (1) and a descriptive error message is returned to queries of 1.3.6.1.4.1.2021.10.1.101.

Note that when you specify a 0 (zero) for all three of the load-max1, load-max5, and load-max15 options, the system does not monitor the load average.

load-max15

Specifies the maximum 15-minute load average of the machine. If the load exceeds this threshold, the associated entry in the 1.3.6.1.4.1.2021.10.1.100 MIB table is set to (1) and a descriptive error message is returned to queries of 1.3.6.1.4.1.2021.10.1.101.

Note that when you specify a 0 (zero) for all three of the load-max1, load-max5, and load-max15 options, the system does not monitor the load average.

process-monitors

Specifies to check the machine to determine if the specified process is running. An error flag (1) and a description message are passed to the 1.3.6.1.4.1.2021.2.1.100 and 1.3.6.1.4.1.2021.2.1.101 MIB columns (respectively) if the specified program is not found in the process table as reported by /bin/ps -e.

F5 Networks recommends that you do not modify or delete system processes; however, you can add, modify, or delete user-defined processes.

The options are:

description

User defined description.

max-processes

Specifies the maximum number of instances of the process that can run. The default value is 1.

If you do not specify values for the min-processes and max-processes options, the max-processes option is 1 by default.

min-processes

Specifies the minimum number of instances of the process that can run. The default value is 1.

If you do not specify a value for the max-processes option, and the min-processes option is not specified, the min-processes option is 0 (zero) by default.

process

Specifies the name of the monitored process. The maximum length for a process name is 16 characters. This option is required.

sys-contact

Specifies the name of the person who administers the snmpd daemon for this system. The default value is "Customer Name"

sys software block-device-hotfix

NAME

block-device-software-hotfix - Manages F5 Networks block device software hotfixes.

MODULE

sys software

SYNTAX

Install or display information about a block-device-hotfix using the syntax in the following sections.

INSTALL

install block-device-hotfix [name] volume [name]

options:

create-volume

reboot

DISPLAY

list block-device-hotfix

list block-device-hotfix [[[name [/slot_id]] | [glob] | [regex]] ...]

options:

build

checksum

device-agent

id

one-line

product

title

resource-id

verified

version

DESCRIPTION

You can use the block-device-hotfix component to install a block-device-hotfix onto a volume, or view information about available block-device-hotfixes.

Use the create-volume option with the block-device-hotfix component to create new volumes.

Note: You use the slot_id option only for chassis systems and only when displaying the values for the options of a specific block-device-hotfix. You do not use the slot_id option when installing or deleting a block-device-hotfix, because these commands operate on all blades or the entire system.

EXAMPLES

list block-device-hotfix Hotfix-BIGIP-11.4.0-2419.0-HF3.iso

Displays information about the specified block-device-hotfix, BIGIP-9.6.1-824.0-HF3.im.

list block-device-hotfix */1

Displays information about the all the block-device-hotfixes on the first slot.

install block-device-hotfix Hotfix-BIGIP-11.4.0-2419.0-HF3.iso volume HD1.1 reboot

Attempts to install the specified block-device-hotfix, Hotfix-BIGIP-11.4.0-2419.0-HF3.iso, onto HD1.1.

Note: If the installation is successful, and you used the reboot option, as in this example, the machine reboots into the newly installed block-device-hotfix.

OPTIONS

build

Displays the build number of the block-device-hotfix.

checksum

Displays the checksum of the block-device-hotfix.

create-volume

Create a new volume using the name specified with the volume option. Mirrored volume names must begin with the prefix MD1.. Mirrored volumes are available only on systems that support RAID, see sys raid.

device-agent

Displays the name of the service which is responsible for managing the type of block device on which a give hotfix is available. vcmp-virtual-cdrom is the device-agent which allows VCMF guests to install hotfixes that reside in the host system, via a virtual cdrom device.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies the name and sequential ID of the block-device-hotfix that you want to install or delete.

product

Displays the F5 Networks product this block-device-hotfix contains.

reboot

Specifies that the system reboots immediately after a successful installation.

resource-id

Displays the resource-id string corresponding to software block-device-hotfix in question. This string is used to identify the image for use in interacting with the device agent that is responsible for management of the resource. In the case of the vcmp-virtual-cdrom device-agent the resource-id is used by the live installation daemon when requesting that the hypervisor make hotfixes available before the installation can proceed.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

slot_id

Specifies the number of the slot on a chassis system that contains the block-device-hotfix about which you want to display information.

title

Displays a textual description of the block-device-hotfix.

verified

When set to yes, indicates that the block-device-hotfix is authentic.

version

Displays the version number of the product the block-device-hotfix contains.

volume

Specifies the name of the volume on which you want to install the block-device-hotfix, or from which you want to delete the block-device-hotfix.

DESCRIPTION

You can use the block-device-image component to install images from block devices onto a volume, or view information about available block-device-images.

INSTALLING A SOFTWARE BLOCK-DEVICE-IMAGE

Before you begin installing a block-device-image, the image must be made available to the system. As of this writing, block device images are only available from within a VCMP guest via a virtual cdrom service. A VCMP host administrator must have provided the images for use by the guest as part of their administration of the VCMP host.

From tmsh, you can use show sys software status to see all of the available disk volumes where you can install the image. You can install the image file in any volume that is not active.

Then use the install command with this component to install the image to an unused volume. You can use the create-volume option if you want to create a new volume. The installation takes some time; you can use show sys software status repetitively to watch the progress of the installation. To put the newly installed software into active service, use the reboot option in the install command, or use the reboot volume vol-name command after the install command completes.

Note: You use the slot_id option only for chassis systems and only when displaying the values for the options of a specific block-device-image. You do not use the slot_id option when installing or deleting a block-device-image, because these commands operate on all blades or the entire system.

CONFIRMING AN BLOCK-DEVICE-IMAGE INSTALLATION

You can use show sys version to confirm that the system is running the new software version. If this is a new module for the current system, you may need to use show sys license and/or install sys license to update your license. For a new module, you may also need to provision CPU, memory, and disk space for the module with the sys provision component.

EXAMPLES

install block-device-image BIGIP-11.4.1.608.0.iso volume HD1.1 reboot

Attempts to install the specified block-device-image, BIGIP-11.4.1.608.0.iso, onto HD1.1. Note: If the installation is successful, the machine reboots into the newly installed block-device-image.

list block-device-image BIGIP-11.4.1.608.0.iso

Displays information about the specified block-device-image, build 608.0 of BIG-IP version 11.4.1.

list block-device-image */1

Displays information about all of the block-device-images located on the first slot.

OPTIONS

build

Displays the build number of the block-device-image.

build-date

Displays the date on which the block-device-image was built.

checksum

Displays the checksum of the block-device-image. You can use this option to verify the integrity of the block-device-image.

create-volume

Creates a new volume using the name specified with the volume option. Mirrored volume names must begin with the prefix MD1.. Mirrored volumes are available only on systems that support RAID, see sys raid.

device-agent

Displays the name of the service which is responsible for managing the type of block device on which a give image is available. vcmp-virtual-cdrom is the device-agent which allows VCMP guests to install images that reside in the host system, via a virtual cdrom device.

file-size

Displays the size of the block-device-image file in megabytes.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

last-modified

Displays the date the file was last modified.

name

Specifies the name of the block-device-image that you want to install or delete.

product

Displays the F5 Networks product the block-device-image contains.

reboot

Specifies that the system reboots immediately after a successful installation.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

resource-id

Displays the resource-id string corresponding to software image in question. This string is used to identify the image for use in interacting with the device agent that is responsible for management of the resource. In the case of the vcmp-virtual-cdrom device-agent the resource-id is used by the live installation daemon when requesting that the hypervisor make images available, before the installation can proceed.

verified

When set to yes, indicates that the block-device-image is authentic.

version

Displays the version number of the product this block-device-image contains.

volume

Specifies the name of the volume on which you want to install the block-device-image, or from which you want to delete the block-device-image.

Note: You cannot install software on the active volume.

BIG-IP **2016-03-14** **sys software block-device-image(1)**

sys software hotfix

NAME

hotfix - Manages F5 Networks software hotfixes.

MODULE

sys software

SYNTAX

Install, display information about, or delete a hotfix using the syntax in the following sections.

INSTALL

install hotfix [name] volume [name]

options:

create-volume
reboot

DISPLAY

list hotfix

list hotfix [[[name [/slot_id]] | [glob] | [regex]] ...]

options:

build
checksum
id
one-line
product
title
verified
version

DELETE

delete hotfix [[name] ...]

options:

all

DESCRIPTION

You can use the hotfix component to install a hotfix onto a volume, view information about available hotfixes, or delete unwanted hotfixes.

Use the create-volume option with the hotfix component to create new volumes.

Note: You use the slot_id option only for chassis systems and only when displaying the values for the options of a specific hotfix. You do not use the slot_id option when installing or deleting a hotfix, because these commands operate on all blades or the entire system.

EXAMPLES

list hotfix Hotfix-BIGIP-9.6.1-824.0-HF3.im

Displays information about the specified hotfix, BIGIP-9.6.1-824.0-HF3.im.

list hotfix */1

Displays information about the all the hotfixes on the first slot.

install hotfix Hotfix-BIGIP-9.6.1-824.0-HF3.im volume HD1.1 reboot

Attempts to install the specified hotfix, BIGIP-9.6.1-824.0-HF3.im, onto HD1.1.

Note: If the installation is successful, and you used the reboot option, as in this example, the machine reboots into the newly installed hotfix.

OPTIONS

build

Displays the build number of the hotfix.

checksum

Displays the checksum of the hotfix. You can use this option to verify the integrity of the hotfix.

create-volume

Create a new volume using the name specified with the volume option. Mirrored volume names must begin with the prefix MD1.. Mirrored volumes are available only on systems that support RAID, see sys raid.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies the name and sequential ID of the hotfix that you want to install or delete.

product

Displays the F5 Networks product this hotfix contains.

reboot

Specifies that the system reboots immediately after a successful installation.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

slot_id

Specifies the number of the slot on a chassis system that contains the hotfix about which you want to display information.

title

Displays a textual description of the hotfix.

verified
When set to yes, indicates that the hotfix is authentic.

version
Displays the version number of the product the hotfix contains.

volume
Specifies the name of the volume on which you want to install the hotfix, or from which you want to delete the hotfix.

SEE ALSO
delete, glob, install, list, regex, sys software image, tmsh

COPYRIGHT

BIG-IP 2012-04-16 sys software hotfix(1)

sys software image

NAME
image - Manages F5 Networks software images.

MODULE
sys software

SYNTAX
Install, display information about, or delete a software image using the syntax in the following sections.

INSTALL
install
options:
create-volume
image [name]
reboot
volume [name]

DISPLAY
list image
list image [[[name [/slot_id]] | [glob] | [regex]] ...]
options:
build
build-date
checksum
file-size
last-modified
one-line
product
verified
version

DELETE
delete image [[[name] ...] | [all]]

DESCRIPTION
You can use the image component to install images onto a volume, view information about available images, or delete unwanted images.

INSTALLING A SOFTWARE IMAGE

Before you begin installing an image, you must download the image file into the /shared/images directory. You can find new software images at <http://downloads.f5.com>. We recommend downloading both the .iso file and the .md5 file. Download the file (or files) to your local machine, then transfer it to the /shared/images directory on the BIG-IP(r). Use the Manager (GUI) interface to make this transfer, or quit tmsh to the Unix command line and use scp or a similar Unix command.

If you downloaded the .md5 file, you can use the Unix md5sum command to check the MD5 hash of the .iso file, and you can compare it to the contents of the .md5 file. They should match. If they do not, retry the download and/or transfer of the .iso file.

From tmsh, you can use show sys software status to see all of the available disk volumes where you can install the .iso file. You can install the .iso file in any volume that is not active.

Then use the install command with this component to install the .iso file to an unused volume. You can use the create-volume option if you want to create a new volume. The installation takes some time; you can use show sys software status repetitively to watch the progress of the installation. To put the .iso file into active service, use the reboot option in the install command, or use the reboot volume vol-name command after the install command completes.

Note: You use the slot_id option only for chassis systems and only when displaying the values for the options of a specific image. You do not use the slot_id option when installing or deleting an image, because these commands operate on all blades or the entire system.

CONFIRMING AN IMAGE INSTALLATION

You can use show sys version to confirm that the system is running the new software version. If this is a new module for the current system, you may need to use show sys license and/or install sys license to update your license. For a new module, you may also need to provision CPU, memory, and disk space for the module with the sys provision component.

EXAMPLES

install image BIGIP-10.0.0.5376.0.iso volume HD1.1 reboot

Attempts to install the specified image, BIGIP-10.0.0.5376.0.iso, onto HD1.1. **Note:** If the installation is successful and the version is permitted, the machine reboots into the newly installed image. If the version is not permitted, add forced to the command to force the reboot.

list image BIGIP-10.0.0.5376.0.iso

Displays information about the specified image, build 5376.0 of BIG-IP version 10.0.0.

list image */1

Displays information about all of the images located on the first slot.

OPTIONS

build

Displays the build number of the image.

build-date

Displays the date on which the image was built.

checksum

Displays the checksum of the image. You can use this option to verify the integrity of the image.

create-volume

Creates a new volume using the name specified with the volume option. Mirrored volume names must begin with the prefix MD1.. Mirrored volumes are available only on systems that support RAID, see sys raid.

file-size

Displays the size of the image file in megabytes.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

last-modified

Displays the date the file was last modified.

name Specifies the name of the image that you want to install or delete.

product

Displays the F5 Networks product the image contains.

reboot

Specifies that the system reboots immediately after a successful installation.

forced

Forces a reboot if the version is not permitted by the license.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

verified

When set to yes, indicates that the image is authentic.

version

Displays the version number of the product this image contains.

volume

Specifies the name of the volume on which you want to install the image, or from which you want to delete the image.

Note: You cannot install software on the active volume.

SEE ALSO

delete, glob, install, list, reboot, regex, sys software hotfix, tmsh, show, sys software status, sys version, sys license, sys provision

BIG-IP 2019-05-02 sys software image(1)

sys software signature

NAME

signature - Manages F5 Networks software signatures.

MODULE

sys software

SYNTAX

Display information about, or delete a signature using the syntax in the following sections.

DISPLAY

list signature

list signature [[[name [/slot_id]] | [glob] | [regex]] ...]

options:

one-line

DELETE

delete signature [[name] ...]

options:

all

DESCRIPTION

You can use the signature component to view information about available signatures, or delete unwanted signatures.

Note: You use the slot_id option only for chassis systems and only when displaying the values for the options of a specific signature. You do not use the slot_id option when deleting a signature, because these commands operate on all blades or the entire system.

EXAMPLES

list signature BIGIP-11.5.0.0.0.135.iso.sig

Displays information about the specified signature, BIGIP-11.5.0.0.0.135.iso.sig.

list signature */1

Displays information about the all the signatures on the first slot.

OPTIONS

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

slot_id

Specifies the number of the slot on a chassis system that contains the hotfix about which you want to display information.

SEE ALSO

delete, glob, list, regex, sys software image, tmsh

BIG-IP 2013-11-18 sys software signature(1)

sys software status

NAME

status - Displays the status of a BIG-IP(r) system software installation.

MODULE

sys software

SYNTAX

Display information about the status component within the sys software module using the following syntax.

DISPLAY

show status
options:
field-fmt

DESCRIPTION

You can use the status component to display the status of the software installation, including whether the system is active, the name of the product being installed, the software version and build number of the software, and the slot and volume on which the software is installed.

After you use the install sys software image command (see install and "sys software image") to install a new software image, you can use this command to monitor the progress of the installation. A percentage meter appears in the Status column.

EXAMPLES

show status

Displays the status of the software installation in a table.

show status field-fmt

Displays the status of the software installation separately for each volume on the system.

root@(big-ip1)(cfg-sync Standalone)(Active)(/Common)(tmsh)# quit
[root@big-ip1:Active:Standalone] images # watch tmsh show sys software status

Launches the Unix watch command from the Unix command line. The command produces auto-updating output similar to this:

Every 2.0s: tmsh show sys software status Thu Oct 18 14:04:04 2012

Sys::Software Status

Volume	Product	Version	Build	Active	Status
HD1.1	EM	3.2.0	222.0	no	installing 6.000 pct
HD1.2	EM	3.2.0	150.0.465	yes	complete
HD1.3	EM	3.2.0	67.0	no	complete

Where the "installing 6.000 pct" status increases until it eventually changes to "complete." It changes to a specific failure message if there is an issue.

OPTIONS

field-fmt
Specifies to display the software status for each volume in a field format, rather than in a table.

SEE ALSO

show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP

2016-03-14

sys software status(1)

sys software update-status

NAME

update-status - Displays the BIG-IP(r) update check results.

MODULE

sys software

SYNTAX

Display the results of an update check contained in the update-status component within the sys software module using the syntax in the following section.

DISPLAY

list update-status

options:

all-properties

one-line

[update type] (e.g. RELEASE)

show update-status

options:

field-fmt

[update type] (e.g. RELEASE)

DESCRIPTION

You can use the update-status component to display the results of the update check feature.

EXAMPLES

list update-status

Displays all update check information for the system.

show update-status RELEASE

Displays update check information for the RELEASE update type for the system in a formatted output.

list update-status GEOLOC all-properties one-line

Displays all update check information for the GEOLOC update type on one line.

list update-status last-checked-version

Displays the last checked version for all update types.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

available

This is the file name of the available update.

check-user

This is the system user that last executed the update check.

label

This is the label used when displaying the status on the GUI.

last-checked

This is the last time this update type was checked.

last-checked-auto-mode

This is false if the last time this update type was checked was performed manually.

last-checked-version

This is the version found at the last time this update type was checked.

progress-status

This is the state of the update check.

supplement

This is the file name of the supplemental file.

url This is the URL linking to the available update.

url-supplement

This is a URL linking to a file supplemental to the available update.

For information about the options that you can use with the command list, see help list.

SEE ALSO

list, tmsh

sys software update

NAME

update - Displays the BIG-IP(r) update check and phone home schedule settings.

MODULE

sys software

SYNTAX

Display and modify the update component within the sys software module using the syntax in the following section.

MODIFY

modify update

options:

auto-check

auto-phonehome

frequency

DISPLAY

list update

options:

all-properties

one-line

show update

options:

field-fmt

DESCRIPTION

You can use the update component to display or modify the configuration of the update check and phone home feature.

EXAMPLES

list update

Displays update check and phone home configuration information for the system.

show update

Displays update check and phone home configuration information for the system formatted for easy viewing.

modify update frequency monthly

Modify the frequency of update checks to monthly.

modify update auto-check disabled

Disable the auto update check feature.

modify update auto-phonehome disabled

Disable the auto phone home feature.

OPTIONS

auto-check

Set this to enabled in order to turn on the auto update check feature. disabled turns the feature off.

auto-phonehome

Set this to enabled in order to turn on the auto phone home feature. disabled turns the feature off.

check-status

This read-only field displays the result of the last update check.

errors

This read-only field displays the number of consecutive errors detected by update checking.

frequency

The frequency of update checks can be one of daily, weekly, or monthly.

For information about the options that you can use with the command list, see help list.

SEE ALSO

list, show, tmsh

BIG-IP 2016-03-14 sys software update(1)

sys software volume

NAME

volume - Manages software volumes on the BIG-IP(r) system.

MODULE

sys software

SYNTAX

Delete, reboot into, or display information about a hard drive volume using the syntax in the following sections.

REBOOT

reboot volume [name]

DISPLAY

list volume

list volume [[[name].[slot_id]] | [glob] | [regex]] ...]

show running-config

show running-config [[[name].[slot_id]] | [glob] | [regex]] ...]

options:

active

active-requested

all-properties

basebuild

build

edition

media [media] [size] [default-boot-location]

one-line

product

status

version

DELETE

delete volume [name]

DESCRIPTION

You can use the volume component to view information about configured volumes, delete unwanted volumes, and reboot the device to a specific volume.

Volumes are created using the install command. See help sys software image and the option create-volume.

Deleting or rebooting into a volume on a VIPRION system affects the entire chassis; therefore, you do not need to specify the slot number.

EXAMPLES

list volume */1

Displays the details of all the volumes located on the first slot in a chassis.

delete volume HD1.5

Deletes the volume named HD1.5.

reboot volume HD1.1

Boots into volume HD1.1 if that volume is not already active. If the volume has an image actively being installed on it, the reboot occurs when the installation is complete.

OPTIONS

active

Specifies if this volume is being run.

active-requested

Specifies if this volume should be active once its status is complete. The system associates this setting

with either the active volume or the volume that is going to become active when its status is complete. If active-requested is set on a volume that is not presently active, the system reboots into the volume when the volume status is complete. As an example, install sys software image BIGIP-10.1.0.3341.0.iso volume HD1.2 reboot will cause active-requested to be set on volume HD1.2, and the system will reboot into volume HD1.2 when the installation is complete. This value is read-only.

basebuild
Displays the build number of either the hotfix presently applied to the system or the original build.

build
Displays the original build number (before any hotfixes).

edition
Displays a textual description of the image. You can use this option to specify the hotfix you want to install.

media
Displays a description of the physical media on which the volume exists. The options are:

media
The type of physical device on which the volume exists, for example, hard drive (hd) or compact flash (cf).

size The space on the slot reserved for the volume.

default-boot-location
Specifies the volume into which the system boots if the slot resets.

name Specifies the name of the volume you are configuring. Volume names are in the format HDX.Y, CFX.Y, or MDX.Y, where X is the hard drive index (HDX), compact flash index (CFX), or RAID index (MDX) (on systems that support RAID), and Y is the volume number on that drive.

product
Displays the F5 Networks product that is installed on the volume.

reboot
Reboots the system into the specified volume.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

status
Displays the installation status of the volume. The options are complete or installing.

version
Displays the version number of the software installed on the volume.

SEE ALSO

BIG-IP 2013-03-21 sys software volume(1)

sys sshd

NAME
sshd - Configures the Secure Shell (SSH) daemon for the BIG-IP(r) system.

MODULE
sys

SYNTAX
Configure the sshd component within the sys module using the syntax in the following sections.

MODIFY
modify sshd
options:
allow [add | delete | replace-all-with] {

```

    [ [hostname] | [IP address] ] ...
}
allow none
banner [disabled | enabled]
banner-text [string]
inactivity-timeout [integer]
include [string]
login [disabled | enabled]
log-level [debug | debug1 | debug2 | debug3 | error | fatal |
info | quiet | verbose]
port [integer]

```

```

edit sshd
options:
  all-properties
  non-default-properties

```

```

DISPLAY
list sshd
list sshd [option]
show running-config sshd
show running-config sshd [option]
options:
  all-properties
  non-default-properties
  one-line

```

DESCRIPTION

You can use the sshd component to configure a secure channel between the BIG-IP system and other devices.

F5 Networks recommends that users of the Configuration utility exit the utility before changes are made to the system using the sshd component. This is because making changes to the system using this component causes a restart of the sshd daemon. Likewise, restarting the sshd daemon creates the necessity for a restart of the Configuration utility.

EXAMPLES

```
modify sshd allow add {192.168.0.0/255.255.0.0}
```

Creates an initial range of IP addresses (192.168.0.0 with a netmask of 255.255.0.0) that are allowed to log in to the system.

```
modify sshd allow add {192.168.1.245}
```

Adds the IP address, 192.168.1.245, to the existing list of IP addresses that are allowed to log in to the system.

```
modify sshd login enabled
```

Enables SSH login to the system.

```
modify sshd inactivity-timeout 3600
```

Sets an inactivity timeout of 60 minutes for SSH logins to the system.

```
modify sshd log-level error
```

Sets the sshd message log level to ERROR.

```
modify sshd banner enabled banner-text "NOTICE: Improper use of this computer may result in prosecution!"
```

Creates a banner that displays when a user attempts to log in to a system using SSH.

Note that you must enclose the banner text in double quotation marks, and then type single quotation marks outside the double quotation marks. You can also use the backslash character to escape each quotation mark as well as any other special characters that the system might process (for example, exclamation point !).

OPTIONS

```
allow
```

Configures servers in the /etc/hosts.allow file. The default value is all.

Warning: Using the value none resets the sshd daemon to allow all servers access to the system. F5 Networks recommends that you do not use the value none with the sshd component.

```
banner
```

Enables or disables the display of the banner text field when a user logs in to the system using SSH. The default value is disabled.

```
banner-text
```

When the banner option is enabled, specifies the text to include in the banner that displays when a user attempts to log on to the system.

```
fips-cipher-version
```

Read-only field for internal use. Non-zero value indicates that the list of ciphers has been set to FIPS 140-2 compliant defaults. The value 1 indicates that the list of ciphers is "aes128-cbc,aes256-cbc". User changes to the list of ciphers will not affect the value of this field. This field is relevant only when FIPS 140-2 compliance is enabled in the license.

inactivity-timeout

Specifies the number of seconds before inactivity causes an SSH session to log out. The default value is 0 (zero) seconds, which indicates that inactivity timeout is disabled.

include

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using the include option. If you use this option incorrectly, you put the functionality of the system at risk.

login

Enables or disables SSH logins to the system. The default value is enabled.

log-level

Specifies the minimum sshd message level to include in the system log. The possible values are:

debug - debug3

Indicates that the minimum sshd message level that the system logs is the specified debugging level of messages.

error

Indicates that the minimum sshd message level that the system logs is error.

fatal

Indicates that the minimum sshd message level that the system logs is fatal.

info Indicates that the minimum sshd message level that the system logs is informational.

quiet

Indicates that the system does not log sshd messages.

verbose

Indicates that the system logs all sshd messages.

port Specifies the TCP port to run SSHD. It is a number in the range of 1 and 65535.

The default value is 22.

list state-mirroring [option]
show running-config state-mirroring
show running-config state-mirroring [option]
options:
all-properties
non-default-properties
one-line

DESCRIPTION

You can use this component to configure connection mirroring on a system that is part of a redundant pair in a high availability system.

Connection mirroring is the process of duplicating connections from the active system to the standby system. Enabling this setting ensures a higher level of connection reliability, but it may also have an impact on system performance.

EXAMPLES

modify state-mirroring state enabled addr 192.168.10.10 peer-addr 192.168.10.20

Enables and configures connection mirroring for a high availability system in which one BIG-IP system has an IP address of 192.168.10.10, and its peer has an IP address of 192.168.10.20.

modify state-mirroring state enabled

Re-enables connection mirroring for a system for which connection mirroring was disabled.

OPTIONS

addr Specifies the primary self-IP address on this unit to which the peer unit in this redundant pair mirrors its connections. The default value is ::.

peer-addr

Specifies the primary self-IP address on the peer unit to which this unit mirrors its connections. The default value is ::.

secondary-addr

Specifies another self-IP address on this unit to which the peer unit mirrors its connections when the primary address is unavailable. The default value is ::.

secondary-peer-addr

Specifies another self-IP address on the peer unit to which this unit mirrors its connections when the primary peer address is unavailable. The default value is ::.

state

Enables or disables connection mirroring. The default value is enabled.

non-default-properties

DISPLAY

list syslog
list syslog [option]
show running-config syslog
show running-config syslog [option]
options:
all-properties
non-default-properties
one-line

DESCRIPTION

You can use the syslog component to configure the system log.

EXAMPLES

modify syslog auth-priv-from warning

Resets the lowest level of messages about user authentication that are included in the system log to messages with a level of warning, error, critical, alert, and emergency.

modify syslog auth-priv-to warning

Resets the highest level of messages about user authentication that are included in the system log to messages with a level of warning, error, critical, alert, and emergency.

OPTIONS

auth-priv-from

Specifies the lowest level of messages about user authentication to include in the system log. The default value is notice.

auth-priv-to

Specifies the highest level of messages about user authentication to include in the system log. The default value is emerg.

clustered-host-name

When enabled, the slash-separated slot ID of the blade that originated the log is prepended to the hostname field. The default value is enabled.

clustered-message-slot

When enabled, the space-separated slot ID of the blade that originated the log is prepended to the message text. The default value is disabled.

cron-from

Specifies the lowest level of messages about time-based scheduling to include in the system log. The default value is warning.

cron-to

Specifies the highest level of messages about time-based scheduling to include in the system log. The default value is emerg.

daemon-from

Specifies the lowest level of messages about daemon performance to include in the system log. The default value is notice.

daemon-to

Specifies the highest level of messages about daemon performance to include in the system log. The default value is emerg.

description

User defined description.

host Specifies the IP address of a remote server to which syslog sends messages. The default value is none.

include

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using the include options. If you use this option incorrectly, you put the functionality of the system at risk.

iso-date

Enables or disables the ISO date format for messages in the log files. The default value is disabled.

console-log

Enables or disables logging emergency syslog messages to the console. The default value is enabled.

kern-from

Specifies the lowest level of kernel messages to include in the system log. The default value is debug.

kern-to

Specifies the highest level of kernel messages to include in the system log. The default value is emerg.

local-ip

Specifies the IP address of the interface syslog binds with in order to log messages to a remote host. For example, if you want syslog to log messages to a remote host that is connected to a VLAN, you set this parameter to the self IP address of the VLAN.

local6-from

Specifies the lowest error level for messages from the local6 facility to include in the log. The default value is notice.

local6-to

Specifies the highest error level for messages from the local6 facility to include in the log. The default value is emerg.

mail-from

Specifies the lowest level of mail log messages to include in the system log. The default value is notice.

mail-to

Specifies the highest level of mail log messages to include in the system log. The default value is emerg.

messages-from

Specifies the lowest level of messages about user authentication to include in the system log. The default value is notice.

messages-to

Specifies the highest level of system messages to include in the system log. The default value is warning.

remote-port

Specifies the port number of a remote server to which syslog sends messages. The default value is 514.

remote-servers

Configures the remote servers, identified by IP address, to which syslog sends messages. The default value is none.

user-log-from

Specifies the lowest level of user account messages to include in the system log. The default value is notice.

user-log-to

Specifies the highest level of user account messages to include in the system log. The default value is emerg.

sys turboflex profile-config

NAME

profile-config - Configures the TurboFlex profile chosen by users.

MODULE

sys turboflex

SYNTAX

Configure the profile-config component within the sys turboflex module using the syntax shown in the following sections.

MODIFY

modify profile-config

options:

type [turboflex-adc | turboflex-highspeed-layer4 | turboflex-security | turboflex-base | turboflex-low-latency | turboflex-private-cloud]

DISPLAY

list profile-config

options:

all-properties

DESCRIPTION

You can use the profile-config component to configure the TurboFlex profile type to use.

EXAMPLES

list profile-config

Displays properties of the current TurboFlex profile configuration.

modify profile-config type

Modify the type of the active TurboFlex profile configuration. The default is turboflex-adc.

OPTIONS

type The type for TurboFlex profile currently chosen on the system.

turboflex-base: The Standard basic profile.

turboflex-adc: The Application Delivery Controller (ADC) profile provides the HW acceleration features normally associated with the ADC use cases. In order to enable this profile, the LTM module must be provisioned.

turboflex-ultrafast-layer4: The Ultra Fast L4 CPS profile provides HW acceleration features normally associated with fast L4 LBing. In order to enable this profile, the LTM module must be provisioned. For full capability, the TAM module must be provisioned after selecting this profile.

turboflex-security: The Security profile provides the HW acceleration features normally associated with the security use cases. In order to enable this profile, the LTM modules must be provisioned. For full capability, the AFM module must be provisioned after selecting this profile.

turboflex-low-latency: The Low Latency FIX profile provides the HW acceleration features normally associated the FIX use case. In order to enable this profile, the Advanced Protocol or FIX-LL add-ons must be licensed and the LTM module must be provisioned.

turboflex-private-cloud: The Private Cloud (PC) profile provides the HW acceleration features normally associated with the PC use cases. In order to enable this profile, the LTM module must be provisioned.

BIG-IP 2017-03-29 sys turboflex warning(1)

sys ucs

NAME

ucs - Loads or saves a UCS (.ucs) file.

MODULE

sys

SYNTAX

Configure the ucs component within the sys module using the syntax in the following sections.

MODIFY

save ucs [file name]

options:

no-private-key

passphrase

load ucs [file name]

options:

include-chassis-level-config

no-license

no-platform-check

passphrase

platform-migrate

reset-trust

delete ucs [file name]

DISPLAY
list ucs
show ucs [file name]

DESCRIPTION

You can use the ucs component to save the running configuration of the system into a UCS file. Additionally, you can modify the running configuration of the system by loading an existing UCS file.

When you save a UCS file, the file is saved to the default directory, /var/local/ucs.

When you load a UCS file in shell mode, the system searches for the file using the relative path to the default directory (/var/local/ucs). When you load a UCS file in bash mode, the system searches the current directory first. If the file is not found in the current directory, the default directory is then searched.

EXAMPLES

save ucs myucs

Saves the running configuration of the system into the file myucs.ucs.

load ucs myucs

Modifies the running configuration of the system by loading the configuration contained in the myucs.ucs file.

delete ucs myucs

Delete myucs.ucs in the default directory, /var/local/ucs/.

list ucs

Displays existing UCS files in the default directory, /var/local/ucs/.

OPTIONS

include-chassis-level-config

During restore of the UCS file, include chassis level configuration that is shared among boot volume sets. For example, cluster default configuration.

no-license

Performs a full restore of the UCS file and all the files it contains, with the exception of the license file. The option must be used to restore a UCS on RMA devices (Returned Materials Authorization).

no-platform-check

Bypasses the platform check and allows a UCS that was created using a different platform to be installed. By default (without this option), a UCS created from a different platform is not allowed to be installed.

no-private-key

Indicates that the UCS file can be saved without private key information.

passphrase

Specifies the passphrase that is necessary to load the specified UCS file.

platform-migrate

Ignore the configuration items specific to a particular platform. The platform-specific objects already present on the device are not removed or modified. The ones included in the UCS archive are not loaded.

This option is not valid for UCS archives from systems provisioned with modules other than LTM and GTM. If the UCS comes from a system running any release of TMOS version 10, only LTM (not GTM) is supported.

This option implies no-license and no-platform-check.

reset-trust

When specified, the device and trust domain certs and keys are not loaded from the UCS. Instead, a new set is regenerated.

SEE ALSO

load, list, save, show, tmsh

sys url-db download-result

NAME

download-result - Lists download result for URL Master and RTSU DB.

MODULE

sys url-db

SYNTAX

List download-result component within the module using the syntax shown in the following sections.

DISPLAY

The download-result consists of the object name (/Common/masterdb or /Common/rtsudb), and version. These objects are created by BIGIP and cannot be modified or deleted.

list url-db download-result [masterdb | rtsudb]/slot_number

options:

all-properties
non-default-properties
one-line

list url-db download-result masterdb/slot_number

db-version [integer]
ret-code 0

list url-db download-result rtsudb/slot_number

db-version [integer]
ret-code 0

DESCRIPTION

Lists download result for Master URL database and Real-Time Security Update (RTSU). These objects are created after the first successful download and updated after every download. For cluster environments the slot number will be shown after the name of the database.

OPTIONS

db-version

Specifies database version for URL Master or Real-Time Security Update DB.

ret-code

Specifies the download result status and always zero now.

SEE ALSO

sys url-db download-schedule sys url-db url-category

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2017-01-19 sys url-db download-result(1)

sys url-db download-schedule

NAME

download-schedule - Configures download schedule for URL Master DB.

MODULE

sys url-db

SYNTAX

Configure a download-schedule component within the module using the syntax shown in the following sections.

MODIFY

The download-schedule consists of the object name (/Common/urldb), download start time (start-time), download end time (end-time) and status. You can have only one download schedule and the download occurs daily.

modify url-db download-schedule urldb

start-time [HH::MM]
end-time [HH::MM]
download-now [true | false]
status [true | false]

use-proxy [true | false]

DISPLAY

list url-db download-schedule urldb
options:
all-properties
non-default-properties
one-line

DESCRIPTION

Configures download schedule for Master URL database.

EXAMPLES

modify download-schedule urldb { start-time 2:00 end-time 4:00 }

Modify the download schedule for Master DB download schedule between 2:00 AM and 4:00 AM. Other downloads such as RTSU (Real-Time Security Update) and ACE (Advanced Classification Engine) DB download occurs at regular intervals.

modify download-schedule urldb { start-time 20:00 end-time 22:00 }

Modify the download schedule for Master DB download schedule between 8:00 PM and 10:00 AM.

modify download-schedule urldb { download-now true }

Master DB Download starts in few minutes after issuing this command. The download-now will be set to false after successful download.

modify download-schedule urldb { status false }

By setting the status flag to false, download (Master and other DB) will not occur any more.

modify download-schedule urldb { use-proxy true }

DB Download uses proxy configuration after issuing this command.

OPTIONS

download-now

Specifies to start download in few minutes and no need to wait for the scheduled window.

end-time

Shows download end time. Download will start between scheduled start time and end time.

start-time

Shows download start time. Download will start between scheduled start time and end time.

status

Shows the download status is enabled. By turning to false, download will not occur.

use-proxy

Specifies to use proxy configuration for database download.

BIG-IP 2016-02-25 sys url-db download-schedule(1)

sys url-db url-category

NAME

url-category - Configures URL categories for URL classification and filtering

MODULE

sys url-db

SYNTAX

Configure a url-category component within the module using the syntax shown in the following sections.

CREATE/MODIFY

Each url-category consists of the object name (/Common/Business_and_Economy), a display-name ("Business and Economy") which is a more user-friendly category name, and a category number. The hundreds and thousands of URLs under a url-category are stored in a database. You can create your own url-category (custom category) and you can add more URLs to an existing category (recategorization).

create url-db url-category [name]

options:

display-name [string]

description [string]

initial-disposition [integer]

is-security-category [string]

parent-cat-number [integer]

severity-level [integer]

**urls [add | delete | modify | replace-all-with] {
[string]
}**

modify url-db url-category [name]

initial-disposition [integer]

is-security-category [string]

parent-cat-number [integer]

severity-level [integer]

**urls [add | delete | modify | replace-all-with] {
[string]
}**

DISPLAY

list url-category

list url-category [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DESCRIPTION

Configures a url-category

NOTE: When you create a new url-category, you must provide a display-name. However, after creation it cannot be changed to another value. The system will provide a cat-number for your newly created url-category. The number is an integer greater than 1900. The url-category you create is considered to be a custom URL category, and so the is-custom flag will be set to true.

NOTE: The only change you can make to a system provided url-category is to add one or more URLs to its list of URLs. This is called recategorization, and the is-recategory flag will be set to true. You need to do this if the URL does not already exist in the database.

EXAMPLES

**create url-category my-own-url-cat display-name "My Own URL Category" urls add { http://a.url.com
http://www.another.url.org }**

Creates a new url-category. The new url-category you create is known as a custom category, as opposed to a system provided url-category. In this case, you must specify the display-name and at least one URL.

modify url-category my-own-url initial-disposition 4 parent-category 0

Modify the initial-disposition and parent-category in a customized url-category.

modify url-category Business_and_Economy urls add { http://www.theneomarxist.com }

Modify a system provided url-category by adding a URL to it. This action is called recategorization. The url-category is recategorized.

OPTIONS

cat-number

Shows a unique category number. Custom URL categories have numbers greater than 1900. This is a read-only attribute.

description

Specifies a unique description for the URL category.

display-name

Specifies a user-friendly name that describes what the URL category represents. This attribute cannot be changed after creation.

initial-disposition

Specifies the action to be taken when a certain URL category is not listed in any url-filter.

is-custom

This flag is set by the system when you create your own URL category. This attribute is read-only.

is-security-category

This flag is not being used. This attribute is read-only.

parent-cat-number

Specifies the category number of a parent url-category. 0 denotes no parent.

severity-level
Specifies the severity level.

SEE ALSO

sys version

NAME

version - Displays software version information for the BIG-IP(r) system.

MODULE

sys

SYNTAX

Display statistics for the version component within the sys module using the syntax in the following section.

DISPLAY

show version
options:
detail

DESCRIPTION

You can use the version component to display the software version running on the system, including a list of hotfixes that you have applied to the system.

EXAMPLES

show version

Displays software version information.

show version detail

Displays more extensive software version information about the system, including the operating system kernel information, and details about each hotfix that you have applied to the system.

OPTIONS

For information about the options that you can use with the command show, see help show.

util

util ccmode

NAME

ccmode - Set Common Criteria mode and a subset of configuration defaults required for a Common-Criteria-compliant BIGIP system.

MODULE

util

SYNTAX

ccmode

DESCRIPTION

Use this command to set a subset of defaults that are required for a Common-Criteria-compliant system.

Run this command **ONLY** if you are creating a Common-Criteria-compliant BIG-IP system, or have otherwise determined that all of the changes are desirable for your BIG-IP configuration. Note that there are runtime changes triggered by this command.

Running the ccmode command is an essential part of the configuration changes required to configure a BIG-IP system as Common-Criteria-compliant. This command changes the base configuration in several ways, including:

• Defining the minimum required password policy.

• Defining the allowed cipher sets for SSL/TLS.

• Disabling some features excluded from the evaluation and therefore not permitted to be used in a compliant system.

• Setting several DB variables, including the Security.CommonCriteria variable, an indicator from which other runtime changes are triggered.

While running this script is essential to creating a Common-Criteria-compliant system, it is not sufficient. Customers wishing to configure compliant systems must consult the configuration Guidance documentation provided when the evaluation is complete, and follow its instructions to completely configure the BIG-IP.

This command has no facility for "undoing" the changes it makes. Instead, the administrator must reverse or revise all of the individual commands, reset the DB variables to their defaults, save the new configuration, and restart the BIG-IP.

BIG-IP 2015-06-26 util clientssl-ciphers(1)

util diadb

NAME

diadb - Run the diadb command to display, filter or delete dia persistence entries.

MODULE

util

SYNTAX

run util diadb

util dnatutil

NAME

dnat - Command providing reverse and forward mapping for deterministic NAT (DNAT).

MODULE

util

SYNTAX

Run the dnat utility from within the util module using the following syntax:

```
run util dnat [] [  
[:]]
```

DESCRIPTION

The dnat utility allows the calculation of forward and reverse source address and port mapping for the deterministic mode of Large Scale NAT.

EXAMPLES

dnat 10.0.0.1 --action forward Shows a list of translation address/port pairs that might be used for a subscriber at 10.0.0.1, using the DNAT states contained in /var/log/ltm.

dnat 173.240.102.139:5678 Performs a reverse mapping back to the subscriber address for the connection from 173.240.102.139:5678, using the DNAT states contained in /var/log/ltm.

dnat --start_time '2012-09-27 06:30:00' --end_time '2012-09-27 12:10:00' 173.240.102.139:5678 Same as the previous example, but only shows the subscriber addresses that used the translation within the specified time range.

dnat --start_time '2012-09-27 06:30:00' --end_time '2012-09-27 12:10:00' --file /var/log/test 173.240.102.139:5678 Same as the previous example, but use the DNAT states contained in /var/log/test

dnat --file /var/log/test Shows summary information, using the DNAT states contained in /var/log/test

dnat --action summary --start_time '2012-09-27 06:30:00' --end_time '2012-09-27 12:10:00' Shows summary information, using the DNAT states within the specified time range.

OPTIONS

client_addr or --client_addr

Used to provide the subscriber address for forward mappings (--action forward), and the translation address for reverse mappings (--action reverse).

client_port or --client_port

Used to provide the subscriber port for forward mappings (--action forward), and the translation port for reverse mappings (--action reverse).

end_time or --end_time

End time of search range. User can specify the time format via the --time-format switch. The time format defaults to 'YYYY-MM-DD HH:MM:SS.'

start_time or --start_time

Start time of search range. User can specify the time format via the --time-format switch. The time format defaults to 'YYYY-MM-DD HH:MM:SS.'

--action

Specify the action to be taken: summary, forward, reverse, reverse_addr. Default: reverse when supplied

with client_addr, summary otherwise.

summary

Provides summary information on the parsed deterministic NAT configuration snippet.

reverse

Returns possible subscriber address for the provided client address and client port (as translation end-point).

forward

Returns possible translation end-points for the provided client address (as subscriber address).

forward_compact

Returns possible subscriber addresses for the provided client address (as translation address), in a compact format with address and port-range.

reverse_addr

Returns possible subscriber addresses for the provided client address (as translation address).

--file /var/log/ltn

Read DNAT state from file (default: /var/log/ltn)

--time_format

Timestamp parse format for --start_time or --end_time (default: '%F %T %Z', this yields 'YYYY-MM-DD HH:MM:SS', with timezone being optional.)

--flags

DAGLIB flags parameter.

--flags_v2or

DAGLIB flags override parameter, apply when deterministic NAT state is from log version 2 or lower only.

--all

Display all entries, even if there are duplicates (default disabled).

--version

Display version and DAG information.

util establish adfs trust

NAME

establish-adfs-trust - Establish trust with ADFS server.

MODULE

util

SYNTAX

establish-adfs-trust --vs [--cert] --username [--password]

- Virtual server name. It should have the "adfs_proxy" profile attached.

- Certificate object name for new trust certificate. If the option is not provided, existing trust certificate will be updated.

/ - Credentials of a local administrator account on the ADFS server. The command will prompt for password if it's not provided on the command line.

DESCRIPTION

The establish-adfs-trust utility allows users to establish trust with ADFS server. During trust establishment, APM generates a self signed certificate and registers it with ADFS. On success, APM adds the newly generated certificate and key to the server SSL profile of given virtual server. Any previously attached certificate and key are detached from the server SSL profile, but remain on the system.

EXAMPLES

```
establish-adfs-trust --vs adfs_vs --cert adfs_cert --username Administrator
```

The above command will prompt for password.

```
establish-adfs-trust --vs adfs_vs --cert adfs_cert --username Administrator --password secret
```

util finalize custom ami

NAME

finalize-custom-ami - Utility to clean-up and prepare the custom AMI for Autoscaling on AWS.

MODULE

util

SYNTAX

Run the finalize-custom-ami utility from within the util module using the following syntax:

```
run util finalize-custom-ami
```

DESCRIPTION

The finalize-custom-ami utility runs the final clean-up steps to prepare the instance for being packaged as a custom AMI that could be autoscaled in AWS. This is a BIG-IP VE on AWS specific utility tool that shouldn't be run on other platforms. This should be used according to supporting documentation provided by F5.

All the output is reported on standard output.

EXAMPLES

```
run util finalize-custom-ami
```

SEE ALSO

run, tmsh

util geodb

NAME

geodb - Run the geodb command to display Diameter Geo Redundancy status.

MODULE

util

SYNTAX

```
run util diadb
```

util geoutil

NAME

geoutil - Run the geoutil command to change topics, hostnames, and ports the georedundancy config files.

MODULE

util

SYNTAX

run util geoutil

DESCRIPTION

The geoutil utility facilitates changing kafka topics by modifying the configuration files for kafka and mirrmaker. It stops the daemons associated with georedundancy (zookeeper, kafka, and mirrmaker). Then it deletes the old topics. It modifies all the necessary config files. Finally, it restarts the daemons.

Before running geoutil, the remote-host entries in sys global-settings should be modified to reflect the new hostnames.

EXAMPLES

One one machine:

```
modify sys global-settings remote-host modify {  
mirrorMakerLocal {  
  hostname seattle addr 127.0.0.1 }  
mirrorMakerRemote {  
  hostname bellevue addr 10.126.2.40 }}
```

```
run util geoutil 10.126.2.1 9092 seattle bellevue
```

On a machine remote from the first:

```
modify sys global-settings remote-host modify {  
mirrorMakerLocal {  
  hostname bellevue addr 127.0.0.1 }  
mirrorMakerRemote {  
  hostname seattle addr 10.126.2.30 }}
```

```
run util geoutil 10.126.2.2 9092 bellevue seattle
```

util ihealth

NAME

ihealth - Run the ihealth utility for the purpose of uploading a new or existent qkview file to ihealth.

MODULE

util

SYNTAX

```
run util ihealth [ -f ] [ -e ] [ -l ]  
[ -a ] [ -u ] [ -p ]  
[ -s ] [ -d ] [ -n ] [ -h ] [ -C ]  
[ -x ] [ -t ]  
[ -z ]
```

or

```
run util ihealth [ --file= ] [ --existing= ]
```

```
[ --auth-url= ] [ --api-url= ]  
[ --user= ] [ --password= ] [ --sr= ]  
[ --description= ] [ --no-upload ] [ --help ]  
[ --exclude-cores ] [ --exclude= ]  
[ --upload-timeout ] [ --max-file-size ]
```

DESCRIPTION

The ihealth utility runs a menu that allows users to select qkview files or creating a new qkview file for uploading to ihealth using DevCentral userid.

OPTIONS

--file

This is the name of the local diagnostics file to use or create.

--existing

This flag can be used to specify to use an existing diagnostics file, rather than create one.

--auth-url

This is an over-ride of the DevCentral login server URL used for connecting to the iHealth diagnostic service.

--api-url

This is an over-ride of the iHealth API service used for storing and processing qkviews.

--user

This is an over-ride of the DevCentral user name stored for connecting to the iHealth diagnostic service.

--password

This is an over-ride of the DevCentral password stored for connecting to the iHealth diagnostic service.

--description

This is a description that is attached to the diagnostics file when uploaded to the iHealth diagnostic service.

--sr This is a service request number that is attached to the diagnostics file when uploaded to the iHealth diagnostic service.

--exclude

This is an over-ride of the stored exclude settings for limiting files collected by qkview. See qkview for the possible values.

--exclude-cores

This directs qkview to exclude core files from it's data collection.

--no-upload

This directs the iHealth command to skip uploading to the iHealth service.

--upload-timeout

Enter the maximum number of seconds that the upload of qkview to ihealth can take. The default is zero, meaning that no --max-time will be passed to curl for the upload. Useful for cron jobs.

--max-file-size

Enter the maximum file size for log files that qkview will truncate to (0-100MB). Setting it to zero signifies 100MB. The floor is 2048, passing a value less than this will be treated as 2048.

--help

Displays the usage for this command.

util ipsecalgdb

NAME

ipsecalgdb - Run the ipsecalgdb command to view IPsecALG translation, and pending IKE connection count entries.

MODULE

util

SYNTAX

run util ipsecalgdb

Commands:

delete

list

Objects:

all

tran[slation] entries

pend[ing] IKE connection count entries

DESCRIPTION

The ipsecalgdb utility allows users to view IPsecALG translation, and pending IKE connection count entries, as well as deleting those entries using this utility.

EXAMPLES

run util ipsecalgdb delete all

Delete all IPsecALG translation, and pending IKE connection count entries.

run util ipsecalgdb delete trans

Delete all IPsecALG translation entries.

run util ipsecalgdb delete pend

Delete all IPsecALG pending IKE connection count entries.

run util ipsecalgdb list all

Shows all IPsecALG translation, as well as pending IKE connection count entries.

OPTIONS

delete

Delete all objects of the specified type.

list Display all objects of the specified type.

all = all available object types.

trans = IPsecALG translation entries.

pend = IPsecALG pending IKE connection count entries.

SEE ALSO

run, tmsh

BIG-IP 2016-08-02 util ipsecalgdb(1)

util lsndb

NAME

lsndb - Run the lsndb command to view Large Scale NAT persistence entries, inbound mappings, client connection counts, and PCP mappings.

MODULE

util

SYNTAX

run util lsndb

Commands:

del[ete]

list

summary

Objects:

all

client

**inbound[-mapping]
pba
pcp
filters
persist[ence]
all**

DESCRIPTION

The **lsndb** utility allows users to view LSN persistence mappings, inbound mappings, PCP mappings, client connection counts and port block entries. Persistence, inbound and PCP mappings can also be deleted using this utility.

EXAMPLES

run util lsndb delete all

Delete all LSN persistence mappings, inbound mappings and PCP mappings.

run util lsndb del inbound

Delete all LSN inbound mappings.

run util lsndb delete pcp

Delete all PCP mappings.

run util lsndb delete persist

Delete all LSN persistence entries.

run util lsndb list all

Shows all LSN persistence mappings, inbound mappings, PCP mappings, client connection counts and port block entries.

run util lsndb list client

Shows all LSN client connection counts. Each line will display the client IP address and the number of connections used by the client. Connection counts are only available for LSN pools with a non-zero client connection limit.

run util lsndb list inbound

Shows all LSN inbound mappings. Each line will display the translation IP address, the client IP address, the DS-Lite tunnel (if configured) and the age of the mapping.

run util lsndb list pba

Shows all LSN port block entries. Each line will display the client IP address, the port block used and the time that the entry will persist in the database (TTL).

run util lsndb list pcp

Shows all PCP mappings. PCP clients send MAP requests to map their private IP address and port to a public IP address and port. The BIG IP system uses those mappings as NAT entries. Each line will display the client IP address, the external address used and the age of the mapping.

run util lsndb list filters

Shows all LSN filters for inbound mappings. Each line will display the inbound mappings along with filter's remote peer IP address and prefix length.

run util lsndb list persist

Shows all LSN persistence entries. Each line will display the client IP address, the translation address used and the time that the entry will persist in the database (TTL).

run util lsndb summary all

Show summary for all LSN persistence mappings, inbound mappings and port block entries.

run util lsndb summary inbound

Show summary for all LSN inbound mapping entries.

run util lsndb summary pba

Show summary for all LSN port block entries.

run util lsndb summary persist

Show summary for all LSN persistence entries.

OPTIONS

delete

Delete all objects of the specified type. Client connection counts and port block entries cannot be deleted.

list Display all objects of the specified type.

summary

Display summary information of the specified type.

Object types are:

all = all available object types.

client = LSN client counts (list only).

inbound = LSN inbound mapping entries.

pba = LSN port block entries.

pcp = PCP mappings entries.

persist = LSN translation persist entries.

util platform check

NAME

platform_check - Runs platform checks available on an active system.

MODULE

util

SYNTAX

Run the **platform_check** utility from within the **util** module using the following syntax:

run util platform_check

DESCRIPTION

The **platform_check** utility runs diagnostics available on an active system to verify correct functionality of platform components. This should be used according to supporting documentation provided by F5.

Output is provided on standard output as well as **/var/log/platform_check**. Running **platform_check** with the **-h** argument will produce available argument listing. Running **platform_check** with the **-l** argument will list the available test suites.

EXAMPLES

run util platform_check

Runs all diagnostics available for an active system.

run util platform_check drive

Runs only the drive suite of diagnostics.

SEE ALSO

util platform diag

NAME

platform_diag - Runs platform diagnostics available on an inactive system

MODULE

util

SYNTAX

Run the platform_diag utility from within the util module using the following syntax:

run util platform_diag

DESCRIPTION

The platform_diag utility runs the diagnostics on an inactive system to verify correct functionality of platform components. This should not be used on an active system. This should be used according to supporting documentation provided by F5.

Output is provided on standard output as well as /var/log/platform_diag. Running platform_diag with the -h argument will produce available argument listing. Running platform_diag with the -l argument will list the available test suites.

EXAMPLES

run util platform_diag

Runs all appropriate diagnostics for this platform.

run util platform_diag hwaccel

Runs only the hwaccel suite of diagnostics.

util qkcloud

NAME

qkcloud - Run the qkcloud utility for the purpose of displaying cloud meta-data.

MODULE

util

SYNTAX

run util qkcloud [-d] [-h] [-j] [-l] [-V] [-v] [-x]

or

run util qkcloud [--human] [--help] [--json] [--latest]
[--version] [--verbose] [--xml]

DESCRIPTION

The qkcloud utility displays meta-data obtained from http://169.254.169.254.

OPTIONS

-d or --human

This directs the qkcloud program to output data in human format (similar to yaml).

-h or --help

Displays this help message.

-j or --json

This directs the qkcloud program to output data in json format.

-l or --latest

This tells qkcloud to only show the latest API.

-V or --version

This will show the qkcloud version and the system type.

-v or --verbose

This will tell qkcloud to turn on the CURL verbose mode in order to see the details of communication with http://169.254.169.254.

-x or --xml

This directs the qkcloud program to output data in xml format.

SEE ALSO

util sipdb

NAME

sipdb - Run the sipdb command to view SIP persistence entries.

MODULE

util

SYNTAX

run util sipdb

util ssh keyswap

NAME

ssh-keyswap - Run the ssh-keyswap command to manage SSH keys on the BIG-IP.

MODULE

util

SYNTAX

run util ssh-keyswap

util test-monitor

NAME

test-monitor - Runs an external monitor and displays the inputs to and output from the monitor.

MODULE

util

SYNTAX

Run the test-monitor utility from within the util module using the following syntax:

run util test-monitor address port

DESCRIPTION

The test-monitor utility runs a single instance of a monitor against the specified ip-address:port. The utility output shows the environment, command-line arguments, and resulting messages on stdout and stderr.

Internal monitors are not supported.

EXAMPLES

run util test-monitor monitorA address 10.10.10.4 port 80

Runs a monitor on the IP address 10.10.10.4 and port 80.

SEE ALSO

run, tmsh

util verify encryption

NAME

verify-encryption - Runs the encrypted attributes diagnostics utility

MODULE

util

SYNTAX

Run the verify-encryption utility from within the util module using the following syntax:

```
run util verify-encryption
run util verify-encryption
```

DESCRIPTION

The verify-encryption runs the /usr/sbin/Issa utility that diagnoses issues with encrypted attributes.

When running this utility, it looks through the files /config/bigip.conf, /config/bigip_base.conf, /config/profile_base.conf, /config/bigip_user.conf and returns lines that match the regular expression of keys, but can't actually be decrypted by the master key. Optionally, a file list can be provided as parameters. Only the specified files will be searched in this case.

EXAMPLES

```
run util verify-encryption
```

Runs the Issa utility for the files /config/bigip.conf, /config/bigip_base.conf, /config/profile_base.conf, /config/bigip_user.conf.

```
run util verify-encryption /config/partitions/partA/bigip.conf /config/partitions/partB/bigip.conf
```

Runs the Issa utility for the space separated file-list.

SEE ALSO

vcmp

vcmp global

NAME

global - Display global vCMP system statistics.

MODULE

vcmp

SYNTAX

Configure the global component within the vcmp module using the following syntax.

DISPLAY

```
show global
```

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

Use the global component within the vcmp module to display high-level vCMP system statistics on a per-slot basis. These are statistics that are not associated with any particular vCMP guest or virtual-disk.

EXAMPLES

```
show vcmp global
```

Display all global vCMP system statistics.

OPTIONS

For information about the options that you can use with the show command, see help show.

vcmp guest

NAME

guest - Configures a cluster of virtual machines (VMs) that run on one or all slots. This cluster is known as a vCMP guest.

MODULE

vcmp

SYNTAX

Configure the guest component within the vcmp module using the syntax in the following sections.

CREATE

```
create guest [name]
modify guest [name]
options:
  hostname [hostname]
  app-service [[string] | none]
  boot-priority [integer]
  initial-hotfix [hotfix-filename]
  initial-image [image-filename]
  management-gw [ip-address]
  management-ip [ip-address/netmask | ip-address/prefixlen]
  management-network [bridged | isolated]
  slots [integer]
  traffic-profile [vcmp-traffic-profile-name]
  min-slots [integer]
  allowed-slots {
[slot ID] ...
}
  cores-per-slot [integer]
  state [configured | provisioned | deployed]
  virtual-disk [filename]
  vlans [add | delete | replace-all-with] {
[VLAN name] ...
}
  capabilities [add | delete | modify | replace-all-with] {
[capability id] [ { value [integer] } ]
}
}
```

DISPLAY

```
list guest
show guest
```

options:

```
all-properties
status
```

DELETE

```
delete guest [name]
```

DESCRIPTION

Manage vCMP guests running on this host.

EXAMPLES

```
list vcmp guest
```

Lists the current configuration of all guests.

```
show vcmp guest
```

Displays detailed information regarding the state and progress of all guests.

```
show vcmp guest status
```

Displays the running state of all guests, including each guest's prompt status.

```
show vcmp guest all-properties
```

Displays greater detailed statistics and information on all guests.

```
create vcmp guest my_guest slots 4 min-slots 2 management-ip 192.168.45.12/24 management-gw 192.168.45.254
initial-image BIGIP-11.0.0.2400.0.iso
```

Creates a guest that should span four slots, but must span at least two, with the given management IP and gateway, and with the image file BIGIP-11.0.0.2400.0.iso, which is used to install TMOS on the guest's virtual disks. By default, this guest is in the configured state and has a management network in Bridged mode.

modify vcmp guest my_guest state provisioned

Moves the guest into the provisioned state, which causes the host to assign the guest to slots, allocate hardware resources to the guest from those slots, and create virtual disks for the guests on those slots.

Moves the guest into the deployed state, which causes the host to start and maintain VMs on each slot that the guest has been assigned to.

modify vcmp guest my_guest state configured

Moves the guest back to the configured state, which causes all of its VMs to shut down and the hardware to be deallocated. The guest is unassigned from all slots. The guest's virtual disks will remain on the host.

modify vcmp guest my_guest traffic-profile fiftyMbpsSLAProfile

Adds a traffic-profile named fiftyMbpsSLAProfile to the guest in question, which is configured under vcmp traffic-profile.

OPTIONS

app-service

Specifies the name of the application service to which the guest belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the guest. Only the application service can modify or delete the guest.

boot-priority

Specifies the boot priority of a guest. Lower values mean higher boot priorities. The default value is 65535. **Note:** Boot priority is only applied when multiple guests start and hardware resources constrain the number of guests starting.

hostname

Assigns the specified host name to the guest. The host name must be a FQDN. If none is given, the default of ".localdomain" is used. If the guest's name contains characters that are not allowed in a FQDN, then "localhost.localdomain" is used.

This is only a suggested value and may be changed on the guest itself. If the guest ever reverts to the default host name, this suggested host name is used instead of the normal system default.

initial-hotfix

Specifies which hotfix image to install on newly created virtual disks for this guest. This image is only used when initially creating the virtual disks. After initial creation, the typical live-install process should be used on the guest to manage software upgrades. The image filename must match a verified software image file that exists in the /shared/images directory, otherwise the guest will sit in a wait state on any slot that is missing the hotfix image until that image is added.

This field is required if the guest state is provisioned or deployed, otherwise it can be left blank.

initial-image

Specifies which software image to install on newly created virtual disks for this guest. This image is only used when initially creating the virtual disks. After initial creation, the typical live-install process should be used on the guest to manage software upgrades. The image filename must match a verified software image file that exists in the /shared/images directory, otherwise the guest will sit in a wait state on any slot that is missing the software image until that image is added.

This field is required if the guest state is provisioned or deployed, otherwise it can be left blank.

management-gw

Specifies the IP address of the default gateway for the management network. This IP address is only a suggested value and can be changed on the guest itself. If the guest ever reverts to the default management gateway, the suggested gateway is used instead of the normal system default.

This field is required if the guest's management-network is bridged, otherwise it can be left blank.

management-ip

Specifies the management IP address and netmask to assign to the guest. This address floats to the primary slot of the guest.

This is only a suggested value and can be changed on the guest itself. If the guest ever reverts to the default management IP address, the suggested IP address is used instead of the normal system default.

This field is required if the guest's management-network is bridged, otherwise it can be left blank.

management-network

Specifies the management network mode for this guest. When in Bridged mode, the management interfaces on the guest's VMs are bridged to the physical management interfaces on the host blades. This enables the guest to communicate with networks attached to these physical interfaces, the host itself, and other guests in Bridged mode.

In Isolated mode, the management interfaces of the guest's VMs are completely disconnected. The only way to manage such a guest is by connecting to the console on each of the guest's VMs by using the /usr/bin/vconsole utility or by connecting through a configured self IP on a guest's VLAN.

The default value is Bridged.

ssl-mode

Specifies the SSL mode for this guest. When in shared mode the guest shares the available non-dedicated ssl resources with other guests that are in shared mode. when in dedicated mode the guest receives dedicated SSL hardware resources proportional to number of vcpu cores. When in none mode the guest receives no hardware ssl resources. The default value is shared.

slots

Specifies the number of slots to which this guest should be assigned. This number must be greater than zero and no bigger than the cluster size. The host will attempt to assign the guest up to this number of slots.

Note that this property can be changed while the guest is in any state. While in the configured state, modifying the slots property has no effect, since the guest has not yet been assigned to any slots. While in the provisioned state, decreasing this field will cause the guest to be unassigned from enough slots to honor the new value. The host will unassign the guest first from slots that have the most allocated resources. When a guest's slots value is increased, the host attempts to assign the guest to as many slots as possible, up to the new slots value. This same behavior occurs when modifying the property while the guest is in the deployed state, except that running VMs are shut down on any slots that the guest is unassigned from, and new VMs are deployed on any slots to which the guest has been newly assigned.

The default value is 1.

traffic-profile

Specifies a traffic-profile to be used in defining characteristics of traffic which transits the guest's data-plane. For instance a traffic-profile with a color-policer on it that limits the network throughput of the guest may be applied to enforce service agreements between a host admin and a guest user, or to help mitigate network level DOS of other guests in the system.

min-slots

This field dictates the number of slots that the guest must be assigned to. If at the end of any allocation attempt the guest is not assigned to at least this many slots, the attempt fails and the change that initiated it is reverted. A guest's min-slots value cannot be greater than its slots value.

The default value is 1.

allowed-slots

This list contains those slots that the guest is allowed to be assigned to. When the host determines which slots this guest should be assigned to, only slots in this list will be considered. This is a good way to force guests to be assigned only to particular slots, or, by configuring disjoint allowed-slots lists on two guests, that those guests are never assigned to the same slot.

By default this list includes every available slot in the cluster. This means by default the guest is allowed to be assigned to any slot.

cores-per-slot

This value dictates how many cores a guest is allocated from each slot that it is assigned to. Possible values are dependent on the type of blades being used in this cluster. Use tab-completion to see a list of possible values on the current system.

The default cores-per-slot value depends on the type of blades being used in this cluster.

state

Guests are put into the configured state by default. In this state, the configuration for the guest exists on the host, but none of the guest's VMs are running and no hardware resources (for example: CPU cores, memory) are allocated to it. When the guest moves to the provisioned state, hardware resources are allocated to it, and if not already present, virtual disks are created, and the initial-image is installed onto them. In the deployed state, the vmcpd daemon on the host blades use the allocated resources to launch the VMs. Note that moving from the configured state to the deployed state implies the actions that occur in the provisioned state. To shut down a guest's VMs without de-allocating its hardware resources, move the guest from the deployed state to the provisioned state. Moving a guest to the configured state causes its hardware resources to be deallocated. This does not cause the guest's virtual disks to be deleted. They persist on disk and are reused when the vCMP moves back to the provisioned/deployed states.

virtual-disk

Specifies the filename of the virtual disk to use for this guest's VMs. If the filename does not end in .img, it is appended. When the guest moves to a state in which virtual disks need to be provisioned (provisioned or deployed), a new virtual disk image will be created for the guest with this given filename on each slot that the guest is assigned to and does not already have a virtual disk image. The initial-image is used when creating and installing new virtual disk images. If this field is left blank when virtual disk images need to be provisioned for this guest, a default value of ".img" is assigned. If a virtual disk by that name already exists, then an error is thrown. This prevents virtual disks from accidentally being reused by this assigning of default virtual disk filenames.

capabilities

This list contains the various capability flags and an optional value associated with the guest. The possible capability flags are: appliance-mode, stats-isolated-mode, and host-software-only-mode. The value attributes for these capability flags are currently ignored and may be omitted. The capabilities may be added or removed from a vCMP guest in any state.

The appliance-mode capability disables root and bash access to the guest.

The stats-isolated-mode capability prevents some guest statistics from being sent to the hypervisor.

The host-software-only-mode capability prevents the guest from installing images and hotfixes other than

those provided by the hypervisor.

vcmp health ha-status

NAME

ha-status - Display vCMP guest high availability (HA) status.

MODULE

vcmp health

SYNTAX

Display guest HA status using the following syntax.

DISPLAY

show ha-status

DESCRIPTION

Use the ha-status component within the vcmp health module to display HA status information about the vCMP guests deployed on this system. This is similar to running tmsh show sys ha-status inside of a guest.

EXAMPLES

show vcmp health ha-status

Display HA status status for all guests.

show vcmp health ha-status my_guest

Display HA status status for a single guest; "my_guest".

OPTIONS

For information about the options that you can use with the show command, see help show.

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-11-05 vcmp health ha-status(1)

vcmp health module-provision

NAME

module-provision - Display vCMP guest module provisioning status.

MODULE

vcmp health

SYNTAX

Display guest module provisioning status using the following syntax.

DISPLAY
show module-provision

DESCRIPTION

Use the module-provision component within the vcmp health module to display module provisioning status information about the vCMP guests deployed on this system. This will show you which modules are provisioned in a guest and at what level.

EXAMPLES

show vcmp health module-provision

Display module provisioning status for all guests.

show vcmp health module-provision my_guest

Display module provisioning status for a single guest; "my_guest".

OPTIONS

For information about the options that you can use with the show command, see help show.

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-11-05 vcmp health module-provision(1)

vcmp health prompt

NAME

prompt - Display vCMP guest prompt status.

MODULE

vcmp health

SYNTAX

Display guest prompt status using the following syntax.

DISPLAY

show prompt

DESCRIPTION

Use the prompt component within the vcmp health module to display the per-slot command-line prompts for the vCMP guests deployed on this system. These are the same prompts that one would see when logging into a guest via SSH. Example: "bigip.mydomain.com:/S1-green-P:Active:Standalone"

EXAMPLES

show vcmp health prompt

Display prompt status for all guests.

show vcmp health prompt my_guest

Display prompt status for a single guest; "my_guest".

OPTIONS

For information about the options that you can use with the show command, see help show.

COPYRIGHT

BIG-IP 2015-11-05 vcmp health prompt(1)

vcmp health software

NAME

software - Display vCMP guest software status.

MODULE

vcmp health

SYNTAX

Display guest software status using the following syntax.

DISPLAY

show software

DESCRIPTION

Use the software component within the vcmp health module to display software status information about the vCMP guests deployed on this system. This is similar to running tmsh show sys software inside the guest.

EXAMPLES

show vcmp health software

Display software status for all guests.

show vcmp health software my_guest

Display software status for a single guest; "my_guest".

OPTIONS

For information about the options that you can use with the show command, see help show.

BIG-IP 2015-11-05 vcmp health software(1)

vcmp traffic-profile

NAME

traffic-profile - Configures a traffic-profile, which can be applied to a vCMP guest to control characteristics of data-plane network traffic to the guest.

MODULE

vcmp

SYNTAX

Configure the traffic-profile component within the vcmp module using the syntax in the following sections.

CREATE

create traffic-profile [name]

modify traffic-profile [name]

options:

color-policer [color-policer-name]

DISPLAY

list traffic-profile

options:

all-properties

DELETE

delete traffic-profile [name]

DESCRIPTION

Manage vCMP traffic-profiles running on this host.

EXAMPLES

list vcmp traffic-profile

Lists the current configuration of all traffic-profiles.

create vcmp traffic-profile fiftyMbpsSLAProfile color-policer fiftyMbpsLimiter

Creates a traffic-profile which makes use of the color-policer fiftyMbpsLimiter.

OPTIONS

color-policer

Specifies the color based policer for metering and shaping traffic destined to a guests data-plane.

SEE ALSO

vcmp virtual-disk-template

NAME

virtual-disk-template - Manages the vCMP virtual disk templates available on this hypervisor.

MODULE

vcmp

SYNTAX

Configure the virtual-disk-template component within the vcmp module using the syntax in the following sections.

DISPLAY

list virtual-disk-template

options:

all-properties

DELETE

delete virtual-disk-template [name]

DESCRIPTION

The virtual-disk-template component is used to list and delete virtual disk templates that are used to create new virtual disk images for vCMP guests. Virtual disk templates are automatically created by vcmpd when guests move to the Provisioned state and a virtual disk template with the version being installed to the guest's virtual disk image doesn't already exist. This is the only way that virtual disk templates are created. Deleting virtual disk templates frees up space but will slow down future virtual disk image installs of that version; the virtual disk template will need to be first re-created.

EXAMPLES

list vcmp virtual-disk-template

Lists all virtual disk templates currently available.

delete vcmp virtual-disk-template my_vdisk

Deletes the virtual disk template named my_vdisk. Note that this is only valid if the virtual-disk-template is not currently attached to any vCMP guest.

SEE ALSO

tmsh vcmp virtual-disk

COPYRIGHT

BIG-IP **2015-01-14** **vcmp virtual-disk-template(1)**

vcmp virtual-disk

NAME

virtual-disk - Manages the vCMP virtual disks available on this hypervisor.

MODULE

vcmp

SYNTAX

Configure the virtual-disk component within the vcmp module using the syntax in the following sections.

DISPLAY

list virtual-disk
show virtual-disk

options:

all-properties

show virtual-disk

DELETE

delete virtual-disk [name]

DESCRIPTION

The virtual-disk component is used to list and delete virtual disks that are used by vCMP guests. Virtual disks are automatically created by vcmpd when guests move to the Provisioned state and do not already have virtual disks attached to them. This is the only way that virtual disks are created. Virtual disks that are not attached to any guest can be deleted. Virtual disks not already in use can be explicitly attached to vCMP guests.

EXAMPLES

list vcmp virtual-disk

Lists all virtual disks currently available.

delete vcmp virtual-disk my_vdisk

Deletes the virtual disk named my_vdisk. Note that this is only valid if the virtual-disk is not currently attached to any vCMP guest.

SEE ALSO

BIG-IP 2014-05-08 vcmp virtual-disk(1)

wam

wam ad-policy

NAME

ad-policy - Configures an ad policy for WebAccelerator for use in ad insertion.

MODULE

wam

SYNTAX

Configure the ad-policy within the wam module using the syntax shown in the following sections.

CREATE/MODIFY

```
create ad-policy [name]
modify ad-policy [name]
options:
  ad-insertion-order [random | sequential]
  ads [add | delete | modify] {
    [name] {
options:
  url [url]
  preroll [yes | no]
    }
  }
description [string]
```

DISPLAY
list ad-policy [name ...]

DELETE
delete ad-policy [name ...]

DESCRIPTION

You can use the ad-policy component to manage the WebAccelerator ad policies. An ad policy defines how the ad insertion is to be performed while processing video resources. Individual ad urls can be configured in the ad-policy along with the insertion order.

EXAMPLES

```
create wam ad-policy my_ad_policy ads add { my_ad1 { preroll yes url http://www.example.com/ad1.m3u8 } }
```

Creates an ad policy named my_ad_policy with an ad named my_ad1 for the url http://www.example.com/ad1.m3u8 and as a preroll candidate.

```
list wam ad-policy my_ad_policy
```

Displays properties of the ad policy named my_ad_policy.

```
delete wam ad-policy my_ad_policy
```

Deletes the ad policy named my_ad_policy.

OPTIONS

ad-insertion-order

Specifies whether the ads are to be inserted randomly or in the order specified in the policy.

ads Specifies the collection of ads.

description

User defined description of an ad policy.

AD OPTIONS

url Specifies the url of the ad.

preroll

Specifies that the ad is a candidate for preroll insertion. Preroll ad is inserted at the beginning of the playlist.

SEE ALSO

create, delete, edit, list, modify, show, tmsh

COPYRIGHT

wam application

NAME

application - Configures application for WebAccelerator.

MODULE

wam

SYNTAX

Configure the application component within the wam module using the syntax shown in the following sections.

```

CREATE/MODIFY
create application [name]
modify application [name]
options:
  app-service [[string] | none]
  code [number]
  content-expiration-time [date and time]
  description [string]
  hosts [add | delete | modify | replace-all-with] {
    [ [host name] | [glob] ] {
options:
  app-service [[string] | none]
  code [number]
  subdomain-number-of-http [number]
  subdomain-number-of-https [number]
  subdomain-prefix [string]
    }
  }
  ibr-adaptive-lifetime [number]
  ibr-default-lifetime [number]
  ibr-prefix [string]
  info-header [none | standard | debug]
  multibox [disabled | farm | symmetric]
  policy [name]
  perf-monitor [enabled | disabled]
  perf-monitor-data-retention-period [number]
  collect-roi-statistics [ enabled | disabled ]
  send-metadata [never | always | uncompressed]
  roi-report-email-addresses { string }
  roi-report-frequency [ every-month | every-week ]
  roi-report-name [string]
  roi-report-next-time [date and time]
  roi-report-smtp-config [ smtp configuration object name ]
  roi-report-collect-statistics { caching-bytes-saved | client-ibred-links |
    compression-bytes-saved | icc-refed-links | inlined-links |
    caching-requests-saved | client-ibred-links-recd | icc-inlined-links |
    image-opt-bytes-saved | minification-bytes-saved }

```

```

edit application [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

```

```

reset-stats application
reset-stats application [ [ [name] | [glob] | [regex] ] ... ]

```

```

DISPLAY
list application [name ...]
show running-config application [name ...]
options:
  all-properties
  non-default-properties
  partition
  predefined

```

```

show application
show application [name]
options:
  all-properties
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

```

```

DELETE
delete application [name ...]

```

Note: You must remove all references to an application before you can delete it.

DESCRIPTION

You can use the application component to configure the host map, select policies, and set application wide parameters that affect WebAccelerator behavior.

EXAMPLES

```
create application my_app hosts add { host1.com host2.com } policy my_local_policy
```

Creates a WebAccelerator application with a host map consisting of two hosts, host1.com and host2.com, and a local policy set to my_local_policy.

```
modify application my_app remote-policy my_remote_policy
```

Sets my_remote_policy as the remote policy for application my_app.

```
modify application my_app modify hosts { host1.com { subdomain-number-of-http 3 subdomain-prefix abcd } }
```

Sets the number of subdomain hosts to 3 and the subdomain prefix to abcd for host host1.com of WebAccelerator application my_app.

```
modify application my_app roi-report-name "my_report" roi-report-frequency monthly roi-report-next-time now
```

```
roi-report-email-addresses add { someone@domain.com } roi-report-smtp-config smtp-config roi-report-collect-
statistics add { caching_bytes_saved caching_requests_saved }
```

Sets the ROI report name to my_report. The ROI report is set to be sent monthly, and the next time to send the report is set to now. The ROI report will be mailed to someone@domain.com. The SMTP configuration used to send the ROI report will be the predefined configuration of name smtp-config. The ROI report will contain the statistics specified by roi-report-collect-statistics, which in this case would be caching_bytes_saved and caching_requests_saved.

```
delete application my_app
```

Deletes WebAccelerator application my_app.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

code Specifies a numeric non-zero code of the application or application host, which is used for troubleshooting and performance reporting. Each application or application host must have a unique code. If not supplied, it will be generated by the system. Use the keyword generate to specify that the system generate a new unique code.

content-expiration-time

Specifies the date and time that limits how old cached documents can be to still be served from the cache. All documents older than this date and time are considered expired. For example, the following example expires all cached documents of the application my_app:

```
modify application my_app content-expiration-time now
```

description

Specifies the object type description.

hosts

Specifies the list of domain names (host names) that might appear in HTTP requests for your Web application. These are the same host names that DNS has mapped to the server machine on which your WebAccelerator system is running. To map a group or range of requested host names to a single destination host, you can use an asterisk (*) as a wildcard for the first part of the host name.

ibr-adaptive-lifetime

Specifies the adaptive lifetime for Intelligent Browser Referencing in seconds. The default value is 864000 (10 days).

ibr-default-lifetime

Specifies the lifetime for Intelligent Browser Referencing in seconds. The default value is 15724800 (6 months).

ibr-prefix

Specifies a prefix for the Intelligent Browser Referencing tag. The default value is ";wa".

info-header

Enables and controls the appearance of HTTP header X-WA-Info: in responses from WebAccelerator. This header can be used for troubleshooting the WebAccelerator system and for tuning policies. The possible values are:

debug

HTTP header X-WA-Info: is included into responses with standard information, with some additional values to aid WebAccelerator troubleshooting.

none HTTP header X-WA-Info: is not included into responses.

standard

HTTP header X-WA-Info: is included into responses with standard information, such as S-code, policy, and node codes, etc.

multibox

Specifies which type of multibox support is required for this application, if any. Options are disabled, for deployments with an independent WebAccelerator; farm, for farm deployments; and symmetric, for symmetric deployments. When this is not disabled, the application should be shared by a config sync device group containing all devices in the deployment. It enables the broadcast of invalidation messages to other devices in the device group, and, when set to symmetric, also enables symmetric processing of traffic.

partition

Displays the administrative partition within which the application resides.

perf-monitor

Specifies whether performance monitoring for this application is enabled. Enabling performance monitoring on many applications may affect the overall performance of WebAccelerator. The default value is disabled.

perf-monitor-data-retention-period

Specifies the time period in days for how long the performance data must be preserved. The default value is 30 days.

collect-roi-statistics

Specifies whether ROI statistics collection for this application is enabled. The default value is

disabled.

roi-report-name

Specifies the name of ROI statistics report if the statistics collection is enabled and report generation is desired.

roi-report-frequency

Specifies the frequency of ROI statistics report, if the statistics collection is enabled and report generation is desired. The options are every week or month.

roi-report-email-addresses

Specifies the email-addresses to which ROI statistics report will be sent.

roi-report-next-time

Specifies the next time when the ROI statistics report will be sent.

roi-report-smtp-config

Specifies the smtp configuration that will be used to send the scheduled ROI report over email.

roi-report-collect-statistics

Specifies which statistics are to be included in the ROI statistics report.

policy

Specifies the acceleration policy to which you want to assign the new Web application.

predefined

Displays if this application is predefined.

send-metadata

Specifies when Etag HTTP headers will be included into responses. The default value is always.

always

Etag HTTP headers will always be included into responses.

never

Etag HTTP headers will not be included into responses.

uncompressed

Metadata HTTP headers will be included only if response is uncompressed.

subdomain-number-of-http

Specifies the number of HTTP subdomains that you want the WebAccelerator system to generate. The WebAccelerator system uses these additional subdomains only on embedded URLs or links that request images or scripts. The default value is 0.

subdomain-number-of-https

Specifies the number of HTTPS subdomains that you want the WebAccelerator system to generate. The WebAccelerator system uses these additional subdomains only on embedded URLs or links that request images or scripts. The default value is 0.

subdomain-prefix

Specifies the prefix that you want the system to assign to the subdomains. The default value is wa.

For example, if the Requested Host is `www.siterequest.com`, and you select 2 from the HTTP Subdomains box and type `wa` in the Subdomain Prefix box, the WebAccelerator system changes the domain on qualifying embedded URLs and links to use the following domains:

`wa1.www.siterequest.com`

`wa2.www.siterequest.com`

Note: You must configure DNS with these entries, and they must map to the same IP address as the base origin server (`www.siterequest.com` in this example).

BIG-IP 2017-05-01 wam application(1)

NAME

domain-list - Configures a list of domains for WebAccelerator for use in inserting DNS prefetch tags.

MODULE

wam

SYNTAX

Configure the domain-list component within the wam resource module using the syntax shown in the following sections.

CREATE/MODIFY

create domain-list [name]

modify domain-list [name]

options:

app-service [[string] | none]

description [[string] | none]

domains

[add | delete | none| replace-all-with] {

[string] ...

}

DISPLAY

list domain-list [name ...]

DELETE

delete domain-list [name ...]

DESCRIPTION

You can use the domain-list component to manage the domain list resources used by the WebAccelerator DNS prefetching feature. A domain-list must be created, then added to the appropriate domain-lists on a WebAccelerator policy node in order for the domains within the domain list to be inserted into a document.

EXAMPLES

create domain-list my_domain_list domains add {example.com example2.com}

Creates a domain list resource for the domains example.com and example2.com for use in inserting DNS prefetch tags.

list domain-list my_domain_list

Displays properties of the domain-list resource named my_domain_list.

delete domain-list my_domain_list

Deletes the domain-list resource named my_domain_list.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

domains

Specifies the domains described by the domain list resource.

SEE ALSO

create, delete, edit, list, modify, show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2014-06-02 wam domain list(1)

wam object-type

NAME

object-type - Configures object types for WebAccelerator.

MODULE

wam

SYNTAX

Configure the object-type component within the wam module using the syntax shown in the following sections.

CREATE/MODIFY

```
create object-type [name]
modify object-type [name]
options:
  app-service [[string] | none]
  code [ [number] | generate]
  compression [disabled | policy-controlled]
  description [string]
  extensions [add | delete | modify | replace-all-with] {
    [document extension]
    ...
  }
  mime-types [add | delete | modify | replace-all-with] {
    [MIME type]
    ...
  }
  symmetric-compression [ disabled | enabled ]
```

```
edit object-type [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list object-type [ [ [name] | [glob] | [regex] ] ... ]
show running-config object-type [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  group
  partition
  predefined
```

DELETE

```
delete object-type [name ...]
```

DESCRIPTION

You can use the object-type component to manage recognized types of objects. These object types are used to classify documents processed by WebAccelerator. A document can be classified by its file extension or MIME type.

EXAMPLES

```
create object-type documents.abcd extensions add { abc abcd } mime-types add { text/abcd text/x-abcd }
description ABCD
```

Creates a WebAccelerator object type named documents.abcd that includes all documents with extensions .abc or .abcd, and MIME types text/abcd or text/x-abcd.

```
delete object-type documents.abcd
```

Deletes the pool named documents.abcd.

```
list object-type documents.abcd
```

Displays properties of the object-type named documents.abcd.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

code Specifies the numeric non-zero code of the object type, which is used troubleshooting and performance reporting. Each object type must have unique code. If not supplied, it will be generated by the system. Use keyword generate to have the system generate a new unique code.

compression

Specifies if this object type supports compression and when it can be enabled. The default value is disabled.

Valid values are:

disabled

Never compresses the response. If you use this option, be aware that it overrides any compression setting configured for the assembly rule that the WebAccelerator system matches to the specified object type. You should use this option only if you want the WebAccelerator system to ignore assembly rules for the specified object type.

policy-controlled

Specifies that compression is controlled by WebAccelerator policy. The compression setting is specified in the assembly rule that the WebAccelerator system matched for this object type. In most cases, you should use this option.

description

Specifies the object type description.

extensions

Specifies the extension the WebAccelerator system should find in the file name or Content-Disposition header of the response, in order to match to the specified object type.

group

Displays the group portion of the name.

mime-types

Specifies the MIME-types that the WebAccelerator system should find in the Content-Type header of the response, in order to match to the specified object type.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify. The name of the object type must be in form group.type where group is used to organize object type based on common usage pattern. for example, documents, binary, pages. The type is used to uniquely identify the object type within a group.

partition

Displays the administrative partition within which the object type resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

symmetric-compression

Specifies whether this object type will be compressed on the WAN link in a symmetric multibox deployment.

SEE ALSO

create, delete, edit, list, modify, show, tmsh

    }
  }
}
}
}
partition [name]
publish-build [integer]
publish-comment [string]
published-on [date]

```

Note: Policies can be created only in the Drafts folder. This is required to support publishing functionality. You may create multiple Drafts folders, one for each folder where published policies are going to reside.

DISPLAY

list policy [name ...]
show running-config policy [name ...]
options:
all-properties
non-default-properties
partition
predefined
state

DELETE

delete policy [name ...]

SAVE/LOAD

save policy [name]
load policy [name]
options:
overwrite
file [filename]

PUBLISH

publish policy [name]
options:
publish-comment [string]
publish-build [integer]

Note: Published policies can be deleted, but cannot be modified. The only way to update a published policy is to edit and then publish its development version.

DESCRIPTION

You can use the policy component to manage WebAccelerator acceleration policies. An acceleration policy is a collection of defined rule parameters that dictate how the WebAccelerator system handles HTTP requests and responses. The WebAccelerator system uses two types of rules to manage content: matching rules and acceleration rules. Matching rules are used to classify requests by object type and match the request to a specific acceleration policy. Once matched to an acceleration policy, the WebAccelerator system applies the associated acceleration rules to manage the requests and responses. There are multiple types of acceleration rules: variation, proxy, proxy override, parameter value substitution, and invalidation. The WebAccelerator system ships with several predefined acceleration policies that are optimized for specific Web applications, in addition to several non-application specific policies for general delivery and one for an optional symmetric deployment.

EXAMPLES

Note: For the following examples, the current folder is assumed to be set to /Common.

create policy "Drafts/My Policy"

Creates a new empty policy named My Policy in the folder /Common/Drafts.

create policy "Drafts/My Policy" copy-from "/Common/Generic Policy - Complete"

Creates a new policy My Policy in the folder /Common/Drafts by copying standard system policy /Common/Generic Policy - Complete.

modify policy "Drafts/My Policy" copy-from "/Common/Generic Policy - Complete"

Modifies the policy My Policy by overwriting it with standard system policy /Common/Generic Policy - Complete.

modify policy "Drafts/My Policy" nodes add { "My Node" { default-from Site } }

Adds a new node My Node as the child node of the node Site.

modify policy "Drafts/My Policy" nodes modify { "My Node" { matching add { content-type { values add { pages.other } } } }

Adds a new matching rule into the node My Node. The rule will match content type of the requests to WAM object type pages.other.

publish policy "Drafts/My Policy" publish-comment "Added new node My Node"

Publishes the policy My Policy.

modify policy "Drafts/My Policy" nodes delete { "My Node" }

Deletes the node My Node from the policy My Policy.

delete policy "My Policy"

Deletes the policy My Policy.

save policy "My Policy" file policy.txt

Saves the policy My Policy into the file /var/local/wam/policy.txt.

load policy "Drafts/My Policy" overwrite file /tmp/policy.txt

Loads the policy My Policy from the file /tmp/policy.txt and overwrites the policy if it already exists.

POLICY OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

code Specifies a numeric non-zero code of the policy that is used for troubleshooting and performance reporting. Each policy must have a unique code. If not supplied, it will be generated by the system. Use the keyword generate to specify that the system generate a new unique code.

copy-from

Specifies the name of an existing policy from which to copy all configuration options. If this field is used in the modify command, the configuration options of the existing policy will be replaced with the new ones. The code, state, publish-build, publish-comment, and published-at options are not updated.

description

User defined description of a policy.

nodes

Specifies the collection of policy nodes. Matching rules and acceleration rules for acceleration policies are organized on the Policy Tree, which consists of nodes. The structure of the Policy Tree supports a parent-child relationship. This enables you to easily randomize rules. That is, because a leaf node in a Policy Tree inherits all the rules from its root node and branch node, you can quickly create multiple leaf nodes that contain the same rule parameters by creating a branch with multiple leaf nodes. If you override or create new rules at the branch node level, the WebAccelerator system reproduces those changes to the associated leaf nodes.

partition

Displays the administrative partition within which the policy resides.

publish-build

Specifies the policy build version that was used during policy publishing. If not specified, this number is automatically incremented by the WebAccelerator system.

publish-comment

Specifies the user supplied comment that describes the changes in the policy that is being published.

published-on

Specifies the date and time when this policy was last published.

file Specifies the file name where the policy is going to be saved or loaded from. If a full path is not specified, it is set to /var/local/wam directory.

overwrite

Specifies that the policy file for the save command or the policy component for the load command can be overwritten if it exists.

NODE OPTIONS

always-proxy

Specifies that all requests matching this node must be proxied. If it enabled, proxy rules are not used, even if configured. proxy-override rules still apply.

app-service

Specifies the name of the application service to which this node belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this node. Only the application service can modify or delete this node.

assembly-compression

Specifies, when enabled, that the WebAccelerator system compresses content for responses, using gzip-encoding. Note that to use this feature, you must set the compression value for the response's object type in the corresponding object-type component, and the client must be able to accept gzip-encoded content. The default value is enabled.

assembly-compression-ows

Specifies, when enabled, that the WebAccelerator system requests gzip-encoded or deflate-encoded content from the origin Web server. Note that the origin Web server will comply only if it supports compression, otherwise it will reply with uncompressed content. The default value is disabled.

assembly-concatenation

Specifies, when enabled, that the WebAccelerator system will perform JavaScript/CSS concatenation in HTML documents. The URLs that may be concatenated are specified using the assembly-concatenation-sets option. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-concatenation-sets

Specifies the concatenation sets that are active for this node. If a URL in the HTML document that belongs to one of the enabled sets is found, it will transformed with concatenation using the URL of the configured set. This is an ordered set, and if the URL exists in multiple active concatenation sets, the first set specified by this option will be used. See the WebAccelerator documentation for more details.

assembly-css-inlining

Specifies, when enabled, that the WebAccelerator system will inline CSS URLs in HTML documents. The CSS URLs that may be inlined are specified using the assembly-css-inlining-urls option. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-css-inlining-urls

Specifies the CSS URLs that may be inlined.

assembly-css-reorder

Specifies, when enabled, that the WebAccelerator system will reorder CSS URLs to the HEAD section of HTML documents. The CSS URLs that may be reordered are specified using the `assembly-css-reorder-urls` option. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-css-reorder-cache-size

Specifies the size of the intermediate cache used to store CSS URLs being reordered. Increasing the size of this cache allows more CSS URLs to be reordered. The default value is 8kB. The maximum value is 8kB.

assembly-css-reorder-urls

Specifies the CSS URLs that may be reordered. The URLs must be fully-qualified and whitespace used to separate URLs. The URLs must correspond to WebAccelerator URL resources created by the command `create wam resource url`. See the help for `wam resource url`.

assembly-dns-prefetch

Specifies, when enabled, that the WebAccelerator system manipulates an HTML document to add DNS prefetch tags at the end of the head. The DNS prefetch tags added are the combined list of domain lists specified in `assembly-dns-prefetch-domain-lists`. DNS prefetch tags will not be inserted in the following conditions: when DNS prefetching is explicitly disabled in the document, either by an HTTP header or by a meta-tag in the head of the HTML document; when the connection is served over HTTPS without `assembly-dns-prefetch-https-enable` enabled; or when the connection is to a client browser that does not support DNS prefetching.

In a document, most browsers will perform DNS prefetching on all domains linked with an HREF. This will speed up performance by having the browser cache possible DNS resolutions before a client clicks on a link, but DNS prefetching cannot automatically occur when a link is created through other means (such as javascript). Inserting DNS prefetch tags addresses this issue.

The default value is disabled.

assembly-dns-prefetch-domain-lists

Specifies the lists of domains that will be inserted into a document. The domain lists must correspond to WebAccelerator domain list resources created by the command `create wam resource domain-list`. See the help for `wam resource domain-list`.

assembly-dns-prefetch-https-enable

Specifies, when enabled, that the WebAccelerator system manipulates an HTML document to add DNS prefetch tags at the end of the head when a document is served over HTTPS when the client browser supports DNS prefetching. By default, most browsers that support DNS prefetching will not do any DNS prefetching on pages served over HTTPS. Enabling `assembly-dns-prefetch-https-enable` will insert a meta-header that will turn on DNS prefetching on the page and a meta-header turning off DNS prefetching for the rest of the page. DNS prefetching cannot be turned on for the rest of an HTML document once the meta-header turning off DNS prefetching is reached.

DNS prefetching is turned off on most browsers serving pages over HTTPS by default as a security measure. DNS prefetching can be used to track which pages are seen over HTTPS by watching the domain resolution requests sent out by the client. According to DNS prefetch standards currently, turning on DNS prefetching on a page will cause all links in the page to have their domains prefetched. This is mitigated by this option with the insertion of an HTTP meta-header turning off DNS prefetching after the DNS tags inserted by the WebAccelerator system. Turning on DNS prefetching for the rest of the page in a request served over HTTPS can be done with the `assembly-dns-prefetch-https-automatic` option.

The default value is disabled.

assembly-dns-prefetch-https-automatic

Specifies, when enabled, that the WebAccelerator system will not insert a meta-tag into an HTML document served over HTTPS turning off DNS prefetching for the rest of a page. By default, most browsers that support DNS prefetching will not do any DNS prefetching on pages served over HTTPS. `assembly-dns-prefetch-https-enable` must be enabled for this option to work.

The default value is disabled.

assembly-ibr

Specifies, when enabled, that the WebAccelerator system manipulates the Web browser cache to reduce requests to your site for relatively static content, such as images and style sheet (CSS) files. The default value is enabled.

assembly-image-inlining

Specifies, when enabled, that the WebAccelerator system will inline image URLs in CSS documents. The image URLs that may be inlined are specified using the `assembly-image-inlining-urls` option. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-image-inlining-max-size

Specifies the maximum size of the image that is allowed to be inlined. The default value is 2kB. The maximum value is 8kB.

assembly-image-inlining-urls

Specifies the image URLs that may be inlined.

assembly-js-inlining

Specifies, when enabled, that the WebAccelerator system will inline JS URLs in HTML documents. The JS URLs that may be inlined are specified using the `assembly-js-inlining-urls` option. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-js-inlining-urls

Specifies the JS URLs that may be inlined.

assembly-js-reorder

Specifies, when enabled, that the WebAccelerator system will reorder JavaScript URLs to the end of HTML documents. The JavaScript URLs that may be reordered are specified using the `assembly-js-reorder-urls` option. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-js-reorder-cache-size

Specifies the size of the intermediate cache used to store JavaScript URLs being reordered. Increasing the size of this cache allows more JavaScript URLs to be reordered. The default value is 8kB. The maximum value is 8kB.

assembly-js-reorder-urls

Specifies the JavaScript URLs that may be reordered. The URLs must be fully-qualified and whitespace used to separate URLs. The URLs must correspond to WebAccelerator URL resources created by the command `create wam resource url`. See the help for `wam resource url`.

assembly-intelligent-client-cache

Specifies, when enabled, that the WebAccelerator system will Intelligent Client Cache HTML documents. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-icc-force

Specifies, when enabled, that the WebAccelerator system will Intelligent Client Cache HTML documents, even if the client does not support HTML5 localstorage. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-icc-image-max-size

Specifies the maximum size of the image that is allowed to be inlined as part of Intelligent Client Caching. The default value is 32kB. The maximum value is 50kB.

assembly-icc-css-max-size

Specifies the maximum size of the CSS that is allowed to be inlined as part of Intelligent Client Caching. The default value is 50kB. The maximum value is 1024kB.

assembly-icc-js-max-size

Specifies the maximum size of the JS that is allowed to be inlined as part of Intelligent Client Caching. The default value is 50kB. The maximum value is 1024kB.

assembly-icc-max-num-urls

Specifies the maximum number of links in an HTML document that are allowed to be inlined as part of Intelligent Client Caching. The default value is 10. The maximum value is 100.

assembly-icc-min-client-expiry

Specifies the minimum client expiry of a resource that is allowed to be inlined as part of Intelligent Client Caching. The default value is 2days.

assembly-minification

Specifies, when enabled, that the WebAccelerator system will minify JavaScript and CSS.

assembly-multiconnect

Specifies, when enabled, that the WebAccelerator system modifies embedded URLs with unique sub-domains that prompt the browser to open more persistent connections for each supported protocol (HTTP or HTTPS). To use this feature, you must configure DNS with the additional domains and map those domains to the same IP address as the base origin server. The default value is enabled.

assembly-on-proxies

Specifies, when enabled, that the WebAccelerator system applies the Content Compression and Intelligent Browser Referencing features (if enabled) to content served to clients, even if the content is not served from the WebAccelerator system's cache. Enable this option if you are using the Content Compression or Intelligent Browser Referencing features. The default value is enabled.

assembly-pdf-linearization

Specifies, when enabled, that the WebAccelerator system applies linearization on PDF documents, if the documents match the node matching rules. PDF linearization transforms the document to include the index of the pages in the beginning. This allows Web browsers to load and show specific pages rather than a whole document. See the WebAccelerator documentation for more details. The default value is disabled.

optimize-image

Specifies whether image optimization should be applied and the format conversion to use. Each of the 4 supported formats (JPEG, PNG, GIF, TIFF) can be converted to any of the others. Images using a capability unique to one format may lose that feature when converted to a format that does not support it. (For example, animated GIFs or multipage-TIFFs will have only the first image when converted to PNG or JPEG). Transparency will be lost when converting from GIF or PNG to JPEG. TIFF is a container for many different image formats so the results will be best-effort and may not list completely.

A converted image will likely have a different number of bytes after conversion. Some conversions are likely to produce fewer bytes; however, a requested conversion will be done even if it results in more bytes (for consistency). For example, you may want to offer multiple formats of an image without storing them all on a server.

A correct Content-Type header will be generated for converted images, but HTML files will not be rewritten.

optimize-for-client Specifies whether to allow conversion to a format and/or size which is optimum for the specific client making the request but which, if saved by that client and later sent elsewhere, might not be

appropriate.

webp-quality WebP is a "lossy" compression format. This means when you convert an image to a WebP and then convert it back, you will not get back exactly the same image you started with. Compression changes the amount of information stored (and therefore the number of bytes), but not the image dimensions (the number of pixels). The webp-quality attribute represents the absolute quality of the WebP produced. Compression (quality) is represented as a number between 1-100 where 1 is minimal quality, but small, and 100 is high-quality, but large. For most images, useful values of quality will be from about 30-70.

jpegxr-quality JPEG-XR is a "lossy" compression format. This means when you convert an image to a JPEG-XR and then convert it back, you will not get back exactly the same image you started with. Compression changes the amount of information stored (and therefore the number of bytes), but not the image dimensions (the number of pixels). The jpegxr-quality attribute represents the absolute quality of the JPEG-XR produced. Compression (quality) is represented as a number between 1-100 where 1 is minimal quality, but small, and 100 is high-quality, but large. For most images, useful values of quality will be from about 5-30.

jpeg-quality-is-relative =item jpeg-quality

JPEG is a "lossy" compression format. This means when you convert an image to a JPEG and then convert it back, you will not get back exactly the same image you started with. Compression changes the amount of information stored (and therefore the number of bytes), but not the image dimensions (the number of pixels). When jpeg-quality-is-relative is set to no, the jpeg-quality attribute represents the absolute quality of the JPEG produced. Compression (quality) is represented as a number between 1-100 where 1 is minimal quality, but small, and 100 is high-quality, but large. For most images, useful values of quality will be from about 30-100. Because information once lost cannot be regained, converting a low-quality JPEG to a higher quality is pointless and image optimization will prevent that (by not changing the original to a higher JPEG quality).

You might be unable to choose a specific absolute quality for JPEG images. When jpeg-quality-is-relative is set to yes, the relative JPEG quality setting is enabled. In this case, jpeg-quality is a percentage (a number between 1-100) that when multiplied by each JPEG's original quality, becomes its optimized quality.

jpeg-strip-exif

JPEG files have a header (called EXIF) that contains optional data such as a date, time, camera model, exposure settings, and so on. The EXIF header can also contain a color profile, which is required when included. EXIF headers can be small or large. Unless they contain a color profile, they do not affect displaying the image, and so can be removed if the loss of the information they contain is acceptable. There are four options for this setting:

no Leaves any EXIF headers alone.

yes Always strips EXIF headers.

if-safe

Only strips EXIF headers if they do not have color profiles (ensures that images display properly).

make-safe

Applies the color profile and then strips the EXIF header (typically decreases image file size).

Applying a color profile requires additional CPU time.

jpeg-strip-keeps-copyright This setting affects the meaning of jpeg-strip-exif. If it is set, stripping the EXIF header will strip everything except the Copyright notice (if one is present).

jpeg-sampling-factor

Sets the sampling factor to be used when producing JPEG images. The default value is preserve, which matches the original file. You can also explicitly specify this option, as it can sometimes improve compression.

jpeg-progressive-encoding

When enabled, progressive encoding will be used in JPEG images. For large JPEG files, this can improve compression. When this is enabled, it will be applied only if the file is large enough to improve compression.

png-256-colors

It is often possible to significantly reduce the size of PNG files without changing their appearance very much by reducing the number of colors to 256 optimally selected values. This optimization is enabled when png-256-colors is set to yes.

cache-complete-only

Specifies, when enabled, that the WebAccelerator system caches HTML pages only if the HTML code within the page contains begin and end tags. When disabled, the WebAccelerator system reviews HTTP response headers to determine if the information contained on the page is complete. The default value is enabled.

cache-first-hit

Specifies that the first response should be cached according to the policy caching settings. When this is off, the response is cached when more than one request for the document has been seen. Turning this on can reduce cache churn for unpopular documents. The default value is no.

cache-mode

Specifies how where the cached documents will be stored. The default value is memory-and-disk. Possible values are:

memory-and-disk

The cached documents will be stored in memory or on disk.

memory-only

The cached documents will be stored in memory only.

cache-priority

Specifies the cache admission priority of documents matching the policy node. Documents with high priority are more likely to be admitted into the cache. The default value is medium. Possible values are:

low Documents will have low priority.

medium

Documents will have medium priority.

high Documents will have high priority.

cache-stand-in-period

Specifies the amount of time that the WebAccelerator system continues to serve content from cache if the origin Web server does not respond to the WebAccelerator system's requests for fresh content. The default value is 0 (zero), which means the WebAccelerator system responds to requests for expired content with a HTTP 404 error.

code Specifies a numeric non-zero code for the node that is used for troubleshooting and performance reporting. All nodes must have unique codes within the policy. If not supplied, the code will be generated by the system. Use the keyword generate to specify that the system generate a new unique code.

coherency

Specifies if the WebAccelerator system will attempt to keep content matching the associated node in sync across the blades of a cluster. The default behavior is to keep content in sync.

blade

The cached documents will not be kept coherent across blades. This causes each blade to have its own copy of a given cached document.

cluster

The cached documents will be kept coherent across blades. This causes the cluster to have single version of a given cached document.

defaults-from

Specifies the node that you want to use as the parent node. Your new node inherits all options and values from the parent node specified. The default value is none, which means this is a root node.

description

User defined description of a node.

invalidations

Specifies the collection of invalidations rules. Invalidations rules enable you to expire cached content before it has reached its time-to-live (TTL) value. This is useful when content updates are event-driven, such as when an item is added to a shopping cart, a request contains a new auction bid, or a poster has submitted content on a forum thread. Invalidations rules can be created only on leaf nodes.

lifetime-cache-control-extensions

Enables you to configure extension tokens to be added to the cache-control header of HTTP response. The WebAccelerator system does not process any of these extensions. It is possible that the origin Web server will send cache-control extensions as well. You can choose whether to preserve them by including the custom-extension in the lifetime-preserve-response-values list.

lifetime-cache-max-age

Specifies the amount of time that the WebAccelerator system serves content from the cache before requesting fresh content from the origin Web server. The default value is 4 hours.

lifetime-honor-ows

Specifies, if enabled, that the WebAccelerator system honors certain cache-control directives from the origin Web server response to determine cache lifetime. The default value is disabled.

lifetime-honor-ows-values

Specifies which Cache-Control directive from the origin Web server response will determine cache lifetime. Available directives are all-values, private, no-cache, no-store, must-revalidate, proxy-revalidate, max-age, s-maxage, and expires. This option is only effective if lifetime-honor-ows is enabled.

lifetime-honor-request

Specifies, if enabled, that the WebAccelerator system honors certain Cache-Control directives from the client's browser request to determine cache lifetime. The default value is enabled.

lifetime-honor-request-values

Specifies which cache-control directive from client's browser request will determine cache lifetime. Available directives are all-values, no-cache, no-store, max-age, max-stale, and min-fresh. This option is only effective if lifetime-honor-request is enabled. The default values are max-age, max-stale, and min-fresh.

lifetime-http-heuristic

Specifies the percentage, based on the HTTP Last-Modified header, that the WebAccelerator system uses to compute TTL values for cached content. For example, if content was modified 30 days ago and the lifetime-http-heuristic option is set to 50%, the WebAccelerator system caches the content for 15 days. This option is applicable only if you use the HTTP Last-Modified headers to identify content lifetime. The default value is 50%. This option is effective only if lifetime-use-heuristic is enabled.

lifetime-insert-no-cache

Specifies, when enabled, that the WebAccelerator system inserts a no-cache directive into the HTTP Cache-Control header, which stops the client's browser from locally caching content. This value overrides the HTTP Cache-Control header cache directives sent to the client by the origin Web server.

lifetime-preserve-response

Specifies, if enabled, that the WebAccelerator system preserves certain Cache-Control directives from the

origin Web server and includes them into client's browser response. The default value is enabled.

lifetime-preserve-response-values

Specifies which Cache-Control directive from the origin web server response will be preserved in response to the client's web browser. Available directives are all-values, private, no-cache, no-store, must-revalidate, proxy-revalidate, max-age, s-maxage, expires, and custom-extension. This option is only effective if lifetime-preserve-response is enabled. The default value is all-values.

lifetime-response-max-age

Specifies, when enabled, the amount of time that the client's browser should locally store content. This value overrides the max-age and expires the directives in the HTTP Cache-Control header that are sent to the client by the origin web server, only if the new value for the max-age is greater than the value supplied by the origin web server. Modify this value only if there is an acceptable trade off between the freshness of the content served to clients and overall site performance.

lifetime-response-s-maxage

Specifies, when enabled, the amount of time that the client's browser should locally store shared content. This value overrides the s-maxage and expires the directives in the HTTP Cache-Control header that are sent to the client by the origin web server, only if the new value for the s-maxage is greater than the value supplied by the origin web server. Modify this value only if there is an acceptable trade off between the freshness of the shared content served to clients and overall site performance.

lifetime-stand-in-codes

Specifies that the WebAccelerator system is allowed to serve stale content from the cache if it is not able to re-validate its freshness with the origin web server. The WebAccelerator system serves invalid content to the downstream proxies or clients if the response code from the origin web server matches one of codes specified with this option. This option is effective only if cache-stand-in-period has a non-zero value. The default values are 404, 500, and 504.

lifetime-use-heuristic

Specifies, when enabled, that the WebAccelerator system uses the percentage from lifetime-use-heuristic option to compute TTL values for cached content. The default value is no.

matching

Specifies the collection of matching rules. The rules consist of the HTTP request data type parameters that the WebAccelerator system uses to match an incoming HTTP request to a specified node. The following types of HTTP parameters are available for matching rules: host, path, extension, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, client-ip, and content-type.

object-min-size

Specifies the minimum object size required in order for content matching the associated node to be eligible for caching. The default behavior is to use the minimum object size specified by the associated web-acceleration profile.

object-max-size

Specifies the maximum object size allowed for content matching the associated node in order to be eligible for caching. The default behavior is to use the maximum object size specified by the associated web-acceleration profile.

order

Specifies the order of the node in the Policy Tree. All nodes in the policy must have an order. The order numbers are sequential, starting from 2. Orders 0 and 1 are reserved for internal use. The child node orders must be greater than the order of their parent node. You can change the order of the nodes by updating the order option of the node that you would like to move. The system honors the specified order if it falls within the range of sibling node orders. Otherwise, the system picks the closest valid order number. The remaining nodes are automatically re-ordered to free requested order number. The node order is also used as a last resort to determine which node to use when multiple nodes match the request. The node with a lower order wins. New nodes have their order assigned automatically to make them last among their siblings.

proxy

Specifies the collection of proxy rules. In general, proxy rules options are relevant to only requests that match their node, rather than to matched responses. The following types of HTTP parameters are available for proxy rules: host, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, and client-ip.

proxy-override

Specifies the collection of proxy override rules. You can define proxy override rules and associated conditions under which the WebAccelerator system should ignore proxying rules options. The following types of HTTP parameters are available for proxy override rules: host, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, and client-ip.

request-queueing

Specifies, when enabled, that the WebAccelerator system will queue requests for expired or new documents and proxy fewer requests to the origin web server (OWS). If the response is cachable, the response will be served to all waiting requests; if not, the waiting requests will proxy normally.

response-codes-cached

Specifies the collection of HTTP response codes that determine whether the WebAccelerator system should cache the content. The valid codes are 300, 301, 302, 307, and 410. The codes 200, 201, 203, and 207 are included into the list implicitly. The default values are 300 and 301.

substitutions

Specifies the collection of parameter value substitution rules. Some requested pages include hyperlinks that require that specific information appear in the response. You can configure parameter value substitution so that when a query parameter contains identification information for a site's visitors, it

prompts the WebAccelerator system to serve different content for the request, based on the specific visitor. Conversely, if parameter value substitution is not configured, the WebAccelerator system uses the value that it cached for the original request, for all subsequent requests after the first, even if the subsequent requests have different values that should be used in the response.

If you configure parameter value substitution, the WebAccelerator system changes the targeted parameters value on the page served from the cache, so that the parameter you specify appears on the URL embedded in that page.

variation

Specifies the collection of variation rules. When the WebAccelerator system caches responses from the origin web server, it uses certain HTTP request parameters to create a Unique Content Identifier (UCI). The WebAccelerator system stores the UCI in the form of a compiled response and uses the UCI to easily match future requests to the correct content in its cache. You can configure variation rules to add or modify the parameters on which the WebAccelerator system bases its caching process. If the WebAccelerator system receives two requests that are identical except for the value of a query parameter defined in the variation rule, it creates a different UCI for each, and caches each response under its unique UCI. The following types of HTTP parameters are available for variation rules: host, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, and client-ip.

viewstate-cache

Specifies, when enabled, that the WebAccelerator system accelerates requests and responses for Web form objects that are generated by ASP.NET web applications. Because the file size of forms can be significant, the WebAccelerator system is able to cache and substitute values, thus reducing the file size and achieving faster performance.

viewstate-cache-size

Specifies the size of the ViewState object cache in kilobytes. The default value is 100 kilobytes.

viewstate-tag

Specifies the name of the web form field where the ViewState object is stored. The default value is `__VIEWSTATE`.

video-optimization-fast-start

Specifies when enabled, that the WebAccelerator system optimizes video by prefetching.

video-optimization-max-bitrate

Specifies, the maximum bitrate of video that can be allowed in kilobits per sec. The default value is 0.

video-optimization-insert-ad

Specifies, when enabled, that the WebAccelerator system can insert ad into the video.

video-optimization-preroll-ad

Specifies, when enabled, that the WebAccelerator system can insert ad at the beginning of the video.

video-optimization-ad-frequency

Specifies the frequency of ad insertion. Units in seconds.

video-optimization-ad-policy

Specifies the ad policy applicable when processing the video.

type Displays the node type. The possible types are:

branch

The branch nodes exist only for the purpose of propagating rule parameters to leaf nodes. The WebAccelerator system does not perform matching against branch nodes. Branch nodes can have multiple leaf (child) nodes, as well as child branch nodes.

leaf A leaf node inherits rule parameters from its parent branch node. The WebAccelerator system performs matching only against leaf nodes, and then applies the leaf nodes corresponding acceleration rules to the request.

HTTP PARAMETERS

Both matching and acceleration rules are identified by the type, and optionally, by the name of HTTP parameters that are used inside the rules. The following types of HTTP parameters are available:

content-type

A rule that uses the content-type parameter is based on type definitions in the object-type components. Unlike the HTTP request data types, a matching rule based on content type is specific to the content type parameter that the WebAccelerator system generates for a response. You specify the regular expression that you want a response's content type to match.

client-ip

A rule that uses the client IP parameter is based on the IP address of the client making the request. The IP address, however, may not always be the address of the client that originated the request. For example, if the client goes through a proxy server, the IP address is the IP address of the proxy server, rather than the client IP address that originated the request. If several clients use a specific proxy server, they all appear to come from the same IP address.

cookie:[name]

A rule that uses the cookie parameter is based on a particular cookie that you identify by name, and for which you provide a value to match against. This value is usually literal and must appear on the cookie in the request or in a regular expression that matches the request's cookie that appears on the cookie HTTP request headers. These are the same names you use to set the cookies, using the HTTP Set-Cookie response headers. The HTTP request can contain multiple cookies, and the rule identifier must include the name of the cookie separated with colon (:).

extension

A rule that uses the extension parameter is based on the value that follows the far-right period, in the far-right segment key of the URL path.

header:[name]

A rule that uses the header parameter is based on a particular header that you identify by name and for which you provide a value to match against. You can use an HTTP request data type header parameter to create rules based on any request header other than one of the recognized HTTP request data types. The HTTP request can contain multiple headers, and the rule identifier must include the name of the header separated with colon (:).

host A rule that uses the host parameter is based on the value provided for the HTTP Host request header field. This header field describes the DNS name that the HTTP request is using.

method

A rule that uses the method parameter is based on whether the request uses the GET or POST method.

query-param:[name]

A rule that uses the query parameter is based on a particular query parameter that you identify by name and for which you provide a value to match against. The value is usually literal and must appear on the query parameter in the request, or in a regular expression that matches the requests query parameter value. The query parameter can be in a request that uses GET or POST methods. The HTTP request can contain multiple query parameters, and the rule identifier must include the name of the header separated with colon (:).

path A rule that uses the path parameter is based on the path portion of the URI. The path is defined as everything in the URL after the host and up to the end of the URL, or up to the question mark (whichever comes first).

path-segment:[name]

A segment is the portion of a URI path that is delimited by a forward slash (/). For example, in the path: /apps/search/full/complex.jsp, apps, search, full, and complex.jsp all represent path segments. The path can contain multiple segments so the rule identifier must include the name of the segment separated with colon (:). The name can be a segment ordinal or some other string to distinguish it from other segments rules in the same node.

protocol

A rule that uses the protocol parameter is based on whether the request uses the HTTP or HTTPS protocol.

referrer

A rule that uses the referrer parameter is based on the value provided for the HTTP Referer in the request header. (Note the misspelling of Referer. This spelling is defined for this request header in all versions of the HTTP specification.) This header provides the URL location that referred the client to the page that the client is requesting. You do not typically base rules on the Referer request header, unless you want your sites behavior to be dependent on the specific referrer. For example, one implementation would be for sites that provide different branding for their pages based on the user's web portal or search engine.

unnamed-query-param:[name]

An unnamed query parameter is a query parameter that has no equal sign. That is, only the query parameter value is provided in the URL of the request. The HTTP request may contain multiple unnamed query parameters so the rule identifier must include the name of it separated with colon (:). The name can be the ordinal of unnamed query parameter or some other string that can make it distinguishable from other unnamed query parameter rules in the same node.

user-agent

A rule that uses the user agent parameter is based on the value provided for the HTTP User-Agent in the request header, which identifies the browser that sent the request.

RULE OPTIONS

active

Specifies, when enabled, that the invalidation trigger rule is enabled. You can use this option to disable a specific invalidation trigger rule temporary, without removing it from the policy.

arg-all

Specifies, when enabled, that the rule matches all HTTP parameters of this type rather than one identified by arg-name or arg-ordinal. This option is applicable to variation rules query-param, unnamed-query-param, path-segment, cookie, and header. Such rules serve as a fallback case for defining document variation. All root nodes must include one variation rule of each type with this option enabled. The default value is disabled.

arg-alias

src-alias

dst-alias

request-data-alias

Specifies the user supplied alias for rules that use ordinals to identify HTTP request data. These include the unnamed-query-param and path-segment rules. The src-alias and dst-alias options are used in parameter value substitution rules to define aliases for the source and target definitions correspondingly. The request-data-alias option defines an alias for the invalidation trigger rules.

arg-direction

src-direction

dst-direction

request-data-direction

Specifies the direction that the WebAccelerator system uses to count the ordinal of path-segment. The src-direction and dst-direction options are used in parameter value substitution rules to define the ordinal direction for the source and target definitions correspondingly. The request-data-direction

option defines the ordinal direction for the invalidation trigger rules. The default value is left-to-right. The possible values are:

left-to-right

The path segment is counted form left to right.

right-to-left

The path segment is counted form right to left.

arg-name
src-name
dst-name
request-data-name

Specifies the name of the parameter type for query-param, cookie, and header. If not specified, arg-name option is initialized from the rule name. This option is not effective if arg-all is enabled. The src-name and dst-dst options are used in parameter value substitution rules to define the parameter name for the source and target definitions correspondingly. The request-data-name option defines the parameter name for the invalidation trigger rules.

arg-ordinal
src-ordinal
dst-ordinal
request-data-ordinal

Specifies, in the form of a number, the location of a parameter for unnamed-query-param and path-segment rules. The numbering starts at 1 and follows the direction specified in the corresponding direction option. This option is not effective if arg-all is enabled. The src-ordinal and dst-ordinal options are used in parameter value substitution rules to define the parameter ordinal for the source and target definitions correspondingly. The request-data-ordinal option defines the parameter ordinal for the invalidation trigger rules.

broadcast

Specifies whether a triggered invalidation rule is broadcast to other members of a multibox deployment. This option is only effective when the application using this policy has multibox set to farm or symmetric.

cache-content

Specifies the parameter for which the WebAccelerator system must obtain fresh content when the invalidations rule is triggered. The available request types are: host, path, extension, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, and client-ip.

Note: You must select and configure the path parameter for the cached content to invalidate, or the invalidations rule will fail to trigger. All other parameters are optional.

description

User-defined description of a rule.

dst-type

Specifies the HTTP parameter type to use as target definition for the request value substitution rule. A target definition contains a value in the embedded URL that you want the WebAccelerator system to replace with the value that you specified for the source definition, during assembly. The possible values are:

path-segment

Specifies that the WebAccelerator system targets the URL parameter, as specified by the dst-ordinal and dst-direction you define.

query-param

Specifies that the WebAccelerator system targets the URL parameter, as specified by the dst-name you define.

unnamed-query-param

Specifies that the WebAccelerator system substitutes the URL parameter, as specified by the dst-ordinal you define.

dst-urls

Specifies the collection of URLs in the request for which you want the WebAccelerator system to replace content.

request

Specifies a parameter in the request that triggers the invalidations rule. The available request types are: host, path, extension, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, and client-ip.

Note: You must select and configure the path parameter for the request header criteria, or the invalidations rule will fail to trigger. All other parameters are optional.

request-data-type

Specifies the HTTP request parameter value that the WebAccelerator system should find in its cache and for which it should request updated content from the origin Web server. The default value is undefined.

The following types of HTTP parameters are available:

host
query-param
unnamed-query-param
path-segment
cookie
user-agent

referrer
header
client-ip

Specifies that the WebAccelerator system should use the corresponding value from the request that triggered the invalidation. Additional data, if required to identify the value, must be specified in the request-data-name, request-data-ordinal, and request-data-direction options. The values option is ignored.

undefined

Specifies that the WebAccelerator system should not use any values from the request that triggered the invalidation. You must add a value into the values option with which to compare the cached content.

src-type

Specifies the HTTP parameter type to use as source definition for the request value substitution rule. A source definition contains the value that the WebAccelerator system embeds in the URL, in place of the cached (target definition) value, during substitution. Typically, the source definition is a specific request element, such as a particular query parameter; however, you can specify another source type, such as a random number. The possible values are:

path-segment

Specifies that the WebAccelerator system substitutes the URL parameter, as specified by the src-ordinal and src-direction options you define.

query-param

Specifies that the WebAccelerator system substitutes the URL parameter, as specified by the src-name option you define.

randomizer

Specifies that the WebAccelerator system generates a random number and places that number on the targeted location in an embedded URL.

request-url

Specifies that the WebAccelerator system is limited to target-specific URLs embedded in a page, as defined in the prefix that an embedded URL must match before the WebAccelerator system performs substitution. If you use the request URL as the source, the WebAccelerator system uses the entire request URL as the value to substitute.

unnamed-query-param

Specifies that the WebAccelerator system substitutes the URL parameter, as specified by the src-ordinal option you define.

src-url

Specifies whether the request URL is a relative URL or an absolute URL. The default value is absolute.

value-case-sensitive

Specifies, when enabled, that the HTTP parameter must be matched against supplied value(s) in case sensitive manner. The default value is no.

values

Values are a collection of rule parameters that enable you to specify different parameter values for the same rule. Most rules allow only one value, while variation rules support multiple values. Each value can prompt a different behavior by the WebAccelerator system. All variation rules must include at least one value with match-all option enabled. A value can be represented by actual string, regex, or multiple strings, or regexes separated by space ().

RULE VALUE OPTIONS

can-be-empty

Specifies, when enabled, that the defined HTTP request parameter is included in the request, but has no value (is an empty string). The default value is no.

can-be-missing

Specifies, when enabled, that the defined HTTP request parameter is absent from the request. The default value is no.

invert-match

Specifies, when enabled, that the defined HTTP request parameter does not match the associated regular expression that you defined. The default value is no.

match-all

Specifies, when enabled, that the defined HTTP request parameter matches all possible values. This option is available only for variation rule values as a fallback case. Each variation rule must have at least one value with this option enabled. The default value is no.

cache-as

Specifies whether the associated value should prompt the WebAccelerator system to reply to matched requests with the same or different content. This option is available only for variation rule values.

wam resource concat-set

NAME

concat-set - Configures concatenation sets for WebAccelerator for use in JavaScript/CSS concatenation

MODULE

wam resource

SYNTAX

Configure the concat-set within the wam resource module using the syntax shown in the following sections.

CREATE/MODIFY

```
create concat-set [name]
modify concat-set [name]
options:
  app-service [[string] | none]
  url [url]
  type [css|js]
  members [string ] ...
```

DISPLAY

```
list concat-set [name ...]
```

DELETE

```
delete concat-set [name ...]
```

DESCRIPTION

You can use the concat-set component to manage the concatenation sets used by the WebAccelerator JavaScript and CSS concatenation feature. A concatenation set must be created, then enabled and activated in the configuration on a WebAccelerator policy node.

EXAMPLES

```
create concat-set testSet url http://www.example.com/concatSet.css type css
```

Creates a set whose URL will be http://www.example.com/concatSet.css for use in concatenation.

```
list concat-set testSet
```

Displays properties of the concatenation set named testSet.

```
delete concat-set testSet
```

Deletes concatenation set named testSet.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

url Specifies the URL that will be used to generate the concatenated link.

type Either "css" or "js". Specifies whether the set is to be used for CSS or JavaScript concatenation.

members

Specifies the members of this set. The set members are the URL resources that are defined by the wam resource url.

SEE ALSO

create, delete, edit, list, modify, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

wam resource domain-list

NAME

domain-list - Configures a list of domains for WebAccelerator for use in inserting DNS prefetch tags.

MODULE

wam resource

SYNTAX

Configure the domain-list component within the wam resource module using the syntax shown in the following sections.

CREATE/MODIFY

create domain-list [name]

modify domain-list [name]

options:

app-service [[string] | none]

description [[string] | none]

domains

[add | delete | none | replace-all-with] {

[string] ...

}

DISPLAY

list domain-list [name ...]

DELETE

delete domain-list [name ...]

DESCRIPTION

You can use the domain-list component to manage the domain list resources used by the WebAccelerator DNS prefetching feature. A domain-list must be created, then added to the appropriate domain-lists on a WebAccelerator policy node in order for the domains within the domain list to be inserted into a document.

EXAMPLES

create domain-list my_domain_list domains add {example.com example2.com}

Creates a domain list resource for the domains example.com and example2.com for use in inserting DNS prefetch tags.

list domain-list my_domain_list

Displays properties of the domain-list resource named my_domain_list.

delete domain-list my_domain_list

Deletes the domain-list resource named my_domain_list.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

domains

Specifies the domains described by the domain list resource.

SEE ALSO

create, delete, edit, list, modify, show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

wam resource url

NAME

url - Configures a URL resource for WebAccelerator for use in reordering whitelists

MODULE

wam resource

SYNTAX

Configure the url component within the wam resource module using the syntax shown in the following sections.

CREATE/MODIFY

create url [name]

modify url [name]

options:

app-service [[string] | none]

url [url]

type [css|js]

DISPLAY

list url [name ...]

DELETE

delete url [name ...]

DESCRIPTION

You can use the url component to manage the URL resources used by the WebAccelerator JavaScript and CSS reordering features. A URL resource must be created, then added to the appropriate whitelist on a WebAccelerator policy node in order for the corresponding URL to be reordered.

EXAMPLES

create url test.css url http://www.example.com/test.css type css

Creates a URL resource for the URL http://www.example.com/test.css for use in CSS reordering whitelists.

list url test.css

Displays properties of the URL resource named test.css.

delete url test.css

Deletes the URL resource named test.css.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

url Specifies the URL described by the URL resource.

type Either "css" or "js". Specifies whether the URL resource is to be used for CSS or JavaScript reordering.

SEE ALSO

create, delete, edit, list, modify, show, tmsh

COPYRIGHT

wam roi-statistics

NAME

roi-statistics - Provides ROI statistics for WAM application.

MODULE

wam

SYNTAX

Provides ROI statistics for configured application within the wam module.

DISPLAY

```
show roi-statistics
show roi-statistics [application-name]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
```

DESCRIPTION

You can use the roi-statistics component to view the ROI statistics of configured WAM application.

EXAMPLES

```
show roi-statistics my_application
```

The show command will display ROI statistics for the configured WAM application.

SEE ALSO

show, tmsh

COPYRIGHT

BIG-IP 2014-07-02 wam roi-statistics(1)

wom

wom advertised-route

NAME

advertised-route - Configures a route advertised by the local endpoint to remote endpoints for WAN optimization.

MODULE

wom

SYNTAX

Configure the advertised-route component within the wom module using the syntax in the following sections.

CREATE/MODIFY

```
create advertised-route [name]
modify advertised-route [name | all]
options:
app-service [[string] | none]
description [string]
dest [ip address/netmask]
include [disabled | enabled]
label [value]
metric [integer]
origin [configured | discovered | manually-saved | persistable]
```

DISPLAY

```
list advertised-route
show advertised-route
options:
running-config
```

DELETE

```
delete advertised-route [name]
```

DESCRIPTION

You can use the advertised-route component to configure a subnet that the system can reach through the local endpoint. You can specify a netmask or use slash format.

Routes are advertised to all connected WAN Optimization Managers. The remote endpoints use the subnet configuration information to determine peer routing and optimization actions.

EXAMPLES

```
list advertised-route all
```

Displays all endpoint advertised routes for the local WAN Optimization Manager.

delete advertised-route adv_rt2

Deletes the advertised route adv_rt2.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

dest Specifies the IP address and netmask of the advertised route.

include

Enables or disables the inclusion of this route in the optimization of traffic. This option allows you to define a subset of IP addresses to exclude from optimization within a larger included subnet. An excluded endpoint advertised route must be a valid address range subset of an included endpoint advertised route. The default is enabled.

label

Specifies an optional descriptive label for this route.

metric

Specifies a routing number to select between WAN Optimization Manager pairs. The higher the number, the more expensive the route in terms of resources. Not currently implemented.

origin

Specifies whether the route was discovered automatically or configured manually. You can change the origin from discovered to persistable, if you want to save the route to the file bigip_local.conf when you use the command save config. After you run the command save config, this attribute changes to manually saved. Endpoints that have the attribute discovered are not saved to the file bigip_local.conf.

The options are:

configured

Indicates that you manually configured this route. The system automatically sets this value, and you cannot change it.

discovered

Indicates that the system automatically discovered this route. Note that route for which the value of the origin property is discovered are not saved to the file bigip_local.conf.

manually-saved

After you run the command save / sys config, the value of the origin property that was set to persistable changes to manually-saved. Note that after the system changes the value to manually-saved, you cannot change it again.

persistable

Change the origin from discovered to persistable, if you want to save the route to the file bigip_local.conf when you use the command save / sys config.

BIG-IP 2017-03-31 wom advertised-route(1)

wom deduplication

NAME

deduplication - Configures symmetric data deduplication for WAN optimization.

MODULE

wom

SYNTAX

Configure the deduplication component within the wom module using the syntax in the following sections.

MODIFY

```
modify deduplication
options:
  codec [sdd-v2 | sdd-v3]
  [disabled | enabled]
  max-endpoint-count [integer]
```

DISPLAY

```
list deduplication
show running-config deduplication
options:
  dictionary-size
  one-line
```

DESCRIPTION

You can use the deduplication component to configure symmetric data deduplication, which compresses data over the WAN by identifying and removing repetitive data patterns.

EXAMPLES

```
list deduplication
```

Displays all the deduplication settings.

```
modify deduplication max-endpoint-count 4
```

Sets the maximum number of remote endpoints to 4.

OPTIONS

codec
Specifies which algorithm the system uses for deduplication.

The options are:

sdd-v2
Used for low number of spokes, such as for data center to data center replication.

sdd-v3
Used for high number of spokes, such as for connecting multiple remote sites or mesh topologies.

dictionary-size
Displays the current size of the dictionary, which deduplication uses to look up byte patterns.

[disabled | enabled]
Enables or disables deduplication. The default value is enabled. Note that if you enable or disable deduplication, you must then restart the BIG-IP WOM system using bigstart restart, or the change takes effect the next time the BIG-IP device reboots.

max-endpoint-count
Specifies the maximum number of concurrent remote endpoints supported by symmetric data deduplication. For codec sdd-v3, the system sets the value at 128.

SEE ALSO

BIG-IP 2012-04-10 wom diagnose-conn(1)

wom endpoint-discovery

NAME

endpoint-discovery - Configures automatic discovery of remote endpoints for WAN optimization.

MODULE

wom

SYNTAX

Configure the endpoint-discovery component with the wom module using the syntax in the following sections.

MODIFY

modify endpoint-discovery

options:

auto-save [disabled | enabled]
description [string]
discoverable [disabled | enabled]
discovered-endpoint [disabled | enabled]
icmp-max-requests [integer]
icmp-min-backoff [integer]
icmp-num-retries [integer]
max-endpoint-count [integer]
mode [disable | enable-all | enable-icmp | enable-tcp]

reset-stats endpoint-discovery

DISPLAY

list endpoint-discovery

show running-config endpoint-discovery

options:

all-properties
non-default-properties
one-line

show endpoint-discovery

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the endpoint-discovery component to specify parameters for automatically discovering remote endpoints for WAN optimization. These endpoints are configured WAN Optimization Managers on remote BIG-IP(r) systems that advertise themselves to the configured WAN Optimization Manager on the local BIG-IP system.

EXAMPLES

modify endpoint-discovery max-endpoint-count 10

Limits the number of remote endpoints that can be discovered to ten. After discovering ten remote endpoints, the WOM stops sending probe messages.

list endpoint-discovery all-properties

Displays the configuration parameters for the discovery of remote endpoints.

OPTIONS

auto-save

Specifies whether the system automatically saves remote endpoints that it discovers. The default value is enabled.

description

User defined description.

discoverable

Specifies whether the WAN Optimization Manager responds to probe messages it receives from WAN Optimization Managers on remote BIG-IP systems. The default value is enabled.

discovered-endpoint

Specifies whether the WAN Optimization Manager sends out probe messages to discover other WAN Optimization Managers on remote BIG-IP systems in the network. The default value is enabled.

icmp-max-requests

Specifies the maximum number of ICMP probe message requests, after which the system stops sending probe message requests until at least one message is cleared from the queue by either a timeout or a response. The default value is 1024.

icmp-min-backoff

Specifies the maximum number of seconds to wait before abandoning an ICMP probe message request and resending it. The range is from 0 to 255. The default value is 5.

icmp-num-retries

Specifies the maximum number of times the system sends an ICMP probe message request for a single flow. The range is from 0 to 255. The default value is 10.

max-endpoint-count

Specifies the highest number of endpoints for the system to discover before it stops sending probe messages. The range is from 0 to 255. The default value is 0, which indicates no limit.

mode Specifies the type of probe messages the system should send. The default value is enable-all.

The options are:

disable

Turns off probe messages.

enable-icmp

Sends only ICMP probe messages.

enable-tcp

Sends only TCP probe messages.

enable-all

Sends both ICMP and TCP probe messages.

SEE ALSO

BIG-IP 2012-04-10 wom endpoint-discovery(1)

wom local-endpoint

NAME

local-endpoint - Configures the local endpoint for the WAN Optimization Manager.

MODULE

wom

SYNTAX

Configure the local-endpoint component within the wom module using the following syntax.

CREATE/MODIFY

create local-endpoint

modify local-endpoint

options:

addresses [add | delete | replace-all-with] {
[ip address]

}

addresses none

allow-nat [disabled | enabled]

description [string]

endpoint [disabled | enabled]
internal-forwarding [disabled | enabled]
ip-encap-mtu [unsigned integer]
ip-encap-profile [none | profile name]
ip-encap-type [gre | ipip | ipsec | none]
no-route [drop | passthru]
server-ssl [none | profile name]
snat [local | none | remote]
tunnel-port [unsigned integer]

DISPLAY

list local-endpoint
show local-endpoint
show running-config local-endpoint
options:
all-properties
non-default-properties
one-line

DELETE

delete local-endpoint

DESCRIPTION

You can use the local-endpoint component to modify the settings for the local endpoint for the WAN Optimization Manager on the local BIG-IP(r) system.

EXAMPLES

modify local-endpoint allow-nat disabled

Disables the allow-nat option, specifying that the system does not accept connections for traffic behind a Network Address Translation (NAT) device.

list local-endpoint all-properties

Displays all of the properties of the local-endpoint component.

OPTIONS

addresses

Specifies a single IP address the system uses for the local endpoint. The IP address must be in the same subnet as a self IP address on the BIG-IP(r) system.

allow-nat

When enabled, specifies that the system accepts connections for traffic behind a Network Address Translation device. The default value is enabled.

description

User defined description.

endpoint

When enabled, specifies that the local endpoint is available for initiating and receiving optimized traffic. The default value is enabled.

To turn off WAN optimization on this endpoint, use disabled.

internal-forwarding

When enabled, specifies that the local endpoint is available for forwarding internal traffic to remote endpoints. The default value is disabled.

This parameter works only if internal-forwarding for remote-endpoint is set to default.

ip-encap-mtu

Specifies the maximum transfer unit for IP encapsulated traffic.

ip-encap-profile

Specifies the name of the profile with the encapsulation settings. This profile must be of the type specified for the setting ip-encap-type.

ip-encap-type

Specifies the type of IP layer encapsulation to perform on iSession(tm) traffic.

The default value is none. The options are:

gre The system uses the Generic Routing Encapsulation (GRE) tunneling protocol.

ipip The system uses the IP over IP (IPIP) tunneling protocol.

ipsec

The system uses IP security (IPsec) encapsulation.

none No IP encapsulation takes place.

no-route

Specifies what the system does with traffic for which there is no remote endpoint to complete the iSession connection.

The default value is passthru. The options are:

drop The system terminates the traffic flow.

passthru

The traffic flow continues without an iSession connection.

server-ssl

Specifies the default server SSL profile the system uses for all encrypted outbound connections. The default value is none.

snat Specifies the IP address the system uses for incoming traffic as the source IP address of the TCP connection between the WAN Optimization Manager and the server.

The default value is none. The options are:

local

The system uses the endpoint IP address closest to the destination. Use this setting to make sure the return route also goes through the BIG-IP system, so that both sides of the connection can be optimized. This setting is useful if responses returning from the server to the client would not normally pass through the BIG-IP system.

none The system uses the original connecting client IP address.

remote

The system uses the source IP address of the incoming iSession connection. Use this setting when an appliance that uses NAT is located between the WAN Optimization endpoints.

tunnel-port

Specifies the number of the port on the local endpoint that the WAN Optimization Manager uses for control connections. The port must have access through the firewall. The range is from 1 to 65535. The default value is 443.

wom profile cifs

NAME

cifs - Configures a Common Internet File System (CIFS) profile.

MODULE

wom profile

SYNTAX

Configure the cifs component within the wom profile module using the syntax shown in the following sections.

CREATE/MODIFY

create cifs [name]

modify cifs [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

fast-close [disabled | enabled]

fast-set-file-info [disabled | enabled]

office-2003-extended [disabled | enabled]

read-ahead [disabled | enabled]

record-replay [disabled | enabled]

write-behind [disabled | enabled]

DISPLAY

list cifs

list cifs [[[name] | [glob] | [regex]] ...]

show running-config cifs

show running-config cifs [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties
one-line
partition

show cifs

show cifs [[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DELETE

delete cifs [name]

DESCRIPTION

You can use the cifs component to manage a CIFS profile.

EXAMPLES

create cifs my_cifs_profile

Creates a CIFS profile named my_cifs_profile using the system defaults.

modify cifs my_cifs_profile fast-close disabled

Turns off fast-close for the CIFS profile named my_cifs_profile.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the profile that you want to use as the parent profile. The new profile inherits all settings and values from the parent profile specified. The default value is cifs.

description

User defined description.

fast-close

Specifies whether the system speeds up file close operations by fulfilling them through the WAN Optimization Manager closer to the request initiator. The default value is enabled.

fast-set-file-info

Specifies whether the system speeds up file metadata change requests by fulfilling the requests through the WAN Optimization Manager closer to the request initiator. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

office-2003-extended

Specifies whether the system performs read-ahead operations based on parsing the Microsoft CDF file and understanding its structure. The default value is enabled.

partition

Displays the administrative partition within which the component resides.

read-ahead

Specifies whether the system speeds up CIFS file downloads by prefetching the file data on the WAN Optimization Manager closer to the request initiator. The default value is enabled.

record-replay

Specifies whether the system opens CIFS files faster by performing more intelligent read-ahead operations. The default value is enabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

write-behind

Specifies whether the system speeds up CIFS file uploads to the server by fulfilling write requests through the WAN Optimization Manager closer to the request initiator. The default value is enabled.

SEE ALSO

create, delete, glob, list, itm virtual, modify, regex, show, tmsh

wom profile isession

NAME

isession - Configures an iSession profile.

MODULE

wom profile

SYNTAX

Configure the iSession component within the wom profile module using the following syntax.

CREATE/MODIFY

create isession [name]

modify isession [name]

options:

adaptive-compression [disabled | enabled]

app-service [[string] | none]

compression [disabled | enabled]

compression-codecs [add | delete | none | replace-all-with] {

options:

bzip2

deflate

lzo

}

data-encryption [disabled | enabled]

deduplication [disabled | enabled]

defaults-from [[name] | none]

deflate-compression-level [integer]

description [string]

mode [disabled | enabled]

port-transparency [disabled | enabled]

reuse-connection [disabled | enabled]

target-virtual [none | host-match-all | host-match-no-isession | virtual-match-all]

reset-stats isession

reset-stats isession [[[name] | [blog] | [regex]] ...]

DISPLAY

list isession

list isession [[[name] | [glob] | [regex]] ...]

show running-config isession

show running-config isession [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

show isession

show isession [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

global

DELETE

delete isession [name]

DESCRIPTION

You can use the isession component to manage an iSession profile.

EXAMPLES

create isession my_isession_profile defaults-from isession

Creates an iSession profile named my_isession_profile using the system defaults.

modify isession my_isession_profile deduplication disabled

Turns off deduplication for the iSession profile named my_isession_profile.

OPTIONS

adaptive-compression

Enables or disables the automatic selection of the optimal compression algorithm for the current traffic, based on link speed. The system can use only compression algorithms that are specified. The default value is enabled.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

compression

Enables or disables the compression of data according to the methods you select for the attribute compression-codecs. The default value is enabled.

compression-codecs

Specifies the codecs to use for compression. The following codecs are available:

bzip2

Specifies the use of the bzip2 compression algorithm, which improves compression ratios on low-bandwidth data links.

deflate

Specifies the use of the Deflate data compression algorithm.

lzo Specifies the use of the Lempel-Ziv-Oberhumer (LZO) data compression algorithm.

data-encryption

Enables or disables encryption of the traffic on the outbound connection. If you select enabled, the system uses the SSL profiles specified on the local and remote endpoints of the iSession connection. The default value is disabled.

deduplication

Enables or disables data deduplication, which replaces previously transmitted data with references, thus reducing the amount of bandwidth needed to transfer data over the WAN. The default value is enabled.

defaults-from

Specifies the profile that you want to use as the parent profile. The new profile inherits all settings and values from the parent profile specified. The default value is isession.

deflate-compression-level

Specifies the level of compression, if deflate-compression is specified and adaptive-compression is disabled. The range is 1 to 9. A higher value causes the CPU to spend more time looking for matches, which may result in better compression. The default value is 1.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

mode Enables or disables the use of this profile for WAN optimization traffic. The default value is enabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

port-transparency

Enables or disables the preservation of the destination port specified by the client over the WAN. The default value is enabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reuse-connection

Enables or disables the saving and reuse of connections between the local and remote WAN Optimization Managers. The default value is enabled.

target-virtual

For terminated iSession traffic, specifies the matching criteria that a client-side BIG-IP system uses to select a target virtual server on the server-side BIG-IP system.

The default value is virtual-match-all. The options are:

none Specifies that the system sends the terminated iSession traffic directly to the server.

host-match-all

Specifies that the system selects the closest match from all the host virtual servers.

host-match-no-isession

Specifies that the system matches only host virtual servers with no iSession profile.

virtual-match-all

Specifies that the system selects the closest match from all the virtual servers.

wom profile mapi

NAME

mapi - Configures a Messaging Application Program Interface (MAPI) profile.

MODULE

wom profile

SYNTAX

Configure the mapi component within the wom profile module using the following syntax.

CREATE/MODIFY

create mapi [name]

modify mapi [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

discover-exchange-servers [disabled | enabled]

native-compression [disabled | enabled]

DISPLAY

list mapi

list mapi [[[name] | [glob] | [regex]] ...]

show running-config mapi

show running-config mapi [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

show mapi

show mapi [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DELETE

delete mapi [name]

DESCRIPTION

You can use the mapi component to manage a MAPI profile.

EXAMPLES

create mapi my_mapi_profile

Creates a MAPI profile named my_mapi_profile using the system defaults.

modify mapi my_mapi_profile native-compression enabled

Turns on native-compression for the MAPI profile named my_mapi_profile.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the profile that you want to use as the parent profile. The new profile inherits all settings and values from the parent profile specified. The default value is mapi.

description

User defined description.

discover-exchange-servers

Enables or disables the automatic discovery of the Microsoft Exchange servers in the network and creation of a virtual server for each one discovered. The default value is disabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

native-compression

Enables or disables native Microsoft Exchange compression. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

BIG-IP 2012-05-22 wom profile mapi(1)

wom remote-endpoint

NAME

remote-endpoint - Configures one or more remote endpoints for the WAN Optimization Manager.

MODULE

wom

SYNTAX

Configure the remote-endpoint component within the wom module using the following syntax.

CREATE/MODIFY

create remote-endpoint [name]

modify remote-endpoint [name]

options:

address [ip address]

allow-routing [disabled | enabled]

app-service [[string] | none]

dedup-action [none | cache-refresh]

description [string]

endpoint [disabled | enabled]

internal-forwarding [default | disabled | enabled]

ip-encap-mtu [unsigned integer]

ip-encap-profile [none | profile name]

ip-encap-type [default | gre | ipip | ipsec | none]

origin [configured | discovered | manually-saved | persistable]

server-ssl [none | profile name]

snat [default | local | none | remote]

tunnel-encrypt [disabled | enabled]

tunnel-port [unsigned integer]

reset-stats remote-endpoint

DISPLAY

list remote-endpoint

list remote-endpoint [name]

show running-config remote-endpoint

show running-config remote-endpoint [name]

options:

all-properties

dedup-codec

non-default-properties

one-line

show remote-endpoint
show remote-endpoint [name]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DELETE
delete remote-endpoint [name]

Note: If you delete a remote endpoint without also disabling the endpoint-discovery component, the remote endpoint may reappear as it is rediscovered. To remove a remote endpoint from traffic initiated by this WAN Optimization Manager, set the endpoint option of the remote-endpoint component to disabled.

DESCRIPTION

You can use the remote-endpoint component to create, modify, or delete a remote endpoint for traffic from the local WAN Optimization Manager.

EXAMPLES

modify remote-endpoint 13.16.0.5 endpoint disabled

Disables the WAN optimization connection to the remote endpoint that is named 13.16.0.5.

list remote-endpoint all-properties

Displays all the properties of all the remote endpoints for traffic from the local WAN Optimization Manager.

OPTIONS

allow-routing

Specifies whether there is a route from the local endpoint to this remote endpoint through which the local endpoint can establish connections. The default value is enabled.

address

Specifies the IP address of the remote endpoint.

app-service

Specifies the name of the application service to which the object belongs. The default value is none.
Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

dedup-action

Clears the cache used for symmetric data deduplication on the specified remote endpoint and immediately resets the value to none.

dedup-codec

Displays the deduplication codec used by the remote endpoint: sdd-v2 or sdd-v3.

endpoint

When enabled, specifies that traffic can be optimized between the local and remote endpoints. The default value is enabled.

Note: Disabling a remote endpoint affects only the connection between the local endpoint and this remote endpoint.

internal-forwarding

When enabled, specifies that the remote endpoint is available for forwarding internal traffic.

When disabled, specifies that the remote endpoint is NOT available for forwarding internal traffic.

When default, specifies that forwarding internal traffic is managed by the local-endpoint.internal-forwarding setting.

The default value is default.

ip-encap-mtu

Specifies the maximum transfer unit for IP encapsulated traffic. The default value is 0.

ip-encap-profile

Specifies the name of a profile with encapsulation settings. This profile must be of the type specified for the setting ip-encap-type.

ip-encap-type

Specifies the type of IP layer encapsulation performed on iSession traffic.

The default value is default. The options are:

default

The system uses the ip-encap-type value set for the local endpoint.

gre The system uses the Generic Routing Encapsulation (GRE) tunneling protocol.

ipip The system uses the IP over IP (IPIP) tunneling protocol.

ipsec

The system uses IP security (IPsec) encapsulation.

none No IP encapsulation takes place.

origin

Specifies whether the remote endpoint was discovered automatically or configured manually.

The options are:

configured

Indicates that you manually configured this remote endpoint. The system automatically sets this value, and you cannot change it.

discovered

Indicates that the system automatically discovered this remote endpoint. Note that endpoints for which the value of the origin property is discovered are not saved to the file `bigip_local.conf`.

manually-saved

After you run the command `save / sys config`, the value of the origin property that was set to `persistable` changes to `manually-saved`. Note that after the system changes the value to `manually-saved`, you cannot change it again.

persistable

Change the origin from `discovered` to `persistable`, if you want to save the endpoint to the file `bigip_local.conf` when you use the command `save / sys config`.

server-ssl

Specifies the server SSL profile the system uses to connect to this remote endpoint. This setting overrides the `server-ssl` setting for the local-endpoint component. The default value is `none`.

snat Specifies the IP address the system uses as the source IP address of the TCP connection between the WAN Optimization Manager and the server.

The default value is `default`. The options are:

default

The system uses the `snat` value set for the local-endpoint component.

local

The system uses the endpoint IP address closest to the destination. Use this setting to make sure the return route also goes through the BIG-IP system, so that both sides of the connection can be optimized. This setting is useful if responses returning from the server to the client would not normally pass through the BIG-IP system.

none The system uses the original connecting client IP address.

remote

The system uses the source IP address of the incoming iSession connection. Use this setting when an appliance that uses NAT is located between the WAN Optimization Manager endpoints.

tunnel-encrypt

Enables or disables encryption of traffic passing between the two WAN Optimization Managers. The default value is `enabled`

tunnel-port

Specifies whether to use a specific port for traffic optimized to this endpoint or to use port transparency (0). The default value is 443.

BIG-IP 2014-05-08 `wom remote-endpoint(1)`

wom remote-route

NAME

`remote-route` - Displays the destination routes learned from the remote endpoints.

MODULE

`wom`

SYNTAX

Display the remote-route component within the wom module using the syntax in the following section.

DISPLAY

show remote-route

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

detail

DESCRIPTION

You can use the remote-route component to view the subnets that the system can reach through the remote endpoint(s). The system can optimize traffic destined for these subnets.

EXAMPLES

show remote-route

Displays the subnets reachable through the remote endpoint(s) configured on the WAN Optimization Manager.

show remote-route detail

Displays detailed information about the remote endpoint(s) through which the displayed subnets can be reached.

SEE ALSO

show, tmsh, wom advertised-route, wom remote-endpoint, wom server-discovery,

min-prefix-length-ipv6 [integer]

mode [disabled | enabled]

rtt-threshold [integer]

subnet-filter [add | delete | none | replace-all-with] {
 [ip address]
}

time-unit [days | hours | minutes]

DISPLAY

list server-discovery

show running-config server-discovery

options:

all-properties

auto-save

current-module

description

filter-mode

idle-time-limit

ip-ttl-limit
max-server-count
min-idle-time
min-prefix-length-ipv4
min-prefix-length-ipv6
mode
non-default-properties
one-line
rtt-threshold
subnet-filter
time-unit

DESCRIPTION

You can use the server-discovery component to configure the dynamic discovery of servers and the routes to reach them through the local endpoint. The local endpoint advertises these routes to any remote endpoints to which it is connected.

EXAMPLES

list server-discovery all-properties

Displays the settings for dynamic discovery of advertised routes.

modify server-discovery mode disabled

Disables the dynamic discovery of advertised routes.

OPTIONS

auto-save

Specifies whether the system automatically saves the subnets that it discovers that can be reached through the local endpoint. The default value is enabled.

description

User defined description.

filter-mode

Specifies whether the subnets you add using the attribute subnet-filter are excluded from or included in the discovery of advertised routes. If you specify include, and do not specify any IP addresses, no subnets are discovered. The default is exclude with no IP addresses specified, which means that all advertised routes that conform to the specified attributes are discovered.

idle-time-limit

Specifies the maximum length of time a route can be idle without being removed from discovery. The default value is 0. Use the attribute time-unit to set the unit of measure. Use the attribute min-idle-time to set the minimum length of idle time.

ip-ttl-limit

Specifies the number of network segments on which a packet is allowed to travel before the route is removed from discovery. The more routers a packet travels through, the smaller the ip ttl value is. The range is 0 to 255. The default value is 5.

max-server-count

Specifies the highest number of servers the system discovers before it stops looking. The default value is 50.

min-idle-time

Specifies the minimum length of time a route must be idle before being removed from discovery. The default value is 0, which indicates that idle time is not considered in discovery. Use the attribute time-unit to set the unit of measure. Use the attribute idle-time-limit to set the maximum length of idle time.

min-prefix-length-ipv4

Specifies the minimum prefix length for route aggregation in IPV4 networks. The range is 0 to 32. The default value is 32.

min-prefix-length-ipv6

Specifies the minimum prefix length for route aggregation in IPV6 networks. The range is 0 to 128. The default value is 128.

mode Enables or disables the dynamic discovery of servers that can be reached through the local endpoint. For server discovery to take place, the setting mode of the component wdm endpoint-discovery must not be set to disabled.

rtt-threshold

Specifies that the system does not add servers it discovers with a round-trip time greater than this value, in milliseconds. The default value is 10.

subnet-filter

Specifies the IP addresses of the subnets to include in or exclude from the discovery of advertised routes, depending on the setting you selected for the attribute filter-mode. The default is none. If you selected include for the attribute filter-mode, and do not specify any IP addresses, no subnets are discovered.

time-unit

Specifies the unit of measure (days, hours, or minutes) for the length of idle time specified using the attributes idle-time-limit and min-idle-time.
